Results: During these two years 140 patients attended the DCU. 53% of them were female, and the mean age was 66.9 (minimum age 20, maximum 94). All patients had calculated the Charlson Comorbidity Index (CCI), and 54.1% of them presented a CCI of 3 or greater. The total number of visits was 609, which represents an average of 4.35 visits/patient/year. These patients were referred to the unit from several departments: Internal Medicine (55%), Gastroenterology (26.4%), Haematology (8.6%), and others (10%). The main diagnoses for being referred to the unit were anaemia (62.2%), inflammatory bowel disease (9.3%), osteoporosis (10%), immunodeficiencies (5%), ascitis (5%), and other conditions (8.6%). With regards to the administered treatments, 37.1% of the patients received intravenous iron, 13.6% intravenous iron plus transfusion of red cells concentrates, 10.7% intravenous biologic therapies, 10.7% intravenous bisphosphonates, 10.7% transfusions of hemoderivatives, and 5% intravenous immunoglobulins. 12.2% of the patients underwent different procedures such as paracentesis, thoracocentesis or intravenous steroids administration. Overall, only 5% of the patients presented any side effects to these treatments or procedures.

Discussion: DCUs are a non-conventional kind of hospitalization mainly developed under few departments such as Haematology, Medical Oncology or Nephrology, but seldom used in other medical specialties or in local hospitals with features like ours. Based on our data, we believe DCU is an ideal set up for follow-up, administration of chronic treatments and performance of several therapeutic or diagnostic techniques. Patients with chronic disorders such as anaemia that require parenteral iron and/or periodic transfusions are the ones that predominantly benefit from this kind of service, although administration of biologic therapies such as infliximab is a growing field. If these procedures were not underwent at DCU these patients would require admission in general wards at this hospital or at a bigger hospital, with all the disadvantages it represents.

Conclusions: DCU is an excellent set up for the administration of treatments and performance of basic procedures that otherwise would require hospital admission. We believe that this management approach should be promoted, in order to be known to all the departments that could benefit.

G-19
IMPACT OF USING HOSPITAL-BASED AMBULATORY RESOURCES (HBAR) VERSUS STANDARD MANAGEMENT OF HOSPITALIZED PATIENTS

J. Rascón[1], E. Esteban[1], L. Martín[1], M. del Río[2], E. García[1], L. Pallarés[1]

[1]Department of Internal Medicine, [2]Hospital at Home Department. Hospital Universitario Son Espases. Palma de Mallorca, Spain.

Objectives: To assess the impact of using Hospital Based Ambulatory Resources (HBAR), like Hospital at Home (HH), Day Hospital (DH) and Rapid Diagnostic Unit (RDU), versus standard management (diagnostic procedures and treatments are scheduled and performed mainly inside the hospital) in a Spanish Internal Medicine Department from a Third Level Hospital.

Material and method: Retrospective analysis of patients admitted from 1/9/2011 to 15/4/2012 (227 days) in the Internal Medicine Department. Patients were assigned without previous selection among six different medical teams. One of them (Pilot Team, PT) checked the potential use of HaH, DH and/or RDU from the first day of admission. If a patient was suitable for any of them, the resource was used and the patient discharged with ambulatory following. We compare the PT with the remaining group of patients (No Pilot Team, NPT), formed by the other 5 medical teams as a whole, in terms of days of hospitalization. Both groups were homogeneous

due to no previous selection of patients (regular admissions in the department). Patients in both teams were classified depending on the number of days they spent at hospital before discharge (0-5, > 5-10, > 10-15,. > 15-20, > 20-25, > 25-30 days). Patients with more than 30 days were excluded in both groups.

Results: Table 1 shows the distribution of patients into the different stay groups for both PT and NPT.

Discussion: 1. The main difference between the two groups is an 11% more patients for the PT in the shortest period of hospitalization. 2. There was always less percentage of patients in the PT for the rest of the groups. 3. There were no differences in readmissions for both teams. 4. In PT, the safety and traceability of the patients were kept during the ambulatory management.

Conclusions: 1. HBAR can be useful for early discharges without decreasing the quality and safety of assistance. 2. The biggest impact of HBAR occurs in the first 5 days of hospitalization, but they are useful during all the hospitalization process. 3. As HBAR are less expensive than standard hospitalization, without generating more readmissions, and they can even be safer than standard hospitalization (less nosocomial infection, immobilization complications, etc.), we think there should be specialized teams of Hospitalists detecting and managing the suitable patients for these resources. 4. Complex patients, as patients managed by Internists usually are, can benefit from these resources.

Table 1 (G-19). Percentage of patients in PT and NPT depending on total days of hospitalization

Days of stay	% patients PT	% patients NPT	PT-NPT (%)
0-5	27.8	27.8	11.1
5-10	34.7	34.7	-2.3
10-15	16.0	16.0	-4.1
15-20	9.0	9.0	-2.5
20-25	5.1	-5.1	-1.3
25-30	7.4	-7.4	-0.9

G-20
ULTRASOUND EXAMINATIONS BY A POCKET-SIZE ULTRASOUND DEVICE IMPROVES IMPATIENT DIAGNOSIS IN AN INTERNAL MEDICINE DEPARTMENT

G. Serralta San Martín, L. Soler Rangel, J. Gómez Cerezo

Department of Internal Medicine. Hospital Universitario Infanta Sofía. San Sebastián de los Reyes (Madrid), Spain.

Objectives: To describe a series of cases in which adding a routine cardiac and abdominal examination by a pocket-size ultrasound device, performed by an internist, improved diagnosis and subsequent medical management of patients admitted to a medical department.

Material and method: Ninety-six patients admitted to our medical department between January and April 2012 underwent cardiac and abdominal screening with a pocket-size ultrasound device with B-mode and colour flow imaging after a principal diagnosis was set. One internist specifically trained performed the examinations. Diagnostic corrections were made and findings were confirmed by high-end echocardiography and examinations at the radiologic department.

Results: The principal diagnosis was changed in 16 patients (17%): 6 with preliminary diagnosis of heart failure (1 loculated pleural effusion, 1 pulmonary fibrosis, 1 focal liver lesion compressing inferior vena cava, 1 lung atelectasis, 2 pneumonia); 2 cases of renal failure interpreted as prerenal resulted in obstructive (full bladder and hydronephrosis); 2 cases of pneumonia resulted in heart failure; 1 case of acute pyelonephritis was diagnosed of renal abscess; 2 cases of supposed cholecystitis resulted in a liver abscess and a gallbladder hydrops; 1 case of constipation in a peritoneal carcinomatosis; 2 pleural effusion were seen to be loculated; and a patient with arm paresthesias was discovered to have a dilated myocardiopathy with low cardiac output. In 18 (18.75%) patients the preliminary diagnosis was verified: 3 cholecystitis, 2 liver abscess, 5 acute heart failure, 4 pneumonia, 3 pleural effusion and 1 pericardial effusion. And finally an additional diagnosis was made in 9 (9.37%) cases: 1 liver cysts, 1 liver hydatidosis, 1 splenomegalia, 2 renal cysts, 1 pleural effusion and 1 severe mitral regurgitation in a patient with SLE. There were no changes in 53 patients (55%).

Discussion: Nowadays, it is challenging to make a correct diagnosis based on medical history, physical examination and goal-directed laboratory tests and imaging procedures. Point-of-care ultrasonography is defined as ultrasonography brought to the patient and performed by the provider in real time, and, as the European Association of Echocardiography published recently, it may serve as a complement to the physical examination and a tool for a fast initial screening. Our study supports this statement, as in more than one of six patients the diagnosis, and thereby the treatment, was significantly corrected when using the pocket ultrasound device. Also, in nearly one of five patients preliminary diagnosis was verified, and an additional diagnosis was made in nearly one of ten. These scanners are quick and easy to use and improve the diagnostic precision. So, we suggest that most medical departments should implement strategies for routinely adding a pocket-size ultrasound examination, and so, internists should be trained for its performance. As limitations, all examinations were performed by the same internist, so our results are mediated by his accuracy.

Conclusions: By adding a pocket-size ultrasound examination of a few minutes to usual care, we were able to correct the diagnosis in many patients admitted to our medical department, which drove to a different treatment strategy without delay. Routinely adding this exploration in medical departments may improve inpatients management.

G-21
FACTORS ASSOCIATED WITH LACK OF RECORDING ALCOHOL USE IN MEDICAL RECORDS OF EUROPEAN MEDICAL INPATIENTS

B. Rosón[1], O. Gonsalves[2], M. Lember[3], P. Pascal[4], R. Puerta[5], R. Stauber[6], J. Vaclavik[7] and the ALCHIMIE STUDY Group

[1]Department of Internal Medicine. Hospital Universitari de Bellvitge. L'Hospitalet de Llobregat (Barcelona), Spain. [2]Department of Internal Medicine. Hospital Santos Silva. Vila Nova Gaia, Portugal. [3]Department of Internal Medicine. West Tallinn Central Hospital. Tallin, Estonia. [4]Department of Addictologie. CHU Carémeau Nîmes. Nîmes, France. [5]Department of Internal Medicine. Hospital de POVISA. Vigo (Pontevedra), Spain. [6]Department of Internal Medicine. Medical University of Graz. Graz, Austria. [7]Department of Internal Medicine. University Hospital Olomouc. Olomouc, Czech Republic.

Objectives: To investigate factors associated with lack of recording alcohol use in medical inpatients.

Material and method: Point-prevalence study performed in 8 European Countries. Alcohol consumption was evaluated with the AUDIT-C, AUDIT and the SIAC questionnaires. Drinking patterns were determined according to clinical evaluation using ICD-10 criteria. Multivariate analysis was performed with the step-wise logistic-regression model of the SPSS software package 13.0 (SPSS, Chicago).

Results: We reviewed 2112 medical records of 2123 interviewed patients. Alcohol consumption was recorded in 918 (43%), adequate quantitative recording was performed in 143 (7%) patients. Overall, 346 (16%) patients had unhealthy alcohol use and 85 alcohol related

admission, of those 67 (19%) and 18 (21%) had adequate quantitative recording, respectively. Independent patient factors associated with lack of recording of alcohol in medical records were female (OR 1.468; 95%CI: 1.828-0.847), and patients who drank occasionally (OR 1.974; 95%CI: 1.237-3.150). Whereas current drinkers (OR 0.530; 95%CI: 0.330-0.850), harmful drinkers (OR 0.343; 95%CI: 0.144-0.821), dependent (OR 0.321; 95%CI: 0.129-0.798), and former dependent patients (OR 0.637; 95%CI: 0.296-0.1373) and those with an admission alcohol related (OR 0.151; 95%CI: 0.071-0.323) had more frequently alcohol use recorded. Physician factors as knowledge of local prevalence (OR 0.371; 95%CI: 0.240-0.573), and obligatory field in medical records (OR 0.471; 95%CI: 0.320-0.695) were inversely associated with lack of recording. Independent Hospital and setting factors associated with lack of recording were: large hospital (> 600 beds) (OR 2.565; 95%CI: 1.529-4.305), population served mainly rural (OR 1.996; 95%CI: 1.000-3.984), or rural and urban (OR 1.966; 95%CI: 1.447-2.670)), intermediate country prevalence (OR 2.008; 95%CI: 1.370-2.943). Being admitted to a university hospital (OR 0.422; 95%CI: 0.547-0.847), Southern (OR 0.0.261; 95%CI: 0.164-0.414) and Central European countries (OR 0.145 95%CI: 0.088-0.239, intermediate local prevalence (OR 0.649; 95%CI: 0.476-0.885) were inversely associated with lack of recording. There were no significant differences in recording related to age, presence of internal medicine specialists, residents in training or electronic or paper medical files.

Discussion: In accordance with previous studies, alcohol use often goes unrecorded during hospitalization even in patients with AUDs and related disorders. Patients with more severe patterns and with related diseases, and physician knowledge of local prevalence and obligatory field in medical records were associated with alcohol use recording. Still proper identification was hardly ever performed. Female patients, those from rural areas, patients in large hospitals and from Northern Countries had alcohol use less frequently recorded.

Conclusions: Opportunity to detect unhealthy alcohol use and intervene was missed in a substantial number of cases. These data may be helpful when designing strategies to improve alcohol use detection among medical inpatients in Europe.

G-22
QUALITY OF CLINICAL RECORDS IN AN INTERNAL MEDICINE SERVICE

R. Simões, L. Tavares

Department of Internal Medicine. Centro Hospitalar Entre Douro e Vouga-Unidade da Feira. Santa Maria da Feira, Portugal.

Objectives: Dr. L. Weed, mentor of the Weed System of medical records, believed "that discipline in training and excellence of patient care can both be achieved with intelligent use of the medical record" (quote). A bibliography search showed a very scarce number of articles published concerning the quality of medical records. For a year, medical records of an Internal Medicine Department were revised and evaluated in order to improve them, and consequently improve patient care.

Material and method: A revision of clinical records was made of 25 files per month, 5 random files chosen in 5 random days of each month, during a period of 12 months, from January 2011 to December 2011, with a total of 300 files. A protocol with a list of quality indicators (QI) was created, with different variables, depending on the moment of the hospitalization. These indicators included the minimal information considered essential in a medical report. At the admission: QI1: personal situation; QI2: family situation; QI3: previous functional state (Karnofsky Performance Status Scale). At the day preceding discharge: QI4: list of medical problems. At the day of discharge: QI5: physical exam at the time of discharge; QI6: functional state at the time of discharge (Karnofsky Performance Status Scale); QI7: exam results during the hospitalization; QI8: predicted prognosis. The information was classified as absent, scarce and adequate or absent and present, depending on the variables. The protocol was presented to the physicians. The three last months before the establishment of the protocol were used as control results. A statistic analysis was made using the Microsoft Office Excel.

Results: An analysis of each of the 12 months was made, comparing the 3 months before the protocol (January to March) with the 9 months after (April to December) in order to evaluate the influence of the protocol in the physicians' daily routine. The results for the QI1 were already satisfying (74-82%) before the protocol and reached 92-96% after its establishment. As for the QI2 and the QI6, both showed a great improvement from 40% to 70% and 14% to 70%, respectively. The QI3, the QI5 and the QI7 showed an elevated compliance, reaching almost 100%. The overall rate of protocol compliance was 67.2%, with the lowest individual percentage being the QI8 (16.3%), followed by the QI4 (37.7%). Concerning the patient's destination on discharge, the medical records of those went to continuous care facilities have the lowest rates of protocol compliance (overall rate: 61.3%; QI8: 6.7%; QI4: 13.3%), followed by the ones sent only to the general practitioner (overall rate: 63.8%; QI8: 11.7%).

Discussion: Results show an improvement in almost all variables after the establishment of the protocol. However, some of the variables, specially the list of medical problems and the prognosis, maintain very low results. This shows that physicians are not yet alert to the importance of the list of medical problems in the approach and decision making regarding a patient. Nor are they well aware of the predicted prognosis that will decide the follow-up according to what is expected from each patient. Furthermore, the quality of the information was shown to change depending on the patient's destination on discharge, with the general practitioner and the continuous care facilities being the most neglected.

Conclusions: The protocol created in the department helped to improve the usual practice and alert to the importance of an accurate medical record. However, physicians are not fully aware of how much a good medical record can improve patient care and medical decision making, hence being a valuable tool in the accomplishment of a better practice. Much work needs to be done in the field of accuracy and quality of medical records, both in their improvement and compliance monitoring, in order to increase efficiency.

G-23
THERAPEUTIC ATTITUDE IN ELDERLY PATIENTS WITH CANCER: EXPERIENCE IN REINA SOFIA HOSPITAL IN TUDELA

M. Bonilla Hernandez[1], I. Gil Arnaiz[2], R. Grandez Ladrón de Guevara[2], R. Vera García[2], B. Hernández Marín[2], R. Sierra Labarta[3], M. Esquillor Rodrigo[1], F. Escolar Castellón[1]

[1]Department of Internal Medicine, [2]Department of Oncology, [3]Department of Urology. Hospital Reina Sofía. Tudela (Navarra), Spain.

Objectives: According to the National Cancer Institute, 60% of new cancer diagnoses are made in over 65 year people. The clinical status of patients in their 75´s is also very variable, depending on their functional impairment, comorbidity and life expectancy. The attitude to an old patient diagnosed with cancer is determined not only by age but also by these parameters. In addition, limited functional reserves kidney, liver and bone marrow make treatments have major side effects, with the largest number of interactions with other drugs in chronic administration. Oncologist should plan an individualized treatment for each patient according with each

clinical situation, patient and family opinion. The principal aim of this study is to analyze retrospectively the therapeutic attitude taken with patients over 75 diagnosed with cancer in Reina Sofia Hospital in 2010.

Material and method: We analyzed retrospectively all patients with cancer diagnosis who needed oncology treatment in Reina Sofia Hospital in 2010. We reviewed 277 patients and we selected 97 patients who were over 75. We recruited them and followed their evolution for 2 years.

Results: The average age was 80 years old (range 75 - 93). The distribution of cancer diagnosis: 75- 80 year old: 54.6%, 81- 85 years old: 23.7%, 86- 90 years old: 19.6% older than 90 years old: 2.1%. Male 43.3%. Female 56.7%. The most primary tumor location was colorectal carcinoma: 28.9%, digestive non-colorectal cancer: 21.6%, breast cancer: 18.6%, lung cancer: 10.3% and gynecologic cancer: 6.2%. At the diagnosis time, 29.9% of our patients had localized disease, 46.4% locally advanced disease, and 2.7% metastatic disease. The first choice of treatment offered was surgery in 43.3% of the patients, chemotherapy in 19.6%, and basic supportive care only in 12.4% of these cases. 46.3% of our patients received standard treatment, according to the guidelines, and 53.6% of our patients received suboptimal treatment because of doses reduction or not administration of drugs or treatments according to their clinical situation. In addition to age, the causes of selection of suboptimal treatment option were the general condition: 22.7%, comorbidity 15.5%, choice of patient or family: 7.2%. The treatment was well tolerated in 59.8% of patients. 8.2% of them needed doses reduction, and 18.6% needed to stop treatment because of high toxicity. In May 2012, 59 of our 97 patients are alive. Only 38 patients have died. One year survival was 65% and 18 months survival was 45%. The progression of the disease was the most frequent cause of death, (28 patients), sepsis and septic shock were the second cause or death (5 patients) Cardiovascular disease was the third cause (1 stroke, 1 myocardial infarction) and other causes were gastrointestinal bleeding (1 patient) and hip fracture (1 patient) and of unknown cause (2 patients).

Discussion: This study results are similar to other published results about therapeutic attitude in senior patients. These reviews highlight the existence of 2 groups. Half of patients aged 75 and older are functionally "old adults" and can be treated with a standard oncologic approach. The other half however, will need more comprehensive care, including a comprehensive geriatric assessment. The most important physician´s task is to distinguish between these 2 groups of patients: those who will benefit from aggressive treatment and those who will benefit over expectant management and symptomatic care. Our experience shows that if physicians select patients properly one year survival will rise 65% in elderly population.

Conclusions: Traditionally, age is the factor that has limited the therapeutic approach in elderly patients with cancer. Despite the limitations of our small study, results lead to think that at least half of well-selected elderly patients can benefit from active cancer treatment. New clinical trials in this population will help us to select patients properly, improve the efficiency of treatments, and improve their quality of life and survival.

G-24
DIAGNOSTIC LIVER BIOPSY: A RETROSPECTIVE STUDY OF 9 YEARS

L. Lourenço, P. Lopes, J. Mariz, N. Bragança

Department of Internal Medicine 3. Hospital Prof. Doutor Fernando Fonseca. Amadora, Portugal.

Objectives: Liver biopsy has been the gold standard in liver pathology; however, over the last decade, the virological and serological testing has made the diagnosis of many liver diseases much easier and precise. Objective: retrospective review clinical aspects related to all liver biopsies performed in our department during a 9 year period of time, with a diagnostic purpose.

Material and method: The authors reviewed the clinical data of adult patients admitted to our department between January 2003 and December 2011 and submitted to a diagnostic liver biopsy in an inpatient basis. The indications, technique performed, diagnostic rate, prevalence of diagnoses in diffuse and focal liver disease, contra-indications and complications of the liver biopsies performed were evaluated. The diagnoses suspected in the biopsy note were compared with the diagnoses post-biopsy. The authors also describe and compare the complications occurred with percutaneous transthoracic liver biopsy palpation/percussion-guided and real-time ultrasound-guided. Patients with signs of hepatic decompensation or in which liver biopsy was performed only for assessment of prognosis (disease staging) or to assist in making therapeutic management decisions were excluded.

Results: We included a total of 85 liver biopsies in our study, performed in 45 males and 40 females, with a median age of 59.8 years. In 4 cases the biopsy was repeated since it was unconclusive due to lack of tissue sample or poor quality of the fixation method. In 85 patients, 87 diagnoses were carried out before biopsy. 40.2% of the diagnoses were confirmed by biopsy but in 27.6%, 25.3% and 6.9% the diagnosis was specified, changed or unconclusive, respectively. Diagnostic rentability in all biopsies performed was therefore 93.9%. A total of 14 new diagnoses were added after biopsy, resulting in 95 final diagnoses. The most common indications for biopsy in diffuse liver disease were hepatitis C, alcoholic liver disease and auto-immune liver disease and for focal liver disease were secondary liver malignancy of unknown (SLMUO) or suspected origin (SLMSO) and primary liver malignancy. Liver biopsy was able to determine the primary tumour in 61.5% cases of SLMUO. All patients were tested prior to the biopsy for impaired hemostasis and all had INR < 1.4 and platelet count > 60,000/mL. The rate of complications was 9.4% and they consisted only of local pain which was successfully treated with analgesics and lasted for a period of time < 24 h. There were no differences in rate of complications between the methods used for liver biopsy.

Discussion: Liver biopsy was able to help confirm and rule out diagnoses in the majority of cases and was also able to establish new diagnoses that were not suspected. In cases of secondary liver malignancy of unsuspected origin, liver biopsy allowed to determine the primary tumour with a high success rate and affect drastically prognosis and management of patients. In our series, liver biopsy had a high diagnostic rate and few complications when no contra-indications were present, similarly to other studies. Also there were no severe complications which make liver biopsy a safe and useful diagnostic tool.

Conclusions: Even in the era of advanced virological, immunological and molecular genetic testing, liver biopsy remains a useful and safe tool leading to changes in patient management. Liver biopsy contributes with very high specificity to the diagnosis of malignancy in focal liver disease and detects non-malignant disease. Improving diagnostic practice requires more development in immunocytochemistry and information on outcomes.

G-25
ENDOTHELIAL DYSFUNCTION AND PSYCHOVEGETATIVE DISORDERS IN PATIENTS WITH CALCULOUS CHOLESYSTITIS BEFORE AND AFTER CHOLESYSTECTOMY

V. Schekotov, Y. Tretyakova, I. Zimmerman

Department of Internal Medicine. Perm State Medical Academy. Perm, Russia.

Objectives: To characterize existence and expressiveness of endothelial dysfunction in chronic calculous cholesystitis (CCH)

patiens with a psychovegetative syndrome (PVS) in the perioperative period of cholesystectomy (HE) and to estimate possibility of correction of the revealed disorders by antidepressant tianeptin.

Material and method: At performance of work 90 patients with chronic calculous cholesystitis are surveyed. Anxious and depressive violations were revealed at 67.7% of patients (61 people). These patients also made group of supervision. To all patients carrying out a HE in surgical office was planned. In research it is included: men - 2 (3.3%), women – 59 (96.7%). Middle age of patients made 50 ± 10.0 years. Patients were divided into 2 groups. 30 patients of 1 group (main) received tianeptin (firm Servier, France) in a dose of 37.5 mg/day in 3 weeks prior to operation and in 3 weeks after HE. The group of comparison consisted of 31 patients, but without antidepressant. For research psychoemotional status the hospital scale of anxiety and a depression (HADS), a scale of Spilberger and Vayne's questionnaires were used. For an assessment of a functional condition of endotelium used definition of desquamated endotheliocytes (DE) in blood (Hladovec, 1978), nitrogen oxide (NO) level and a method of an endothelium dependent vasodilatation (EDVD).

Results: The psychovegetative syndrome (SVD) was revealed at 87% of patients in 3 weeks prior to HE. The correlation analysis showed existence of authentic direct interrelation between quantity of DE and age of patients, degree of PVS and return interrelation of these indicators with NO level and EDVD percent. Antidepressive therapy led to authentic improvement of the mental and vegetative status and endothelial function at patients in the postoperative period. Increase of level of NO from 10.94 ± 2.46 to 21.82 ± 14.78 in μmol/l ($p = 0.02$), reduction of quantity of DE from 7.46 ± 3.02 to 3.61 ± 1.86×104/l ($p < 0.0001$) in the main group in 3 weeks after operation is noted. EDVD increased from 4.23% to 43.85% ($p = 0.0006$) after therapy in 1 group. In group of comparison after HE aggravation of endothelial dysfunction in parallel with PVS progressing was noted.

Discussion: Thus, the interrelation between aggravation of a psychovegetative syndrome on the one hand and deterioration of a functional condition of endothelium with another at CCH patients in the perioperative period is revealed. Impact on the psychoemotional status of patients by means of tianeptine made positive impact, including on correction of endothelial dysfunction.

Conclusions: Psychovegetative disorders and the endothelial dysfunction, available at chronic calculous cholesystitis patients before operation, progress in the postoperative period. Application of antidepressant tianeptin allows to reduce frequency and expressiveness of emotional and vegetative disorders after operation, and also leads to reduction of endothelial dysfunction.

G-26
CONTINUITY OF CARE: FIVE MONTH EXPERIENCE OF ON-LINE CONSULT BETWEEN PRIMARY CARE AND INTERNAL MEDICINE

C. Navarro San Francisco[1], C. Fernández Capitán[1], F. Arnalich Fernández[1], M. Amengual Pliego[2], M. Fernández de Castro[3], Group of Primary Care Center Directors[4], Group of Attending Physicians[1]

[1]Department of Internal Medicine, [2]Director of Continuing Care, [3]Deputy Managing Director General Hospital, [4]Primary Care Centers. Hospital Universitario La Paz. Madrid, Spain.

Objectives: To describe the implementation and pilot experience of on-line consultation between the Primary Care Centers affiliated to Hospital Universitario La Paz (Community of Madrid) and the Internal Medicine Service of this reference hospital.

Material and method: From November 2011 the Department of Internal Medicine in Hospital La Paz (Tertiary Hospital with 1,328 beds) made available to primary care specialists a program of on-line consultation, previously in place for its use between different hospital specialists. The project was presented in each of the Primary Care Centers belonging to Hospital Universitario La Paz, providing healthcare to a population (urban and rural) of 600,000 people. During the visit, was explained how to use the software tool of on-line consultation. It was reminded the portfolio of outpatient services available. This system allows the consultant to generate a question to his internist, having a system of allocation of the primary care center from which makes the identification of the patient, the consultant, the date and time when the consult was done and the reason for the consult. Furthermore, as is done through the computer program of clinical data management are also available analytical data, diagnostic imaging tests and pathology. The query and response are recorded as part of the patient's medical history.

Results: The incorporation of the different Primary Care Centers, has been gradual as presentation visit were made. From November 2011 until April 2012 (5 months) has responded to a total of 263 consultations. The response time is one business day. The average number of responses per patient, is also one with a range between 1 and 4 responses. The issues raised in the consultants could be grouped into: -Questions on diagnose or guidance in the management; -Management for not accessible from Primary Care in the citation vehiculization monographic consultations inpatients already diagnosed; -Streamlining access for patients with potentially serious pathologies to query Rapid Assessment; -Coordination and facilitation of admission, avoiding the pass through the emergency department; -Planning for treatments or diagnostic tests from the Day Hospital of Internal Medicine.

Conclusions: On-line consult between Primary Care and Internal Medicine help to improve the quality of care provided to our patients, bringing together professionals from different levels of care, primary care and specialized hospital care. It solves diagnostic or therapeutic doubts and have been avoided displacements of patients to the hospital and referrals to the emergency department. The use of online technology makes available questions and answers immediately, as part of the patient's medical record and available to others who might participate in patient care. We believe that this pilot experience has been helpful for both the patient and medical specialists involved in their care, and improves the use of health resources.

G-27
MALNUTRITION IN OUR MEDICAL PATIENTS. ARE THERE CONSEQUENCES?

A. Tejera Concepción[1], C. Hernández Carballo[1], J. del Arco Delgado[1], F. Pereyra García-Castro[2], M. Muros de Fuentes[3], J. Romero Pérez[1], P. Laynez Cerdeña[1]

[1]Department of Internal Medicine, [2]Department of Endocrinology and Nutrition, [3]Department of Clinical Analysis and Laboratory. Complejo Hospital Universitario Nuestra Señora de Candelaria. Santa Cruz de Tenerife, Spain.

Objectives: To detect malnutrition in our patients. To assess the influence of malnutrition in mortality, readmissions and inpatient length of stay.

Material and method: We carried out a prospective study that enclosed 202 consecutives patients admitted to the internal medicine wards, between June and December 2011. Being reviewed in May 2012. At admission: 1. The body mass index (BMI) was measured, therefore the height and weight were needed. The length of the forearm and a chair to weight were used in case the patient stayed in bed. 2. A biochemical screening that included total proteins, cholesterol and lynfocytes was performed. 3. If the biochemical screening detected malnutrition, a red bell appeared in the computer system, when the patient was visualized. Then the short mininutritional assessment test (MNA), in patients with 65

years or older or the malnutrition universal tool (must), if younger than 65 years, were done. 4. If moderate or severe malnutrition was confirmed, a 3-day written control of daily food intake was executed. Adjustments in diet were taken, and oral supplements or enteral or parenteral feeding were then given if necessary.

Results: A total of 202 patients were initially comprised, 4 of which were excluded because of incomplete data. The 198 patients left were analized with the SPSS software 18.0. The proportion of males 125 was higher than females 73. The media of age was 62 (± 19) years. The median length of hospital stay was 14 days (9-21). The more frequent diagnosis were: sepsis (64%), cancer (21%) and cirrhosis (6%). 43 patients died: 14 (7%) during the hospital stay and 29 (9.5%) after discharge. The causes of death are coincident with the diagnosis during the hospital stay, in the case of sepsis is the respiratory one the most prevalent. 79 patients had to be readmitted usually once or twice. Except for one patient that was readmitted 8 times with problems related to alcoholism. The biochemical screening detected malnutrition in 42 patients (21%): 34 with medium risk and 8 with high risk. When the must or MNA screening in these patients was done: 37 (18.7%) were malnourished, 14 moderate and 23 severe malnutrition. More males (25) than females (12). 9 of these patients had a daily food intake control during 3 days of 50% or less or could not eat at all because of medical prescription and had intravenously saline solutions. 8 of the 9 patients were malnourished or at risk of malnutrition. 7 of the 8 patients received supplements. Mortality during hospital stay was significantly higher in malnourished patients (21%) compared to patients without malnutrition (3%), $p < 0.001$. No significant differences were detected between patients with and without malnutrition in the number of hospital readmission, length of stay, mortality after discharge, age, sex, or BMI.

Discussion: The prevalence of malnutrition in the general population is 22%, but in older persons with comorbidity admitted to hospitals it is close to 50%. We reported a prevalence of 21% in patients admitted to internal medicine wards. Possibly the malnutrition screening test used is not sensitive enough. When comparing both groups of patients malnourished and without malnutrition, we confirmed that malnourished patients have a higher short-term mortality than those without malnutrition as expected. No higher rates of hospital readmission, length of stay, long-term mortality or influence of age, sex, BMI could be detected. The nutritional subjective global assessment method that includes physical examination findings and the clinician´s judgment could be a good option.

Conclusions: The prevalence of malnutrition reported in our study was 21%. The malnutrition biochemical screening test used probably underestimates the levels of malnutrition present in our medical patients. A more sensitive screening test should be implemented. A higher short-term mortality rate was observed in malnourished patients compared to patients without malnutrition. No higher rates of hospital readmission, length of stay or long-term mortality was registered.

G-28
MEDICATION DOSING IN PATIENTS WITH RENAL IMPAIRMENT AT ACUTE MEDICAL ADMISSIONS

M. González Benítez[1], C. Luque Amado[1], M. Godoy Guerrero[1], A. Ruz Zafra[1], N. Navarro Fernández[1], C. Martínez Gil[2], A. Ríos Pérez[1], A. Ruiz Cantero[1]

[1]Department of Internal Medicine, [2]Department of Pharmacy. Hospital la Serranía. Ronda (Málaga), Spain.

Objectives: The growing prevalence of hypertension and diabetes, as well as population aging, has increased progressively the appearance of renal chronic disease. The aim of the present study was to detect renal failure at admission among hospitalized patients and to assess if medications that require dosage adjustment for patients with renal disease were correctly prescribed.

Material and method: A cross-sectional study was performed including all hospitalized patients at the Internal Medicine Department at eight different times (one month apart). Kidney function was assessed by estimation of glomerular filtration rate (eGFR) using Modification of Diet in Renal Disease (MDRD) equation. Renal insufficiency was diagnosed when eGFR was minor to 60 ml/min/1.73 m^2. Analyzed variables were sex, age, serum creatinine levels at admission, eGFR at admission, renal insufficiency and, among patients with renal impairment, number of prescribed drugs, if medications that require dosage adjustment were prescribed, if excessive doses of medications were prescribed, number of dosage errors and which drugs were involved. Continuous variables were expressed as average ± standard deviation (median and interquartile range in asymmetric variables). Nominal variables were reported as frequencies and percentages.

Results: 301 patients were included (133 women, 44.2%), with a median of age of 73 years (60, 80). The median of serum creatinine levels was 1.12 mg/dl (0.9, 1.5). The average of eGFR was 60.60; 26.05 ml/min/1.73 m^2. 151 patients (50.2%) had renal insufficiency at admission (43 of them had an eGFR minor to 30 ml/min/1.73 m^2). Among patients with renal impairment the median of prescribed drugs per patient was 8 (6.10), prescribed medications that require dosage adjustment were present in 115 cases (76.5%), excessive doses of medications were detected in 48 cases (32%) and a total of 63 dosage errors were detected (median of dosage errors: 1 per patient, maximum of 4 errors in one patient).). Drugs involved in dosage errors were, in order of frequency: enoxaparin 28 cases (18.7%), antibiotics 13 (8.7%), antiemetics 11 (7.3%), spironolactone 5 (3.3%), digoxin 2 (1.3%) and other isolated errors (ranitidine, memantine, anti-retroviral agent). Most cases of dosage errors (32, 66.7%) were detected among patients with eGFR minor to 30 ml/min/1.73 m^2.

Discussion: A high prevalence of renal failure at acute medical admission was found. Medications that require dosage adjustment were prescribed in most cases. Excessive doses of medications were a frequent problem, detected in 1 each 3 patients. The most frequent dosage error was excessive dose of enoxaparin, which can cause a serious problem in patient safety, as it can lead to bleeding complications.

Conclusions: Renal insufficiency is a common problem among hospitalized patients at the Internal Medicine Department. There is a rather high risk of dosage errors due to excessive doses of medications, which can endanger the inpatient safety. Reducing medication errors is critical for medication safety. Awareness of dosage errors is a key step to enhance patient safety.

G-30
DIABETIC FOOT PATIENTS' 3 AND 5 YEAR FOLLOW UP: ULCER OCCURRENCE, AMPUTATION AND MORTALITY

D. Martins Mendes[1], M. Monteiro Soares[2], J. Lima[3], R. Soares[4]

[1]Department of Internal Medicine, [2]Diabetic Foot Clinic-Department of Endocrinology, Diabetes and Metabolism. CHVNG/Espinho EPE. Vila Nova de Gaia, Portugal. [3]Cancer Biology Group. IPATIMUP. Oporto, Portugal. [4]Department of Biochemistry. Faculty of Medicine of Oporto University. Oporto, Portugal.

Objectives: Diabetes mellitus is one of the most frequent metabolic disorders, with a prevalence of 13.9% in the Oporto district in Portugal (our referral area). Diabetic foot is one of the major complications of this disease and causes a considerable burden in health care and patient well-being. Literature reports high rates of morbi-mortality associated with this condition. Therefore we considered essential to estimate the risk at 3 and 5 years of ulcer occurrence (1st or re-ulceration), amputation and death in a population of patients followed in our Diabetic Foot Outpatient Clinic as well as determine their causes and predictive variables.

Material and method: A retrospective cohort study is being conducted including all patients recurring to our Diabetic Foot

Outpatient Clinic from January 2002 until September 2012. Patients will be followed for at least 3 years or death. Those lost to follow-up will be excluded, as well as those with missing data apart from tunning fork exam (record only started in the middle of 2008). The following variables will be collected from clinical file: age; gender; scholar degree; diabetes type, treatment and duration; A1C hemoglobin (HbA1C); retinopathy; nephropathy; cardiovascular disease; stroke; smoking habits; physical disability and visual acuity; previous foot ulcer and/or amputation; diabetic foot characterization related variables. Death causes will be analysed. Association between outcomes' and the collected variables will be assessed.

Results: At baseline, patients (N = 392 so far) had a mean age of 64 (17-94) years; diabetes duration of 16 (1-64) years; HbA1C of 7.7% (5.2-15.3%). 48% were male; 83% had basic school level or less; 97% were type 2 diabetics; 41% insulin treated; 50% had retinopathy, 15% myocardial infarction, 18% stroke, 16% nephropathy; 20% were smokers (present or past); 42% physical disabled; 41% visual disabled; 39% presented peripheral vascular disease (PVD); 60% neuropathy symptoms; 49% altered Semmes-Weinstein monofilament sensation (SWMS) and 34% altered tunning fork sensation (TFS); 31% previous DFU history and 12% present at baseline; 14% had previous lower extremity amputation (LEA). So far, patients have a mean follow-up of 57 (1-123) months; 25% died; 36% patients have 3 years follow-up and 39% for at least 5 years. During the entire follow-up period: 42% developed a DFU, 19% recurred, 11% had LEA and 3% re-LEA. In univariate analysis, variables associated with DFU occurrence were male gender, retinopathy, visual impairment, scholar degree, previous DFU history, previous LEA, physical disability, onychomycosis, foot deformity, PVD, altered SWMS, altered TFS, HbA1C; with recurrence retinopathy, previous DFU history, previous LEA, foot deformity, PVD, altered SWMS, altered TFS; with LEA male gender, smoking, previous DFU history, previous LEA, PVD; and with death male gender, myocardial infarction, stroke, nephropathy, scholar degree, physical disability, PVD, age. Multivariate and more detailed analysis will be done in September.

Discussion: Our data reveals a quite high rate of DFU development (42%), justified by our high risk context (43% had previous DFU). Conversely, there was a low rate of DFU recurrence and LEA. We observed that no variable was associated with re-LEA. Moreover, different outcomes seem to share several common predictive variables such as male gender, retinopathy, scholar degree, previous DFU or LEA, physical disability and PVD.

Conclusions: It was reported that diabetics have high comorbidity rates and should be adequately followed and stratified by their risk of comorbidities development. With these findings we will attempt to create a model with the same core variables for the prediction of all the assessed outcomes: DFU, LEA and death.

G-31
QUALITY OF CARE FOR MYOCARDIAL INFARCTION AT NONACADEMIC HOSPITALS. LONG-TERM DATA FROM REGISTRIES OF MYOCARDIAL INFARCTION IN THE CZECH REPUBLIC

Z. Monhart[1], J. Reissigova[2], P. Widimsky[3], P. Jansky[4], J. Zvarova[2], H. Grunfeldova[5]

[1]Department of Internal Medicine. Hospital Znojmo. Znojmo, Czech Republic. [2]Centre of Biomedical Informatics. Institute of Computer Science. Prague, Czech Republic. [3]3rd Department of Internal Medicine. Faculty Hospital Kralovske Vinohrady. Prague, Czech Republic. [4]Cardiovascular Centre. University Hospital Motol. Prague, Czech Republic. [5]Department of Internal Medicine. Hospital Caslav. Caslav, Czech Republic.

Objectives: The most important task of our work is to assess quality of care provided to myocardial infarction (MI) patients in internal medicine departments of nonacademic hospitals. Furthermore we decided to evaluate utilization of evidence-based treatments and identify subpopulations of these patients at high risk of insufficient therapy.

Material and method: The data originated from MI registries in nonacademic hospitals from 2003-2010. In total, 7,324 consecutive MI cases were included in the analysis. None of the participating hospitals had catheterisation facilities. Interventional treatment (if indicated) was provided in another hospital. All participating internal medicine departments provided a comparable level of acute cardiac care and a similar spectrum of diagnostic and therapeutic procedures; therefore, these hospitals were considered to be an adequate sample of non-PCI hospitals in the Czech Republic. We analyzed the medical charts of all patients (acute therapy within the first 24 hours) and reviewed discharge letters (pharmacotherapy recommended post discharge).

Results: In total, 7,324 consecutive MI cases were included in the analysis. Acute pharmacotherapy within the first 24 hours after admission was as follows: aspirin (oral or i.v.) was used in 89.2% cases, clopidogrel in 60.3%, unfractionated, low molecular weight heparin or fondaparinux in 94.1%, beta-blocker (oral or i.v.) in 59.2%, and statins in 56.9%. All recommended drugs were used in 33.6%. The number of the recommended medications used within the first 24 hours was significantly influenced by age and gender; older patients (> 65 years) and women had a lower chance of receiving more drugs ($p = 0.001$ and $p = 0.003$). The presence of diabetes had an adverse influence on the quality of pharmacotherapy with borderline statistical significance ($p = 0.050$). Reperfusion therapy (transfer for primary PCI or thrombolytic therapy) was used in 71.8% of STEMI cases, transfer for primary PCI was conducted in 70.2%. Reperfusion treatment in patients with STEMI was less often used in older patients ($p = 0.033$), patients with diabetes ($p = 0.001$) and those with a higher Killip class ($p < 0.001$). In total, 703 of 7,324 patients died in the hospital (9.6%). At discharge we found the following incidence of prescribed drugs: aspirin in 90.1% cases, clopidogrel in 62.8%, beta-blockers in 81.4%, ACE inhibitors and/or ARBs in 78.5%, and statins in 81.3% of cases. All recommended drugs were prescribed in 44.3%. The quality of therapy prescribed at discharge was significantly lower in older patients ($p < 0.001$) and in women ($p = 0.001$). Patients with hypertension and hyperlipidaemia had a higher chance of receiving more of the recommended pharmacological agents within the first 24 hours and also at discharge ($p < 0.001$ and $p < 0.001$). The presence of diabetes or a history of MI did not decrease the adjusted quality of discharge pharmacotherapy.

Conclusions: We revealed underutilization of evidence-based treatments within the first 24 hours after admission especially in case of statins and clopidogrel. Therapy prescribed at discharge met the criteria for quality comprehensive therapy more frequently. Quality of treatment provided in the acute stage and at discharge was significantly lower in older patients and in women. The underutilization of various medical therapies and medical procedures (such as cardiac catheterization) among diabetic patients and women is consistent with data from other registries that evaluated MI patients. Patients with a history of hypertension and hyperlipidaemia received more comprehensive acute and discharge pharmacotherapy. Generally, quality of treatment in patients with MI at nonacademic hospitals has increased substantially in recent years. However, opportunities to improve care should be considered.

G-32
UNRECOGNIZED RENAL INSUFFICIENCY AND CHEMOTHERAPY-ASSOCIATED ADVERSE EFFECTS AMONG BREAST CANCER PATIENTS

A. Leader[1], E. Lotan[1], M. Lishner[1], M. Gottfried[2], D. Pereg[3]

[1]Department of Internal Medicine A, [2]Institute of Oncology, [3]Department of Cardiology. Meir Medical Center. Kfar Saba, Israel.

Objectives: Several studies have demonstrated a 50% prevalence of unrecognized renal insufficiency (RI) (i.e. decreased estimated glomerular filtration rate (eGFR) in subjects with normal serum creatinine) among cancer patients. This has also been shown in patients with breast cancer. Antimicrobial therapy is the main field of internal medicine that widely utilizes eGFR in dose adjustment, while there is a paucity of evidence in other fields. Since cyclophosphamide is excreted renally, we retrospectively assessed whether there was an increased frequency of chemotherapy-associated adverse effects among breast cancer patients with unrecognized RI, treated with the AC protocol (cyclophosphamide and doxorubicin).

Material and method: We retrospectively accessed the computerized records of patients diagnosed with adenocarcinoma of breast and treated with the AC protocol, for 4 planned courses every 21 days, at our institute's oncology unit from 1/2005 to 8/2009. We only included those with a normal serum creatinine (< 1.4 mg/dl). Patients with insufficient data or treated with prophylactic granulocyte colony stimulating factors (GCSF), were excluded. The primary outcome was the occurrence of any chemotherapy-associated adverse effect during treatment or three weeks after the final course. This was defined as a composite of the following: neutropenic fever with hospital admission, a delay in chemotherapy treatment for a medical reason, dose adjustment due to toxicity of the chemotherapeutic drugs, and the use of GCSF. The Cockcroft-Gault formula was used to estimate the GFR. The patients were divided into two eGFR groups: eGFR > 75 ml/min/1.73 m^2 and eGFR < 75 ml/min/1.73 m^2. The incidence of the primary outcome was compared between the two eGFR groups.

Results: 218 subjects underwent screening, of which 95 patients fulfilled our study criteria. The mean (± SD) eGFR was 80.1 ± 19.1 ml/min/1.73 m^2. 53 patients (56%) had an eGFR of at least 75 ml/min/1.73 m^2 whereas 42 (44%) had an eGFR of less than 75 ml/min/1.73 m^2 (i.e. unrecognized RI). Patients in the eGFR < 75 group were older, had a lower body weight and higher creatinine levels at study entry (0.9 mg/dl vs 0.8 mg/dl, p < 0.001). 49 (52%) patients experienced the primary outcome of at least one chemotherapy-associated adverse effect. The incidence of these adverse effects was higher in patients with eGFR < 75 compared to those with eGFR > 75 (64% vs 42%, OR 5.29, 95%CI 2.10-13.33) and remained statistically significant after adjustment for age, BMI and initial doses of chemotherapeutic drugs (OR 3.56, 95%CI 1.08-11.67). Neutropenic fever, dose delay and dose adjustment as separate outcomes, occurred more frequently in the eGFR < 75 group but lost statistical significance after adjustment. Hemoglobin levels gradually decreased in both groups throughout the treatment period, and were significantly lower in the eGFR < 75 group than in the eGFR > 75 group, 3 weeks after the final cycle of treatment (10.9 vs 11.5, p = 0.017).

Discussion: Our results confirm previous findings that unrecognized RI is a common entity among breast cancer patients undergoing chemotherapy. To our knowledge, this in the first study evaluating the influence of unrecognized RI in on the adverse effects of chemotherapy. We have shown an association between lower eGFR and increased adverse effects of chemotherapeutic drugs among breast cancer patients with normal creatinine, treated with the AC protocol. Whether eGFR-guided dose adjustment leads to more favorable treatment outcomes, needs to be established.

Conclusions: Unrecognized RI increases the risk of chemotherapy-associated adverse effects among breast cancer patients with normal serum creatinine, treated with the AC protocol. Further studies are needed to determine whether unrecognized RI influences treatment outcomes in other disciplines of internal medicine.

G-33
INTENSIVE FOLLOW-UP IN COPD TO IMPROVE ADHERENCE TO TREATMENT

M. Vaquero, E. Zubillaga, A. Eguiluz, K. Leizaola, M. Ibarguren, M. Elola, A. Fuertes, N. Pérez

Department of Internal Medicine- Dr. G. Zubillaga. Hospital Universitario Donostia UPV/EHU. Guipúzcoa, Spain.

Objectives: We aimed to provide a reference physician and his telephone number making easier physician-patient relationship by telephone to fix a quick meeting. In that way, we encourage patients to submit the prescribed treatment, to answer questions about problems would come up and to improve non-pharmacological strategies.

Material and method: We asked Medical Record Department of our hospital to provide us all the 227 COPD patients discharged between July and December 2010. 117 patients were randomly assigned to monthly telephonic following during 6 months (Group Follow up) and 110 patients to Group Control. Each patient was followed by the same internist during all the period. In the Group Follow up, 27 patients were excluded (9 deads, 9 wrong phone number, 4 refused to participate, 3 were non-COPD, 2 repeated records), thus we included 90 patients. In the Group Control, 10 of them were excluded for similar reasons. At the end of the following period, 100 patients in Group Control were asked about their

Table 1 (G-33). Basal characteristics

Characteristic	Dates
Age	Mean 71.5 years (SD 12)
Sex (M/F)	64/26
BMI (kg/m2)	Mean 27 (SD 4)
Written treatment	92% (82 p)
Chronic oxygen therapy	35% (32 p)
30 min walking daily	62% (56 p)

Table 2 (G-33). Pharmacologic treatment

LAMA + LABA + ICS	LABA	LAMA	LAMA + LABA	Antibiotic rounds
90%	4%	4%	2%	None 53%. Yes 47% (24-1r, 12-2r, 4-3r, 1-5r, 1-6r)

pharmacologic and non-pharmacologic treatment, lifestyle and admissions.

Results: In the table below, we show basal characteristics and treatment in Group Follow up. We also recorded information about admissions in the previous 6 months and readmissions during follow-up period, which is shown in another poster. Finally, we made an enquiry about satisfaction with the following results: 60% of patients were satisfied, 20% very satisfied, 10% excellent idea, 1% no satisfied and 9% did not answer.

Discussion: Follow up of discharged COPD patients by Hospitalists is considered a good clinical practice to improve patients´ management answering their questions, avoid comorbility and assure quality in medical practice.

Conclusions: A personalized monthly phone call during six months of discharged COPD patients gives a transitional care and a coherent follow up and continuity of cares. Most of patients are satisfied with the intervention, asking us about therapy, relapses, clinical visits and motivated in order to improve non-pharmacological measures and treatment adherence.

G-34
RECOGNITION AND INITIAL MANAGEMENT OF SEPTIC PATIENTS IN A DISTRICT GENERAL HOSPITAL. A JUNIOR DOCTOR PATIENT SAFETY INTERVENTION

V. Robba, L. Deacon, J. Lingard, R. Lewis, T. Dove, S. Stinchcombe

Junior Doctor Patient Safety Group. Kings Mill Hospital. Mansfield, United Kingdom.

Objectives: Assess recognition and management of sepsis at Kings Mill Hospital (KMH). Develop simple strategies to improve this in line with the 'Surviving Sepsis' campaign.

Material and method: Sepsis is a major cause of mortality. Implementing a care 'bundle', such as the 'Sepsis Six', can reduce mortality rates. The records of 142 patients receiving intravenous antibiotics in KMH's emergency assessment unit (EAU) between January and May 2012 were analysed for compliance with the 'Sepsis Six'. Baseline data (dataset 1) was collected. Stickers detailing sepsis (two or more signs of systemic inflammatory response syndrome (SIRS) with a source of infection) and the 'Sepsis Six' were applied to EAU notes folders. Post-intervention data (dataset 2) was collected and analysed. Posters and computer banners with the same information were then added in the emergency department (ED), where all patients were initially assessed, prior to collection of the last dataset (dataset 3).

Results: Data was normally distributed and analysed using a t-test (Table).

Discussion: Patients with two or more signs of SIRS were consistently recognised and managed faster. Following ED interventions, such patients were managed significantly quicker than earlier datasets. This suggests ED based interventions had the greatest impact. For these patients time from diagnosis to prescription of antibiotics reduced significantly, as did time from admission to administration of antibiotics. Time from prescription to administration of antibiotics did not significantly improve. This is primarily a nursing task and suggests the interventions were most successful at improving doctors' awareness of sepsis.

Conclusions: Management of sepsis remains poor and non-compliant with evidence based care bundles. Simple prompts in the acute care setting significantly improved doctors' recognition and prompt treatment of sepsis. This could be further developed in other clinical settings and adapted for other professionals.

G-36
ONLINE CONSULTING AS NEW MODEL OF DISTANCE SPECIALIZED CARE

C. Royo, M. Fernández-Quevedo, C. Sanclemente, C. Capdevila, A. Salazar, X. Corbella, R. Pujol

Department of Internal Medicine. Hospital Universitari de Bellvitge. L'Hospitalet de Llobregat (Barcelona), Spain.

Objectives: Creation of online consultancies in different medical and surgical specialties to facilitate access and communication between Primary Care physicians (PC) and Specialized Care physicians (SC) for better and faster response, avoiding referrals and unnecessary journeys for patients.

Material and method: Medical Management designed a project whose target was the improvement of quality of care; and to facilitate the continuum of care and patient accessibility, creating email addresses for different medical specialties. The response is fast -within 48 hours,-at different medical consultations created by PC physicians. After the creation of a generic email address for each medical service, we send the information to AP. Each e-mail address has a responsible specialist. In the past 2 years 23 email addresses have been created over 10 medical and surgical hospital services: Neurology, Cardiology, Internal Medicine, Endocrinology, Pneumology, Nephrology, Urology, Rheumatology, Gastroenterology and Infectious diseases.

Results: Data are presented on the total activity of 2011, a total of 833 e-mails, representing an increase from 2010. The internal medicine department received 183 emails (145 of the Rapid Assessment, 20 of the Geriatric, 18 of Vascular Risk Unit), Neurology 174 (96 were general Neurology and 78 of the Dementia Unit), Endocrinology received 140, Cardiology 120 (20 for general Cardiology and 100 of arrhythmia) Pneumology 93,Nephrology 46, Gastroenterology 38, Rheumatology 16 and Urology 23. We emphasise the resolution in the Nephrology department: 24 of the 46 consultations could be resolved without needing patient referral. Pneumology resolved 35% of cases and the Rapid Assessment Unit 21% with only communication between physicians via e-mail.

Conclusions: 1. It is an activity of great interest for the convenience that it represents for the PC doctor, with a quick and effective response from AE, avoiding visits or delays in making clinical/or therapeutic decisions for the patients. 2. It is an underutilized tool, because although these types of consultations are growing, the number of doctors who use them is low. 3. Importance of streamlining/prioritization of visits and complementary explorations in patients who may have potentially serious diseases.

Table 1 (G-34). Two-tailed t-test comparing times between dataset 1 and 3 in patients with two or more signs of SIRS

Parameter	Mean of Dataset 1 (mins)	Mean of Dataset 3 (mins)	T value	p value	0.95 Confidence interval	0.99 Confidence interval

G-37
IMPLEMENTATION OF A NUTRITIONAL SCREENING METHOD, AT A TEACHING HOSPITAL. DIFFICULTIES AND ACHIEVEMENTS

A. Tejera Concepción[1], F. Pereyra García-Castro[2], M. Muros de Fuentes[3], P. Laynez Cerdeña[1], N. Benítez Brito[2], J. Delgado Casamayor[1], C. Hernández Carballo[1], J. del Arco Delgado[1]

[1]Department of Internal Medicine, [2]Department of Clinical Nutrition and Endocrinology, [3]Department of Clinical Analysis and Laboratory. Complejo Hospital Universitario Nuestra Señora de Candelaria. Santa Cruz de Tenerife, Spain.

Objectives: To establish a nutritional screening method, in all patients at hospital admission. Starting from the internal medicine wards, in order to gradually expand it to all hospitalized patients.

Material and method: Prospective study with 330 patients, 133 patients excluded. Method: 1. Measurement of the body mass index (BMI). 2. Biochemical nutritional screening: albumin or total proteins, lynfocytes and cholesterol. 3. Patients with medium and high malnutrition risk underwent a second screening: short MNA (65 years or older), or must (younger than 65 years). If moderate or severe malnutrition is confirmed, a written control of daily food intake during 3 days was done. Adjustments in the diet were carried out, and supplements were given if necessary.

Results: First 15 days: 49 patients. Malnutrition in 33 (67%), moderate in 25 (51%) and severe in 8 (16%). Must/MNA done in 8 out of 33 patients. A higher sensitivity to detect malnutrition was observed when the albumin was used. We continued using total proteins because of saving costs. These 49 patients were excluded. 3 months: 79 patients were excluded. 60 patients had completed the protocol. Malnutrition in 14 out of 60 patients (23%), moderate in 10 (17%), and severe in 4 (7%). 6 months: 202 patients, 5 excluded. Malnutrition in 42 out of 198 patients (21%), moderate in 34 (17%) and severe in 8 (4%).

Discussion: The prevalence of intrahospitalary malnutrition in Spain is 30-50%. An early identification of malnutrition allows a prompt nutritional intervention with short-term benefits. In our study the prevalence of malnutrition in the wards of internal medicine was 21%. A more sensitive method is required. The total number of patients included in our study was 330, 133 of which were eliminated because of incomplete data. It took time to persuade the hospital staff to follow the protocol.

Conclusions: The prevalence of malnutrition in the wards of internal medicine is 21%, despite of the age and comorbidity of our patients. The implementation of a new method is difficult. The adequate training and acceptance by the hospital involved staff is needed. Interdisciplinar coordination is essential.

G-38
DETECTION OF THE RISK OF MALNUTRITION IN THE DEPARTMENT OF INTERNAL MEDICINE: CROSS SECTIONAL STUDY

E. Huarte[1], A. Zugasti[2], M. Ruiz[1], A. Villanueva[1], S. Clemos[1], B. Lacruz[1], M. López[1], E. Bidegain[1]

[1]Department of Internal Medicine "B", [2]Department of Nutrition and Dietetic. Complejo Hospitalario de Navarra. Pamplona. Navarra, Spain.

Objectives: 1. To assess the risk of malnutrition in patients in our Internal Medicine Department 2. To assess which patients require the evaluation of Nutrition Department and/or artificial nutrition support.

Material and method: We did a prospective observational cross-sectional study. 76 patients admitted to the Internal Medicine Department have been studied, 6 without sufficient data. 35 (50%) were female and 35 (50%) were male. Mean age was 73.2 ± 17.3 years (ranging from 23 to 93), days in hospital at the time of the assessment was 6.78 ± 5.76 days (ranging from 1 to 27). We assessed the risk of malnutrition with the parameters used by the CONUT® program (Table 1), clasifiying them in patients without risk (0-1), low (2-4), moderate (5-8) and high risk (9-12). Demographic, clinical and nutritional characteristics of each nutritional group has been evaluated.

Results: 36 patients (51.4%) had low risk of malnutrition, 10 (14.3%) had moderate risk and 3 (4.3%) had high risk. Weight was registered on 10.5% of the patients. No patients with high or moderate risk had registered weight, evaluation by Nutrition Department or artificial nutritional support. 31.5% of patients had a history of Type 2 Diabetes and 31% had low hemoglobin (< 12.1 g/dL). Demographic, clinical and analytical characteristics are detailed in Table 2.

Discussion: Malnutrition is a common, potentially serious, and under-diagnosed condition among elderly patients in Internal Medicine Departments. The early detection and treatment has been shown to improve hospitalisation outcomes in medical elderly patients, decreasing mortality, morbidity and length of hospital stay. These findings emphasize the importance of detecting and treating malnutrition, for what we can use biochemical parameters and/or a computer application like the CONUT® program. In addition, we want to emphasize the importance of recording the weight and adapt diet to each patient.

Conclusions: The detection of malnutrition with biochemical parameters and/or a computer application like the CONUT® program can be a useful tool in our hospital ward. The record of the weight and adaptation of diet is essential among the hospitalized patients in Internal Medicine Departments.

Table 1 (G-38). Malnutrition risk calculated by Conut programme

Parameters	Without deficit	Mild deficit	Moderate deficit	Severe deficit
Albumine (points)	≥ 3.5 (0)	3.00-3.49 (2)	2.50-2.99 (4)	< 2.50 (6)
Total lymphocytes (points)	≥ 1,600 (0)	1,200-1,599 (1)	800-1,199 (2)	< 100 (3)
Total cholesterol (points)	≥ 180 (0)	140-179 (1)	100-179 (2)	< 100 (3)

.

Table 2 (G-38). Results

Risk	Number of patients	Hb	Lymphos	Cholest	Album
High	3 (10)	10.5	875.6	99	2.53

G-40
NEUROENDOCRINE TUMORS: CLINICAL EXPERIENCE IN THE LAST 10 YEARS UNIVERSITY HOSPITAL OF MOSTOLES, MADRID

I. Rodríguez Goncer[1], M. Romero Brugera[1], S. Piedrabuena García[1], Y. Pérez González[2], A. Muñana Fuentes[1], R. Ruiz Esteban[1], V. Moreno Cuerda[1], J. Ruiz Galiana[1]

[1]Department of Internal Medicine, [2]Department of Pathological Anatomy. Hospital Universitario de Móstoles. Madrid, Spain.

Objectives: Gastroenteropancreatic neuroendocrine tumors are rare neoplasms which can occur anywhere in the gastrointestinal tract. Depending on their size, anatomical location and upon whether or not metastasis has occurred, these tumors can show different clinical patterns and have different prognoses. The aim of this review is to show the characteristics of gastroenteropancreatic neuroendocrine tumors attended in our institution in the last 10 years.

Material and method: Descriptive, retrospective and transversal study about 28 patients diagnosed of gastrointestinal neuroendocrine tumors during the period 2006-2011 and recorded by the Department of Pathology in our hospital. Data regarding demographic, clinical, anatomopathological and diagnostic variables were collected.

Results: We identified 28 patients diagnosed with gastrointestinal neuroendocrine tumor, the mean age was 53.21 years and the male-female rate was 1.33. The most common symptom was abdominal pain(n = 8), follow by rectorrhagia (n = 5) and anemia (n = 5). Clinical manifestations are not different from standard adenocarcinoma, in colon and rectum. Most tumors were well differentiated (78.6%) and localized (67.86%). The most affected organs were gastric (n = 7), rectum (n = 7) and apendicular (n = 6). Small intestine (66.6% metastatic) and pancreatic site (100% metastatic), and a poor degree of tumor cell differentiation are the major negative prognostic factors for having metastases. The most common treatment was surgical resection. Any of our patients developed carcinoid syndrome.

Conclusions: Early diagnosis is essential for treating these lesions and improving the patients prognoses, but it requires a high degree of suspicion and confirmation by special testing. The localization and the degree of hystological differentiation seem to be the main prognostic factors. Surgical treatment is the first choice, but other medical therapy can be helpful for patients who have unresectable disease.

G-41
NUTRITIONAL STATE IN PATIENTS ADMITTED AT INTERNAL MEDICINE SERVICE

M. Esteban Moreno, A. Lazo Torres, C. Maldonado Úbeda, S. Domingo Roa, P. Sánchez López, B. Hernández Sierra, A. García Peña, L. Díez García

Department of Internal Medicine. Complejo Hospitalario Torrecárdenas. Almería, Spain.

Objectives: The nutritional state is very important, mainly in patients admitted in Internal Medicine Service, but it is rare that this evaluation appears in the clinical histories of the patients. We analyzed the clinical histories and reports of patients admitted in our hospital at Internal Medicine Service during six months with the diagnosis of malnutrition in their discharging reports.

Material and method: We analyzed the discharging reports of 61 patients admitted in Internal Medicine in our hospital.

Results: We analyzed the clinical histories of a total of 61 patients, 29 males (47.5%) and 32 females (52.3%), with global half age of 80.54 years (range 46 to 101 years), the average age of males was 79.86 years and females 81.16 years. The half stay was 12.4 days. The medium level of proteins was 5.4 g/dl (5.38 g/dl males-5.41 females). The medium level of albumin was 2.51 g/dl (2.55 g/dl males-2.47 females). 34.43% of patients received protein supplements and 9.84% received enteral nutrition with nasogastric tube. They were carried out dietary recommendations to 93.45% of patients.

Conclusions: An evaluation of the nutritional state is very important in old patients because it is very probably that they suffer malnutrition. In our study, less the half of patients received treatment for that problem.

G-42
IS FOLLOW-UP OF GASTRIC ULCERS REQUIRED?

I. Torres[2], P. Lacarta[1], T. Revuelto[1], Y. Ber[1], A. Lue[1], Y. Arguedas[1], M. Rodero[2]

[1]Department of Digestive, [2]Department of Internal Medicine. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: To evaluate assessment of patients diagnosed of gastric ulcer in our Hospital.

Material and method: We designed a descriptive retrospective case series study, about patients diagnosed of gastric ulcer by endoscopy in our Hospital from January to December 2009. We collected epidemiological data (age, sex) and endoscopic data (endoscopy instruction, ulcer location, size ulcer, execution of biopsy to discard malignancy and Helicobacter pylori infection and upper endoscopy after two months).

Results: 3199 upper endoscopy were performed during 2009. 124 gastric ulcers were observed, more frequently in patients older than 65 years old (59% older than 65, 40.7% 65 or less). 65.9% were men. The main application reason for upper-endoscopy were digestive bleeding (60.2%), secondly abdominal pain (13.8%) and anemia (8.1%). More than half of ulcers cases were located in antrum, 31.7% in gastric body, and 12% in fundus. 26% presented a diameter bigger than 1 cm and 39% had appearance of malignancy. Biopsies were taken in 66.6% of subjects, histology were positive for adenocarcinoma in 13.8%. Biopsies for testing Helicobacter Pylori were taken in less than half of cases (41.5%) and 18.7% were positive. After two months follow-up gastroscopy was performed in only 25% of cases, biopsy was taken to 21%, and 6 new cases (4.9%) of neoplasia was detected.

Discussion: Gastric ulcer is frequent in patients older than 65 years, in our study, 59% of cases were in that group of age. Elderly patients present higher rate of digestive bleeding (33.8% vs 66.2% p = 0.05) and deeper ulcers (25% vs 75% p = 0.05), probably due to the associated use of drugs. Only in 41.5% of patients Helicobacter Pylori was tested despite being a treatable ulcer cause. Only 25% of patients were reviewed two months later, 6 new adenocarcinoma cases were observed. Adenocarcinoma incidence during de ulcer studying (diagnostic control endoscopy) was 17.9%. For this reason in this group of subject a correct follow-up of gastric ulcer including control gastroscopy at two months should be performed to make an early diagnosis of gastric cancer. Adenocarcinoma was not significantly associated to age (p = 0.15), neither to ulcer location (p = 0.53). It was only associated to ulcer size bigger than 1 cm (p = 0.05).

Conclusions: Follow-up of gastric ulcers, including biopsies of borders and upper-endoscopy after two months is advisable due to the remarkable rate of malignancy. It is important to stress the low number of border ulcer biopsies rate, either the Helicobacter pylori testing.

G-43
DRUG INTERACTIONS IN INTERNAL MEDICINE

A. Braña Cardeñosa[1], C. Fernández Pérez[3], R. Cigüenza Gabriel[2], J. Antolín Arias[2], E. Calvo Manuel[2]

[1]Department of Emergency. Hospital Ramón y Cajal. Madrid, Spain. [3]Department of Preventive Medicine, [2]Department of Internal Medicine. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: Assessment of the usefulness of different databases for the identification of drug interactions, and their degree of agreement (and Lexi-Interact Medinteract). We propose that the appropriate use of existing databases allow us adequate management of patients by the medical staff, minimizing the risk of adverse reactions resulting from misuse of existing drugs to decrease the likelihood of drug interactions. Also take the opportunity to review the profile of patients discharged from Internal Medicine service and the existence of potential drug interactions.

Material and method: Discharge reports of patients admitted to all the different medical service HCSC Internal Medicine in 2009. The total number of discharges from the Internal Medicine Department in 2009 was 1,023. Sample size required for accuracy of 5% and a confidence interval of 95% with p < 0.001: 280. 300 randomly selected patients discharged in 2009 For the analysis of potential drug interactions using two databases accessible via on-line (Lexi-Interact; Medinteract).

Results: We reviewed 346 discharge reports of which 41 were excluded for the death of the patient during admission, leaving 305 that were analyzable, 55.1% were males and 44.9% women, median age was 72.42 years (IQR 77-85), minimum age of 15 years and maximum of 99 years. The median length of stay was 13.27 days (IQR 10-16) with a minimum of 1 day to 90. The median number of drugs prescribed at discharge was 6, minimum 1 and maximum of 19, the most prescribed drug was omeprazole (6.7%) followed by furosemide (5%). In the analysis with Lexi-Interact drug interactions were identified in 220 cases analyzed, the 1775 drug pairs analyzed type interaction was observed like A: 1.27%, B:7.05%, C: 61.61%, D: 7.83% and X: 2.5%. In the case of Medi-interact interaction was observed in 207 cases, showing rate by 6.2% and 41.3% severe to moderate type. We found a significant relationship with readmission in those patients with drug interactions in treatment when analyzed by using Medi-interact (p 0.039).

Discussion: The frequency of drug interactions found in our study was relatively high (Lexi-Interact: 72.1% and Medi-interact: 67.9%). Being even higher than the margin of the literature ranges from 1.9 per 1000 patient-years in a study in British health area and 60% found in a Swiss hospital study. Perhaps due to the characteristics of our population, it is elderly with multiple pathologies. The drugs involved are usually of normal management by the clinician and, possibly, in many cases have taken appropriate steps. It should be noted the increased likelihood of readmission for patients who have some type of interaction in their treatment.

Conclusions: The main factor associated with drug interactions is the number of drugs prescribed at discharge so you should try to minimize the amount of drugs. The use of readily available programs for physicians (Lexi-Interact, Medi-Interact) could improve the quality of care and that a large number of drugs complicate patient management.

G-44
REVIEW OF THE FIRST STEPS OF A PREFERENTIAL CARE CLINIC

A. González Munera, E. Oliveros Acebes, J. Sevillano Fernández, A. Albiñana Pérez, A. López Aparicio, M. Villalba García, C. López González-Cobos, L. Audibert Mena

Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: Preferential Care Clinics (PCC) are an alternative way of diagnosing patients who may suffer from a severe condition, but whose clinical status allows an outpatient process. We wanted to analyze the characteristics of the patients attended at the beginning of our Clinic and the most frequently diagnosed conditions, in order to improve the quality of our PCC.

Material and method: The PCC started working in our hospital in July 2010. It comprises two offices attended by two Internal Medicine specialists and residents of our specialty. One nurse and one administrative assistant complete the team. It works from Monday to Friday; from 8 am to 3 pm. Patients can be submitted from the emergency department, Primary Care or from any other specialist. Many tests can be prescribed from the PCC, and are performed with a preferential waiting list. We analyzed the patients attended one weekday (Wednesday) during the first year of work.

Results: A total of 50 patients were received, 24 of them were males (48%), with a mean age of 61.42 years (SD 17.95). Most of the patients were submitted from the emergency department (94% of them) and the mean delay time to the first visit was 3.74 days (SD 3.49). The mean time to the end of the study was 22.22 days (SD 18.62). The reason for consultation was always included in one of the eight available protocols, the most common being constitutional syndrome (38%), anemia and fever (20% each). In order to get a quick diagnosis, different tests were performed. The most frequently performed were abdominal ultrasound and CT with 27 patients (54%), followed by microbiology studies (either serologies or cultures) (50%), colonoscopy (48%), upper endoscopy (46%) and biopsy (24%). The final diagnostic was in 11 patients a malign neoplastic process (22%). In 9 patients (18%), the only finding was anemia with no signs of malignancy. 7 patients (14%) suffered from a psychiatric disorder, 6 patients (12%) from some infectious specific disease, 5 patients (10%) were suspected a viral undetermined infection and 4 patients (8%) suffered from a benign tumour. At the end of the study, 29 patients (58%) were submitted to a different outpatient department for the follow-up. 8 patients (16%) required being admitted to the hospital and 4 patients (8%) were programmed for surgery. 16% of patients required no further assistance after the diagnosis. Only one patient dies during the study.

Discussion: In the past few years, alternative ways of patient assistance have developed. One of them is the PDC. The objective of these units is the quick diagnosis of potential severe conditions, without the expenses coming from an admittance to the hospital. During the time of this study, the main stay time in the Internal Medicine Department of our hospital was 7.1 days. As we studied 50 patients who, otherwise, should have been admitted to get a diagnosis, the saving was 355 days of admittance, with the resultant monetary save. Compared to other quick diagnostic units, such as rapid diagnosis units or immediate health care clinics, our PDC had a longer delay in diagnosis. This can be due to the fact that the doctors in charge of the Clinic vary every weekday, thus leading to a weekly follow-up (although this could change depending on the test findings).

Conclusions: PDC is an efficient alternative to hospital admittance. Potentially severe conditions must be quickly discarded or diagnosed, in order to start treatment as soon as possible.-In order to improve our unit, we should prioritize the follow-up of potential malignant disorders and reduce the time between visits.

G-45
THE ROLE OF BLOOD CULTURES IN MEDICAL WARDS, COSTS OR BENEFITS?

H. Pêgo, C. Rodrigues, S. Cardoso, M. Fevereiro, M. Amorim, L. Borges

Department of Internal Medicine 1.4. Hospital São José. Lisboa, Portugal.

Objectives: Microbiological tests, although of great importance for the diagnosis, and more appropriate treatment of various infectious diseases, have, most of the times, negative results; being unable to lead to diagnosis or therapeutic adjustment, leaving behind only the costs not the benefits. With this review the authors want to know what are the real results of the blood cultures (for aerobic agents) they are doing to their patients, and the costs for a positive result driving the improvement of treatment. We focused on the rentability of blood cultures (aerobic agents) in medical ward's every day patient assumed not to have criteria to higher level of care (intermediate care unit or critical care unit). More than establish a validated standard we want to adjust the requests to our reality, knowing the specific limitations of this resource in our specific workplace.

Material and method: We review all the admissions (from emergency department or outpatient consultations, excluding intra-hospital transfers) during one year (July 2011-June 2012) asking for the number of blood cultures for aerobic agents, the percentage of positive results, the kind of agents isolated and the costs associated. We have determined the duration of the survey in 12 months, to exclude seasonal fluctuations occurring during the year.

Results: The partial results (being the survey still runnig by the time of abstract submission) are disappointing. In the already processed data we documented more than 45% requests for all admissions with the criteria expressed, and despite not expecting high results, we are finding about 10% bacterial isolations. Leaving a cost of more than 350 euros per positive test. Since most of the isolations are of multi-sensitive bacteria, which means patients received microbiologically correct and effective empirical antibiotic therapy, the costs are much further increased when considering a useful positive test.

Discussion: Microbiological tests will always be of great value in clinical practice, however their rentability depend on several factors. Technical issues like collecting, transporting and processing can always be improved as the decision to ask for the test. The probability to find a bacteriemic patient is higher, the more severe the condition is. Establishing severity criteria to ask for cultures will optimize results, leaving the often done, infection = blood cultures, behind.

Conclusions: Worldwide there is an urgent need to optimize resources, and 45% can't be the probability of request at admission, of blood culture for any given patient; even more if only 10% will be positive. Knowing this data must help us to find the way to have positive results more frequently or, simply, stopping having the negative ones. This work pretends to be a wakeup call, for us to see, in our own workplaces, if the benefit worth the cost.

G-46
ELECTRONIC WHITEBOARDS: FIRST STEPS TOWARDS EUROPEAN STANDARDS FOR ACUTE MEDICAL ADMISSIONS?

P. Parulekar, R. Duckitt

Department of Medicine. Worthing Hospital. West Sussex, United Kingdom.

Objectives: 1. To establish sustainable use of reliable key performance indicators (KPIs) to improve efficiency and patient care through service management and re-design. 2. To establish the use of an electronic whiteboard system to support the use of KPIs. 3. To determine performance benchmarks for acute Emergency Medical admissions.

Material and method: An Intranet-based electronic-Whiteboard database was used to capture data from the point of referral throughout the patient journey. Data collated and analysed by the Information Department are presented in spreadsheet format on a weekly basis. Data includes times of referral and admission, medical review, presenting conditions and discharges. Performance is analysed over time to identify trends and areas of poor performance.

Results: 4 out of the 9 Key Performance Indicators are regularly monitored, 3 partially measured, and 2 not measured electronically. We have established the sustainable use of the electronic whiteboard. It is used by physicians and nurses to organise and prioritise work. Staffing numbers have been matched to patient flow and waiting times have been reduced by 54% to an average of 40 minutes.

Discussion: By comparing practice of acute medical admissions across Europe one would aim to maintain and improve local acute services to patients. This suggests requirement for European benchmark standards for measuring KPIs for all medical admissions, enabling trusts across Europe to track how well they match up to these standards. Collaborative use of KPIs for improvement priorities could improve quality of acute patient care and reduce cost. Features of the electronic whiteboard such as usability and interactivity promote sustainability through enhanced clinician engagement.

Conclusions: Measuring KPIs for acute admission services reflect the quality of patient care being given and encourages continuous improvement. Implementation of European benchmarks could enable comparison of standards between units and may result in enhanced performance of acute care across Europe.

G-47
IMPACT OF FOCUSED CARDIAC ULTRASOUND IN THE MANAGEMENT OF FIRST EPISODE OF ATRIAL FIBRILLATION

J. Torres Macho, J. Antón Santos, S. Gámez Díez, M. de Castro García, G. Latorre Barcenilla, S. Remesal Blanco, I. García Gutiérrez, G. García de Casasola

Department of Internal Medicine and Emergency. Hospital Infanta Cristina. Madrid, Spain.

Objectives: The aim of this study was to assess changes in clinical management (medical or surgical treatment and/or admission to Hospital) with the use of focused cardiac ultrasound performed by internists in patients with a first episode of atrial fibrillation.

Material and method: We performed a prospective observational study at an Emergency Department (ED) of a University affiliated Hospital from July 2011 to march 2012. We included all patients who presented with a first episode of atrial fibrillation. Inclusion criteria were: age older than 18 years old and the absence of a previously known heart disease. The attendant physician performed a routinary evaluation of these patients performing and registering anamnesis, clinical examination, electrocardiogram and chest X-ray results. We also registered if the physician suspected any significant cardiac alteration with these data and the proposed treatment following ESC guidelines for the management of atrial fibrillation. After the initial evaluation an internist with previous training in focused cardiac ultrasound evaluated subjective left and right ventricular ejection fraction, the presence of significant pericardial effusion and the diameter of left atrium, left ventricle, interventricular septum and ascending aorta. All the echocardiographic results were confirmed with a subsequent

cardiologist performed echocardiogram. We recorded all discrepancies between the attending physician suspected diagnosis and proposed management (treatment and decision about admission to Hospital) and the internist proposal using focused cardiac ultrasound information.

Results: 92 patients were included during the study period. Mean age was 68 ± 15 years. 54 patients (60%) were male. There were 8 patients (8.7%) with no suspected underlying significant structural heart disease by the attending physician who showed significant structural alterations on the focused cardiac ultrasound (5 patients with severe left ventricular dysfunction, one patient with an acute severe right ventricular dysfunction, one patient with a severe acute mitral regurgitation and one patient with an ascending aortic dissection). Attending physicians suspected underlying significant cardiopathy in 8 patients (8.7%) which was discarded by focused cardiac ultrasound. There was a significant change in medical treatment in 13 (14%) patients and urgent surgical treatment was ordered after focused ultrasound in 2 (2%) patients. In 14 patients (15.2%) admission to Hospital decision was changed due to focused cardiac ultrasound information.

Discussion: Focused cardiac ultrasound is a noninvasive technique which can be performed by internists. It is capable of providing useful and rapid information about heart structure and function. Echocardiographic aspects that can be evaluated by a non-cardiologist with a short training period and good accuracy are well defined. A first episode of atrial fibrillation is usually evaluated in the ED by non-cardiologists. There are no previous reports which analyze the impact of this tool in the evaluation of this clinical situation.

Conclusions: Systematic use of focused cardiac ultrasound by non-cardiologists in the evaluation of patients with a first episode of atrial fibrillation modifies treatment or admission decision in approximately 15% of patients.

G-48
IMPROVEMENT IN PAIN MANAGEMENT AFTER ON-SITE EDUCATIONAL INTERVENTION: RESULTS FROM THE DOMINO STUDY BY THE ITALIAN SCIENTIFIC SOCIETY FADOI

G. Civardi[1], A. Valerio[2], G. Gussoni[2], A. Fontanella[3], M. Ferraro[4], G. Vescovo[5], A. Mazzone[6], C. Nozzoli[7]

[1]Department of Internal Medicine. Hospital of Fiorenzuola di Arda. Piacenza, Italy. [2]Department of Research. FADOI Foundation. Milan, Italy. [3]Department of Internal Medicine. Hospital Fatebenefratelli. Naples, Italy. [4]Department of Internal Medicine. Hospital of Acri. Cosenza, Italy. [5]Department of Internal Medicine S. Bortolo. Vicenza, Italy. [6]Department of Internal Medicine. Hospital Civile. Legnano, Italy. [7]Department of Internal Medicine. Hospital Careggi. Florence, Italy.

Objectives: Internal Medicine (IM) patients are very frequently elderly, with multiple concomitant diseases and therapies. Chronic pain is a relevant clinical component of many medical diseases in elderly and complex patients, but few real-world data are available on its frequency and management. Aims of our study were to assess the prevalence of pain in IM, and to evaluate the possible effects on pain management of a standardized educational program.

Material and method: The study was performed in 26 Units of IM in Italy, with a three-step design. In step A each centre retrospectively reviewed the hospital charts of the last 100 consecutive patients hospitalized for any cause and discharged. General data on patients' characteristics, and more specific information on the possible presence of chronic pain and its management were collected. The educational program (step B) was conducted by means of the so-called outreach visits, a face-to-face meeting between an expert teacher external to the Unit and the staff (physicians and nurses) of the IM centre. The contents of the intervention by the teacher had been previously defined by a central Scientific Committee, on the basis of international guidelines and major deviations from best medical practice detected in step A. Around 6 months following the outreach visit, each centre had to retrospectively review the hospital charts of the last 100 consecutive patients discharged (step C), in a way specular to step A.

Results: A total of 5,200 medical charts were analyzed in the study. The general characteristics of study populations in step A and C were very similar, around 70% of patients had an age > 70 years, and three or more diseases. Chronic clinically relevant pain (defined by explicit citation in hospital charts and/or by the presence of a specific treatment) was documented in 37.5% of the patients. In more than half of cases pain was of osteo-muscular origin, and in around 20% it was related to cancer. After the educational intervention, the intensity of pain was assessed by using validated scales in a higher percentage of patients (47.8% in step A vs 77.4% in step C, p value = 0.0001), and it was more frequently monitored during hospitalization. Appropriate qualitative definition of pain (pathogenesis, duration etc.) increased in step C (75.4% vs 62.7%, p value = 0.0001). If compared to step A, at the end of step C it has been detected a 16% increase in the use of strong opioids.

Discussion: Chronic pain is a frequent issue in IM, since it affects 4 out of 10 in-hospital patients. According to our large real-world study, to implement a standardized one-shot educational program may persistently improve the attitude of physicians and nurses towards the characterization and management of chronic pain.

Conclusions: Due to the relevant burden in IM, and its impact on quality of life of the patients, chronic pain requires specific attention by the health personnel. It is plausible that a more aggressive educational intervention than we did could further improve the attitude towards the optimal management of pain in medically ill in-hospital patients.

G-49
EFFECTS OF A STANDARDIZED EDUCATIONAL PROGRAM ON THE MANAGEMENT OF TYPE 2 DIABETES IN MEDICAL INPATIENTS THE DIAMOND STUDY FROM THE SCIENTIFIC SOCIETY FADOI

G. Gulli[1], S. Frasson[2], V. Borzì[3], M. Grandi[4], A. Nicolucci[5], R. Pastorelli[6], G. Augello[7], G. Gussoni[2]

[1]Department of Internal Medicine. Hospital of Savigliano. Cuneo, Italy. [2]Department of Research. FADOI Foundation. Milan, Italy. [3]Department of Internal Medicine. Hospital Policlinico Vittorio Emanuele. Catania, Italy. [4]Department of Internal Medicine. Hospital of Sassuolo. Modena, Italy. [5]Department of Clinical Pharmacology and Epidemiology. Consorzio Mario Negri Sud. S. Maria Imbaro, Italy. [6]Department of Internal Medicine. Hospital of Colleferro. Rome, Italy. [7]Department of Internal Medicine. Hospital of Canicattì. Agrigento, Italy.

Objectives: Although glucose levels to pursue in chronic diabetes treatment are not yet well defined, clinical evidence suggests that appropriate blood glucose management during hospitalization improves clinical outcomes of medical patients with type 2 diabetes (T2D). Aim of the study was to collect information about the management of T2D patients hospitalized for any cause before and after a standardized educational intervention on health professionals in Internal Medicine Units (IMU).

Material and method: The study was performed in 53 Italy IMU with a three-step design. In step A, each IMU retrospectively reviewed the hospital charts of the last 30 consecutive patients hospitalized for any cause except for stroke or acute myocardial infarction, and with a known diagnosis of T2D. The educational program (step B), was carried out by an outreach visits, a face-to-

face meeting between an expert teacher external to the IMU and the staff (physicians and nurses) of the IMU. The contents of the intervention by the teacher had been previously defined by the FADOI DIAMOND Steering Committee, on the basis of international guidelines and major deviations from best medical practice detected in step A. Around 6 months after the outreach visit, a retrospective survey, specular to step A, was conducted in each IMU (step C).

Results: A total of 3,167 patients were recruited (1,588 step A, 1,579 step C). General characteristics of patients analyzed in step A and step C were superimposable. From step A to C, it has been showed a significant decline of missing anthropometric data collected in medical records, namely body weight and height (54.1% vs 74.9%, p < 0.0001). After the educational program, a higher percentage of patients (62.8% vs 48.2%, p < 0.0001) had in-hospital measurement of glycated hemoglobin. More patients had in-hospital changes of treatment for diabetes in step C (77%) vs step A (72.6%). After educational program less IMU (47.2% vs 52.8%, p = 0.0017) used a sliding scale to control blood glucose levels. Indications for diet were delivered to 53.5% vs 71.1% of patients (p < 0.0001) during step A and C, respectively.

Discussion: The improvement of clinical outcomes in hospitalized diabetic patients is known to be strictly related to an appropriate blood glucose control. Our study was not designed to assess the impact of educational intervention on patient outcomes, but the trend towards more intensive monitoring and therapeutic intervention could be of clinical relevance.

Conclusions: In our large, real-world study, a standardized one-shot educational program led to significant and persistent changes in the management of hospitalized patients with known T2D. It is plausible that a more aggressive educational intervention than we did, could further improve the attitude towards the optimal management of diabetes in hospitalized patients.

G-50
HEART FAILURE TREATED IN A SHORT STAY UNIT

J. Medina García[1], C. Hernández Carballo[1], J. Del Arco Delgado[1], M. Dávila Ramos[1], A. Castellano Higuera[1], M. López Gámez[1], P. Láynez Cerdeña[1], F. Gutiérrez Nicolás[2]

[1]Department of Internal Medicine, [2]Department of Pharmacy. Complejo Hospital Universitario Nuestra Señora de Candelaria. Santa Cruz de Tenerife, Spain.

Objectives: to analyse the demographic and clinical features of patients admitted with Heart Failure (HF) into a Short Stay Unit (SSU) in a general Internal Medicine Service. Length of stay and readmission-related factors are also investigated.

Material and method: Descriptive, retrospective design performed on patients admitted into a SSU because of decompensated HF. 260 clinical reports between February 2011 and February 2012 were reviewed, along with results from complementary tests when these were not available. Cuantitaive variables are expressed as mean ± SD. Categorical non-parametrical variables were compared using non-parametric tests. Time to readmission was assessed with a Kaplan Meier analysis.

Results: 73 (28%) episodes computed as HF at discharge. Basal characteristics are shown on Table 1. The primary symptom on presentation was dyspnea (30%). Transthoracic echocardiography was performed in 19 (26%) of the patients, finding low ejection fraction in only 2 (2.7%) patients. Mean NYHA score was 2.3 ± 0.54, with 18 (24.7%) patients at a basal NYHA score of III or worse. Mean length of stay was 3.08 ± 1.37 days. Only 5 patients (6.8%) stayed for longer than 5 days (SSU failure). 13 (17%), and 6 (8.2%) needed readmission during the next 30 and 14 days. No patient was readmitted within 3 days after discharge. Neither fulfilling pluripathology (PP) criteria nor having some degree of dependence showed any association with readmission or SSU failure. Yugular ingurgitation on admission was associated with readmission at 30 days (p = 0.022, Plot 2). No patient died during the first 60 days after discharge.

Discussion: In this short cohort, complexity or senescence did not affect length of stay or readmission rate. This, along with the extremely low mortality at 30 days opens new ways of managing prevalent and complex problems that often crowd conventional hospitalization units. The cohort size might limit interpretation of the afore-mentioned data. Lack of comparison with conventional hospitalisation can also limit these results.

Conclusions: Most patients with decompensated HF can be discharged after 3 days of treatment in a SSU, even with a high rate of complex comorbidities. SSU is a safe, efficient way of managing chronic diseases such as HF. Dependence or PP did not affect readmission rates. Basic exploratory signs of HF could help identify patients in risk of readmission. Randomised controlled trials could help establish the best treatment setting for decompensated HF.

G-51
HF_MIRAP CONSULTATION: EVALUATION OF TEN NEW PATIENTS DAILY IN AFTERNOON TIME (PART 2, CLINICAL PROFILE)

N. Mesa, E. Madroñal, R. Calderón, R. Martín, D. Rejas, J. Ortiz, A. Castro, A. Zapatero

Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: Describe the characteristics of patients attended in the consultation of internal medicine department of the Hospital de Fuenlabrada, designed to value daily 10 new patients (30 minutes per patient, 2 to 4 days per week depending on the month) in afternoon time, to provide coordination with primary care.

Material and method: Cross-sectional study of 1,140 new patients attended from January to December 2011 at a consultation of internal medicine department in afternoon time. Statistics: %, mean + sd. Comparison: ANOVA, chi^2.

Results: The overall mean age was 50 ± 18 years (9 to 96), higher in women (56% 51 ± 18 years) than in men (44%, 48 ± 18 years p = 0.02). There are 158 reasons for consultation. The most frequent were: hypertension (11%), anemia (9%), weight loss (8%), adenopathy study (4%), asthenia (4%), abdominal pain (3%), genetic study/family study (3%), hyperferritinemia (3%) and fever (3%). There were 163 final diagnoses. The more frequent were: without disease (21%), essential hypertension (14%), iron deficiency anemia (5%), no pathology of IM (4%), weight loss determined (3%), anxiety/depression (2.4%), non-pathological lymphadenopathy (2%), HIV infection (2%), dyslipidemia (2%), hemochromatosis (1%), fatty liver

Table 1 (G-50)

N = 73	Woman	Age	Dependence	Pluripathology	Pluripath. Categories	NYHA	Length of stay
No. (%); Mean ± -SD;	40	80.1 ± 7.53	24	55	2.15 ± 0.98	2.3 ± 0.54	3.08 ± 1.37
(Range)	(54.8%)	(77-85)	(32.9%)	(75.3%)	(2-3)	(2-3)	(2-4)

(1%), thromboembolic disease (1%). In 4.5% of the cases does not match the diagnoses with the initial suspicion. Requested test on 65.5% of patients, mean 2 ± 1 test. Type of test: analytical (41%), radiology (31%), digestive endoscopy (7%), echocardiogram (5%) and ambulatory blood pressure monitoring (5%). Requiring hospitalization 1.5% to advance the study and 1% for acute disease. Evolution and resolution of cases: 26% discharge in first visit, 24% in second visit, 5% in third visit and 1% in the fourth visit. Follow-up 20% of patients, loss 20% and outstanding results 4%. The resolution time was 65 ± 8 days (640 patients, 56%) and decreases to 49 days at early discharges (1st and 2nd visits). There is no difference between the most common diseases. Delayed diagnosis and assessment of delays in testing in 16% cases (digestive endoscopy, echocardiography, brain scan and EMG). Discharge consultation for: primary care (73%), medical specialty (15%), IM monographic (6%) and surgical specialty (4%).

Conclusions: Low mean age (50 years), lower in men. The main causes of consult were hypertension (11%), anemia (9%), weight loss (8%) and lymph node study (4%). Final diagnosis: 21% without disease, 15% essential hypertension, 5% iron deficiency anemia and 4% not internal medicine pathology. In 4.5% of the cases does not match the diagnoses with the initial suspicion Tests were requested in 65% of patients. Mean of 2 tests. Delay tests in 16% cases (endoscopies, echocardiogram, brain scan and EMG). Finally, 50% are resolved between the 1st and 2nd visits with a time resolution of 49 days.

G-52
UNINTENTIONAL WEIGHT LOSS IN AN OUTPATIENT INTERNAL MEDICINE CONSULTATION

M. Rodríguez Cordero, M. Valcárcel García, J. Díaz Peromingo, A. González Quintela

Department of Internal Medicine. Complejo Hospitalario Universitario de Santiago. Santiago de Compostela. A Coruña, Spain.

Objectives: Unintentional weight loss (UWL) is not uncommon and is associated with increased morbidity and mortality rates being often a harbinger of underlying systemic disease. Common causes of UWL are i. e. cancer, gastrointestinal disorders, infections, medications, and psychiatric disorders. Sometimes the cause remains as idiopathic alter accurate diagnosis testing. Frequently patients with UWL used to be admitted to an Internal Medicine Department to complete diagnosis. Our aim is to report the clinical and analytical features of patients with UWL studied in an outpatient Internal Medicine consultation and identify predicting factors of eventually non-malignant or malignant diagnosis.

Material and method: This is an observational, retrospective study of 145 patients referred to an Internal Medicine consultation because of UWL in 9 months. All of them were older than 18 years. Variables included were demographics, toxic habits, amount of weight loss and time, physical assessment, analytical parameters, radiological and endoscopic studies, final diagnosis, the need of hospital admission and its cause. Statistical analyses include frequencies, correlation tests and non-parametric studies when needed using SPSS vs 17 for Windows.

Results: Mean age was 70 years old, median 76. Men were 73, women 72. In 30.3% alcohol and in 24.8% tobacco consumption was reported. Mean weight loss was 7.19 ± 4.61 kg in 4.67 ± 4.97 months. Physical assessment was positive in 30 patients. Anaemia was reported in 37.2% patients, renal failure in 15.9%, cholestasis in 18.6%, positive fecal occult blood test in 10.3%. Tumour markers were positive in 55.9% patients being the most frequent CEA-II, Ca 19.9 and TPS. Mean ESR was 32.92 mm/h, LDH 300.45 UI/L, and CRP 32.19 mg/dl. Useful complementary explorations were: chest radiography 10.3%, abdominal ultrasonography 15.9%, CT scanning 37.9%, upper gastrointestinal endoscopy 17.2% and colonoscopy 13.1%. The most frequent causes of UWL were cancer (45), benign gastrointestinal (43), idiopathic (15), psychiatric disorders (14), and infectious diseases (8). In 21 (14.50%) patients there was no need to complete study in the in-hospital setting. There was positive correlation between an organic cause and the duration of symptoms, physical exploration, anaemia, renal impairment, cholestasis, tumour markers, abnormal CT scan, upper gastrointestinal endoscopy and colonoscopy as well as with the need of hospital admission to complete studies. By sex there were statistical differences in alcohol and tobacco consumption, positive tumour markers, ESR, CRP and abnormal chest radiography and CT scan, being higher in men. Regarding to diagnosis of malignancy, there were statistical association with duration of symptoms, haemoglobin, tumour markers, ESR, CRP, abnormalities in chest radiography, CT scan, upper gastrointestinal endoscopy, colonoscopy, and with the need of hospital admission.

Conclusions: 1. In our study, most of patients were elderly who lost more than 7 kg in almost 5 months. Less than a third had a previous toxic habit. 2. Only 20% had a positive physical assessment but barely 4 out of 10 had anaemia. 3. A half of patients had an elevated level of tumour markers mainly related to digestive malignancies. 4. CT scanning was the most useful exploration, followed by abdominal ultrasonography and endoscopic studies. 5. Almost a third of our patients had cancer or a benign gastrointestinal disease. There was no need of in-hospital setting in the majority of them.

G-53
USEFULNESS OF CARCINOEMBRYONIC ANTIGEN IN THE STAGING OF RECTAL CANCER

E. Salazar-Thieroldt[1], V. Portillo Tuñón[1], S. Molinero Abad[1], E. Iglesias Julián[1], M. Quiñones[1], C. Pérez Tárrago[2], N. de la Torre[2], J. Boado Lama[2]

[1]MIR Department of Internal Medicine, [2]FEA Department of Internal Medicine. Complejo Asistencial de Burgos. Burgos, Spain.

Objectives: To correlate preoperative carcinoembryonic antigen (CEA) levels and the presence of distant metastases in rectal cancer.

Material and method: Retrospective cohort study (2010-2011) in a tertiary care hospital. After excluding patients without TNM staging and without preoperative CEA levels, 150 patients with rectal cancer were included and stratified in Group 1 (with distant metastases) and Group 2 (without distant metastases). Preoperative CEA levels were measured and compared between the two groups. CEA < 4.5 ng/ml was the cut-point between elevated and normal levels. Results were statistically analyzed with chi square and OR. Significance was reached at $p < 0.05$.

Results: Seventy-two percent were men, with a mean age 70 years old (range 33-92), all had adenocarcinoma. One hundred and six (70.7%) of patients were in TNM stage I-III and 44 (29.3%) in stage IV (metastasic disease). The most common metastases sites were: liver (31.8%), liver and lungs (25%), lungs (13.6%) and other (15.9%). Seventy-nine percent of patients in the Group 1 had elevated CEA levels, meanwhile 28% in the Group 2 had elevated CEA levels. Eighty-nine percent of patients with CEA within normal levels had no metastasis. Statistical association between Group 1 and preoperative CEA levels above 4.5 ng/ml was found (chi square 33.25, $p < 0.05$, OR = 9.85, CI [4.2-22.9]).

Discussion: The CEA is an oncofetal glycoprotein that appears overexpressed in colon and rectal adenocarcinoma, whose use has been clearly established to monitor response to systemic therapy and to assess the rate of recurrence. It is not recommended as a screening method for colorectal cancer, and its usefulness in the

staging and treatment strategy is not clearly established yet. However, we found a strong association between high preoperative CEA levels and advanced metastasic disease.

Conclusions: We consider useful the determination of preoperative CEA levels in patients with rectal cancer for initial assessment of metastasic disease. Further research is needed to check the impact of these findings in the context of preoperatory assessment.

G-54
CHRONIC KIDNEY DISEASE AND HEPATITIS C IN PATIENTS WITH TYPE 2 DIABETES MELLITUS

C. Parpala[1], E. Rusu[1], R. Dragut[1], R. Nan[1], G. Enache[1], F. Rusu[2], M. Jinga[3], G. Radulian[3]

[1]Department of Diabetes II. National Institute of Diabetes Nutrition and Metabolic Diseases. Bucharest, Romania. [2]Department of Urology. Emergency Military Hospital Carol Davila. Bucharest, Romania. [3]Department of General Medicine. University of Medicine and Farmacy Carol Davila. Bucharest, Romania.

Objectives: Many population studies have provided evidence of chronic kidney disease (CKD) and hepatitis C (HCV) in patients with type 2 diabetes. Association of CKD and hepatitis C cause increased morbidity and mortality in patients with type 2 diabetes. Of the mechanisms underlying the correlation between diabetes and HCV can be mentioned: insulin resistance and hyperinsulinemia, decreased insulin secretion or deficiency, hepatic steatosis, inflammation and proinflammatory cytokines, autoimmune destruction of pancreatic β cells. The aim of this study was to investigate the prevalence and severity of reduced estimated glomerular filtration rate (eGFR) in patients with diabetes and HCV.

Material and method: Included in the study were 179 consecutive patients with type 2 diabetes and HCV, hospitalized in INDNBM "N.C. Paulescu" during 01.01-31.12.2011. The average duration of evolution of diabetes was 6.3 years. We evaluated kidney disease or by proteinuria (+ on urine dipstick) or by calculating the estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73 m^2. Estimated glomerular filtration rates (eGFRs) were calculated by Cockroft-Gault and Modification of Diet in Renal Disease equations (MDRD). The characteristics of cases with CKD and controls were compared in analysis and in multivariate logistic regression models with stepwise selection.

Results: CKD was present in 86 patients (48%). Proteinuria was present in 93 patients (52%). 61 (34.1%) of 179 enrolled patients had normal eGFRs stage 1, above 90 ml/min per 1.73 m. Stage 2 renal dysfunction (eGFR between 60 and 89 ml/min per 1.73 m^2) was present in 65 patients (36.3%), 28 patients (15.6%) had stage 3 dysfunction (eGFR between 30 and 59 ml/min per 1.73 m^2), 16 patients (8.9%) had stage 4 dysfunction (eGFR between 15 and 29 ml/min per 1.73 m^2), and 9 patients (5%) stage 5 (eGFR < 15 or dialysis-dependent). Factors predictive of renal dysfunction in multivariate analysis included female sex [odds ratio (OR) 1.46, 95% confidence interval (1.07-2.009), p = 0.01], BMI less than 20 [OR 1.3 (1.1-3.2), p = 0.04], hypertension [OR 1.98 (1.01-3.9), p = 0.03], elevated gamma-glutamyl transpeptidase over 110 UI/L [OR 1.3 (1.04-1.8), p = 0.03], and hepatic steatosis [OR 3.4 (1.5-7.6), p = 0.002].

Conclusions: Was noticed that patients with diabetes and HCV presents high prevalence of renal dysfunction. The presence of normal serum creatinine in patients with HCV do not provide normal kidney function. Therefore screening the renal disease in patients with HCV and diabetes, should be started early and, also, to be more rigorous due to high prevalence of eGFR decline.

G-55
INFECTIONS IN A HOSPITAL AT HOME UNIT

M. Arteaga Mazuelas[1], V. Jarne Betrán[1], Á. Cecilio Irazola[1], C. González Rodríguez[1], V. Fernández Ladrón[1], O. Ateka-Barrutia[2], P. Navarro San Pedro[3], F. del Cazo Irazola[1]

[1]Department of Internal Medicine, [3]Department of Pharmacy. Hospital García Orcoyen. Estella (Navarra), Spain. [2]Department of Lupus Research. St Thomas' Hospital. London, United Kingdom.

Objectives: To conduct a descriptive and retrospective study about the characteristics of patients admitted due to infectious conditions to the Hospital at Home Unit (HHU), at the Garcia Orcoyen Hospital (Navarra, Spain), during a period of 7 months. This is a community local hospital (second-level) with 97 beds and 10 HHU beds. HHU depends directly on Internal Medicine Department.

Material and method: We retrospectively reviewed the medical records of patients admitted in HHU for a period of 7 months (from 1st September 2011 to 31st March 2012).

Results: Amongst the 170 patients admitted to HHU during this period, 138 (81.2%) were admitted because of infectious processes. 92 of them (66.7%) were male, and the mean age was 76. All patients had calculated the Charlson Comorbidity Index (CCI), and 79 patients (57.3%) presented a CCI of 3 or greater. The departments from where most of the patients were referred to HHU were Internal Medicine, with 106 patients (76.8%); General Surgery, 11 (8%); Emergency Department, 10 (7.3%); Orthopaedic and Trauma, 5 (3.6%); and other departments, 6 (4.4%). With regards to the cause of admission, 96 patients (69.6%) were admitted because of respiratory infections, 16 (11.6%) because of intra-abdominal infections, 11 (8%) due to urinary tract infections, 11 (8%) due to skin and soft tissue infections, and 4 (3.9%) due to osteoarticular or endovascular infections. The average length of stay was 9.9 days. During the study period, 123 patients (89.1%) were discharged after being cured or after improvement, while 12 (8.7%) died and 3 (2.2%) required re-entering the hospital for different reasons.

Discussion: HHU is a booming alternative to conventional hospitalization, which can benefit patients with different disorders. Our data show that patients admitted in HHU because of infectious conditions represent mainly elderly and multi-morbidity patients, as in more than half of the cases CCI were 3 or greater. Likewise, most of these patients come from the Internal Medicine Department, suffer from respiratory infections, and require antibiotic therapy. Based on our experience, these patients need long hospital admissions, and therefore their stabilization on the ward followed by transfer to a HHU seems a noteworthy and beneficial plan of management. Bigger multidisciplinary studies may clarify the role of these units.

Conclusions: HHU is an excellent alternative for the management of patients with infectious diseases, regardless the cause, and especially for respiratory infections. We believe that this non-conventional way of hospitalization should be enhanced.

G-56
DESCRIPTIVE STUDY OF PATIENTS TREATED IN A HOSPITAL AT HOME UNIT OF A DISTRICT GENERAL HOSPITAL

M. Arteaga Mazuelas[1], V. Jarne Betrán[1], Á. Cecilio Irazola[1], P. Navarro San Pedro[2], O. Ateka-Barrutia[3], C. González Rodríguez[1], J. Velasco Montes[1], F. del Cazo Cativiela[1]

[1]Department of Internal Medicine, [2]Department of Pharmacy. Hospital García Orcoyen. Estella (Navarra), Spain. [3]Department of Lupus Research. St Thomas' Hospital. London, United Kingdom.

Objectives: To conduct a descriptive study about the characteristics of patients admitted to the Hospital at Home Unit

(HHU) at the Garcia Orcoyen Hospital (Navarra, Spain), during a period of 7 months. This is a community local hospital with 97 beds and 10 HHU beds. HHU depends directly on Internal Medicine Department.

Material and method: We retrospectively reviewed the medical records of patients admitted in HHU for a period of 7 months (from 1st September 2011 to 31st March 2012).

Results: During the mentioned period, there were 170 HHU admissions. 110 (64.7%) were male, and the mean age was 75.7. All patients had calculated the Charlson Comorbidity Index (CCI), and the average was 3.32 (60% of patients had CCI ≥ 3). The departments from where most of the patients were referred to HHU were Internal Medicine, with 134 patients (78.8%); Emergency Department, 14 (8.2%); General Surgery, 11 (6.5%); and Orthopaedic and Trauma, 5 (3%). The disorders that led to admission were: infectious, 81.2% of cases (138); heart failure, 10% (17); thromboembolic disease, 5.3% (9); and other reasons such as inflammatory bowel disease, diabetes mellitus, or stage of life, 3.5% (6). Among the infectious processes, the most common were respiratory infections, in 96 patients (56.5%). Up to 89.4% of patients (152) received antibiotics during hospitalization. The average length of stay was 9.8 days. 67 patients (39.5%) stayed less than 8 days, 80 (47%) between 8 and 14 days, and 23 (13.5%) over 14 days. During the study period, 13 patients (7.6%) were admitted ≥ 2 times, while 14 (8.2%) died and 7 (4.1%) required re-entering the hospital for different reasons. 149 patients (87.7%) were discharged after being cured or after improvement.

Discussion: HHU is an alternative to conventional hospitalization that was initially developed in major centres, but which is now also emerging in local hospitals like ours. The presented data show that patients admitted in HHU had advanced age and multiple morbidities, with an average CCI of 3.32. Most of these patients come from the Internal Medicine Department, suffering from infections (predominantly respiratory), and require intravenous antibiotic therapy. Patients with these characteristics need long hospital stays, which increase hospital overcrowding, costs and risk of hospital acquired complications. Thus, home transfer after stabilization of the patient represents a great advantage.

Conclusions: HHU is an excellent alternative to conventional hospitalization for monitoring and treatment of multiple diseases, and should therefore be promoted in all hospitals.

G-57
RESPIRATORY INFECTIONS IN A HOSPITAL AT HOME UNIT

V. Jarne Betrán[1], M. Arteaga Mazuelas[1], Á. Cecilio Irazola[1], O. Ateka-Barrutia[3], P. Navarro San Pedro[2], C. González Rodríguez[1], J. Velasco Montes[1], F. del Cazo Cativiela[1]

[1]Department of Internal Medicine, [2]Department of Pharmacy. Hospital García Orcoyen. Estella (Navarra), Spain. [3]Department of Lupus Research. St Thomas' Hospital. London, United Kingdom.

Objectives: To conduct a descriptive and retrospective study about the characteristics of patients admitted due to respiratory infections to the Hospital at Home Unit (HHU), at the Garcia Orcoyen Hospital (Navarra, Spain), during a period of 7 months. This is a community local hospital (second-level) with 97 beds and 10 HHU beds. HHU depends directly on Internal Medicine Department.

Material and method: We retrospectively reviewed the medical records of patients admitted in HHU for a period of 7 months (from 1st September 2011 to 31st March 2012).

Results: Amongst the 170 patients admitted to HHU during this period, 138 (81.2%) were admitted because of infectious processes, and 96 of them (69.6%) were due to respiratory infections. 64 of these patients (66.7%) were male, and the mean age was 80. All patients had calculated the Charlson Comorbidity Index (CCI), and 63 patients (65.6%) presented a CCI of 3 or greater. The departments from where most of the patients were referred to HHU were Internal Medicine, with 86 patients (89.6%); Emergency Department, 8 (8.3%); and Primary Care, 2 (2.1%). With regards to the cause of admission, 36 patients (37.5%) were admitted because of respiratory infections, 23 (24%) because of pneumonia, 32 (33.3%) due to COPD exacerbations, 3 (3.1%) due to asthma exacerbations, and 2 (2.1%) because of diffuse interstitial lung disease. The average length of stay was 9.4 days. During the study period, 84 patients (87.5%) were discharged after being cured or after improvement, while 11 (11.5%) died and 1 (1%) required re-entering the hospital. The mean duration of the antibiotic therapy was 9 days. 43 patients (44.8%) were treated with only one antibiotic, 39 (40.6%) with two different antibiotics, and 14 (14.6%) with 3 or more antibiotics. The most used antibiotic was ceftriaxone, in 34 patients (35.4%), followed by levofloxacin in 25 (26%), amoxicillin plus clavulanic acid in 23 (23.9%), piperacillin plus tazobactam in 15 (15.6%), and ertapenem in 10 (10.4%).

Discussion: HHU is a booming alternative to conventional hospitalization, which can benefit patients with different disorders. This kind of hospitalization enables early hospital ward discharge and thus prevents hospital acquired complications. Our data show that amongst patients admitted in HHU due to respiratory infections, despite their advanced age and multiple morbidities, only 40% of them presented a previously known chronic respiratory condition. COPD was the most prevalent of the latter conditions. Most of the patients were referred from Internal Medicine Department, and underwent long admissions. Around half of the patients were treated with two or more antibiotics. For the administration of antibiotics, either parenteral or oral therapy can be used. The latter is predominantly used in sequential antibiotic therapy (e.g. amoxicillin plus clavulanic acid). With regards to parenteral antibiotics, those that require a single daily dose are the most used ones in our environment (e.g. ceftriaxone and levofloxacin), although pumps for antibiotic infusion can also be used (as in case of piperacillin plus tazobactam).

Conclusions: HHU is an excellent alternative for the management of patients with respiratory infectious diseases. Parenteral antibiotics that require a single daily dose are the most used antibiotics. We believe that this non-conventional way of hospitalization should be enhanced.

G-58
MANAGEMENT OF GASTROINTESTINAL BLEEDING IN A SHORT STAY UNIT

J. Medina García[1], C. Hernández Carballo[1], M. Bethendourt Feria[1], M. López Gámez[1], F. Gutiérrez Nicolás[2], N. Felipe Pérez[1], P. Laynez Cerdeña[1], S. Morales González[3]

[1]Department of Internal Medicine, [2]Department of Pharmacy, [3]Department of Digestive System. Complejo Hospital Universitario Nuestra Señora de Candelaria. Santa Cruz de Tenerife, Spain.

Objectives: To analyse the performance of Short Stay Units (SSU) in the management of gastrointestinal bleeding disorders.

Material and method: 260 clinical reports between february 2011 and february 2012 from a SSU in a general Internal Medicine Service were reviewed. Cuantitative variables are expressed in means ± SD. Non-parametric tests were performed for comparing variables without a normal distribution.

Results: 23 (8.8%) of the 260 patients were discharged as gastrointestinal bleeding. 10 (43.5%) were women. Patients were aged 73.91 ± 14.47 years. 4 (17.4%) reported smoking habit or active drinking. 6 patients (26.1%) had some degree of dependence or fulfilled criteria for pluripathological patients. 9 (39%), 5 (21.7%) and 3 (13%) patients took antiaggregants, oral anticoagulation or NSAIDs on a daily basis. 13 patients were on PBIs and none took anti-H2 drugs. Endoscopy was performed in 22 (95.7%) patients, with 16 (69.6%) of upper tract

endoscopies. Bleeding was from upper origin in 15 (65.2%) of patients. Patients stayed for 2.13 ± 1.25 days, with no patient staying for longer than 5 days. 4 (17.4%) needed readmission 30 days after discharge. However, only one of them consulted for new gastrointestinal bleeding. Only one patient (4.3) died in the first month after discharge. Haemoglobin under 10 g/dl on discharge was marginally associated with readmission (U = 8; p = 0.053).

Discussion: In this short cohort, gastrointestinal bleeding is safely managed in a SSU environment, with all patients being discharged in 5 days. The small amount of patients probably accounts for the extremely low mortality rate at 30 days. This may also explain the high readmission rate at 30 days.

Conclusions: Short-Stay-Unit-attended gastrointestinal bleeding have favourable outcome and might pose as an alternative to conventional in-hospital care of this prevalent, often severe diseases. More data are needed to identify patients that might not benefit from this modality of patient-care management.

G-59
DESCRIPTIVE STUDY OF INTERCONSULTATION CASES FROM UROLOGY SERVICE (US) TARGET TO INTERNAL MEDICINE (IM)

S. Romero Salado, G. Ruiz Villena, R. Aranda Blázquez, M. Guzmán García, E. Sánchez Relinque, O. Mera Gallardo, G. García Domínguez, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: Describe patient profile hospitalized on US involved on incterconsultation cases target to IM, during one year, and identify their nature and main reason for inter consultation.

Material and method: Selection of inter consultation cases from US, registered on IM Clinic Management Unit during 2011. We put on practice a descriptive retrospective study. Variables studied: number of inter consultation cases, basic patient profile, nature and reason for consultation.

Results: They were included 13 (17.34) inter consultation cases. Age between 30 and 88 (12 men 1 woman). Nature: ordinary 5 (38.46%), preferential 4 (30.76%) equal as urgent. Reason for consultation: patient Service transfer 3 (23.08%), dyspnea and PD 2 (15.38% each). Miscellany: therapeutic assessment, low conscious level, chest pain, fever, HT and headache 1 (7.69% each).

Discussion: Based on our numbers we noticed they are frequent inter consultation cases target to IM from US. Used to be ordinary, most men, age between 19 and 88, being main reason patient transfer to our service looking for an integral management, followed by dyspnea and PD.

Conclusions: The clinic knowledge of the IM professional and its integral management of different pathologies, makes him able to prevent and treat the complications appeared on medical surgery services where patients day by day have more comorbidities.

G-60
IMPORTANCE OF GUIDELINES FOR DECISIONS TO WITHHOLD OR WITHDRAW MEDICAL TREATMENT IN TERMINAL PATIENTS

C. Rodrigues, H. Pêgo, J. Ferreira, C. Fevereiro, S. Campos, U. Caixas, A. Godinho

Department of Internal Medicine 1.4. Hospital de São José. Lisboa, Portugal.

Objectives: The terminal phase of a person´s life has been raising ethical issues and doubts throughout the years, particularly when there is a possibility to medically intervene to relieve pain and suffering. In fact, the evolution of medicine created the possibility to prolong human existence beyond what would be naturally expected; therefore it is important to establish criteria for a good clinical practice at this stage of life.

Material and method: We will present different types of guidelines for decision involving competent or incompetent patients specifically, referring to withhold or withdraw futile or disproportional medical treatment. In addition, we submitted a survey on this subject to 50 medical doctors of our hospital in order to establish de Internal Medicine point of view.

Results: In Portugal, the debate started on 2006 and, in 2009, a law on this matter was approved but quickly dismissed because of the lack of consensus. The results of the survey, still on application, will be presented for discussion.

Discussion: For us, the ideal situation would be the suspension or abstention of disproportionate means of treatment – including cardio-pulmonary resuscitation, also known as orthotanasia; as opposed to therapeutical stubbornness or distanasia. We will also discuss the problem of living will as an inalienable and basic right of self determination.

Conclusions: We intent to show the importance of promoting an agreement on this issue involving not only health professionals but the all society, including our own governments.

G-61
ELECTRONIC INTERCONSULTATION BETWEEN LEVELS OF CARE: AN INNOVATIVE CIT APPLICATION TO THE HEALTH SYSTEM

P. Comas Casanova[1], A. Mínguez Sanz[1], D. Arnau Fernandez[1], V. Estrada Pujol[2], F. Bàguena Escolano[1], I. Pons Martín del Campo[1]

[1]Department of Internal Medicine. Hospital d'Igualada. Barcelona, Spain. [2]Department of Primary Care. Sap Anoia. Igualada (Barcelona), Spain.

Objectives: Usually, interconsultations from primary care to hospital specialists are based on referral of patients or telephone requests. The large amount of referrals and limited capacity of clinics usually leads to a continuous increase of waiting lists. Moreover, a non-negligible amount of referrals could be resolved with pertinent counselling. From this starting point, a new model of clinical case problem counselling via e-mail, was set up in 2009. After two year trial, favourable results in terms of resolution capacity and primary physicians satisfaction were achieved. At this point, we have been linking this feature to the electronic medical history after the availability of a proper interface between software programs of both levels of care. The aim of our study was to analyze electronic interconsultation demand regarding each specialty and its evolution over time as well as to collect feedback from primary care physicians regarding usefulness and satisfaction.

Material and method: Since June 2011, electronic interconsultation focusing on particular clinical case problems has been available to all primary care physicians in our hospital related basic health areas. Images or other files attachment were permitted. All medical specialties in our department took part in this new scheme. The reports were saved in the electronic medical history and were immediate and easily available to the petitioner physician. An inquiry about referral need, usefulness and satisfaction was launched to primary care physicians at the end of every report consultation. Inquiries featured 4 items: referral saving (yes/no), request saving (immediate referral, telephone consultation and others), usefulness (five degrees: from very high to none) and satisfaction (five degrees: from very high to very low). We analyzed the amount of interconsultations and their distribution among specialties as well as the results of inquiries collected from June 2011 to May 2012. We performed descriptive statistical analysis and compared qualitative variables using SPSS.

Results: Globally, 591 interconsultations were performed and 338 requests (57%) were answered. Quarterly analysis of demand shows a sustained increase along the time, from 75 to 212 interconsultations, with smaller increases between successive periods (from 75 to 23%). The most requested specialties were dermatology (42%) and cardiology (19%). Inquiries results (average percentage and range in brackets): referral saving 71% (50-100%); immediate referral saving 28% (24-31%); telephone consultation saving 24% (17-40%); high and very high usefulness 86% (77-95%); low and very low usefulness 2% (0-6%); high and very high satisfaction 85% (71-100%); and low and very low satisfaction 3% (0-9%). Globally, results among specialties were quite homogeneous with slightly higher immediate referral savings in cardiology (31%) and dermatology (29%).

Discussion: Progressive increase in the use of electronic interconsultation along the time clearly shows the wide acceptance and vast utility perception of this model among primary care physicians. Its use has allowed primary care resolution capacity to increase and has saved a non-negligible amount of referrals and telephone consultations in a very satisfactory way. Its largest using and best efficiency results concerning two specialties: dermatology and cardiology are remarkable. This could be partly due to their characteristically image related concerns (skin lesions and ECG interpretation) as well as their longer waiting lists.

Conclusions: Integrated interconsultations in the electronic medical history between primary care physicians and hospital specialists provide a very useful interrelation between care levels in terms of efficiency and satisfaction. Widespread use of this innovative CIT application in the health system as a regular feature within the range of specialized care services should be taken into account.

G-62
HYPERTENSION IN AN EMERGENCY DEPARTMENT: THE INTERNIST'S APPROACH

V. Cunha[1], M. Escarigo[1], R. Nortadas[1], M. Ferreira[1], A. Fonseca[1], M. Amaro[1], F. Delerue[1], J. Clemente[2]

[1]Department of Internal Medicine, [2]Department of Emergency. Hospital Garcia de Orta. Almada, Portugal.

Objectives: To review admissions and medical approach to acute elevations in blood pressure (BP; hypertension crisis) in the Emergency Department (ED) of a Portuguese Central Hospital.

Material and method: Retrospective Descriptive Analysis of patients discharged with the diagnosis of Hypertension (HTN), admitted to a Portuguese Central Hospital's ED during a 10 month period (from January to October of 2011). Use of Microsoft Office Excel 2007 for analysis.

Results: A sample of 917 patients was obtained, with an average age of 64 years old and a discrete predominance of female sex patients (62.5%). Seventy eight percent of the patients had a previous diagnosis of HTN and 68.7% were medicated; 21% were diabetic, 20.7% had dyslipidemia, 16.5% had previous cerebro- or cardiovascular events. Of the antihypertensive medications: 16.1% were under monotherapy and 24.1% under fixed associations; 25.2% were medicated with ACEI, 25.6% with ARAB, 30.5% with diuretics, 16.9% with CCBs, 16.6% with BB and 1.5% with Direct renin inhibitors. Only 10% of the patients were followed in the ambulatory by Internal Medicine or Cardiology Specialists. In 21% of the cases, patients had already come to the ED before for HTN crisis: of these, only 10.4% were not medicated, and only 18.7% were followed in ambulatory by a specialist (vs 76.2% followed by the general practitioner). Of the symptoms that motivated ED admission, the most prevalent was headache in 34.7%, chest pain in 19.7%, dizziness in 17.7%. In 11.0% of the patients, high BP measured in ambulatory was the only admission reason. Most were admitted with the yellow bracelet according to the Manchester Triage System. In 19.8% of cases, patients had already took some antihypertensive drug before admission at the ED (mostly ACEI). At admission, 31.2% had Systolic BP (SBP) between 180-199 mmHg and 24.6% above 200 mmHg; 13.5% had SBP > 200 and DBP > 110 mmHg, and 12.5% had isolated systolic HTN (SBP > 160. DBp < 84 mmHg). Diastolic BP (DBP) was above 110 mmHg in 31.7% and 100-109 mmHg in 23.4%. To most patients was administrated some antihypertensive drug at the ED: in more than 80% were given oral and/or sublingual ACEI, in 39.5% diazepam, in 31.5% a diuretic, in 28.3% a CCB; in 10.6% no drug was administrated. At discharge, 34.2% had SBP between 140-159 mmHg; 25.1% below 140 and 17.2% above 160 mmHg; 42.7% had DBP below 84 mmHg and 22.1% above 90 mmHg. In 35.3% of cases antihypertensive treatment was started or the added new drugs to the ambulatory medication and/or doses raised. Only 3.7% of patients were discharged to a specialist consult.

Conclusions: Uncontrolled BP remains a significant challenge, not only for the ED frequent visits but also in the daily basis of the clinical practice. There is still a significant number not only of undiagnosed patients, but surprisingly of undertreated hypertensive patients. At admission BP levels are markedly elevated and pharmacological intervention at discharge was important. This small study does not describe true HTN urgencies or emergencies, but it reflects a significant parcel of admissions at the ED for uncontrolled BP, partially caused by under-treatment. Controversy remains about the best approach to HTN crisis: the authors recommend the development of Protocols for the best management of the patient at ED, in which the Internist plays the main role.

G-63
IN-HOSPITAL MORTALITY OF THE PATIENTS WITH ACUTE CORONARY SYNDROMES PRIMARILY ADMITTED TO NONACADEMIC HOSPITALS

Z. Monhart[1], J. Reissigova[2], P. Widimsky[3], P. Jansky[4], J. Zvarova[2], H. Grunfeldova[5]

[1]Department of Internal Medicine. Hospital Znojmo. Znojmo, Czech Republic. [2]Centre of Biomedical Informatics. Institute of Computer Science. Prague, Czech Republic. [3]3rd Department of Internal Medicine. Faculty Hospital Kralovske Vinohrady. Prague, Czech Republic. [4]Cardiovascular Centre. University hospital Motol. Prague, Czech Republic. [5]Department of Internal Medicine. Hospital Caslav. Caslav, Czech Republic.

Objectives: Despite low in-hospital mortality (4-6%) seen in the latest randomized trials of myocardioal infarction, mortality rates in registry studies are much higher, suggesting that the patients included in the randomized studies are at a lower risk when compared with those seen in the real world. The main task of our work was to determine in-hospital mortality of patients with acute coronary syndromes (ACS) primarily admitted to internal medicine departments of nonacademic hospitals. Secondarily we decided to identify baseline predictors of in-hospital mortality of our ACS patients, and so define population at high risk of in-hospital death.

Material and method: The data originated from ALERT-CZ (Acute coronary syndromes – Longitudinal Evaluation of Real-life Treatment in non-PCI hospitals in the Czech Republic) registry in nonacademic hospitals from 1.7.2008 to 30.6.2011. None of the participating hospitals had catheterisation facilities. Interventional treatment (if indicated) was provided in a catchment faculty hospital with PCI-centre. All internal departments provided a comparable level of acute cardiology care and a similar spectrum of diagnostic and therapeutic procedures (with the exception of interventional therapy); therefore, these hospitals were considered to be an adequate sample of non-PCI hospitals in the Czech Republic. All participating internal medicine departments admitted an unselected

population of patients from their surrounding area. We evaluated the effect of cardiovascular risk factors, patient´s baseline characteristics and acute therapy on in-hospital mortality of ACS patients.

Results: In total, 6.013 ACS patients were included. The majority of patients were men (59.0%), and the average age of all ACS patients was 70.3 ± 12.1 years (range, 20.9-103.8). The proportion of patients > 75 years was 40.2%. Average length of hospital stay was 6.6 days (median, 5.0 days). Total in-hospital mortality in our ACS population was 7.5%; in STEMI patients 12.7%, in NSTEMI 9.0 % and in patients with unstable angina 0.3%. In multivariate analysis known history of hyperlipidaemia, diabetes and hypertension did not significantly influence odds of death in ACS patients, similarly as a history of MI and baseline value of haemoglobin. Increasing age had an adverse influence on the odds of in-hospital death (< 0.001). Higher systolic blood pressure on admission was significantly associated with the lower odds of death (< 0.001). Heart rate on admission between 80-155/min significantly increased the odds of death (0.004). The higher baseline creatinin (> 100 µmol/l) had a significantly negative effect on the odds of death (< 0.001). Odds of in-hospital death also increased along with the decreasing number of recommended medications used in acute phase of ACS. Compared with a total number of 5 recommended medications, odds of death was 1.5 times higher for 4 medications, 2.8 times higher for 3 medications, 2.9 times higher for 2 medications, 8.1 times higher for 0-1 medications.

Conclusions: Total in-hospital mortality in our ACS population was 7.5%. We identified several patients' characteristics predicting adverse outcomes of patients with acute coronary syndromes (myocardial infarction and unstable angina). Higher age, heart failure at presentation, lower systolic blood pressure at admission, heart rate 80-155/min and elevated initial creatinin values at admission were independent negative predictors of inhospital death. Administration of all recommended pharmacotherapy within the first 24 hours significantly decreased odds of in-hospital death of patients with acute coronary syndromes. Clinicians involved in the care of patients with ACS should pay particular attention to these subpopulations to select the best management strategies for these patients in accordance with the guidelines.

G-64
ANALYSIS OF THE MEDICAL CONSULTATIONS PERFORMED IN AN INTERNAL MEDICINE DEPARTMENT DURING TWO YEARS

A. Cecilio Irazola, M. Arteaga Mazuelas, V. Jarne Betrán, V. Fernández Ladrón, C. González Rodríguez, J. Velasco Montes, J. Sáinz de Murieta Usabiaga, F. del Cazo Cativiela

Department of Internal Medicine. Hospital García Orcoyen. Estella (Navarra), Spain.

Objectives: A descriptive and retrospective study about the medical consultations received in the Internal Medicine Department at the Garcia Orcoyen Hospital (Navarra-Spain) during 24 months. This is a community local hospital (second level) with 97 beds, one third directly depending on that Department.

Material and method: We reviewed the digital medical records of the patients we received consultation request from January 2010 to December 2011.

Results: 309 consultation requests were submitted during this time, approximately 3 per week. The average age was 74.1 years; 46% were between 66 and 80 years; 56% were female. The most of the assistances were continuous (70.8%). The principal reference Department was Traumatology (62%), followed by General Surgery (28%). The mean duration of the patients monitoring (number of visiting days) was 4.75, with 36.2% of the patients tracked 2 to 4 days and 31.4% during 5 to 10 days. The global account of visits was 1487. This means two extra patients per day in the 24 months analyzed. By age, the most of the patients visited more than 5 days (73%) were 65 years old or above. About the clinical entities diagnosed/treated, diabetes and its complications was the main cause of consultation (23%), followed by hypertension (14.8%), respiratory tract infection/pneumonia (13.2%), chronic/acute renal failure (12.6%), heart failure (11.6%), anaemia (11.3%), arrhythmias (10.6%) or delirium (7.1%). Other common diseases were skin/soft tissues infection or vomiting/ileus. Related to the surgical patients, 45% underwent a hip-repairment surgery, in 19% a gastro-intestinal surgery was performed and 15% had other Trauma disorders different from knee-repairment (11%).

Discussion: First proposals about formal consultation between surgical and medical physicians were carried out by Goldman in 1983. In recent studies, 5 to 55% of the patients admitted to a surgical Department were seen by internists. Sometimes easy and grateful, many other times visits are hard and difficult because of the wide variety of diseases and the special conditions related to surgical patients. Our data show that the population assisted is similar in age, sex distribution and comorbidities to those patients admitted to the internal medicine Department. Similar to other series, Traumatology referred the highest number of consultations. Length of the diseases assisted (the average was almost 5 days, some until three weeks) shows the complexity of the patients and the additional charge they involve for the medical staff who take care of them. As supposed, elderly patients and most prevalent entities in that range of age (cardiovascular diseases, diabetes…) concerned the majority of consultations, whereas the common complications of the surgical procedures. We did not compare mortality rates.

Conclusions: Medical consultations are very relevant tasks in the daily work of internists, some cases with special dedication and difficulty. It is quite important to work hard in this area, in order to achieve good results in this kind of subspecialty. Maybe specific protocols and guidelines should help in the management of these patients, so we could improve actual results.

G-65
ACUTE INFECTIONS IN THE SETTING OF A SHORT STAY UNIT

J. Medina García[1], N. Felipe Pérez[1], M. Monedero Prieto[1], F. Gutiérrez Nicolás[2], M. López Gámez[1], S. Vicente Rodrigues[1], J. del Arco Delgado[1], P. Laynez Cerdeña[1]

[1]Department of Internal Medicine, [2]Department of Pharmacy. Complejo Hospital Universitario Nuestra Señora de Candelaria. Santa Cruz de Tenerife, Spain.

Objectives: to describe the clinical features of patients admitted to a Short Stay Unit (SSU) because of an infectious disease different from chronic obstructive pulmonary disease (COPD) exacerbations. To describe factors associated with length of stay, readmission rate and mortality.

Material and method: 260 clinical reports about patients admitted into a SSU because of an infectious disease were reviewed. Patients discharged with diagnosis of COPD or CAP were excluded. Categorical variables were compared by means of χ^2 test, cuantitative variables were compared with correlation coefficients. Statistical Package SPSS 15.0 was used for the management of the study data.

Results: a total of 128 patients were included. Mean age (± SD) was 74.11 ± 15.99 years. 77 (60.2%) were women. 66 (51.6%) had at least two items computing for pluripathological patients, with 1.63 ± 1.24 categories. 31 patients (24.8%) had 3 or more categories. 55 (43%) had some degree of dependence. 87 (68%) were polymedicated. 17 (13.3%), 10 (7.8%) and 4 (3.1%) patients needed readmission 30, 14 and 3 days after discharge, respectively. Length

of stay was 3.06 ± 1.43 days with 6 (4.7%) patients staying for longer than 5 days. 4 patients (3.1%) died during the first 30 days after discharge. There was a marginal relationship between pluripathology and readmission (p = 0.055). More computing categories also correlated with readmission (p = 0.048), and so did polymedication (p = 0.02). Positive blood cultures did not relate with readmission. Site of infection did not affect readmission.

Discussion: Acute infections are common processes that often motivate long hospitalization periods in elderly, fragile patients. SSU stand as an alternative to conventional management that appears to be safe, although the relative small size of this cohort might not allow to correctly predict adverse outcomes.

Conclusions: Common infections are safely managed in a SSU environment, even among elderly patients with multiple comorbidities. In these patients, more often than not, can be more adequate in order to prevent iatrogenic complications. More data are needed in order to identify which patients will benefit more from this approach.

G-66
THE COMPARISON OF QUALITY OF LIFE IN PREDIALYTIC, DIALYTIC AND POST KIDNEY TRANSPLANTATION PATIENTS

Z. Dimitrijevic, G. Paunovic, M. Stojanovic, B. Mitic, K. Paunovic

Department of Nephrology. Clinical Center Nis, Serbia.

Objectives: The quality of life (QoL) is a complex concept that includes physical, psychological and social domain of health and is influenced by human experiences, beliefs and perceptions. Chronic renal failure (CRF) is a clinical syndrome that indicates a progressive loss of kidney function. Renal replacement therapy prolongs patients survival, but also has a significant impact on the QoL. The aim of our study was to compare biochemical and hematological parameters as well as the QoL in patients with CRF treated by three different ways.

Material and method: We performed prospective study conducted on 120 patients divided into three groups: 40 patients with transplanted kidney, 40 patients on chronic hemodialysis and 40 patients treated only by conservative therapy.

Results: The results of the SF-36 test show that there are differences in seven of eight fields of questionnaire between transplant patients on one hand and the subjects treated by hemodialysis and conservative therapy on the other hand. The highest scores in all eight areas were obtained in the transplanted patients group. In both summary scales the highest values were obtained in the transplant group, while almost the same value was verified in patients undergoing hemodialysis therapy and conservative treatment.

Conclusions: According to results obtained by examination of various aspects of QoL, we concluded that kidney transplantation is the type of therapy for end-stage renal disease that provides the best QoL to patients.

G-67
SPECIALIZED CARE COORDINATION IN THE AMYOTROPHIC LATERAL SCLEROSIS THROUGH NURSING MANAGEMENT OF CASES IN A UNIT OF INTERNAL MEDICINE

A. Ortegón Gallego, R. Tirado Miranda, D. Pérez Tejero, C. Nevado Barbero, I. Mejías Real, D. Navarro Hidalgo, E. Guisado Espartero

UGC Department of Internal Medicine. Hospital Comarcal Infanta Margarita. Córdoba, Spain.

Objectives: Specialized care in so-called rare diseases is a challenge in community hospitals due to technological limitations. However, this should not be an obstacle to coordinate treatment interventions required for each case. In a coordinated sequence of care called single act. (Acto único).

Material and method: Since 2008 have been captured for monitoring and review patients with amyotrophic lateral sclerosis (ALS) derived from the Regional Hospital, (University Hospital Reina Sofia, Córdoba, Spain) with clinical reports of altered needs to be covered by our hospital. They are referred to Case Management Nursing Hospital Infanta Margarita, Cabra, Córdoba (Spain). Initially they are controlled in single acts of review by the medical departments of Pulmonology, Clinical Nutrition, Rehabilitation and other hospital departments: pharmacy, customer service, etc. From the initial contact with the patient is done a general evaluation of the patient's family and level of information they possess. In one case, with high dependence on mechanical ventilation and required the presence of multiple specialists: ORL, Intensivist, Pulmonologist and Nutritionist and medicalized ambulance was needed for moving the patient from home to hospital and back to the return address.

Results: Since jan.2008 till May, 2012 a total of 16 cases of patients affected by ALS has treated: Lucena 8 cases, 2 cases of Priego de Córdoba, 4 cases of Córdoba Cabra, 2 cases Rute. In 8 cases, the single act: Neumology + + Rehabilitation Clinical Nutrition has been done. In one case, the multidisciplinary care offered by Intensivist + Neumology + Clinical Nutrition and medicalized transport to change tracheostomy tube because thre was tracheal deformity and risk of loss of ability to breathe. The patient was under mechanical ventilation with 6 hours of autonomy portable fans. It requested the presence of the intensivist after the revocation of the desire not to resuscitate the patient had previously expressed. The rest of experts evaluated the patient´s health after the change of the cannula in the same room, previously prepared. The coordinated acts through corporate phones allowed a coordinated care professionals. The tracking by satellite of the ambulance transporting a patient on mechanical ventilation until his arrival at the hospital allowed the coordination of specialists needed for therapeutic actions sequentially.

Discussion: Currently, five patients have died: 2 in Cabra, 2 in Priego and 1 in Lucena because of the gradual progress of the disease. Four patients died at home and one in the hospital. The rest are still alive, with acceptable quality of family life. Nursing Case Management Center assigns the card "+ Cuidados" to the carers of these patients. The coordination in hospital medical health cares through Nursing Case Management and various specialists required by ALS cases is not only possible but necessary.

G-68
INCIDENCE, PROGNOSIS FACTORS AND TREATMENT OF ACUTE CHOLANGITIS IN A DIGESTIVE DEPARTMENT

M. Navarro Aguilar[2], Y. Arguedas[1], T. Revuelto[1], I. Ariño[1], M. Solano[1], A. Lué[1], M. Rodero[2]

[1]Department of Digestive, [2]Department of Internal Medicine. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: To evaluate epidemiological characteristics and severity of acute cholangitis (AC) cases in our department, as well as safety of endoscopy treatment (ERCP) in this entity.

Material and method: We performed a retrospective descriptive study of hospitalized episodes of acute cholangitis from January 2008 to April 2012. We analyzed clinical data of patients, the etiology and severity of AC and the treatment received.

Results: 143 patients were diagnosed with AC. 60.8% were male, with a mean age of 73.25 years (range 21-99). With an average hospital stay of 10.65 days. Main cause of acute cholangitis was choledocholithiasis (69.2%) followed by hepatobiliopancreatic neoplastic disease (7.7%). Most cases (86.7%) debuted with the classic triad (pain, fever and jaundice). Remainder (13%), made

their debut with laboratory abnormalities or atypical symptoms. Half of patients underwent blood cultures being positive 18.9% (14% gram negative Escherichia coli predominating, gram-positive cocci 3.5% and 1.6% polymicrobial). In one third of cases (9 of 27 positive cultures) were isolated resistant organisms to common used antibiotics. Half of patients, were treated with piperacillin-tazobactan, 15.5% required return for broader spectrum antibiotic. 82.5% of the cases were mild cholangitis, while 5.6% met criteria for severe sepsis needing ICU admission. Overall mortality was 6.3%. The severity of AC is associated with the presence of comorbidity and resistance in the isolated microorganisms ($p \leq 0.03$). In 108 patients (75.5%) biliary drainage with ERCP was performed (54% sphincterotomy and 21% biliary stent placement). 21% of cases only medical treatment was required and 3.5% required surgery or CPTH for infection solution. After ERCP only a 9.8% patients had technical complications (2.8% acute pancreatitis, gastrointestinal bleeding 4.2% and 2.8% cardiovascular or respiratory disorders) no mortality was associated to technique. We found no association between complications of ERCP and the patient's age nor comorbidity ($p = 0.28$). 17.5% of cases had a second episode of AC, being more frequent in patients with previous biliary tract surgery (13.9% vs 38% $p = 0.013$) and prosthesis/biliary drainage (11% vs 37% $p = 0.001$), founding no association with etiology or presence of malignancy ($p = 0.1$).Overall mortality was 6.3%, being 4 of the 9 patients due to advanced biliary malignancies and it was associated with the presence of resistant organisms (11% VS33% $p = 0.001$) and recurrence of AC ($p = 009$).

Discussion: AC is a prevalent disease in males, especially in advanced middle age and comorbidity patients. The most common etiology is obstructive choledocholithiasis. 13% of cases are clinically latent, so the diagnosis should be suspected. In 42% of cases it is profitable to carry out blood cultures of microorganism producing of AC and knowledge of new resistances, related to morbidity and mortality of this entity. The main treatment is an early antibiotics administration (especially beta-lactam), and drainage by ERCP in 75% of cases (9.8% had complications not associated to the patient's age or comorbidity). Recurrent cholangitis is nearly three times more frequent in patients with previous biliary tract surgery and patients with prostheses/biliary drainage ($p \leq 0.013$) with high mortality in these cases.

Conclusions: Blood cultures are profitable in AC suspicion, because resistant organisms are associated with increased morbidity and mortality. Endoscopic treatment of AC is safe and effective, with a high success rate in resolving the acute illness, even in elderly patients.

G-69
STUDY ON THE ASSOCIATION OF THE RS1948 POLYMORPHISM IN THE CHRNB4 GENE, WITH ALCOHOL CONSUMPTION AND TOBACCO SMOKING IN A MEDITERRANEAN POPULATION

F. Francés[1], O. Portolés[1], J. Costa[2], R. Montón[1], E. Asensio[1], D. Godoy[3], J. Sorlí[1], D. Corella[1]

[1]Department of Preventive Medicine and CIBER obn. University of Valencia. Valencia, Spain. [2]Clínica Atenea Aldaia. Clínica Atenea. Valencia, Spain. [3]Department of Internal Medicine. University General Hospital. Valencia, Spain.

Objectives: Tobacco and alcohol consumption supposes a world-wide serious health problem. The existing evidence suggests some genetic factors underlying these conducts. The rs1948 polymorphism in the neuronal Acetylcholine Receptor subunit beta-4 (CHRNB4) gene, that is part of the CHRNA5-CHRNA3-CHRNB4 cluster, has been proposed as a modulating factor of the beginning and maintenance of the tobacco and alcohol use.

Material and method: As a part of a wider research project on the genetic bases of tobacco and alcohol use in Spanish population, we show here preliminary data on 372 individuals. All participants filled a questionnaire in which alcohol and tobacco consumption variables were measured. Also, Fagerstrom and AUDIT tests were undertaken in order to estimate the level of addiction to these substances. The rs1948 polymorphism was genotyped by using the TaqMan® assay (Applied Biosystems). Multivariate regression analyses were carried out to test associations.

Results: Genotype distribution was G/G 49.4%; G/A 39.1%; A/A 11.5%. This was in agreement with the Hardy-Weinberg equilibrium. No associations were found between the rs1948 polymorphism and the tobacco smoking and addiction variables. Regarding with alcohol consumption, and after performing the stratification of the sample by age, and after adjusting by sex, civil status and instruction level, we found that individuals between 18-40 years that were carriers of the A variant, had an increased alcohol consumption estimated by daily mean alcohol intake (3.02 ± 0.65 g in A carriers versus 1.40 ± 0.39 g in G/G, $p = 0.004$), and by standard beverage units (SBU) (0.50 ± 0.09 SBU in A carriers versus 0.23 ± 0.06 SBU in G/G, $p = 0.003$). Furthermore, the carriers of the A allele had a nearly 4-fold increased risk of being alcohol consumer than the G/G individuals (OR = 3.85; 95%CI: 1.73-8.56, $p = 0.001$). The carriers of the A allele also showed greater AUDIT test scores than the G/G individuals (2.41 ± 0.31 in A carriers in front of 1.72 ± 0.39 in G/G, $p = 0.011$).

Conclusions: The rs1948 polymorphism in CHRNB4 gene is significantly associated with alcohol consumption and addiction in the 18-40 years subsample. These preliminary results suggest that this genetic variant may be a determinant of alcohol consumption in the Mediterranean population. Acknowledgments: This work has been supported by grants UV-INV-AE11-41946.

G-70
UCIA (UNIT AND CLINIC IMMEDIATELY ATTENTION): A NEW WAY OF MAKING INTERNAL MEDICINE

M. León Téllez, P. Sánchez Oliva, M. Carrera Izquierdo, O. Terry López, D. López Delgado, J. Barraza Vengoechea, J. Gutiérrez Salcedo, P. Arribas Arribas

Department of Internal Medicine. Hospital Santa Bárbara. Soria, Spain.

Objectives: To demonstrate the usefulness of new created units to improve the medical attention of specific processes, avoiding unnecessary admissions patients and also an excessive long waiting list that obstruct and delay the diagnosis. We would like to tell you about our experience and labor along one year of operation, the first one, of UCIA.

Material and method: A retrospective observational study reviewing the register of UCIA, the clinic histories, and the data of Admission Service that counts 338 patients. We collected data referred to: number of patient, age, sex, medical and surgical records, usual treatment, symptoms, place, required tests or studies, time to attending, suspect diagnosis, waiting time for results, other Medical Services collaboration, number of visits and final diagnosis.

Results: Along one year working (April 2011-April 2012) 338 patients has been attended. 179 were males and 159 females, the prevalence of pluripathologic patients were 64% with same grade of presentation for men and women. The mean time to attention was 38 hours, 81% of patients comes from Emergency, 1% comes from other hospital Speciality and the rest from Primary Care. The mean number of visiting for patient is 2.4 times and the final diagnosis has been classified in different categories: Heart pathology 49 cases; Digestive pathology 30; Cancer 21; Reumathologic pathology 12; Infectious diseases 9; Neuropathology 9; Multifactorial anaemia

8, ferropenic 11, megaloblastic 3, Deep venous thrombosis 23; Secondary effects or iatrogenic effects 4; Haemathologic disorders 5; Diabetic debut 3; Thyroid pathology 5; 1 Cushing's syndrome; 2 Mondor's syndrome; Syncope 3 cardiogenic, 2 neurogenic and 6 vasovagal; 4 Allergic pathology; 2 vasculitis; we don't have wrong findings in 62 patients; 31 patients continue following and don't have data about the rest.

Discussion: We know one year is a short time of work and the accumulated experience with only 338 patients could be not enough, also to find data to compare our Unit to other one with similar characteristic is difficult, because this is not a common way to make Internal Medicine practice. On the other hand we would like to find a useful scoreboard or index to calculate the efficiency of the UCIA and in addition to quantify the avoided admissions and the saved time to wait attention.

Conclusions: The global approach of illness and a good relation between different Medical Services as Primary Care, Emergency and Internal Medicine is the most important ingredient to make working this kind of "fast diagnosis units".

G-71
THE SHORT STAY MEDICAL UNIT IN A PRIVATE HOSPITAL: A RETROSPECTIVE STUDY

A. de Giorgi[1], G. Pons-Estel Silvestre[1], M. Guzmán Fernández[1], R. Serrano Morales[2], M. Suppo[1]

[1]Department of Emergency Medicine, [2]Department of Internal Medicine. Capio Hospital General de Catalunya. Sant Cugat del Vallés (Barcelona), Spain.

Objectives: The aim of the present study was to examine a Short Stay Medical Unit (SSMU) in a tertiary private owned-hospital of Catalonia (Spain), in order to compare the characteristics of admitted patients and their pathologies with those from SSMUs of Spanish public health-hospitals.

Material and method: Retrospective study of all patients admitted to our SSMU between January and December 2011, using descriptive statistical methods.

Results: A total of 1098 patients (54.2% females, average 41.9 ± 10.3 years old) were admitted to our SSMU in 2011; 1037 patients were discharged from the same Unit, while 61 patients (5.6%) were transferred to other departments due to changes in diagnosis or clinical complications. The average stay was 1.51 days, the mortality and readmission rates were 0.1% and 2.4%, respectively. The most prevalent diagnoses at discharge are depicted in table 1. The averaged age and length of stay for patients with a diagnosis of urinary tract infection were 45.1 years and 1.9 days, respectively, for those with a diagnosis of community acquired pneumonia were 38.9 years and 2.8 days, respectively, for patients with esophagitis and gastritis 39.5 years and 0.8 days, respectively.

Discussion: The SSMU can be an alternative to conventional hospitalization; it provides targeted care to patients dischargeable in less than 5 days and is usually linked to the Emergency Department. When comparing our data with Spanish registries about patients admitted to SSMUs in public health-hospitals, we can see that in our Center patients are significantly younger (41.9 vs 75.4 years), with a higher percentage of males (45.8 vs 36.8%), and stay less time in the Unit (1.51 vs 2.37 days); mortality and readmission rates are very low, as is the percentage of patients who need to continue their hospitalization in other departments. Infectious diseases are by far the most prevalent pathologies, more than in public SSMUs.

Conclusions: In public hospitals SSMUs represent an alternative to ordinary ward, mainly directed towards exacerbations in chronic patients. In our hospital, that receives mainly subscribers of private health insurances, this model of "light" hospitalization is offered to selected acute patients with low-grade comorbidities, so allowing a rapid diagnosis and effective initial treatment and increasing patients' satisfaction.

Table 1 (G-71). The Most Prevalent Diagnoses at Discharge from our Short Stay Medical Unit in 2011

Diagnosis	Prevalence (%)
Urinary tract infections	12.5
Community acquired pneumonia	10.9
Esophagitis and gastritis	9.2
Acute gastroenteritis	7.5
Other causes of abdominal pain	7.4
Acute bronchitis and chronic obstructive pulmonary disease	6.8
Upper respiratory infections	6.8

G-72
UNINTENDED DISCREPANCIES AT DISCHARGE FROM AN INTERNAL MEDICINE SERVICE

T. Fonseca[1], C. Cunha[1], P. Caiano Gil[1], D. Lopes[2], A. Silva[1], J. Silva[1], L. Andrade[1], V. Paixão Dias[1]

[1]Department of Internal Medicine, [2]Department of Nephrology. Centro Hospitalar de Vila Nova de Gaia/Espinho. Vila Nova de Gaia, Portugal.

Objectives: Unintended discrepancies are unjustified differences between patient home regimen and medications prescribed at discharge. The aim of reconciliation is to guarantee that patients receive all necessary medicines adapted to their clinical and social situation. The objectives of this study were to identify and characterize the unintended discrepancies between the medication list at admission and the physicians discharge medication orders obtained by an internal medicine specialist physician through the analysis of the hospital discharge reports.

Material and method: This was a descriptive and retrospective study of adult patients admitted in Internal medicine service. It was based on the review of consecutive hospital discharge reports that were produced by 14 services specialist physicians during the first two months of the year. Patients who died or were transferred to other units of care, were excluded from the study. The classification that we use was: no discrepancies, when the medication at discharge was the same as that at admission, and medication discrepancies that means any difference between medication list at admission and at discharge. These medication discrepancies can be unintentional or intentional discrepancies.

Results: We reviewed 412 discharge reports, and 145 reports were excluded. A total of 267 reports were analyzed in the study. These corresponded to 254 patients, since in 13 cases the reports corresponded to patients that were hospitalized more than once during the study period. In the reconciliation process, we found discrepancies in 242 (90.6%) of them. Both Intentional and unintentional discrepancies were found in half of the cases (121). The most frequent medication error was omission of a medication detected in 61% of cases, followed by commission of a medication (a medication was ordered at discharge which the patient did not take before hospitalization, and there was no clinical explanation for adding the medication) detected in 26% of cases. Incomplete information at the medication list at the admission was detected in 56% of cases and 51% of them were dependent in the daily activity.

Discussion: Unintended discrepancies at the discharge were prevalent for patients admitted in a general internal medicine service (50%). The most frequent medication error was omission of a medication detected in 61% of cases.

Conclusions: Therefore, appropriate routines for ensuring an accurate collection of the medication history and the methodical completion of the medication list at the discharge when performed by trained internist are important factors for an adequate medication reconciliation process.

G-73
HEPATIC PERTURBATIONS IN PATIENTS WITH TREATED WILSON'S DISEASE

M. Bezna, S. Bezna, C. Becherescu, C. Bezna, V. Padureanu

Department of Internal Medicine. University of Medecine and Pharmacy, Emergency Hospital. Craiova, Romania.

Objectives: In Wilson disease, hepatic involvement is variable, from fatty liver to hepatitis- acute, chronic active- and cirrhosis. Wilson disease is an autosomal recessive genetic disorder caused by abnormal gene ATP7B of chromosome 13, in which accumulation of cooper leads to liver disease and neuropsychiatric manifestations. The prognosis may be improved by persistent and precocious treatment. Aim: the observation of hepatic damage in evolution of two young patients diagnosed with Wilson disease and treated 17 years.

Material and method: There are presented 2 patients, sister and brother, 31 and 27 years old, diagnosed at 14 and 10 years old with Wilson disease by clinical manifestations with hepatomegaly, extrapyramidal syndrome, behavioral changes and laboratory tests (low serum ceruloplasmin and copper, increased level of urine copper), liver biopsy, imagistic investigations.

Results: In these familial cases, the hepatomegaly was a fatty liver, confirmed imagistic and at the liver biopsy: micro and macro vesicular steatosis. The mutations of gene for ATP-ase which link the copper to ceruloplasmin in hepatic cells decrease this linkage and the biliary clearance of copper causing a toxic effect of copper: the accumulation of free radicals, the oxidation of lipids, enzymes and proteins and in time cell apoptosis. The continuous treatment with copper chelators (penicilamine, trientine, zinc) and diet maintained only the steatosis and the severe evolution to cirrhosis were stopped.

Conclusions: 1. Hepatic manifestation with steatosis by metabolic perturbations copper induced may be observed in treated Wilson disease. 2. If the disorder is early detected and treated, the fatty liver remained non aggravated long time. 3. The specific treatment to control the copper can stopped the evolution to severe liver lesions long time.

G-74
ONE YEAR EXPERIENCE OF A SHORT STAY UNIT IN A TERTIARY HOSPITAL. REPORT FROM FIRST RESULTS

J. Del Arco Delgado, J. Medina García, C. Hernández Carballo, J. Delgado Casamayor, L. Abraham Pérez, M. Bethencourt Feria, M. López Gámez, P. Laynez Cerdeña

Department of Internal Medicine. Complejo Hospital Universitario Nuestra Señora de Candelaria. Santa Cruz de Tenerife, Spain.

Objectives: To describe the profile of patients admitted to the SSU and analyze the most prevalent disease groups. Objectify if SSU can be a good way to treat some acute pathologies and if we meet the targets set for an SSU. We believe that the patient readmission to the emergency is defined by a 24 hours stay in the month following into the hospital.

Material and method: Descriptive, retrospective design performed on patients admitted into a SSU between February 2011 and February 2012. 260 clinical reports were reviewed. Categorical non parametrical variables were compared using non parametric tests.

Results: We have an average stay of 3 days +/-2.2 days (± SD) with a mean age of 73.13 ± 16.26 years (± SD). (49.8%) of them fulfilled criteria of pluripathological patients. (34.1%) had some degree of dependence in basic activities of daily living. The most prevalent chronic diseases were: hypertension (65.8%), dyslipidemia (46.5%), diabetes (42.3%), chronic kidney disease (25.8%), COPD (24.2%) and atrial fibrillation (23.1%). The most frequent main diagnoses at discharge were: heart failure (17%), lower respiratory tract infections (11.2%), community-acquired pneumonia (11.2%), gastrointestinal bleeding (8.07%), renal failure (7.7%), urinary tract infections (6.53%), exacerbated COPD (5%), acute gastroenteritis (3.46%). (16.9%) of patients met criteria for readmission of which (2.4%) was within the first three days after discharge. Median days to readmission was 17.88 days ± 14.78 (± SD). (47.7%) of readmissions were due to same reason which led to their admission to the SSU. Of 6 patients who were readmitted within the first 3 days after discharge, only 2 of them for the same reason. There is an association between polymedicated patient (χ^2 = 4.35; p = 0.037) and pluripathological criteria (χ^2 = 8.71 p = 0.003) with patient readmission. Category A (heart disease NYHA II or chronic ischemic disease) and category B (Chronic renal disease) are associated with readmission (χ^2 = 6.57; p = 0.01) (χ^2 = 6.073; p = 0.014). Other categories and dependency did not relate with readmission. 42.7% of patients were referred for outpatient internal medicine after discharge, but this did not affect readmission. (11.9%) of patients died during the follow-up. One of them did while in the SSU. 8 patients (3.1%) died during the first month after discharge. Anemia at the time of discharge correlated with mortality (p < 0.001) Patients that needed readmission also had a higher mortality at 90 days (p = 0.006), which was also the case among patients readmitted 14 days after discharge (p < 0.001) during the first 72 hours after discharge (p < 0.001). 5% of patients required conventional hospitalisation.

Conclusions: SSU can help reduce length of hospital stay and has a low readmission rate when considering the same process that caused the original admission to the SSU. Our population comprises elderly people and mostly with criteria of comorbidity and certain degree of dependency. SSU management allows for short stays that reduce economic costs and avoid typical complications for prolonged stays. This is specially sensible considering both patients with chronic diseases that are exacerbated and acute diseases such as mild gastrointestinal bleeding.

G-75
CAUSES OF HYPONATREMIA IN INTENSIVE CARE UNIT PATIENTS: A RETROSPECTIVE ANALYSIS

R. Acar[1], R. Öcal[2], G. Büyükturan[1], M. Cakar[1], B. Yildiz[1], E. Sertoilu[3], E. Arslan[1], H. Yamanel[2]

[1]Department of Internal Medicine. Science Department, [2]Department of Intensive Care. Science Department, [3]Department of Biochemistry. Science Department. Gülhane Military Medical Faculty. Ankara, Turkey.

Objectives: Hyponatremia is defined as plasma sodium level to be below 135 mEq/L. It is a frequent finding and seen in 10-15% of the hospitalized patients. In this study, we aimed to retrospectively investigate the patients with hyponatremia during the admission or hospital stay in the intensive care unit.

Material and method: The study included a total of 107 patients that were detected to have hyponatremia and admitted in intensive

care unit for a variety of reasons between 01 January 2011 and December 31, 2011. The mean age of patients was 70.5 ± 14.3 years. Of patients, 57.9% (62) were male. The medical records of these patients were assessed retrospectively. Patients were divided into groups according to hyponatremia levels: 125-134 mEq/L as mild hyponatremia, 115-124 mEq/L as moderate hyponatremia, and < 115 mEq/L were grouped into severe hyponatremia. SPSS 15.0 was used for statistical analysis.

Results: Among the severe hyponatremia cases, 2 of 3 patients (66.7%) had hypervolemic hypotonic hyponatremia due to heart failure and acute renal failure, 1 patient (33.3%) had hypovolemic hyponatremia due to diuretic use. Of the moderate hyponatremia cases, 8 of 29 patients (27.6%) had normovolemic hypotonic hyponatremia which was due to SIADH (6 patients), tricyclic antidepressant medication (1 patient), and pituitary insufficiency (1 patient); 16 of 29 patients (55.2%) had hypervolemic hypotonic hyponatremia because of heart failure (10 patients), acute renal failure (5 patients) and chronic renal failure (1 patient); 4 patients (13.8%) had hypovolemic hypotonic hyponatremia due to use of the diuretic drug; one patient (0.04%) had isotonic hyponatremia which was found to be related to hypertriglyceridemia. Of the mild hyponatremia-75 patients, 50 (66.7%) had hypervolemic hypotonic hyponatremia that was due to heart failure (24 patients), cirrhosis (4 patients), acute renal failure (18 patients), chronic renal failure (4 patients); 14 patients (18.7%) had normovolemic hypotonic hyponatremia due to SIADH (11 patients), hypothyroidism (3 patients); 7 patients (9.3%) had hypovolemic hypotonic hyponatremia due to use of diuretics (3 patients), sepsis (1 patient), dehydration (1 patient); 4 patients (5.3%) had hypertonic hyponatremia found to be due to hyperglycemia. When the causes of hyponatremia in patients who died during hospital stay were considered, 39% of patients had heart failure, 17.1% had SIADH (usually associated with malignancy), 17.1% had acute renal failure and 26.8% had other causes.

Discussion: As a result, after the etiological evaluation, 63.6% of these patients had heart failure, cirrhosis, acute renal failure and chronic renal failure which are the cause of hypervolemic hypotonic hyponatremia. In internal medicine intensive care clinics, fluid and electrolyte balance, evaluation and treatment of comorbid diseases and causes of hyponatremia is an important factor.

Conclusions: In internal medicine intensive care clinics, fluid and electrolyte balance, evaluation and treatment of comorbid diseases and causes of hyponatremia is an important factor.

G-76
PROFILE OF CEREBRAL BIOACTIVITY IN PATIENTS WITH VIRAL HEPATIC DISEASES

M. Bezna, S. Bezna, A. Nestianu, C. Bezna, V. Padureanu, C. Becherescu, V. Nestianu

Department of Internal Medicine. University of Medicine and Pharmacy. Craiova, Romania.

Objectives: The patients with viral hepatic diseases may record modifications in cerebral bioactivity. Aim: observation the profile of brain modifications in viral hepatic diseases.

Material and method: The study was conducted on 80 patients with viral (B and C virus) hepatic diseases (hepatitis and cirrhosis) to whom were recorded visually evoked potential (VEP) and electroencephalography (EEG).

Results: Precise information about affectation degree in viral hepatic disease can be obtained with quantifiable methods (VEP and EEG). Variation of VEP wave's parameters was influenced by the increase of waves latency up to 119% and timing up to 48%, amplitudes being reduced to 55% of normal, the surfaces reduced to 48% and sharpness (speed of amplitude growth) reduced through wave's aplatisation to 52%. The most important modifications were suffered by the differences in cerebral answer between eyes (increase to 480%). EEG was undervolted or plane, rich in rhythms or with three phased waves.

G-77
PRESCRIPTION OF FLUORODEOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY IN THE INTERNAL MEDICINE UNIT: A MULTICENTRIC STUDY ABOUT THE FRENCH EXPERIENCE

X. Roux[1], S. Georgin-Lavialle[2], F. Ackermann[2], C. Durand[3], B. Ranque[2], G. Geri[4], J. Arlet[2]

[1]Department of Internal Medicine and Infectious Diseases. Hopital d'Instruction Legouest. Metz, France. [2]Department of Internal Medicine. Hôpital Européen Georges Pompidou. Paris, France. [3]Department of Internal Medicine. CHU de Nantes. Nantes, France. [4]Amicale des jeunes internistes. Société Nationale Française de Médecine Interne. France.

Objectives: [(18) F] Fluorodeoxyglucose positron emission tomography (FDG PET) is a functional imaging developed for oncologic investigations. Recently, the use of FDG TEP increased for clinical solving problem and non oncological diseases in internal medicine department, as unexplained fever and lymphadenopathy, vascularitis and several inflammatory diseases. To describe the current motivations for FDG TEP prescription in internal medicine clinical practice. Secondary objectives were to identify the motivations of prescription in which FDG TEP had the best performance to make a positive diagnosis for a non oncological indications.

Material and method: We conducted a prospective, multicentric study within 20 French internal medicine departments. During a period of six months, all consecutive patients who underwent FDG TEP for a non oncological indication were included The indication of the exam was collected at inclusion (before FDG TEP). After TEP was performed, radiologist conclusion as well the critical biological and histological exams practiced in order to obtain the definitive medical diagnosis were collected.

Results: 166 patients were included (92 males, 74 females) with a median age of 60 years old (18-88). Twelve FDG TEP were not performed (6 patients lost to follow-up, 4 patients for too long delay, one person on pregnancy, one refused the exam Among the 154 FDG TEP performed, main motivations were: unexplained inflammatory syndrome (n = 38), clinical status impairment (n = 30), unexplained lymphadenopathy (n = 28), fever of unknown origin (n = 25), vascularitis (n = 19) and infectious diseases (n = 18FDG TEP showed frequent abnormalities (n = 120/154; 78%). FDG TEP was considered by the practitioner as a decisive exam for the final diagnosis among 56 cases (34%), directly or by directing further exams such as biopsy or biological assessments.

Discussion: FDG TEP prescriptions increased for difficult clinical case solving in internal medicine. Nevertheless there is no published study leading to guidelines for TEP prescriptions in non oncological diseases, The performance of the exam was modest in our study; TEP leading only to 34% of positive diagnosis. Our results are preliminary, but more statistical studies are now necessary to find the clinical motivations of prescription where TEP has the best performance to find a correct a final diagnosis.

Conclusions: FDG TEP appears to become a useful tool for the internists with complicated clinical case solving. Its indications are not well codified yet but should be studied in some precise clinical situations. Several studies about efficiency and relevance of such examination in internal medicine diseases should be performed to assess its usefulness.

G-79
EPIDEMIOLOGY OF DIABETES MELLITUS IN THE AMBULATORY HIV CLINIC OF A COMMUNITY HOSPITAL IN THE SOUTH OF PORTUGAL.

R. Pinho, J. Estevão, Y. Yurchenko, R. Agapii, R. Louro, D. Faria, C. Santos, L. Arez

Department of Medicine. Centro Hospitalar do Barlavento Algarvio. Portimão, Portugal.

Objectives: Epidemiological characterization of DM in a population of HIV infected persons under antiretroviral therapy (ARV-T) with evaluation of immunological, virological and metabolic control, therapy interactions and incidence of vascular events and death.

Material and method: We conducted a descriptive transversal study in our HIV patients who are under ARV-T and have incident DM. Demographic and clinical data were registered and analyzed in Excel DataBase.

Results: We had until 31/12/2011 480 HIV patients in our clinic under ARV-T, 16 (3.3%) has DM (88% DM type2) DM preceded the diagnosis of HIV infection in 4 patients (25%) all of them were DM type 2. Mean age is now 54 years (42-75), with a mean time since HIV diagnosis of 11 years (1-23) and 9 years (1-24) since DM diagnosis. The mean time since the beginning of ARV-T is 9 years. Other associated vascular risk factors were arterial hypertension (81%), dyslipidemia (81%), smoking (69%) and obesity (31%). Five patients were coinfected with HCV, and 2 of them developed DM type 1 during the follow up care. The ARV-T included 2 nucleosides in all patients, associated to a non-nucleoside in 8, to a protease inhibitor in 6 and an integrase inhibitor in 2 patients. Concerning anti-hyperglycemic therapy (AHT), insulin is now being used in 6 of the patients with DM type 2. The most frequently oral agent was metformin, alone or associated with other oral agents or insulin. The mean CD4 at HIV infection diagnosis was 348 cells/mm^3 (12-1496) and is now 512 cells/mm^3 (209-975) and 87% of the patients have now undetectable viral load. The mean glycated hemoglobin is now 7.9% (5.1-12.4%) with a mean seric creatinine of 0.86 mg/dl. No interactions leading to a change in medication, both ARV-T or AHT were reported. There were 8 vascular events in 5 patients, no deaths were reported: 4 retinopathy, 1 terminal chronic renal disease, 1 coronary disease, 1 peripheral arteriopathy.

Discussion: Disorders of glucose metabolism have been associated with HIV infection and treatment. The estimated incidence of Diabetes Mellitus (DM) in these patients ranges from 1 to 10% in various studies. In our patients DM was mostly diagnosed during follow up of HIV chronic infection, including 2 cases of type 1 DM in patients coinfected with HCV. In general all patients had a good immunological, virological and metabolic control and there were no relevant interactions between ARV-T and AHT, but almost half of type 2 DM patients needed insulinotherapy and one third of all patients had already a major vascular event. Maybe this was related to insufficient control of the other vascular risk factors, which should be further investigated.

Conclusions: As patients grow older in HIV clinics it is important to include in the regular care of this patients continuous education for a healthy style of life, with rigorous surveillance and control of all vascular risk factors, including early diagnosis of DM.

G-80
NON-CLINICAL MORTALITY PREDICTORS IN AN INTERNAL MEDICINE WARD

C. Teixeira Pinto, C. Cabrita, A. Lopes

Department of Internal Medicine 1. Hospital de Faro, E.P.E. Faro, Portugal.

Objectives: Many comorbidity indexes are currently used to predict inpatient mortality risk (MortR). Nevertheless, the majority of these indexes contemplate only clinical data, failing to acknowledge the impact of social and demographic factors. The authors aim to demonstrate the impact of non-clinical data in predicting mortality in an Internal Medicine ward.

Material and method: Retrospective case-control study. Data was collected from the medical charts of the 211 patients who died in this Internal Medicine ward during 2011 (cases). These cases were paired for sex and age with discharged patients from the same Internal Medicine ward (controls) during the same period. For Odds Ratio (OR) calculation statistical significance was considered when $p < 0.05$, with a confidence interval (CI) of 95%.

Results: The average age was 80.2 (± 11.81) years, being 66.4% of the cases very elderly. 58.8% (124) of the cases were men. 24.6% (52) of the cases were institutionalized, with this representing a higher MortR (OR 1.645, CI 1.018-2.655, p 0.041). 34.6% of the cases were dependent in their daily life activities and 25.6% (54) were confined to bed, which also led to an increased MortR (OR 2.811, CI 1.652-4.786, p 0.000). The cases presented with an average of 0.5 (± 0.89) previous admissions (past 6 months), significantly higher than the controls (0.3 ± 0.61 previous admissions). Having a previous admission also increased the MortR (OR 1.834, CI 1.195-2.815, p 0.005).

Discussion: The cases in this study had an average age 3 to 5 years higher than in other mortality epidemiological series from the same country. There was also an important dominance of very-elderly patients, which may magnify the impact of the studied factors. As multimorbidity increases with age, the authors believe so does the patients' vulnerability to social and epidemiologic factors. The results suggest that the institutionalization, the limitation to bed and previous admissions signal an increased mortality risk in the patients admitted to this Internal Medicine ward.

Conclusions: The authors consider important to further validate these findings in a wider population. Since non-clinical factors, as the patient's institutionalization, level of daily life dependency and previous admissions, seem to have a significant impact in the MortR, its addition to the existing common-use comorbidity indexes should be considered. As the holistic view of the Internal Medicine patient must not neglect its social aptitude and the burden of epidemiologic factors, the authors suggest a revision of the present approach to mortality risk assessment.

G-81
PREVALENCE OF ALCOHOL USE DISORDERS AND ALCOHOL RELATED DISEASE AMONG MEDICAL INPATIENTS IN EUROPE. ALCHIMIE STUDY PHASE II DATA

B. Rosón[1], I. Marusenko[2], N. Oliveira[3], R. Monte[4], S. Condouret[5], A. Liberdová[6], R. Salupere[7] and the Alchimie Study Group

[1]Department of Internal Medicine. Hospital Universitari de Bellvitge. L'Hospitalet de Llobregat (Barcelona), Spain. [2]Department of Pneumonology. Republican Hospital n.a. V.A. Baranova. Petrozavodsk, Russia. [3]Department of Internal Medicine. Hospital de Braga. Braga, Portugal. [4]Department of Internal Medicine. Hospital Lucus Augusti. Lugo, Spain. [5]Department of Pneumonology. CH Carcassonne. Carcassonne, France. [6]Department of Internal Medicine. Nemocnice Ve Frýdku-Mistku. Frýdek-Místek, Czech Republic. [7]Department of Internal Medicine. Tartu University Hospital. Tartu, Estonia.

Objectives: Unhealthy alcohol use is common in medical inpatients hospitalized for reasons not alcohol related. The spectrum and rate of detection of unhealthy alcohol use, including alcohol use disorders (AUDs) and other alcohol related diseases (ARDs) is not well known. The aim was determine the prevalence, spectrum and rate of detection of AUDs and ARDs among medical inpatients across Europe.

Material and method: Participants were medical inpatients from 38 European hospitals who screened positive and underwent clinical evaluation for unhealthy alcohol use and consented to have their medical records reviewed to detect AUDS and ARDs.

Results: We screened 2,123 inpatients [1,115 (52%) men; mean age (SD) 67.9 ± 17.3 years]. Overall, 343 screened positive and 301 (14%) patients had unhealthy drinking patterns. There were 280 patients who gave their consent [220 (79%) men; mean age (SD) 60.6 ± 15.9 years]. Reasons for admission were not alcohol-related 216 (77%), acute intoxication 5 (2%), withdrawal 12 (4%), alcohol related acute-disease 29 (10%), acute decompensation of alcohol-related chronic disease 18 (6%). Alcohol use was not evaluated in the admission note in 100 (36%) of patients, and it was properly documented in 71 (25%) cases. Documentation of AUDS was 32 (48%) of 67 dependent patients, 25 (44%) of 57 harmful drinkers and 21 (22%) of 94 risky-drinkers. Overall 161 (57%) had ARDs at admission, and 50 (18%) patients had a new alcohol related diagnosis in the discharge note. Most frequent ARDs reported in discharge note were: arterial hypertension 76 (%), hepatic steatosis 44 (16%), hematological disorders 44 (16%), hepatic cirrhosis 31 (19%), stroke 18(6%), and alcoholic cardiomyopathy 12 (5%).

Discussion: Our study shows that AUDs are frequent in hospitalized patients, and these patients had often associated ARDs. Despite the prevalence and impact of unhealthy alcohol use in medical inpatients documentation of alcohol use and AUDs in discharge notes is infrequently performed, particularly in patients with less severe patterns. Even patients with ARDs had rarely documented alcohol use and AUDs in admission and discharge notes. Study limitations include: AUDs were evaluated by self-report; the presence of ADRs was calculated according to medical records review. Prevalence for both might had been underestimated Study strengths were: significant number of patients from a variety of hospitals in Europe screened with standardized tests and clinical evaluation of unhealthy patterns.

Conclusions: Detection of unhealthy alcohol use and management of patients with AUDs and ARDs was sub-optimal. An effort should be done to improve detection and documentation of AUDs in medical inpatients.

G-82
ASSOCIATIONS OF HYPERGLYCEMIA AND EARLY COMPLICATIONS OF ACUTE CORONARY AND STROKE EVENTS

E. Buchaca, Y. Arbona, L. Rodríguez, F. Fernández, A. Gutiérrez, S. Bermúdez

Department of Internal Medicine. Hospital CQ Hermanos Ameijeiras. La Habana, Cuba.

Objectives: An analytic, longitudinal and prospective study was carried out on a cohort of two hundred patients suffering from acute macrovascular afflictions who were treated at the coronary and ictus unit of "Hermanos Ameijeiras" Hospital in the period 2010 – 2011. The main goal was to assess whether there was a relationship between the hyperglycaemia and any other immediate complication after an acute macrovascular events.

Material and method: Blood tests and glycaemia were taken from all patients when admitted to hospital both under admission, fasting and postprandial conditions, glycosylated hemoglobin (HbA1c). In order to analyze the data summary measurement and standard deviation (SD) were used, as well as the Student t test in order to compare the mean value of different time of glycaemias and complications.

Results: 18% of the sample presented complications. The group of patients with complications in coronary setting showed an average increased of glycaemia at fast (p = 0.012), postprandial (p = 0.001) and admission (p = 0.009), compared with the group without complications. HbA1c was associated with complications in this group of patients too (p = 0.003). The group of brain vascular events only showed an associations of complications with a more mean value of glycaemias at admission (p = 0.016) and no associations with higher mean value of fasting (p = 0.232) postprandial (p = 0.567) glycaemias, as well as HbA1c (p = 0.159).

Conclusions: We conclude that the disorders of glycaemia under fasting and postprandial are associated with early medical complication after afflictions at coronary territories, which were different in the brain vascular events.

G-83
INCIDENCE AND TEMPORAL VARIABILITY OF EMERGENCY DEPARTMENT VISITS FOR HYPERTENSION

F. Sarabia Marco, A. Pérez Pérez, J. Laso Trillo, E. García Villalba, A. Sobrao López, B. Medina Tovar, A. Melgarejo González, J. Fernández Pardo

Department of Internal Medicine. Hospital General Universitario Reina Sofía. Murcia, Spain.

Objectives: To determine the incidence and the temporal distribution of emergency department (ED) visits directly related to hypertension (HT) and its complications.

Material and method: Based on the computerized medical records of all assisted processes in the ED of our hospital for any cause during four consecutive years (from January 2008 to December 2011), and in preserving patients anonymity, we collected information on the age, sex, first-listed diagnosis (which was subsequently coded according to ICD-9 MC, using an application software developed by our Clinical Documentation Dept.), date and entry time of all patients attended. All these variables were imported into a database and, using the computer program SPSS® 15.0, we conducted a descriptive study and a statistical data

Table 1 (G-82). Acute Coronary Syndrome

Glycaemia mmol/L	Complicated mean	Not complicated mean	p value
Admission	11.76 SD:5.83	7.89 SD:2.79	0.009
Fasting	8.85 SD:4.90	5.81 SD:1.24	0.012
Postprandial	10.19 SD:3.09	7.56 SD:	0.001
	n = 20	n = 80	

.

Table 2 (G-82). Stroke

Glycaemia mmol/L	Complicated	Not complicated	p value
Admission	11.67 SD:5.07	8.12 SD:3.89	p = 0.016*
Fasting	7.51 SD:2.77	6.56 SD:3.03	p = 0.232
Postprandial	8.77 SD:2.98	8.31 SD:2.35	p = 0.567

analysis, with the objectives set out, for patients who presented hypertensive disease as main reason for attendance (ICD-9 MC codes 401 to 405).

Results: The total number of patients visiting our ED from all causes during the study period was 401678. The patients mean age (± standard deviation) was 43.7 ± 21.4 years and 50.3% were women. Among the total assisted, 3716 patients (0.93%) were primarily because of HT. Of these, 2,274 (60.8%) were female, with a mean age 65.5 ± 14.3 years and 1,463 (39.1%) were men with a mean age of 58.9 ± 14.9 years ($p < 0.001$). There was a progressive increase in the age-specific prevalence with advancing age, especially in women, and 56% of the patients attended for HT were older than 60 years. Season with highest HT patients demand was winter (from December to February) with a 29.2% (December was the month of highest incidence [12.7%]) and the lowest was summer (June-August) with 18.5% (August had the lowest [5.5%]). Mondays was the day of peak demand by HT (16.4%) and Saturdays with the lowest (12.1%). The incidence was maximum from 19 to 24 hours with 36.6% of cases, while less than 7% were attended between 2 am and 8 am.

Discussion: Blood pressure has a high temporal variability and the chronobiology opens new perspectives for its study as a result of a better knowledge of their biological rhythms.

Conclusions: HT, as main consulting reason, has a relatively importance in hospital emergencies, especially among women and those over 60 years old. Major differences are shown in attendance between different months of the year, days of the week and hours of the day, which are to be explained.

G-84
TEN-YEARS TRENDS IN MANAGEMENT OF HOSPITALIZED PATIENTS WITH ACUTE CORONARY SYNDROME AT A REFERENCE HOSPITAL

C. Aranda López, P. García García, L. García Serrano, J. Nogales Asensio, C. García Corrales, P. Márquez Lozano, J. López Mínguez, A. Merchán Herrera

Department of Cardiology. Complejo Hospital Universitario de Badajoz. Badajoz, Spain.

Objectives: Social changes and development over last years have led to increment in life expectancy. At the same time, there have been important improvements in the management of patients with acute coronary syndrome (ACS), mainly in the field of percutaneous coronary intervention (PCI). The aim of our study was to analyze the changes at baseline characteristics, therapeutic management related variables and in-hospital outcome in patients admitted with ACS to our center over the past 10 years.

Material and method: We performed a retrospective study that included 8,463 consecutive patients hospitalized with ACS diagnosis. We divided the patients into 2-year periods according to the date of admission in order to analyze changes in the variables along the time (table).

Results: The prevalence of the different basal cardiovascular risk factors and the average age of the patients (68.1 ± 12.5 years) admitted for ACS remained constant over the ten-year study period. The prevalence of patients over 75 years (> 75 y.o.) admitted with ACS slightly increased during the last years. In addition, the proportion of patients undergoing percutaneous coronary intervention (PCI) has increased, mainly in the elderly. The prevalence of female gender hospitalized due to ACS remained the same over the study period (31.3%), although we did not observe an increase of the invasive therapeutic management in this population, in line with previously published studies. In relation to ST elevation (STE) ACS therapeutic strategy, the percentage of patients who underwent urgent PCI increased as well as the thrombolytic therapy use progressively decreased, even in elderly patients. Radial access has become the elective vascular access for PCI in ACS in all the subgroup of patients. We observed decreasing mortality rates for all subgroups of patients, although it remains higher among women and > 75 y.o.

Conclusions: There have been important changes in the management of patients hospitalized with ACS over the past years. The prevalence of PCI increased during hospitalization even at elderly patients. The changes have produced a higher survival rate and a shorter hospital length of stay. However mortality remains high in some subgroups of patients such as elderly and women. The increased use of PCI may reduce mortality in these patients in the future.

G-85
ELECTROLYTIC DISORDERS IN COLONOSCOPY PREPARATION IN AN INTERNAL MEDICINE SERVICE

A. Nieto Sánchez[1], C. Clemente Callejo[2], V. Fernández-Roldán Galán[2], N. Tobares Carrasco[1]

[1]Department of Internal Medicine III. Hospital Clínico San Carlos. Madrid, Spain. [2]Department of Medicine. Universidad Complutense Madrid. Madrid, Spain.

Objectives: The main target was to assess potential kidney failure, metabolic and ionic disturbance during the colonoscopy preparation. The different preparation procedures also were evaluated in order to check the possible induced alterations.

Material and method: It was a descriptive study. It included a sample of the whole inpatients in Internal Medicine III from October 2011 to April 2012 to whom a colonoscopy was indicated. All clinical data patients were recorded and information about the preparation process and product used. The following data were also collected: glucose, creatinine, sodium, potassium, chloride, calcium, phosphorus. These data were collected three times: basal, the day before and the day after the colonoscopy.

Results: It was done 43 colonoscopies. 52% were men and 48% were women. The age average was 68.67 ± 17.53 years. The reason to indicate the colonoscopy was: 37% bleeding, 33% constitutional syndrome, 19% anaemia, 9% constipation, 7% diarrhoeas and 2% abdominal pain. The colonoscopy results were 21% diverticulosis, 21% haemorrhoids, 16% colon cancer, 2% volvulus, and 12% did not show disease. The colonoscopy objective was diagnostic in the 60% of the cases, 35% diagnostic and therapeutic and in the 5%

Table 1 (G-84). Trends in different variables over time by two-years periods in patients admitted with ACS

2-years period	Age > 75 y.o.	PCI	PCI in > 75 y.o.	Dead	Dead in > 75 y.o.	Dead in women	Length of stay (days)
2002-2003	31.4%	53.6%	36.0%	6.5%	10.9%	8.6%	11.8 ± 8.4
2004-2005	31.7%	61.8%	45.2%	6.2%	12.1%	7.7%	8.8 ± 5.5
2006-2007	35.6%	62.6%	49.7%	4.1%	5.8%	6.1%	7.8 ± 5.5
2008-2009	39.9%	66.8%	55.6%	3.5%	6.5%	4.9%	7.5 ± 5.3
2010-2011	33.4%	66.3%	55.0%	3.6%	6.4%	4.1%	7.1 ± 5.3

incomplete procedure was performed. We had the next complications: one patient suffered bleeding, another perforation and the last one a splenic laceration. We had not any complications in the 94% of the patients. The preparation was made with magnesium citrate (Citrafleet®) in 34%; 34% polyethylene glycol (Bohm evacuating solution®) and 33% with phosphates (Fosfosoda®-Fosfoevac®).

Discussion: We found a high average age in our sample. This point has a strong influence on potential complications when a colonoscopy is performed. In fact there are a lot of diseases or chronic conditions which can be decompensated by the preparation or the procedure itself. The most of the colonoscopy were performed due to bleeding or constitutional syndrome. These conditions grow the likelihood to diagnosis a serious disease. In relation with this point, we found a 16% of colon cancer what is a high rate. We obtained a similar complications rate than other studies. The most important and common is the perforation of colon, especially in elder people who have a increased fragility of the colonic mucosa. When we have studied the biochemical disorders, we found that the three preparation procedures are not significantly different, with the exception of phosphates solution which has demonstrated a statistically significant phosphorus raise and clinically relevant (0.7 mg/dL).

Conclusions: The colonoscopy is a procedure done to elder people group mainly. This circumstance leads to a non-negligible complications rate both in the preparation as in the procedure itself. It is indicated frequently due to bleeding or constitutional syndrome. There are many diagnoses but there is a high rate of neoplasias. The main preparation procedures are magnesium citrate (Citrafleet®), polyethylene glycol (Bohm evacuating solution®) and phosphates (Fosfosoda®-Fosfoevac®). There were no statistically significant alterations for glucose, renal function, sodium, potassium, chloride and calcium during the preparation. It was obtained a significant increase of phosphorus with de phosphates solution, not currently in use.

G-86
COMPARATIVE VARIABILITY OF CLINIC ASSISTANCE PATIENT PROFILE DESCRIPTIVE ANALYSIS OF HOSPITALARIAN URGENCY SERVICE ASSISTED BY 2 INTERNAL MEDICINE RESIDENT (IMR) DURING HIGH AND LOW ASSISTANCE PERIODS

S. Romero Salado, G. Ruiz Villena, R. Aranda Blázquez, V. Manzano Román, V. Lechuga Flores, O. Mera Gallardo, G. García Domínguez, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: Describe clinic basic patient profile assisted on a hospitalarian urgency office by two IMR during high and low assistance period in our centre.

Material and method: Transversal descriptive study, in which were included patients who assisted to an urgency office during two days first of February, -Fb- (high assistance period) and other two at lasts of April – Ap- (low assistance period) on 2012. Studied variables: age, sex, time spent on assistance, complementary tests and development.

Results: Total patients: 89 (50 Fb/39 Ap). Age between 5 months and 96 years old, 62% men, average time spent 3h 28 min with a maximum of 8h 49 min –Fb-, and the minimum 12 min – Ap-. Complementary tests Ap: lab test 61%, Fb, X- Rays 60.53% - Fb-, EKG 62.5% Fb, 2 TC and 2 Ecography equal number. 22.47% were discharge to specialist (20.51% Ap). Hospitalized 10% Fb (5.13% Ap).

Discussion: Assistance pressure on Urgency Service used to be high and carried by IMR on our centre. Clinic changes during high and low assistance period, identify high assistance period as: most men, wide age range, more time spent, more tests and hospitalizations, specialist discharge and less primary attention discharge. Here the global view done by IMR makes him able for a qualify management of these pluripathology patients.

Conclusions: Most professional who carry on the Urgency Service are internal medicine doctors. It is true there is a great difference between patient profiles assisted during high or low assistance period. IMR job is essential for a complete management of this kind of patients and pathologies.

G-87
CONSTITUTIONAL SYNDROME ON AN INTERNAL MEDICINE HIGH RESOLUTION CONSULTATION OFFICE (IMHRCO) ON A SPECIALIZED HOSPITAL FROM SAS

M. Escobar Llompart, S. Romero Salado, V. Manzano Román, V. Lechuga Flores, G. García Domínguez, O. Mera Gallardo, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: IMHRCO is a choice beside hospitalization, which improves patient's access and contorts, avoiding hospitalization. The aim is recognize efficiency of this kind of service provided with a unit for high resolution and early diagnosis without need hospitalization on potential serious entities.

Material and method: Transversal chart study review of patients assisted on IMHRCO being apply constitutional syndrome criteria, between first of April 2011 and 30 April 2012. We made up a protocol to create a database including: sex, age, pondered weight lost, start date, etiology, hospitalization required and time spent on diagnosis.

Results: They were included 146 patients, 97 men 49 women (age between 15 and 93). Average age 49.6. Average pondered weight lost was 8.6%, from basal weight. Main etiology was neoplasia: 71 patients (48.63%), 35 (49.29%) digestive (20 colonic (28.16%), 11 stomach 15.49%) and 4 esophagic (5.63%)), followed by lung neoplasia 14(19.71%), pancreatic 8 (11.26) and breast 6 (8.4%). 64.78% neoplasia was advanced or with local infiltration. Second etiology was infectious, 32 patients: TBC 8 (25%), AIDS 6 (18.75%), zoonotic disease 6 (18.75), BHV/CHV 3 (9.37%), other 9 (28.18%). Digestive pathology, 12: 5 IIP (41.66%), 5 malabsorption (41.66%). Metabolic 11 (7.53): 6 hyperthyroidism and 5 diabetic debut. Toxic 11 (7.53%) considered 8 chronic alcohol abuse and 3 drug dependence. 7 psychiatric (4.79%): 4 anxious-depressive disorder (57.14%), 3 nutritional disorders. Miscellany 20 (57.14%) including heart failure, drugs and idiopathic. 12 patients needed hospitalization (8.21%). Average time spent on hospital was 18.7 days.

Discussion: We noticed a high neoplasia presence (most advanced or with local infiltration) and infectious chronic process as hidden reason for constitutional syndrome. Other pathologies: IIP, metabolic and toxic reasons. Patient's percent who required hospitalization was low, 8% on their own interest. Average time spent on diagnosis was on range, consider high neoplasia incidence and it difficult diagnosis.

Conclusions: Constitutional syndrome requires special attention, high percent, related with serious entities. Neoplasia and chronic infectious disease are frequent reasons for it. IMHRCO it is an efficient and early diagnosis, associated with contort choice to avoid hospitalization and reduce administration cost for avoidable hospitalizations.

G-88
ARE GOALS ACHIEVE CONTROLLING LIPIDS LEVELS BASED ON RECOMMENDED RANGE BY THE AMERICAN HEART ASSOCIATION ON PATIENTS WITH PREVIOUS ACUTE CORONARY EVENTS? SECOND YEAR INTERNAL MEDICINE RESIDENT EXPERIENCE THROUGH CARDIOLOGY DEPARTMENT

M. Guzmán García, R. Aranda Blázquez, S. Romero Salado, G. Ruiz Villena, E. Sánchez Relinque, O. Mera Gallardo, R. Tinoco Gardón, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: It is not a noticed the importance of lipids level range control as a secondary prevention measure on high cardiovascular risk patient. Our aim is recognize level achievement on patients with previous acute ischemic coronary events.

Material and method: They were included patients hospitalized on Cardiology Service during 2011. Descriptive chart study was made up. Studied variables: dyslipidemia, Lipid levels: triglycerides TG, cholesterol CO, LDL-C, HDL, HDL cholesterol ratio, during hospitalisation or 3 previous months.

Results: 392 patients were included. Dyslipidemia appears on 50% cases. Lipid levels: TG (134.651 ± 10.715), CO (179.738 ± 4.018), LDL-C (99.94 ± 3.3263), HDL (41.811 ± 1.212), HDL cholesterol ratio (4.313 ± 0.146).

Discussion: Analysis data prove lipids level is higher compared to goal level range recommended by AHA on coronary patients. Higher TG levels 34.737%, CO 33.5%, LDL-c 25.1% and lower HDL levels 42.934% form patients included. In spite of, recommended levels are not achieve, as cardiovascular risk factor.

Conclusions: It is important to determinate and achieve adequate measures to prevent cardiovascular risk on our patients. Clinic practice guidelines determinate correct levels to achieve. It is also important to monitorize and control cardiovascular risk, where lipids control is essential to improve cardiovascular risk and to prevent new ischemic events.

G-89
CLINICAL PROFILE OF PATIENTS WITH CHEST PAIN AND NO SIGNIFICANT LESIONS AFTER PERCUTANEOUS TRANSLUMINAL CORONARY ANGIOPLASTY (PTCA)

R. Aranda Blázquez, M. Guzmán García, M. Escobar Llompart, G. García Domínguez, G. Ruiz Villena, O. Mera Gallardo, L. Fernández Ávila, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: Our goal is to determine the clinical profile of patients who presents atypical chest pain and after PTCA no significant lesions.

Material and method: We made a descriptive study that included patients admitted with chest pain who had no coronary lesions after PTCA in 2011. Study variables: age, sex, medical history (hypertension, dyslipidemia, knew heart disease, antiplatelet therapy, atrioventricular block and/or a pacemaker, atrial fibrillation resulting in hemodynamic angina, PTCA).

Results: Total patients admitted, 392, being 10.4% of patients who had PTCA without significant findings. Mean age was 59 years. Gender: female 69%. Main clinical characteristics: hypertension (57.1%), no history of unknown origin dyslipidemia (71.43%), no history of previous heart disease (71.4%), previous antiplatelet therapy (80.95%), diagnosed of AV block with or without pacemaker implantation (35.71%), hemodynamic angina by the presence of atrial fibrillation with rapid ventricular response (16.67%), scheduled PTCA (14.21%).

Discussion: In our study, patients with chest pain who had non-significant findings in the PTCA are usually women of about 60 years (postmenopausal period) and less cardiovascular risk factors (hypertension, dyslipidemia).

Conclusions: The presence of cardiovascular risk factors is lower in patients with chest pain and no significant lesions in the PTCA. The work of Internal Medicine physician is essential when a comprehensive approach to these patients.

G-90
INCIDENCE OF TAKO-TSUBO VENTRICULAR DYSFUNCTION OR DISEASE IN A SPECIALTY HOSPITAL IN THE SAS. SHOULD WE TAKE THIS INTO ACCOUNT IN PATIENTS WITH ATYPICAL CHEST PAIN? EXPERIENCE OF A SECOND-YEAR RESIDENT IN INTERNAL MEDICINE AT THE ROTARY AT THE DEPARTMENT

M. Guzmán García, E. Sánchez Relinque, S. Romero Salado, R. Aranda Blázquez, G. Ruiz Villena, O. Mera Gallardo, G. García Domínguez, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: The Tako-Tsubo syndrome is a clinical entity that shows changes similar to those produced by acute coronary syndromes, both in clinic and analytical sphere. This process is characterized by showing acute chest pain, cardiac enzyme elevation and anterior akinesia, but no significant alterations occur in coronary vessels and recovery of segmental dysfunctions in a no specific period of time (weeks or months) in patients affected.

Material and method: From the MBDS registry of our hospital inpatients, were selected those with Tako-Tsubo diagnosis in 2011. Study variables: patient's clinical profile (sex, age, cardiovascular risk factors, previous heart disease, clinical presentation) complementary tests (analytical cardiac enzymes, ECG, echocardiography, percutaneous transluminal coronary angioplasty (-PTCA-), clinic outcome.

Results: 3 patients were collected from 429 patients of a 300.000 population, with the next ages: 53. 68 and 72 years. No history of cardiovascular risk factors was found in two of those patients studied. In the third one we realised that he presents hypertension and type 2 diabetes mellitus. None of the patients had a history of cardiac disease. The clinical presentation was oppressive chest pain with elevation of cardiac enzymes (CPK, CPK-MB and troponin) with presence of elevated ST segment in precordial derivations of their ECG, that broke in within 48-72h after admission. In all 3 cases proceeded to percutaneous transluminal angioplasty, with no need of acute stent implantation in that income. Reduced EF was found in all patients at this time. In one case where it made a drug-eluting stent implantation by sinuous anterior descending artery dating as AMI, presenting ventricular apical akinesia, which improved spontaneously after performing echocardiogram. Evolution: echocardiogram was performed within 2-3 months showing normalization of ventricular mobility in all cases.

Discussion: In our study, patients were males with age range 53-72 years, no history of underlying heart disease, most did not require implementation of Stens after PTCA, ventricular apical akinesia recover within 3 months.

Conclusions: In the differential diagnosis of atypical chest pain is important to note the Tako-Tsubo syndrome and also generally have a good prognosis.

G-91
PATIENT CLINIC PROFILE REFERRED FROM EMERGENCY DEPARTMENT TO INTENSIVE VIGILANCE SERVICE (IVS) ON A SPECIALIZED HOSPITAL FROM SAS

O. Mera Gallardo, G. García Domínguez, J. Borrallo Torrejón, V. Lechuga Flores, V. Manzano Román, M. Guzmán García, E. Sánchez Relinque, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: Recognize clinic and epidemiology profile from patients hospitalized on IVS, on our centre, referred from Emergency Service, during 9 months, between 2011 and 2012.

Material and method: Descriptive chart study, they were included 225 (38.2%) patients referred from Emergency Service about 330 total patients hospitalized on IVS during that period. Studied variables: age, sex, reason for hospitalization, time spent on IVS, toxic habits, cardiovascular risk factors, other pathologies and discharge diagnosis. Analysis was done by SPSS 15.0 statistic programme.

Results: Average age 60, 71.6% men, 28.4% women. Cardiovascular risk factors, considered smoking 16% did smoke before 5.8%, chronic alcoholism 20.4%, ex- alcohol addicted 0.9%. 34.2% DM, 28% hypertension, 24.9% dislypemia, 14.7% obesity. 53.3% diagnosed for Ischemic coronary syndrome, 40% COPD and 21.8% heart failure. 5.8% suffered ischemic stroke before, 8.4% renal chronic failure. Main reason for hospitalization was ischemic coronary syndrome on 45.8% followed by stroke 5.8%, shock 5.7% and respiratory failure 4.4%. Average time spent on IVS was 3.74 days, discharge diagnosis: acute ischemic coronary syndrome 55.3%, serious respiratory infection 4.4%, hemorrhagic stroke 2.7%, ischemic stroke 2.7%, digestive hemorrhage 2.2% and percutaneous transluminal coronary angioplasty (PTCA) 1.3%. Referral Services were Cardiology 63.9%, Internal Medicine 17%, Neurology and Neumology both 4.6% and 4.1% each. Reaming other.

Discussion: Patient profile hospitalized on IVS referred from Emergency Service: men, 60 years old, smoker, cardiovascular risk factors, and previous ischemic cardiopathy disease hospitalized for acute ischemic coronary event which needs a hemodynamic specialized treatment. Stroke patients also, less percent, without losing atherosclerosis relation. Time spent is short and main referral service: Cardiology followed by Internal Medicine, probably because of multimorbidity and difficult management. Results are not different from main morbidity and mortal pathologies on medium age. First assistance is done by Emergency Services on more than 50%, by internal medicine professionals.

Conclusions: It is important to consider correct management of these patients, starting on Emergency Service by Internal medicine professional. Internal medicine professional global view makes him able to deal and well manage these patients.

G-92
PATIENTS WITH PROLONGED FEVER REFERRED TO A QUICK DIAGNOSIS UNIT: PREDICTORS OF HOSPITAL MANAGEMENT IN A TERTIARY HOSPITAL

P. Brito Zerón, A. López Soto, A. Jordán, X. Bosch

Department of Quick Diagnosis. Hospital Clínic. Barcelona, Spain.

Objectives: Background: Patients with prolonged fever are becoming frequently sent to the Quick Diagnosis Unit for diagnosis. Some of these patients, after being visited in our Unit, require hospital admission or consultation with other specialized Departments from our hospital. Predictors for hospital management will help us improve the circuit performance of this Unit and the rest of Departments involved. Objectives: To analyze the mean time to the final diagnosis and the number of visits required in patients with prolonged fever referred to the Quick Diagnosis Unit. Main departments of referral after diagnosis and to analyze the predictors of hospital management defined as admission or consultation with specialized departments from a tertiary hospital.

Material and method: We studied 188 patients referred to the Quick Diagnosis Unit for prolonged fever from November 2008 to September 2011. All patients were evaluated retrospectively.

Results: Mean time to final diagnosis was 21 days (0-151). One hundred and seventy patients required 2 visits, 80 needed 3 visits, 30 required 4, 8 required 5 and 4 patients needed more than 5 visits to achieve the final diagnosis. The main diagnoses were infectious diseases in 113 (60%) patients, autoimmune diseases in 19 (10%) and neoplasia in 3 (2%) patients. When the final diagnosis was reached, 142 patients (75%) were referred to their primary care center, 36 patients (19%) were referred to specialized Departments of our tertiary hospital and 3 patients (2%) required hospital admission. Seven patients were lost to follow-up. Of the 36 patients who required specialized referral after diagnosis, 7 (19%) were referred to rheumatology, 5 (14%) to the systemic autoimmune diseases department, 4 (11%) to the infectious diseases department, and 3 (8%) patients to the nephrology, hematology and Chronic Fatigue Unit, respectively. The remaining 11 patients were referred to other hospital departments. Patients who required hospital management were older (48.38 years vs 43.48 years, $p = 0.095$), had a higher mean number of visits in our Unit (3.03 vs 2.52, $p = 0.024$) and had more frequently a newly diagnosed systemic autoimmune disease (36% vs 2%, $p = 0.000$) in comparison with patients who were managed in an outpatient basis.

Conclusions: A final diagnosis for patients with prolonged fever visited in the Quick Diagnosis Unit was achieved after a mean time of 20 days. Predictors for hospital management after being diagnosed included an older age, an increased number of visits in the Quick Diagnosis Unit and a final diagnosis of systemic autoimmune disease.

G-93
THE OPINION OF MEDICAL STAFF (SPECIALISTS, RESIDENTS) ON DOCTOR-FAMILY COMMUNICATION DURING AN EMERGENCY SITUATION IN A HOSPITAL BELONGING TO THE ANDALUSIAN HEALTH SERVICE

V. Lechuga Flores, V. Manzano Román, M. Escobar Llompart, M. Guzmán García, E. Sánchez Relinque, G. Ruiz Villena, R. Aranda Blázquez, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: To gain knowledge of opinions concerning the communications existing between health professionals and family members during a grave clinical situation.

Material and method: Once the medical staff (consultants-cn/ and residents-rs) of the Intensive Care Unit (ICU) was selected, they were asked to complete the following questionnaire on communication skills: 1st question: Is it easy for relatives to find the ICU on the first day? 2nd: Are the family always informed of the clinical situation of their relatives when they are admitted? 3rd: Do you think family members understand the information received during the admission of their relative? 4th: Do you think that the family receives enough information concerning visiting hours, unit rules, etc. from the nursing staff on admission? 5th: Do you think the family should always receive information from the same doctor? 6th: Do you think that family members would rather sit down beside their relatives during visiting hours? 7th: What do you think the family-nurse relationship is like? (Very fluid, fluid, nonexistent). 8th: Do you think that the family receives help from the nursing staff to

facilitate communication with their relative? The results were analyzed based on the characteristics of a descriptive study.

Results: Total surveyed: 15 (10 cn/5 rs). 1st question: yes 25% cn/50% rs. 2nd: yes, 75% cn/25% rs. 3rd: yes, 75% cn/62% rs. 4th: yes, 88% cn, 100% rs. 5th: yes, 90% cn/50% rs. 6th: yes, 50% cn/75% rs. 7th. fluid, 90% cn/50% rs. 8th: yes, el 75% cn/100% rs.

Discussion: Doctor-patient-family communication and relations are complicated during situation of extreme gravity. Our study shows that the opinion of the cn is different from that of the rs as regards the following points: Information given to the family by doctors-nurses, continuous attention from the same doctor and the fluidity of nursing staff-family relations. It is necessary to work on these points adequately in order to improve our communications.

Conclusions: In the field of Internal Medicine and in the ICU we are faced with extremely grave clinical conditions in which it is necessary optimal doctor/patient/family/nursing staff relations, as well as to be trained in communication skills.

G-94
EPIDEMIOLOGICAL CHARACTERISTICS, REASONS FOR REFERRAL, DIAGNOSTIC PROCEDURES AND FINAL DIAGNOSIS IN 188 PATIENTS WITH PROLONGED FEVER ATTENDED IN A QUICK DIAGNOSIS UNIT

P. Brito Zerón, A. Jordán, A. López Soto, X. Bosch

Department of Quick Diagnosis. Hospital Clínic. Barcelona, Spain.

Objectives: Background: Prolonged fever is a common cause for hospital admission. Since 2008, The Quick Diagnosis Unit has taken an important role in the diagnosis of prolonged fever, with the advantage of making quick diagnosis and reducing the large number of hospital admissions. Objectives: To analyze the epidemiological characteristics, reasons for referral, diagnostic procedures and final diagnosis in patients with prolonged fever referred to the Quick Diagnosis Unit of the Department of Internal Medicine.

Material and method: We studied 2232 patients visited in our Unit between November 2008 and September 2011. We investigated the epidemiological and clinical features, diagnostic procedures and final diagnosis in those patients referred for prolonged fever.

Results: One hundred and eighty-eight (8.4%) patients were referred for the study of prolonged fever, 98 were women (52%) and 90 were men (48%) with a mean age of 44.25 years (range 15-90). Patients were mainly referred by the emergency (53%) and primary care (37%) departments. The main diagnostic procedures included blood analysis in 174 patients (49 patients required 2 blood analysis and 7 required more than 2), microbiological cultures in 59, chest X-rays in 52, abdominal ultrasound in 33 and CT-scan in 20 patients. Final diagnosis consisted mainly of infectious diseases in 113 (60%) patients, autoimmune diseases in 19 (10%) and neoplasias in 3 (2%) patients. Six patients were lost to follow-up without diagnosis. The main infectious diseases included viral diseases in 68 (acute cytomegalovirus infection in 26, acute Epstein-Barr virus infection in 7, acute Parvovirus B19 infection in 3, primary HIV infection in 3 and non-specific viral infections in the remaining 29), bacterial infections in 44 patients (respiratory infections/pneumonias in 24, urinary tract infections in 9 and others in 11), parasite infection in 1 patient. The main autoimmune diseases diagnosed included vasculitis in 6, arthritis in 4, Mediterranean fever in 2 and Sjögren syndrome, SLE, Still's disease, inflammatory myopathy, retroperitoneal fibrosis, erythema nodosum and undefined autoimmune disease in 1 patient, respectively. Neoplasias diagnosed included lung adenocarcinoma, Hodgkin lymphoma and B-cell lymphoma in 1 patient, respectively.

Conclusions: Prolonged fever represents 8.4% of visits in our Quick Diagnosis Unit. Most patients are young women referred from the emergency department. Nearly two thirds of patients are diagnosed with infection, mainly with viral infections (cytomegalovirus and Epstein-Barr). Blood analysis, microbiological cultures and chest-X rays are the most common diagnostic procedures. Seventy-five percent of patients are further managed in primary care health centers.

G-95
CLINICAL PROFILE OF THE PATIENTS ADMITTED IN PSYCHIATRY WHO WERE INTERCONSULTED TO INTERNAL MEDICINE (IM) IN A HOSPITAL OF THE ASH

M. Escobar Llompart, V. Lechuga Flores, R. Aranda Blázquez, G. Ruiz Villena, M. Guzmán García, E. Sánchez Relinque, S. Romero Salado, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: To know the clinical characteristics of the patients admitted in psychiatry who were consulted to IM.

Material and method: We included the consults proceeding from psychiatry, registered in the Unit of Clinical Management of IM of our hospital during four months of 2012. Variables of study: age, sex, number of reports per month, motive of consult. The results were analyzed on the basis of the proper characteristics of a descriptive study.

Results: Total of consults: 11 (16.2%). Middle Ages: 46 years (15 to 72 years), 73% men. 50% of these consultations carried out during January. The principal motive of consult was to discount the organicity in the patient with drowsiness or cognitive deterioration not justified by the psychiatric medicaments (36.4%). Secondly, consultations were realized to Internal Medicine for the managing of the patient by feverish syndrome in the context of an infectious process, (27.3%) fundamentally of respiratory origin. In 18.2% of the cases there was requested readjustment of treatment of factors of cardiovascular risk.

Discussion: The majority of the consultations proceeding from psychiatry are based in rejecting organic damage in the patient. In the valuation of fever and drowsiness in a psychiatric patient confusion raises the etiology of this pathology, furthermore when these patients meet in treatment neuroleptics. Clinical global valuation of these patients is necessary to establish a differential correct diagnosis.

Conclusions: The integral formation that the internist realizes is fundamental for a suitable assistance of the patients with pathologies that can create confusion. In psychiatry it is fundamental to distinguish between the existence of organic/psychiatric pathology. For that, they are not infrequent the request of consults directed to IM.

G-96
DESCRIPTIVE ANALYSIS OF PATIENTS PRESENTING CARDIAC ENZYMES MOVEMENT FINALLY UNDERGOING CARDIAC CATHETERIZATION IN A SPECIALTY HOSPITAL IN THE SSPA. FROM SERIATE CARDIAC ENZYMES TO CARDIAC CATHETERIZATION

M. Escobar Llompart, S. Romero Salado, M. Guzmán García, V. Lechuga Flores, V. Manzano Román, O. Mera Gallardo, G. García Domínguez, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: Develop the need of percutaneous transluminal coronary angioplasty (PTCA) in patients attended in E.R. with chest pain, which presents biochemical signs of myocardial damage in our center.

Material and method: We included patients presenting chest pain and biochemical signs of myocardial damage in the last 12-24h from their admission in E.R. in 2011. Variables studied: the presence of rising levels cardicac enzymes (myocardial damage) in established acute coronary syndrome (ACS), PTCA.

Results: Total patients included: 392. Troponin, CPK and CPK-MB in the last 12-24 hours altered in 38.9%. Evolution ACS in 57.6%. PTCA: 96.46% of the patients.

Discussion: Our study objective classical biochemical parameters of myocardial damage have no early positivity in patients requiring invasive measures immediately, it being necessary to perform an overall assessment of the situation of ischemia (biochemical data, clinical and electrocardiographic abnormalities).

Conclusions: Ischemic heart disease is increasing more and more in the population. Patients are getting older and have greater comorbidity, these patients usually enter the Internal Medicine Department when not needed invasive or surgical measures. We need a comprehensive assessment of acute ischemia (biochemical, clinical and ECG abnormalities) for an effective approach to this clinical entity.

G-97
REAL USE OF CLINICAL GOVERNANCE TOOLS IN ITALIAN INTERNAL MEDICINE WARDS

M. La Regina[2], V. Nuzzo[1], E. Porazzi[3], E. Foglia[3], C. Nozzoli[4], A. Mazzone[5] on the behalf of 2° Master Course in Clinical Governance[3]

[1]Department of Internal Medicine. Ospedale San Gennaro. Napoli, Italy. [2]Department of Internal Medicine. Ospedale S. Andrea. La Spezia, Italy. [3]CREMS. Università LIUC. Castellanza, Italy. [4]Department of Internal Medicine and Emergency. Az Ospedaliero-Universitaria Careggi. Firenze, Italy. [5]Department of Internal Medicine. Az. Ospedaliera Ospedali di Legnano. Legnano, Italy.

Objectives: Increased health expectations, new technologies and decreased economic resources, have led to the development of Clinical Governance (CG), a multidimensional tool to improve appropriateness and promote excellence. To evaluate the actual use of CG in Internal Medicine Wards of Italian hospitals, we administered a 67-item validated questionnaire to 39 physicians from 33 IMW, participating in a master course organized by FADOI (Federazione delle Associazioni dei Dirigenti Oapedalieri Internisti), and CREMS (Centro di Ricerca in Economia e Management in Sanità) at LIUC University in Castellanza, Italy. We examined the perceived usefulness (graded from 0 to 4), the utilization rate of 46 CG tools and correlations between CG use and ward characteristics/location. We also investigated the level (organization, department, ward) of CG use.

Material and method: We examined the perceived usefulness (graded from 0 to 4), the utilization rate of 46 CG tools, and correlations between CG use and ward characteristics/location. We also investigated the level (organization, department, ward) of CG use.

Results: The 33 IMW cared for 44,700 in- and 197,000 outpatients in 2010 (mean length of stay 8.83 days; mean occupancy rate 94.6 ± 13.6%, mean DRG weight 1.2). The mean age of medical staff was 48.7 ys. On average 52% (8-89%) of the studied tools are used by the investigated hospitals.. Clinical guidelines resulted the most used (100%) and most useful tool. Regression analysis showed a direct relationship between the utilization rate and the age of medical staff ($p = 0.013$, $r = -0.44$), the age of interviewed physicians ($p = 0.048$, $r = -0.34$), the number of hospitalizations ($p = 0.024$, $r = 0.44$) and hospital beds ($p = 0.001$, $r = 0.68$).

Conclusions: The present study showed that CG is quite used in Italian hospitals, mainly at ward level. CG questionnaire is an opportunity to make inter-organizations comparisons about GC utilization.

G-98
CUM FADOI DOCET: AN AUDIT ABOUT THE MANAGEMENT OF PATIENTS WITH ACUTE PANCREATITIS

M. La Regina[1], C. Canale[1], A. Patti[2], A. Mazzone[3], C. Nozzoli[4] on the behalf of 2nd Master Course in Clinical Governance[1]

[1]II Master Course in Clinical Governance. Università LIUC. Castellanza, Italy. [2]Department of Internal Medicine. Ospedale San Camillo-Forlanini. Roma, Italy. [3]Department of Internal Medicine. Azienda ospedaliera Ospedali di Legnano. Legnano, Italy. [4]Department of Internal Medicine and Emergency. Azienda Ospedaliero-Universitaria Careggi. Firenze, Italy.

Objectives: The second level Master course on Clinical Governance in Internal Medicine becomes a diffusion network, while maintaining the link between the nodes: master participants faced with the guidelines in an extended audit experiment. Aim of this study was to audit the management of patients with acute pancreatitis (AP) against the standards of practice in 12 centres of different Italian Regions.

Material and method: The study retrospectively analyzed 188 patients with AP in 2011. Audit targets: mortality for AP and for severe acute pancreatitis (SAP); severity assessment by APACHE II score; adequate fluid replacement and analgesia; in SAP, CT after 48 h from illness onset, enteral feeding and prophylactic use of a carbapenemic antibiotic. Results were graded through a quintile classification range: very poor, poor, average, good and excellent.

Results: Out of 188 AP patients, 64 (34%) had SAP. Patient mortality was 2.1% in AP and 6.25% in SAP. We have also evidenced excellent fluid replacement (97%) and good pain control (75%) but poor APACHE II score evaluation (35%). In the 64 patients with SAP the inappropriateness of the CT timing was high (78.1% within 48 hours of illness onset), enteral feeding was very poor (5%) and the use of a carbapenemic antibiotic on average (42%).

Conclusions: The study, despite of the excellent outcomes, highlights a wide spectrum of opportune improvement actions in terms of implementation APACHE II score, enteral feeding, appropriateness of CT timing and carbapenemic use. The re-audit is going to be performed within 1 year.

G-99
FOLLOW-UP OF PATIENTS DIAGNOSED GESTATIONAL DIABETES (GD) FOR 9 MONTHS IN A HOSPITAL IN SPECIALTIES OF THE SAS. EXPERIENCE OF A RESIDENT IN INTERNAL MEDICINE

M. Escobar Llompart, V. Lechuga Flores, V. Manzano Román, G. Ruiz Villena, R. Aranda Blázquez, M. Guzmán García, E. Sánchez Relinque, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: The impact of the GD on pregnancy and perinatal adverse effects both the mother and the fetus is recognized. The objective of the study is to know the clinical follow-up of diagnosed GD patients about the risk of maternal or perinatal complications develop.

Material and method: GD diagnosed patients were selected in a period of 9 months. Tracked during pregnancy, delivery and postpartum. We analyzed data on the basis of the characteristics of a descriptive observational study. Variable study: age, type of used insulin, risk factors for GD, fetal, perinatal, maternal complications, progression of diabetes in the postpartum.

Results: Total of diagnosed patients of GD: 28 patients, with a median age of 31. They pointed out insulinotherapy the 32.14%. In these patients, the main risk factors that they were, in order of

frequency were: age > 25 years (100%), family history of diabetes (55.5%) and overweight/obesity (33.3%). NPH insulin was used in monotherapy in the 44.4% of the cases, NPH + rapid insulin in 33.3%, rapid insulin monotherapy in 11.1% and pre-mixed insulin + NPH in 11.1%. The most frequent fetal complications were: prematurity (17.8%), hypoglycemia (14.2%), macrosomy (> 4 kg) (10.7%), hyperbilirubinemia (3.5%). Perinatal mortality in this series of cases was 0%. The most frequent maternal complications were: caesarean section (32.2%), polyhydramnios (7.14%) and pre-eclampsia (3.57%). Linking the maternal and fetal complications with patients that require insulinotherapy, 55% of cases were premature and 55% said caesarean section, other complications were present in an 11.1% (macrosomy, polyhydramnios, hypoglycemia, pre-eclampsia). In reference to the postpartum maternal complications, only 1 case developed diabetes mellitus (3.57%), the rest presented normoglycemia after giving birth.

Discussion: GD increases the risk of various such as prematurity, macrosomy and neonatal problems obstetric complications, in addition to maternal problems; these complications reflected in the bibliography were observed in similar frequency in our study. In turn, our percentage of patients who developed diabetes mellitus after childbirth is similar (3.57%) with the described the bibliography. The insulinotherapy should be used whenever that fails a good glycemic control with the use of the treatment dietary, alone or associated with the exercise, in our study, the percentage of patients that required insulinotherapy, if equally similar to the present in different revisions (around 30%).

Conclusions: For a proper clinical evolution of patients with GG needed adequate control of blood glucose, which is why it is important to make a diagnosis and begin treatment early.

G-100
FOLLOW-UP OF PATIENTS WITH A DIAGNOSIS OF HYPOTHYROIDISM GESTATIONAL (GH) DURING 9 MONTHS IN A HOSPITAL OF SPECIALTIES OF THE SAS

V. Manzano Román, S. Romero Salado, V. Lechuga Flores, R. Aranda Blázquez, E. Sánchez Relinque, G. Ruiz Villena, M. Guzmán García, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: T4 requirements increase from the fifth week of pregnancy, moment in which the maternal contribution is important. Hypothyroidism not treated during pregnancy is associated with maternal and fetal, complications with increase in perinatal mortality and congenital abnormalities. Therefore we perform follow-up to those diagnosed patients of GH to assess the requirement for T4 dose pointed out as well as possible complications.

Material and method: It is a descriptive observational study which was in follow-up to those patients with diagnosis of HG during the fall months between June 2011 and February 2012. Variable study: age, time of start of treatment, maximum dose used, average values of thyroid hormones, maternal and fetal complications, breast-feeding and evolution postpartum hormonal control.

Results: 52 Patients with GH were included in the study. Middle age: 30 years. Thyroid hormone therapy began at 11 weeks on average (first quarter: 55.76%). The maximum dose of thyroid hormone which pointed out throughout the pregnancy was 53.03 µg a day. The final average values of TSH were: 2.22 µUI/ml, T4L: 0.96 ng/dl and T3: 0.27 ng/dl. The majority of pregnant women and infants had no complications, still inside of these, the most frequent were: underweight newborn (11.53%) prematurity (7.7%), pre-eclampsia (3.84%), polyhydramnios (1.92%). Got breastfeeding the 42.3% of the patients, making treatment with iodine during this, the 81.8% of them. Thyroid hormones control made at 6-8 weeks delivery, average of TSH figures presented: 1.05 µUI/ml, T4: 2.43 ng/dl and T3 0.29 ng/dl; While in thyroid hormone therapy at the time and therefore, with hypothyroidism post-pregnancy the 23.07% of patients in our study.

Discussion: The most frequent complications found in our sample of patients was similar to those described in the literature (low baby weight and prematurity). The 23.07% of patients continued with hypothyroidism at 6-8 weeks after childbirth, with Ac AntiTPO positive in 50% of these and Ac AntiTg by 25%. The 58.3% of these patients had a family history of thyroid pathology.

Conclusions: It is important to make a diagnosis and early treatment of hypothyroidism in pregnancy for prevention of possible maternal and fetal complications. Antibody positive patients are more likely to introduce hypothyroidism after delivery.

G-102
WHEN SHOULD WE USE MAGNETIC RESONANCE IMAGING IN THE DIAGNOSIS OF HEMOCHROMATOSIS?

E. Zubillaga[1], J. Alustiza[2], A. Castiella[3], J. Emparanza[4], M. de Juan[5], J. Artetxe[1], A. Azkune[1], G. Zubillaga[1]

[1]Department of Internal Medicine, [4]Department of Epidemiology, [5]Department of Immunology. Hospital Universitario Donostia UPV/EHU. San Sebastian (Guipúzcoa), Spain. [2]Department of Radiology. Osatek Donostia. San Sebastian (Guipúzcoa), Spain. [3]Department of Gastroenterology. Hospital Mendaro. Mendaro (Guipúzcoa), Spain.

Objectives: Primary- To define the Magnetic Resonance Imaging (MRI) indication in the high iron overload of the liver (HIO), within the hemochromatosis diagnostic algorithm. Secondary- To evaluate the utility of the transferrin saturation index (TS) and seric ferritin (SF) in the HIO diagnostic algorithm.

Material and method: Retrospective study of all the consecutive patients studied by MRI to determine the liver iron concentration (LIC) at the Osatek-Donostia Unit, between 2002 -2008. MRI results were compared to TS (n < 45%), SF (n: < 300 µg/L) and genetic study (HFE gene mutations); Specificity (Sp), Sensitivity (Se), Positive predictive value (PPV) and Negative predictive value (NPV) were calculated. The gold standard for HIO diagnosis was Hepatic iron index > 1.9 (LIC by MRI/age) (Alustiza et al. Radiology. 2004;230:479-84).

Results: From 478 patients studied by MRI we retrieved all the other study parameters in 242 (198 men/44 women). Mean age: 52.4 (SD 13.3). From the 242 patients included, 206 had not HIO and 36 had HIO. TS was raised in 141 patients (108 NHIO/33 HIO); SF raised in 207 patients (35/175). Genetic study revealed 28 C282Y (20/8), 27 H63/H63D (4/23), 25 C282Y/H63D (2/23). Statistics: raised TS obtained a 91.7% (78.2-97.1 95%CI) sensitivity (Se) and a 48% (41-51.4) specificity (Sp); raised SF, Se 97% (85.8-99.5) and Sp 16% (12-22.2). C282Y/C282Y, Se 56% (40-70.5), Sp 96 (92.5-98); H63D/H63D, Se 11% (4.4-25.3), Sp 89% (84-92.4); C282Y/H63D, Se 6 (1.5-18), Sp 89 (84-92.4). The raised TS-SF combination, Se 89% (74.7-95.6), Sp 59% (51.9-65.2). The genetic combination C282Y/C282Y and raised TS-SF, Se 50% Sp 98% (95-99). From 125 patients with not raised TS or SF (52%), 121 without HIO: NPV 97%. From 22 patients with C282Y/C282Y and raised TS-SF (9%), 18 presented HIO: PPV 82%. From 95 patients with negative genetic study and normal TS-SF (39%), 94 without HIO: NPV 99%.

Discussion: MRI has the capacity to exactly measure liver iron concentration and it is a non-invasive technique. In this study we observe that the 61% (147/242) of the patients do not need MRI for HIO diagnosis, because analytical and genetic parameters are enough to confirm or rule out HIO in them. However, MRI for HIO determination is indicated in the other 39% (95/242) of the patients. MRI is necessary in the intermediate LIC values (18 HIO patients; 77 without HIO) for the diagnosis of HIO.

Conclusions: Normal TS or SF have high NPV for HIO. The combination of raised TS and SF with C282Y/C282Y mutation have high PPV for HIO. MRI is indicated in patients with raised ST and SF without C282Y/C282Y mutation.

G-103
COPD ATTENDED IN A SHORT STAY UNIT (SSU)

M. Monedero Prieto, J. Medina García, C. Hernández Carballo, J. Del Arco Delgado, M. López Gámez, L. Abraham Pérez, M. Bethencourt Feria, P. Laynez Cerdeña

Department of Internal Medicine. Complejo Hospital Universitario Nuestra Señora de Candelaria. Santa Cruz de Tenerife, Spain.

Objectives: To describe the features of patients admitted because of COPD into a General Internal Medicine Short Stay Unit (SSU), as well as to identify factores associated with poor outcome (SSU failure, readmissions, death by any cause).

Material and method: Data were acquired from discharge reports between February 2011 and February 2012 from the SSU. Data are given as mean ± SD (range) and absolute numbers (percentage) were applicable. Categorical data are compared by means of Chi-square test, numerical variables are compared with Spearman's correlation coefficient. Kaplan-Meier analysis was performed to evaluate time to readmission associated-factors.

Results: A total of 63 (24.2%) patients out of a cohort of 260 had a history of COPD. 24 patients were discharged as "COPD exacerbation". There were 10 (41.7%) women. Patients were 77.91 ± 8.8 years old. 7 patients (29.2%) had no prior history of COPD and 6 (25%) denied ever smoking. Among smokers, mean packets/year index was 44 ± 27.29. From the available data 6 patients (54.6%) had moderate to severe disease. 16 (66.7%) patients were on inhaled corticosteroids. 16 patients (66.7%) computed as pluripathological patients. Patients fulfilled 1.86 ± 1.14 (1-3) pluripathological criteria. Length of stay was 3.46 ± 1.61. No patient died within 30 days of discharge. 4 (16.7%), 1 (4.2%) and no patient required readmission within 30, 14 and 3 days of discharge, respectively. Cardiopathy (A Category) was closely related with readmission (X square = 4.8; p = 0.028). Staying days related negatively with number of pluripathology categories (r = -0.54; p = 0.008). Basal C-reactive protein levels correlated (negatively) with basal O_2 levels (r = -0.899; p = 0.015). However, none of these variables were useful to predict readmission.

Discussion: It's possible to attend COPD patients in a SSU with safety, even when they have large comorbidities and are of old age. Due to the shortness of our study population it should be necessary to carry on recruiting patients in order to reaffirm our results.

Conclusions: COPD exacerbations can be managed in a Short Stay Unit environment. Age, comorbidities, low basal O_2 levels and high basal CPR did not affect readmission rates. More patients are needed to further evaluate SSU performance with our chronic exacerbating disease such as COPD.

G-104
ANTICOAGULATION AND NONTRAUMATIC ABDOMINAL HEMATOMA

J. Laso Trillo[1], A. Pérez Pérez[1], C. Vera Sánchez-Rojas[1], C. López Rodríguez[2], B. Medina Tovar[1], J. Gómez Verdú[1], E. Rashid Jiménez[1], C. Royo-Villanova Reparaz[1]

[1]Department of Internal Medicine. Hospital General Universitario Reina Sofía. Murcia, Spain. [2]Department of Internal Medicine. Fundación Jiménez Díaz. Madrid, Spain.

Objectives: To analyze the clinical characteristics of patients with discharge diagnosis of rectus abdominis and retroperitoneal hematoma in an area hospital.

Material and method: A retrospective study of a group of patients diagnosed with rectus abdominis hematoma (RAH) and retroperitoneal hematoma (RH) between 2006 and 2011 was performed. Data were processed using a statistical program (SPSS-15).

Results: During the study period 31 patients were identified (52% women). The mean age was 77.6 years and 90% were over 65 years old. The hematoma was the cause of admission in a 42%, in the remaining 52% it occurred as a complication in patients admitted for another reason. 90% patients were receiving anticoagulants (38.7% acenocoumarol, 35.4% LMWH, 12.9% acenocoumarol and LMWH and 3.22% UFH). In addition, 45.16% also received antiplatelet agents. Of those who were treated with LMWH, 63.63% were receiving a therapeutic dose and 36.36% a prophylactic dose. In a 43.3% cough was a predisposing factor. Clinical onset was abdominal pain in 74.2%, palpable mass in 38.7%, hypovolemic shock in 19.35% and a drop of hemoglobin levels without associated symptoms in 9.67% with an average decrease of 3.15 mg/dl. Among patients treated with LMWH a 72.7% had creatinine clearance lower than 60 ml/min (MDMR-4). Of those treated with acenocoumarol, 66.67% had an INR over 3.5. In most patients the initial diagnosis was clinical (80.6%) confirmed by CT in a 56.67%, ultrasound in a 76.67% and 6.46% without imaging test. The most frequent locations were rectus abdominis (58%), retroperitoneal (32.26%) and both in a 9.7%. Treatment was conservative in all cases and consisted of remove anticoagulant therapy (96.77%), 67.64% required blood transfusion, bleeding vessel selective embolization in a 5.2% and surgery was no needed. The average stay was 17.9 days and hospital mortality 10%.

Discussion: As we have seen in our series, RAH and RH are rare entities that often occur in elderly whose receiving anticoagulant therapy. We also observed a slight women predominance. Even though most hematomas occur spontaneously predisposing factors are considered, such as coughing which was present in up to half of patients. We also identified as risk factors: moderate renal failure in patients treated with heparin and INR over therapeutic range in patients treated with acenocoumarol. A small percentage of patients associated RAH and RH, a circumstance not present in the revised series. Although the diagnosis was clinical in most cases, an image study was performed for confirmation in nearly 90% of patients. Conservative treatment was adopted in most cases. The average stay was 17.9 days and mortality of 10%, having found a large variability in the revised series (1.6-12%).

Conclusions: Slight female predominance and preferential incidence in elderly patients whose are receiving anticoagulant treatment. Although RAH and RH are not a frequent pathology, they have a high morbidity and mortality. Cough and renal failure appear to be predisposing factors. We must avoid LMWH injection in the abdominal wall in patients with severe cough. Necessity to adjust LMWH doses in patients with moderate or severe renal failure.

G-105
HIP FRACTURE IN THE ELDERLY. IMPLEMENTATION OF A COMPREHENSIVE CARE PROGRAM AND EVALUATION OF HEALTH OUTCOMES

A. Fernández Moyano[1], R. Fernández Ojeda[1], C. Palmero Palmero[1], M. Álvarez Alcina[1], B. García Benítez[2], F. Baquero Garcés[2], V. Romero Ruiz[3], A. Vergara Díaz[1]

[1]Department of Internal Medicine, [2]Department of Orthopaedic Surgery and Traumatology, [3]Department of Quality of Care. Hospital San Juan de Dios de El Aljarafe. Sevilla, Spain.

Objectives: Report the health outcomes of a multidisciplinary care program for patients with hip fracture in an acute general hospital.

Material and method: In this model involved a team of orthopedic surgeons, internists, family physicians, emergency, intensive care,

physical therapists, anesthesiologists, nurses and social workers. Retrospectively include all patients over 65 years, diagnosed with hip fracture from January 1, 2006 to December 31, 2010. They were followed for one year.

Results: It includes a total of 1,000 events, corresponding to 956 patients. The total length of stay was 6.68 days. The percentage of patients operated on within 72 hours, has become of 91.21%. The incidence of surgical site infection was 0.4%. Readmissions per year were 14.3% and year mortality of 23.1%. From the beginning there has been a progressive reduction in the average stay. In Table 1 we show the comparative results of the first and last Period of program development.

Discussion: There is a significant variation among the published data, where the percentages of patients that had early surgery range from a minimum of 52% to a maximum of 83% The total average length of stay achieved in our study is lower than that reported by other authors which ranges from 14 to 25 days. There is a large disparity among results from the available studies, ranging mortality rate during episode from 1.5% to 10%. There is also a large variation in annual mortality results among the studies published ranging from 10.4% to 45%.

Conclusions: 1. The development of a a multidisciplinary care program to the patient with hip fracture, leads to beneficial results in health, with a high percentage of patients operated on early, low length of stay, incidence of surgical site infections, readmission rates and mortality intraepisodio and one year follow-up. 2. The integration of this program in the normal activity of an acute regional hospital, offer allows easy incorporation, the organizational model hospital care elsewhere.

G-106
EFFECT OF FASTING FOR DIAGNOSTIC PROCEDURES ON NUTRITIONAL STATUS OF HOSPITALIZED PATIENTS. A PROSPECTIVE STUDY

I. Les[1], J. Vinuesa[2], R. Batanero[2], T. Ruiz de Azúa[2], L. Laborda[2], M.V. Egurbide[1]

[1]Department of Internal Medicine, [2]Department of Nutrition. Hospital Cruces. Barakaldo (Vizcaya), Spain.

Objectives: To investigate nutritional status and to identify factors associated with nutritional deterioration in a cohort of patients during admission. We focused on the impact of fasting due to diagnostic procedures on malnutrition.

Material and method: Prospective study conducted in a tertiary care hospital that included admitted patients with viability of gastrointestinal tract. Patients received a diet according to their medical condition supervised by a dietician, who fulfilled a food intake record including periods of fasting due to diagnostic procedures. Nutritional status was evaluated by the Subjective Global Assessment (SGA) and the Mininutritional Assessment (MNA) at baseline and by analytic variables (total proteins, prealbumin, C-reactive protein, cholesterol, lymphocytes) and anthropometric parameters (weight, body mass index [BMI], bicipital and tricipital skinfolds thickness, mid-arm muscle circumference [MAMC] and muscular strength measured by handgrip) at baseline and at discharge. Association between nutritional parameters and several variables such as age, gender, education level, previous alcohol intake, Charlson and Barthel indexes, cognitive dysfunction, mastication problems, drugs and number of pills per day during admission, main diagnoses at discharge, length of stay, amount of intake, time of fasting and number of lost meals was assessed by univariate analysis followed by a multiple linear regression.

Results: Twenty-one consecutive patients (13 men, 8 women; 69.8 ± 12.1 years) without marked pluripathology (Charlson index 1.9 ± 1.7) or autonomy impairment (Barthel score 90.9 ± 12.9) were admitted for 10.2 ± 6.6 days. The main causes of admission were new-onset cancer (9 cases) and infections (8 cases). The majority of patients exhibited an acceptable nutritional status at baseline (SGA A: 9 patients, B: 8, C: 4; MNA: 23.0 ± 4.8; BMI: 26.1 ± 3.8). The amount of intake and time of fasting were 71.2 ± 21.5% and 9.3 ± 8.3 hours, respectively. Thirteen of 21 patients (62%) lost 1 or more meals in preparation for diagnostic tests. During follow-up, a decrease in weight (final-baseline = -1.1 ± 3.1 Kg), MAMC (final-baseline = -0.6 ± 1.2 cm) and handgrip (final-baseline = -0.8 ± 4.3 Kg) and an increase in prealbumin (final-baseline = 2.0 ± 7.5 mg/dL) were observed. However, bicipital and tricipital skinfolds remained unchanged. The only independent factors associated with reduction in MAMC (R2 = 0.37) and handgrip (R2 = 0.33) were the number of lost meals (regression coefficient, B = -0.64) and alcohol intake prior to admission (B = -7.23), respectively.

Discussion: In hospitalized patients, malnutrition is a common complication that increases morbidity and mortality. To date, few studies have assessed the impact of fasting for diagnostic tests on nutritional deterioration. According to previous data, protein-energy impairment was the leading form of malnutrition in our patients. The reduction in muscle mass and strength detected in those patients who skipped some meal or were drinkers suggests a deleterious effect mediated by fasting and alcohol. Other traditional factors such as age, malignancy, pluripathology, polypharmacy and cognitive dysfunction did not affect nutritional status in our cohort.

Table 1 (G-105). Healhtcare outcomes. Final and initial periods

Variables	First semester of 2006 (n = 90 episodes)	First semester of 2010 (n = 101 episodes)	p value
Total average length of stay (days) Median, (IQ range)	7.82 (5.53; 10.27)	6.68 (5.18; 8.64)	p = 0.045
Patients operated in < 48 hours n (%)	46 (52.87%)	74 (81.32%)	p < 0.001
Patients operated in < 72 hours n (%)	58 (66.67%)	83 (91.21%)	p < 0.001
Mortality during episode. N (%)	4 (4.49%)	7 (7.37%)	p = 0.411
Re-hospitalisation after 1 year. N (%)	17 (19.10%)	16 (16.84%)	p = 0.690
Mortality after 1 year. N (%)	24 (26.97%)	20 (21.05%)	p = 0.347

Table (G-126). Outcome of mid-arm muscle circumference (MAMC) in patients. With and without lost meals during follow-up

	Without lost meals (n = 8)			With lost meals (n = 13)		
	Baseline	Final	p value	Baseline	Final	p value
MAMC (cm)	24.8 ± 2.7	25.1 ± 3.1	0.471	23.6 ± 3.6	22.5 ± 3.0	0.009

Conclusions: During admission, fasting and previous alcoholism impair the nutritional status of patients. A decrease in MAMC may be an early marker of protein malnutrition that is associated with the number of lost meals due to diagnostic procedures.

G-108
EVOLUTION AND CLINICAL FOLLOW-UP OF PATIENTS WITH THYROID CANCER (TC) IN A HOSPITAL OF SSPA

V. Manzano Román[1], V. Lechuga Flores[1], F. Carral San Laureano[2], O. Mera Gallardo[1], G. García Domínguez[1], M. Guzmán García[1], E. Sánchez Relinque[1], F. Gómez Rodríguez[1]

[1]Department of Internal Medicine, [2]Department of Endocrinology. Hospital Universitario de Puerto Real. Puerto Real (Cádiz), Spain.

Objectives: The favourable biological course of differentiated thyroid cancer allows long free periods of disease, but recurrences can occur decades after treatment, it forces to the long-term follow-up of these patients. We describe the characteristics of patients diagnosed TC and operated between the years 1994 and 2011 attending consultations review.

Material and method: It's a descriptive observational study in which we analyze those diagnosed patients TC attending outpatient. The variables to be measured were: classification according to histology, TNM classification, stadium and calculation of risk, post-intervention detectable thyroglobulin, ant-thyroglobulin antibodies, TSH levels and doses of thyroid hormone LT4, presence of secondary hypoparathyroidism.

Results: Patients included: 71. Average age: 43 years. Female dominance: 76.05%. According to the final histology patients were classified as: Ca. papillary (76.56%), Ca. follicular (21.87%) and Ca. spinal cord (1.57%). According to the TNM classification postoperative: tumor size: T1 (< 2 cm tumor): 42.85%, T2 (> 2 and < 4 cm): 30.61%, T3 (> 4 cm tumor, limited to the thyroid): 22.44%, T4 (tumor any size that is extended beyond the thyroid Capsule): 2.04%, Tx (unknown size): 2.06%. Lymph nodes: N0 (no ganglion metastases): 71.42%, N1a (central pretracheals, paratracheals and prelaryngeus metastases): 10.20%, N1b (unilateral, bilateral or contralateral cervical or superior mediastinum metastases): 20.40%. M1 (distant metastases): 2.04% (Lung). Stadium: I (51.02%), II (18.36%), III (20.40%), IV (10.20%). According to this, the category of risk: very low risk (26.53%), low risk (32.65%), high risk (40.81%). Analytical controls, had detectable thyroglobulin levels the 8.45% of the patients. The average levels of anti-thyroglobulin antibodies was 14.49 IU/mL, the value of medium TSH was of 2.38 µUI/mL, with a suppressed TSH (TSH < 0.3 µUI/mL) the 16.90% of patients and values by above 15 µUI/mL the 9.85% of patients. The average dose of LT4 needed patients was 124.6 µg. They presented secondary hypoparathyroidism the 15.49% of the patients.

Discussion: Highlights in our study, the percentage of patients with high risk according to the TNM postoperative, the survival rate of these cases usually 50% according to the revisions. It is recommended one TSH levels suppressed to prevent the stimulation of the residual thyroid tissue, in our series of cases this was achieved in the 16.90% of patients. Hypoparathyroidism is a complication relatively common in the total thyroidectomy by cancer.

Conclusions: Differentiated papillary carcinoma and follicular carcinoma tumors, usually have good prognosis and are curable in almost all cases if detected in the early stages. Levels Tg detectable relate to the persistence of the disease, although not always, being stimulated the serum level of this by TSH.

G-109
THERAPEUTIC APPROACH AT THE END OF LIFE. A YEAR EXPERIENCE AT A PALLIATIVE CARE UNIT

B. Montenegro Puche, F. Carmona Espinazo, J. Soto Benítez, B. Ruiz Estévez, B. López Alonso, M. Martín Zamorano, E. Segura Fernández, A. Mogollo Galván

Department of Internal Medicine. Department of Palliative and Transitional Care. Hospital Universitario Puerta del Mar. Cádiz, Spain.

Objectives: The aim of this study was to analyze at our palliative care unit wether the specific treatments used were effective or other therapies was required. We also intended to determine the symptoms that motivate the admissions; to assess the patients who needed symptomatic measures; to find out when it had to be used the sedation to control the symptoms and to check the kind of consent obtained to use this therapeutic manoeuvre.

Material and method: A retrospective, descriptive, observational study was performed of all the admitted patients consecutively to the palliative care unit from 1st January to 31st December 2011. Medical records were reviewed and we analyzed age, gender, underlying disease and if it was cancer or not, the hospital admission cause or symptom, the syndrome or the clinical situation that underlay that symptom and when it was multifactorial, specific and expectant treatment of the syndrome, as well as the need of sedation to control refractory symptom and how the consent was obtained in these patients, how many patients were discharged and how many died. The data was analyzed by Excel system.

Results: 266 patients were analyzed. The average age was 68 years, with a male sex predominance (59%). Most of patients (94%) suffered from cancer and it supposed the clinical situation which brought about the admission, most frequent tumours were gastrointestinal (35%), followed by lung (21%) and breast (8%). The main symptom of admission was pain, then dyspnea and delirium, up to 66% of patients presented asthenia and more than a single symptom was the cause of the 84% of admissions. The failure related to a vital organ, mainly respiratory and hepatic, was the main reason of symptoms. Respiratory infection and bowel obstruction are highlighted as well. An important percentage of patients (36%) are classified as cancer development. Nearly 80% of patients presented more than a cause which could justify their discomfort. Specific treatment was received in 61%, but 86% required a symptomatic one. 70% of patients died, 23% of them needed sedation. Informed consent was obtained in all of that it was possible, considering the cognitive situation of the patient. In those that the patient was not able to make the decision (67%), the family gave the consent.

Discussion: Clinical care at the end of life tries to improve quality of life of patients and their relatives, when to cure or to increase the survival cannot be the purpose. The relief of symptoms is one of the objectives of the global assistance given in palliative care, there the psychological, spiritual and social needs are also addressed. Nowadays we have at our disposal measures to relieve most of symptoms which cause discomfort at the end of life. First of all, the treatment has to be based on the clinical clues, that is to say, a specific but conservative therapy. When the progression is not satisfactory, symptomatic treatment and, in the end, palliative sedation may be the best options to control the refractory symptoms.

Conclusions: More than the half of admitted patients received a specific treatment with a little long-lasting relief. The most frequent symptoms were pain, dyspnea and delirium. Asthenia was associated in most patients. Despite therapies, a very high percentage of cases required a symptomatic manage to get relief. Almost a quarter of patients who died needed a palliative sedation in the last days. The explicit consent was obtained in all the patients whose cognitive level allowed it, and it was delegated in the rest.

G-110
INSPIRATORY CRACKLES IN COPD: IS IT THE LUNG OR THE HEART?

F. Gómez[1], P. Martínez-Camblor[2], L. Bernacer[1], M. Castresana[3], D. Bachiller[3]

[1]Department of Internal Medicine. Hospital de Manacor. Manacor (Mallorca), Spain. [2]Department of Clinical Epidemiology. Oficina de Investigación Biosanitaria del Principado de Asturias. Oviedo (Asturias), Spain. [3]Department of Development and Regeneration Program. Fundación Caubet-CIMERA. Bunyola (Mallorca), Spain.

Objectives: Inspiratory Crackles (IC) are intermittent short-lived sounds heard on chest auscultation, associated with pulmonary disorders and Congestive Heart Failure (CHF). Smoking is a risk factor for Chronic Obstructive Pulmonary Disease (COPD) and CHF, two common conditions that frequently coexist. IC may be found in both conditions; however, the clinical significance of crackling in lung auscultation of smokers or ex-smokers is unknown. We aim to determine whether IC are associated with the diagnosis of COPD.

Material and method: We performed an observational study in smokers or ex-smokers, older than 50 years and with more than 10 pack-years smoking history. All subjects had to be clinically stable for at least six weeks. The subjects were examined by a physician who had no clinical information of the patient. Subjects with respiratory disorders other than COPD were excluded. A full clinical and respiratory evaluation was done.

Results: We included 87 subjects, 62 had COPD (71%), and 25 had no COPD (29%) (controls). IC were more frequent in COPD (47%) than in controls (4%) (p-value < 0.001). Heart Disease (HD) was similar in COPD (56.5%) and controls (48%), (p-value 0.48). The presence of IC was not associated with HD (p-value 0.114). Clinical parameters associated with IC were the diagnosis of COPD (p-value < 0.001), age (p-value < 0.001) and renal function (creatinine clearance) (p-value 0.006). In step wise logistic regression analysis in the presence of IC as dependent variable, including age, gender, Renal Function, HD and COPD, only age [Odds Ratio (95% confidence intervals)]: [1.094 (1.021-1.173); p-value 0.011], and COPD [11.706 (1,412-97.065); p-value 0.023] entered in the model. Using ROC curve for the presence of IC, AUC for the diagnosis COPD was 0.714 (95%CI 0.606-0.822); p-value 0.002.

Discussion: Crackles were first described in 1818 by the French physician Laënnec, who called them "rales". Laënnec invented the stethoscope, and was the first physician to describe the presence of "rales" in the chest of patients with emphysema. In 1957 Robertson and Coope introduced the term "crackles", although both terms are still in use. Nath et al (1974) described the early characteristics of crackles in Chronic Airway Obstruction and found them to be highly specific. However, this clinical sign has received little attention in the medical literature in the evaluation of COPD patients. In the present study, we have blindly evaluated the presence of crackles in a high risk population for COPD and Heart Disease. We found a strong association between inspiratory crackles (IC) and the diagnosis of COPD, regardless of a diagnosis of heart disease. Our findings suggest that in clinically stable smokers or ex-smokers with IC on lung auscultation, COPD must be ruled out with a spirometry.

Conclusions: In our study population, inspiratory crackles were associated to aging and the diagnosis of COPD, but not to heart disease.

G-112
BLEEDING RISK ASSESSMENT IN ANTICOAGULATED PATIENTS TAKING LOW MOLECULAR WEIGHT HEPARINS VS ACENOCOUMAROL

A. Menéndez, M. Núñez, T. Sancho, A. Gil

Department of Internal Medicine. Hospital Universitario La Paz. Madrid, Spain.

Objectives: There are several previous studies linking the use of anticoagulant therapy with the occurrence of bleeding in both soft tissue and in internal organs. We propose to verify this association in patients admitted to our service.

Material and method: We performed a retrospective observational study, selecting those patients admitted to internal medicine ward since January 2011 to January 2012, coded as patients who presented an adverse reaction to anticoagulant therapy (E934). We studied the CVRF present and bleeding risk factors, the indication for anticoagulation, adverse events and diagnosis at discharge. Bleeding complications were determined as primary endpoint. These complications were defined as soft tissue hematoma, other bleeding (hematuria, rectal bleeding, epistaxis...), and severe bleeding. We tried to relate them to the use of any anticoagulation therapy, assessing the presence of overdosage of acenocoumarol and, in this case case, the INR value presented by the patient.

Results: We analyzed 119 patients, 62 women (52%) and 57 males (48%) with a mean age of 80.9 to presenting T2D (35%), hypertension (75%) and heart disease (69%). Among the risk factors for bleeding, 6.7% had known liver disease, 32% chronic renal failure and 12.6% were receiving antiagregant therap. The main indication for anticoagulation was atrial fibrillation (75%) followed by VTE (17.6%) and valvular disease (7.6%). 16 patients (13.4%) received LMWH treatment, while 102 patients (85.7%) were taking acenocoumarol, of which 80% were overdosed with a mean INR of 6.3. 22 patients had a soft tissue hematoma (18.5%), while 29 (25%) had other types of bleeding but only 5% had severe bleeding. None of the previously described demographic factors were statistically significantly associated with bleeding events. 9 of the 16 patients treated with LMWH (56%) had a soft tissue hematoma. We observed an association between both with statistically significant χ^2 ($p < 0.0005$). Only 13 of the 102 patients treated with acenocoumarol (12.7%) showed this complication, without statistical significance. Nor is the association between INR and the appearance of a soft tissue hematoma. When comparing patients treated with LMWH or acenocoumarol, there was a statistically significant difference ($p < 0.0001$) with increased bleeding risk in patients treated with heparin. 7 of the 16 patients treated with LMWH (43.8%) had other types of hemorrhage, showing a weak association ($p < 0.65$) between them. Of the 102 patients treated with acenocoumarol, only 22 (21.6%) had this side effect, without a statically significant association. There was no difference between the risk of this type of bleeding when comparing patients treated with LMWH or Sintrom ($p < 0.1$). No association was found between adverse bleeding events and increased mortality.

Discussion: In this study an association between the use of LMWH and increased incidence of soft tissue hematoma was demonstrated, but that risk seems to be absent in patients anticoagulated with acenocoumarol. However, the main limitation of our study has been the selection of patients with adverse effects associated to anticoagulant therapy. We did not found an association between previously described risk factors for hemorraghe, such as advanced age and impaired renal function, and bleeding events. These results should be evaluated in a larger study, selecting a control group.

Conclusions: LMWH is associated with an increased incidence of soft tissue hematomas, and with a slight increase in incidence of other types of bleeding. Patients treated with LMWH have increased risk of soft tissue hematoma than those treated with acenocoumarol. There is no clear association between the value of INR in patients treated with acenocoumarol and the occurrence of bleeding.

G-113
INTERNAL MEDICINE CONSULTING: ANALYSIS ABOUT MEDICAL PATHOLOGY OF PATIENTS ADMITTED IN SURGICAL SERVICES

P. Sánchez, D. López, M. León, M. Carrera, Ó. Terry, J. Barraza, B. Loureiro, I. Olazo

Department of Internal Medicine. Hospital Santa Bárbara. Soria, Spain.

Objectives: To analyse the prevalence of medical pathology in surgical Services following the questions and interconsulting directed to Internal Medicine physicians, to know the comorbidities of this kind of patients, and the complications they have during the admission.

Material and method: We report the 46 consultations directed to Internal Medicine in the first trimester of 2012, about patients admitted in all the Surgical Services as: General Surgery, Orthopedic Surgery, Urology, Oftalmology and Otorhinolaryngology. The analysed data were: origin of interconsulting, sex, age, reason for admission, comorbidities, pursuit's days and diagnosis.

Results: Our data shows that: medium age of patients 78 years, 17 females (37%), 29 males (63%). The requesting of the different Services were: 19 from General Surgery, 18 from Orthopedic Surgery, 7 from Urology and 2 from Otorhinolaryngology. The aim questions were: dysnea the most frequent, heart failure and fever.

Discussion: Nowadays the admitted patients also in Surgical Services are really old and with lots of comorbidities, and for us is more evident for our local area attention. Soria is a little Spanish town with majority population older than 65 years. These conditions are favorable to create consultations to Internal Medicine department looking for help in the global management.

Conclusions: We consider that it's very remarkeable the attention of patients admitted in Surgical Services by Internal Medicine physicians because we contemplate the global vision of these patients, and we try to diagnose all the symptoms and the occasional complications and also to treat them. We would like to notice the importance of a good relationship between Surgical Service and Internal Medicine jus to make the best management of patients.

G-114
UTILITY OF GOLD AND CAT SCALES IN THE COPD PATIENT CLINICAL PRACTICE

L. Gallo Padilla, L. Ruiz Rivera, R. Gálvez López, S. Moya Roldán

Department of General Internal Medicine. Hospital de Especialidades San Cecilio. Granada, Spain.

Objectives: Patients with COPD are usually classified with the GOLD classification, which measure the airflow limitation severity. Spirometry is required to make a diagnosis of COPD; the presence of a postbronchodilator FEV1/FVC < 0.70 confirms the diagnosis of COPD. But the goals of COPD assessment are to determine the severity of the disease, its impact on patient´s health status and the risk of future events. That is not possible only with spirometry, and we need to assess other aspects such as symptoms, so we have created questionnaires as the COPD Assessment Test (CAT). We want to evaluate the applicability and importance in controlling the disease of these scales in COPD patients.

Material and method: We collected the patients hospitalized for COPD exacerbation for one month (April 2012) in our Department of Internal Medicine. We have collected epidemiological data (age, sex, influenza vaccination and active smoking), comorbidity, routine treatment, and previous hospitalization for COPD exacerbation in the last year. GOLD scale was calculated in patients with available spirometry, and all patients admitted were asked to fill in the questionnaire CAT. We analized results with SPSS 17.0 program.

Results: In this period 31 patients were admitted to our department with a diagnosis of exacerbation of COPD. In the epidemiological data highlighted a mean age of 77.45 years (median 77 years), with predominance of male sex (87.1%), 83.9% correctly performed seasonal flu vaccination and 22.6% continued smoking. Comorbidity in the patients was very high (83.9%), mainly the presence of hypertension and heart failure (80.6 and 74.2% respectively). 83.9% performed bronchodilator therapy, 60% received treatment with oral corticosteroids in the last 3 months and 51.6% had oxygen therapy. 48.4% required hospital admission in the last year for exacerbation of COPD. Only 48.4% (15 patients) had spirometry previously performed in our hospital, so GOLD level could be used. They were classified into GOLD 1: 20%, GOLD: 2: 53.3%, GOLD: 3 20% and GOLD 4: 6.7%. The CAT score has a median of 22 points, and classifies into groups according to the impact level that COPD has on their daily activity; only 6.5% has a low impact level (CAT score < 10), 25.8% has a medium impact level (10-20), 51.6% has a high impact level (21-30) and 16.1% has a very high impact level (> 30).

Discussion: The patients seen in Internal Medicine Services like ours have significant comorbidity, probably conditioning the scales that assess the life quality of patients affected with COPD and show a classification not closest to reality. Pulmonary function tests such as spirometry, are not regularly performed for patients diagnosed with COPD, especially when they have other comorbidities or are elderly patients, so the GOLD scale does not allow us to really know the involvement of many of our patients, being misclassified from the functional point of view. We found no relationship between the two scales, it seems reasonable to think that the management of this disease should be conducted in a combined assessment, which will assess the symptoms and spirometric classification.

Conclusions: Spirometry would be periodically needed to patients diagnosed with COPD to know their current respiratory functional status, being a common error in our attitude not to perform spirometry after diagnosis. A good tool to know the impact of COPD on the patient may be the CAT scale, being a reproducible questionnaire for patients admitted with COPD, but it must always be done trying to prevent mistakes in the collection.

G-115
HOW ARE WE TREATING INFECTIONS? A CASUISTIC OF A SURGICAL WARD

M. Jonet, L. Pimenta Bento, M. Sassetti, V. Nunes

Department of Surgery (Unit B). Hospital Professor Fernando Fonseca. Amadora, Portugal.

Objectives: The occurrence of infections amongst patients in surgical wards increases patients morbidity, mortality, length of hospital stay and treatment cost. Therefore, knowledge about the frequency and distribution of infections is important to improve infection control measures as well as to develop effective preventive and curative strategies which, in turn, will help us in decreasing incidence, morbidity, mortality and associated treatment cost. Having this goal in mind and with the aim of improving infections treatments, we have characterized the antibiotics prescription pattern, concerning to costs, adequacy to antibiogram tests and principal medication errors, amongst patients admitted to a surgical ward.

Material and method: Retrospective analysis of the clinical processes of all patients admitted from January to March of 2011 in a surgical ward.

Results: 525 patients were admitted in the referred period; 40 patients had at least one positive culture during the admission. We divided the patients into two groups: the patients with no

positive culture (Group A, n = 485) and the patients with at least one positive culture (Group B, n = 40). In group A, 58% patients were males, mean age of 58 years (minimum age: 18; maximum: 93). The mean duration of admission was 7 days. 46% were admitted for less than 48 hours. The most frequent reason for admission was abdominal hernia (25%) and malignant tumors (15%). In group (B), 53% were males, medium age of 67 years (minimum age: 32; maximum age: 91). The mean duration of admission was 25.4 days. 25% had admissions longer than 1 month. The most frequent pathologies were malignant tumors (23%) and diabetic wounds (18%). On group B, 25% of the patients had a previous admission on the past three months; 73% had been submitted to a surgical intervention; 28% were submitted to prophylaxis therapy; and 38% had been temporary admitted on an intensive care unit. From a total of 66 positive cultures, the most common isolates were methicillin-resistant-Staphylococcus aureus (9patients), Acinetobacter baumannii (7 patients), Escherichia coli (7 patients) and Pseudomonas aeruginosa (6 patients). 13 patients (32.5%) had more than one microorganism isolated during the admission. 46% were found in the operatory wound, 24% in urine cultures and 14% in blood cultures (central venous catheter, lung secretions and CSF were less representative). On group A, the most common prescribed antibiotic were gentamicin and metronidazole (almost 4200 doses (d) representing altogether 3,200€, mostly for intra-operatory prophylaxis), followed by piperacillin/tazobactam (830d). Relating to economic burden, the most representatives antibiotics were tigecicline (3,300€ - 66d), meropenem (2,500€ - 250d) and colistine (15,00€ – 8 d). On group B the most prescribed antibiotics were the same: metronidazole (22 patients), gentamicin (19 patients) and piperacillin/tazobactam (18 patients). 45% of patients received 3 or more different courses of antibiotics. Of 40 infected patients, 11 were overmedicated, with a more expensive antibiotic (even after the antibiogram test); 8 received an inadequate antibiotic. Only 1 patient was treated with the more adequate antibiotic (concerning to adequacy to antibiogram test and the choice of the cheaper antibiotic). On the studied period, the total cost for the prescribed antibiotics was 17,600€. If we consider all patient of group B, the cost per day of admission was 838€; it could had been only 382€ per day, if we had use the cheaper of the most adequate antibiotic.

Discussion: The mean age of group A patients were 10 years lower. Mean duration of admission was almost four times higher in group B and malignant pathology was two times more frequent, as well as infected diabetic wound. We found 14 patients without clinical information on the charts (35% of group B). 97.5% of group B were not receiving the most adequate infection treatment. We could had spare almost 450€ per day of admission, considering the group B p altogether.

Conclusions: Antibiotic prescription according to antibiogram test not only avoid mistreatment but also lead to a more economically effective medical practice.

G-116
MULTIPLE SYMMETRICAL LIPOMATOSIS. ANALYSIS OF CLINICAL AND EPIDEMIOLOGICAL CHARACTERISTICS IN THE HEALTH AREA OF VIGO

M. Alonso[1], M. Freire[1], A. Soto[1], I. Marín[2], A. Sousa[1], A. Rivera[1], B. Sopeña[1], C. Martínez[1]

[1]Department of Thrombosis and Vasculitis, Department of Internal Medicine, [2]Department of Occupational Medicine. Complejo Universitario de Vigo. Vigo (Pontevedra), Spain.

Objectives: Multiple symmetric lipomatosis (MSL), also known as Madelung disease, Launois-Bensaude disease and diffuse symmetric lipomatosis, is a rare condition characterized by deposition of uncapsulated subcutaneous adipose tissue in different locations, mainly in middle aged men and related to alcohol intake. There are two types: type I (Madelung) characterized by circumscribed rounded clumps that protrude on the body surface, predominantly in the posterior cervical region, and type II, with more diffuse involvement of the abdomen and proximal regions of the extremities. Objective: to analyze the clinical and epidemiological characteristics of patients diagnosed with MSL in our health area.

Material and method: 21 cases of patients diagnosed with MSL disease were detected through the coding system of our hospital, mainly procedent from surgical services (plastic surgery and otolaryngology). Their medical records were retrospectively reviewed.

Results: 21 patients (18 men and 3 women) were selected. Mean age at diagnosis was 51.9 years. Mean body mass index was 26.75. 20 patients recognized at least moderate alcohol intake. Most frequent locations of subcutaneous lipomatous masses were occipital and neck (57.1%), and submental region (52.4%). Histology showed adipose tissue hyperplasia and hypertrophy, without atypia or malignant degeneration. 3 patients had compression symptoms: 2 sleep apnea hypopnea syndrome and one mechanical hip pain. Three patients had sensory-motor axonal polyneuropathy of lower limbs, one of them with also upper limb involvement. One patient had clinical autonomic neuropathy with postural hypotension and tachycardia. Laboratory findings more frequently altered were elevated mean corpuscular volume (42.8%), thrombocytopenia (23.8%), abnormal liver function tests (57.1%) and hypercholesterolemia (38%). 61.9% of the patients had chronic alcoholic liver disease. 90.5% of patients underwent dermolipectomy, that had to be done on several occasions in many patients for recurrence of lipomas. No other treatments were applied unless the recommendation of cessation of alcohol consumption that was not followed in either case.

Discussion: MSL primarily affects men between 40 and 60 years old. Etiology is unknown but has been associated with lipid metabolism disorders, alcohol intake and changes in mitochondrial DNA. There are also inherited forms. It is associated with axonal polyneuropathy in nearly 85% of cases and with autonomic neuropathy in certain patients. Active search for neurological data can prevent sudden death. However, in our series the incidence of neurologic involvement is much lower, most likely underestimated because the patients have been evaluated mainly in surgical services. Respiratory compression and aesthetic deformities are the main points for surgery, but it is crucial advice of quitting alcohol to prevent recurrences.

Conclusions: 1. In our series, as in literature, alcohol intake could act as a triggering factor in genetically predisposed individuals. 2. The management of these patients in Internal Medicine services could help in early detection and management of neuropathy as well as general measures such as inclusion in alcoholic detoxification programs.

G-117
REVIEW CLINICAL OF CASES OF FAHR'S DISEASE (FD) IN A HOSPITAL OF THE SSPA

V. Manzano Román[1], E. Sánchez Relinque[1], M. Sillero Sánchez[2], G. Ruiz Villena[1], R. Aranda Blázquez[1], M. Guzmán García[1], V. Lechuga Flores[1], F. Gómez Rodríguez[1]

[1]Department of Internal Medicine, [2]Department of Neurology. Hospital Universitario de Puerto Real. Puerto Real (Cádiz), Spain.

Objectives: To know the incident and clinical profile of FD in a hospital of SSPA.

Material and method: We chose patients diagnosed with Fahr's Disease Of the total of patients valued from Service of Internal Medicine, Neurology and Emergency department during the year 2011. The variables to study used were the following ones: age,

sex, comorbility, forms (trains) of clinical presentation and evolution. The information was analyzed on the basis of the characteristics of a descriptive market study.

Results: Total patients: 3. The first case is that of a 71-year-old woman with a history of high blood pressure who came to the emergency department due to left hemifacial paresthesias and some difficulty with speech which lasted for some hours compatible with a temporary ischemic accident. Case 2 concerns a 79-year-old woman with history of HBP, obesity, Diabetes Mellitus type II and depressive syndrome who comes to consultation at the Dept. of Internal Medicine after presenting symptoms of a syncopal episode. Case 3 is a young woman aged 38, with no personal history of interest, studied in Neurology for repeated headaches with characteristics compatible to migraine with visual aura. Complete analyses were carried out in all three cases (including calcium, total proteins, phosphate, paratohormone, thyroid hormones, PCR...), ECG, and Rx of thorax which were normal. The neuroimaging studies showed widespread bilateral and relatively symmetrical calcifications affecting the basal ganglions and both hemispheres of the cerebellum. In the case 3 the calcifications also included both pulvinar thalamic nuclei. These findings suggest the diagnosis of Fahr's disease.

Discussion: Fahr's disease is characterized by bilateral and symmetrical calcifications limited to central grey nuclei or which have extended to other cerebral areas (thalamuses and hemispheres of the cerebellum), associated with neurological disorders and with no anomalies whatsoever in the metabolism of calcium. It can begin during childhood or in adult life. The form of presentation is variable: manifestations may be extrapyramidal. In our study we obtain three patients with diagnosis of Fahr's Disease presented similar distribution for sex with middle ages of average of 62 years who came to the emergency department, to the Neurology and to consultation at the Dept. of Internal Medicine. The clinic that prevailed to the revenue was: 33% hemifacial parestesias, 33% syncopal episode and 33% headaches. Only 33% needed treatment for headaches with characteristics compatible visual to migraine with aura (topiramate). From the steals of its diagnostics, two of the patients remain asymptomatic and 1 marries died ace to result of to cerebro-vascular accident.

Conclusions: Fahr's disease is an infrequent, idiopathic, familial disorder which usually appears in the form of dementia, Parkinsonism, ataxia or neuropsychiatric alterations. None of three cases presented showed this symptomathology, the intracerebral calcifications appearing as incidental findings from neuroimaging. We must rule out secondary causes of treatable diffuse cerebral calcifications such as hyperparathyroidism and hypo and pseudohypoparathyroidism. It is necessary to carry out Ca2+/P+ metabolism and hormonal studies as well as a computerized tomography in order to confirm the diagnosis of Fahr's disease and rule out other neurodegenerative diseases. The diagnosis of suspicion is clinical and that of confirmation is realized by image. SPECT studies have revealed a marked decrease of the ganglier blood flow in these patients. There is no cure.

G-118
HIGH SENSITIVITY CARDIAC TROPONININ T IN THE EMERGENCY DEPARTMENT. PRELIMINARY STUDY

F. de la Calle Prieto, S. Gordo Remartínez, E. Gargallo García, J. Nuevo González, J. Andueza Lillo, J. Cano Ballesteros, M. García Leoni

Department of Emergency. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: The development of highly sensitive cardiac troponin (hsTt) has increased the number of true and false positive results for patients suspected of AMI. To check the diagnoses behind hsTt elevated, requested from the Emergency Department. To know the results of hsTt and the true pathology when the physician suspects coronary disease and/or "typical" chest pain.

Material and method: In our study we analysed those patients admitted to the Emergency Ward in Gregorio Marañón hospital from the 1st to the 5th of November of 2011 who had a troponine test performed. We took these dates to take place our study after a randomized selection regarding the minimum period time required to achieve the "n" we prior calculated. For troponine values; we considered resulting test was significantly elevated when troponine was higher than 14 according to our laboratory range parameters. When several tests were performed for the same patient, we took the highest value for our study. Physician that ordered the troponine test were asked, at the time of request, how high was coronary risk factor and how typical was the chest pain in each particular case.

Results: 74.5% of patients were classified as "high coronary risk factors" (only 38.2% of them had elevated hsTt levels), and 68.2% were classified as "typical chest pain" (only 27.3% of them had elevated hsTt). Between the tested hsTt, 47.3% were > 14. 15.45% of patients with elevated hsTt were diagnosed with Heart Failure, 6.4% were diagnosed with arrhythmia, pneumonia 5.5%, 4.6% angina of any kind and the same percentage with kidney failure, a 3.6% appears NSTEACS, anemia and non consolidative respiratory infection. 100% of pneumonias, 81% of Heart Cardiac Failure, 71.4% of the angina pectoris (of any type), 50% of hypertensive crisis, 44.5% of non consolidative respiratory infection, 43.8% of arrhythmias raised hsTt levels. The two pulmonary embolism show levels greater than 14. 30% of musculoskeletal pain diagnoses and 11% of atypical chest pain raised hsTt. About 20% of diagnoses of NSTEACS displayed elevation of hsTt. 39.1% of patients were hospitalized for different reasons.

Discussion: It is interesting low percentage of patients with hsTt > 14 when the physician classified as "high coronary risk factor" and/or "typical chest pain". This troponin, more sensitive, achieves high levels in acute respiratory processes. Heart Failure also often reaches high hsTt values; as well as angina and arrhythmias.

Conclusions: It is very important a careful history and correctly classify the patient's symptoms. Non-AMI patients with acute cardiac injury can produce hsTt results that mimic AMI. Therefore serial hsTt testing must be used in conjunction with clinic presentation and other laboratory findings. Positive values without cardiac causes are increased using hsTt. The acute respiratory processes appear to increase the hsTt.

G-119
TIME IS MYOCARDIUM: A NEW REGIONAL PROTOCOL FOR PRIMARY PERCUTANEOUS CORONARY INTERVENTION IN STEMI GETS TO REDUCE TIME-TO-REPERFUSION

I. López Neyra[1], J. Córdoba Soriano[1], M. Bellón Munera[2], R. Cordero Bernabé[2], D. Prieto Mateos[1], J. Jiménez Mazúecos[1], E. Cambronero Cortinas[1], M. Rodríguez Carcelén[1]

[1]Department of Cardiology, [2]Department of Internal Medicine. Hospital General de Albacete. Albacete, Spain.

Objectives: The primary percutaneous coronary intervention (PCI) is the treatment of choice in ST-segment elevation myocardial infarction (STEMI) provided an experienced team and minimal delay. Our main aim is to assess whether the implementation of a regional protocol is a useful strategy to reduce time-to-reperfusion.

Material and method: All patients (P) who underwent primary PCI in our hospital were over 5 years, according to the then current protocol, and were prospectively studied. Patients were divided into 3 groups. Group A: P attended to between 2006 and 2007 in the absence of strategies to reduce reperfusion times (RT), 79 P. Group B: P attended to between 2008 and 2010 according to a few local

strategies to reduce RT, 198 P. Group C: 133 P attended to in 2011 according to a regional reperfusion protocol that coordinates the care of these P between an outpatient emergency system and three hospitals with primary PCI capability. We compared the door-to-balloon times (DTB) between the three groups defined as the time that a patient is in-hospital until the culprit artery has normal flow.

Results: Between 2006 and 2011 a total of 410 P (76% Male) with a mean age of 64 ± 13 years old were treated with primary PCI. The most common location of the STEMI was the inferior wall (42.6%) and the anterior wall was affected in 37%. In-hospital mortality was 4% for all patients and 6% in 1 year follow-up. The median DTB time was significantly shorter in Group B (75 minutes; Interquartile range, 52´-105´) than in Group A (100 minutes; Interquartile range, 75´-120´; $p < 0.001$). Patients of Group C also had significantly shorter DTB time than the two anterior groups (Median 38 minutes; Interquartile range, 26´-71´; $p < 0.001$).

Conclusions: The implementation of a regional protocol for primary percutaneous coronary intervention in STEMI with collaboration between out-hospital emergency system and in-hospital cardiology team is a very useful strategy to reduce the time-to-reperfusion.

G-120
RAPID RESOLUTION AMBULATORY CLINIC. RESULTS FROM THE FIRST 200 PATIENTS

J. Medina García, M. López Gámez, A. Tejera Concepción, A. Castellano Higuera, M. Bethencourt Feria, M. Monedero Prieto, L. Abella Vázquez, P. Láynez Cerdeña

Department of Internal Medicine. Complejo Hospital Universitario Nuestra Señora de Candelaria. Santa Cruz de Tenerife, Spain.

Objectives: To describe the clinical features of patients visiting a rapid resolution clinic within a General Internal Medicine Service.

Material and method: Data from patients attending the clinic during the last 18 months were recorded. Epidemiological features were analysed. Numerical variables are expressed by means ± SD (range) and compared using Pearson's correlation coefficient. Categorical variables are expressed in absolute numbers (percentage) and compared by means of Chi-square test.

Results: A total of 200 cases were reviewed. Patients were 61 ± 68 (46.25-77) years old. 87 (43.5%) were women. Most of the patients were either illiterate (35; 17.5%) or had only primary studies (87; 47.5%,). Referral origins vary, being the Short Stay Unit (SSU, 77 patients, 38.5%) and a preferent Primary Care telematic consultation center (n = 101, 50.5%) the most preferent options. Referral causes were protean (Table 1). Among classical cardiovascular risk factors, obesity (n = 65; 32.5%), blood hypertension (n = 120; 60%) and dyslipidemia (n = 91; 45.5%) were the most common. 60 patients (30%) fulfilled multimorbidity criteria A total of 7 (3.5%) patients needed hospital admission, despite management in the clinic. A typical Internal Medicine admission was avoided in 122 (61%) cases. Only 6 patients (3%) died during the current follow-up. Poor cultural background was related with poor outcome (need for admission, death by any cause, Chi-square = 30.36; $p = 0.002$). Fulfilling multimorbidity criteria also was correlated with a poorer outcome (Chi-square = 23.42; $p < 0.001$). Cardiovascular risk assed by SCORE also correlated with decease or hospital admission (Chi-square = 212.29; $p < 0.001$).

Discussion: This cohort shows that typical causes of hospital admission might be managed in an ambulatory setting. However, lack of a more robust cohort might limit this interpretation, since it's not possible to foresee saturation of complementary tests, should this procedure be generalized.

Conclusions: An ambulatory setting and appropriate for managing complex clinical problems. However, patients with multi morbidity and/or at high cardiovascular risk should be closely considered in the event of obtaining poor outcomes.

G-121
DIAGNOSTIC PROCEDURES IN OUR AREA OF BRAIN MASS WITHOUT KNOWN PRIMARY NEOPLASM

L. Vela Manzano, C. Collado Pérez, C. Rodríguez Leal, E. López Tinoco, A. Fernández Rodríguez, I. Ríos Holgado, I. Tinoco Racero

Department of Internal Medicine. Hospital Universitario Puerta del Mar. Cádiz, Spain.

Objectives: To analyze the diagnostic procedure performed to patients with finding of space-occupying lesion (SOL) of the brain, without systemic symptoms that points to a primary tumor in another location, in our area.

Material and method: A retrospective study realized beginning with patients admitted from the emergency department of the Hospital Universitario Puerta del Mar (Cádiz) in the past 2 years, in Internal Medicine, Neurosurgery and Neurology departments, with discovery of brain SOL. In the database, 40 patients were collected, from which were excluded those with known primary neoplasm, assuming that the SOL corresponded with metastases thereof.

Results: From the 40 patients chosen for this study, 15 patients were excluded. The median age of presentation was 52, 68% (n = 17) were male. The average of days admitted was 18 days. Of those that were analized, 17 patients did not present any risk factors, the rest were smokers and/or drinkers. The principal complaint of admittance was focal neurological (40%) or more than one symptom (40%), other symptoms such as headache were seen in 16% of patients and seizures in 4%. In 96% and 88% of the patients the analysis and X-ray of the thorax were normal, respectively. Craneal TAC and brain RMN were pathological in 100% of the cases. 76% presented negative tumor markers. Thorax TAC was done on 52% of patients, of which 62.5% were normal. 44% of the patients had an abdominal TAC done, of which 91% were normal. Abdominal ultrasound was done on 36% of patients and was normal in all cases. Around 84% did not have any complementary test done, while the remaining 16% did (mammogram, bone scintigraphy, digestive study, fiberoptic scope). In 50% of cases the presumptive diagnosis was primary brain neoplasia and the other 50% was metastases with no history of known brain neoplasm. Of all of the patients, 56% had a cerebral biopsy done, with 56% resulting in a CNS primary tumor of different histological types, 35% metastases, and 7% of vascular origin. 100% of the biopsies did not have any complications resulting from the procedure. Only 4% of the patients needed anticonvulsive treatment and 64% received corticosteroids treatment. After diagnosis, 32% received radiotherapy and chemotherapy, the rest received other treatments (surgery, antiretrovirals, hormone therapy). 32% of the patients died, with an average of 77 days between admittance and death. Of the dead, 62.5% were patients with a diagnosis of brain metastases.

Table 1 (G-120)

	SSU	General Syndrome	Lymphadenopathy	Anemia	CV Risk Factors	Fever	Others
N (%)	23 (11.5)	31 (15.5)	7 (3.5)	18 (9)	10 (5)	9 (4.5)	76 (53)

Discussion: The presentation of neurological symptoms in patients with a brain lesion in the absence of a known primary neoplasm is not an uncommon occurrence in clinical practice. The initial evaluations of these patients principally includes diagnosis imaging followed by a brain biopsy. However, there is no methodical, well-defined study for the evaluation and management of these patients. Patients with a recently detected brain mass and no history of cancer are often submitted to extensive diagnostic tests in search of a systemic primary neoplasm before carrying out a brain biopsy.

Conclusions: In our area, after obtaining a high percentage of patients diagnosed with a primary CNS tumor with further studies being negative for a primary tumor in another location or for metastases, we conclude that if an analysis, including of a hepatic profile, and an X-ray of the thorax show no trace of a tumor, it may be valuable to do directly a RMN and brain biopsy to arrive at a diagnosis. Although a brain biopsy is an invasive procedure, patients had no complications related to it.

G-122
CHARACTERISTICS AND OUTCOME OF INTERNAL MEDICINE PATIENTS ADMITTED IN AN INTENSIVE CARE UNIT

D. Nicolás Ocejo[1], S. Fernández Méndez[1], C. Hernández García[2], P. Castro Rebollo[3], J. Pericás Pulido[1], J. Nicolás Arfelis[3]

[1]Department of Internal Medicine, [2]Department of Infectious Diseases, [3]Department of Medical Intensive Care. Hospital Clínic de Barcelona. Barcelona, Spain.

Objectives: Describe the characteristics and outcome of patients admitted to a Medical Intensive Care Unit from the Internal Medicine ward and compare them to the rest of patients admitted in the medical ICU.

Material and method: We evaluated 967 patients admitted into a Medical Intensive Care Unit (ICU) of a third level hospital, during a two year period (2006-2007). We selected 81 (8.4%) patients that were admitted coming from the Internal Medicine ward. Age, comorbidities and Modified Charlson Comorbidity Index, severity scores at the time of admission (Acute Physiology And Chronic Health Evaluation III (APACHE-III) and Sepsis-related Organ Failure Assessment (SOFA)), mechanical ventilation requirements (both invasive and noninvasive modes), vasoactive/inotropic drugs requirements, duration of the stay and mortality were registered. Finally we compared both populations (patients coming from the Internal Medicine ward and the rest of ICU admitted patients) to assess differences between them and prognostic factors predicting survival.

Results: From the 81 patients coming from the Internal Medicine ward 48 (59.3%) were men, the mean age was 61.4. The mean Modified Charlson Index was 2.69 and this group presented a mean of 0.481 comorbidities. The main diagnosis at admission was respiratory failure (16%), followed by community acquired pneumonia (11%) and nosocomial pneumonia (8.6%). At ICU admission patients severity and prognosis was evaluated with an APACHE-III index mean of 20 points (SD 6.1), and a SOFA index mean of 6.3 (SD 3.6). During admission non-invasive mechanical ventilation was required in 8.3% of patients, while orotracheal intubation and mechanical ventilation was performed in 50.6%. Other intensive cares such as vasoactive and inotropic drug support was needed in 50.6% of the cases being noradrenaline the most used drug. 13.6% of patients presented severe renal failure during ICU admission needing substitutive renal therapy with hemodiafiltration. Mean ICU stay was 7.4 days, and global survival during hospital admission was 63%. From the 37% of mortality 7.4% of patients died during ICU admission, and 29.6% during regular ward admission after leaving ICU. We finally compared the characteristics of patients admitted in the ICU coming from the Internal Medicine ward (81 patients, 8.4%) and those coming from other departments or the Emergency Room (886 patients, 91.6%). Both groups were statistically equal in characteristics. Statistically significant difference was found only in mortality rate, being global mortality (intra and extra ICU) of patients coming from Internal Medicine ward 37% versus the 20% from those coming from other departments ($p < 0.001$).

Discussion: Patients from Internal Medicine ward are thought to be old patients with much comorbidity, with a high mortality making decision of transfer to ICU a hard choice for clinicians. In this study we characterized all the patients coming from the Internal Medicine ward no matter their age, comorbidity or diagnosis at admission. The results show that this subgroup of patients does not differ in characteristics from the rest of patients admitted in the medical ICU, but they differ in outcome, being mortality of internal medicine patients much higher than mortality of the rest of patients. This fact is not explained by any of the characteristics evaluated in the present study, being necessary to perform further studies.

Conclusions: Patients admitted in the ICU coming from the Internal Medicine ward do not differ in characteristics from those coming from other departments, being mortality the only statistically significant difference, with a higher global mortality in internal medicine patients. With the present study we are not able to infer a cause to explain this difference, so further prospective studies need to be done.

Heart failure

IC-1
PROGNOSTIC INFORMATION OF RENAL FUNCTION MEASUREMENTS IN ACUTE HEART FAILURE

J. Pérez Calvo[1], F. Ruiz Ruiz[1], J. Morales Rull[2], J. Carrasco Sánchez[3], S. Manzano Fernández[4], D. Pascual Figal[4]

[1]Department of Internal Medicine. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain. [2]Department of Internal Medicine. Hospital Universitari Arnau de Vilanova. Lleida, Spain. [3]Department of Internal Medicine. Hospital General Juan Ramón Jiménez. Huelva, Spain. [4]Department of Cardiology. Hospital Universitario Virgen de la Arrixaca. Murcia, Spain.

Objectives: Renal function is a powerful prognostic marker in patients with, both acute and chronic, heart failure. We aimed to evaluate prognostic information yielded by different parameters used to estimate renal function in patients with acutely decompensated heart failure (ADHF), at the time of hospital admission.

Material and method: Five hundred and twenty six patients with ADHF and NTpro-BNP concentration above 900 pg/mL were included in the study. Forty-two patients (7.98%) died during the first 30 days after discharge, and 37 (7.03%) during the following 90 days. Admission blood urea, creatinine, MDRD and Cystatin C were compared between both groups.

Results: age, serum creatinine, MDRD, blood urea and Cystatin serum levels were significantly higher among patients deceased during the first month ($p < 0.05$) (table 1). There were not differences between groups by sex, type of heart failure or comorbidities (atrial fibrillation, diabetes mellitus, hypertension, chronic obstructive pulmonary disease or peripheral artery disease). Kaplan–Meier survival curves at first month showed significant differences according to quartiles of blood urea ($p < 0.05$). Patients with highest concentration of blood urea at admission had the highest one-month mortality. Quartiles of MDRD and cystatin showed no significant differences.

Table (IC-1)

	Age (years)	Creatinine (mg/dL)	MDRD (mL/min/1.73 m2)	Urea (mg/dL)	Cystatin (mg/dL)
Deceased before 30 days	80.3 ± 6.6	1.6 ± 0.6	47.2 ± 21	95.3 ± 42	2.1 ± 0.9
Deceased between 30-90 days	75.7 ± 9.6	1.3 ± 0.7	63.8 ± 33.6	63.4 ± 29.9	1.6 ± 0.7

Discussion: Among patients with ADHF, admission blood urea concentration seems a stronger predictor of short-term mortality with respect to other methods of estimating of renal function. Blood urea concentration is determined by glomerular filtration rate (GFR) plus its reabsorption in the collecting tube. Angiotensin and adrenergic stimulation in acute HF, cause renal vasoconstriction and decrease GFR and renal blood flow, followed by a decreased distal fluid delivery with slow tubular flow in the collecting duct, which enhances the flow-dependent urea reabsorption. It is plausible that blood urea may serve as an index of neurohumoral activation over and above any fall in GFR. This interpretation may explain, at least in part, the strongest predictive capacity showed by urea, in our study, over other estimates of renal function.

Conclusions: among the different estimations of renal function, in patients hospitalised for ADHF, admission blood urea is the strongest predictor of short-term mortality. A blood urea concentration above 0.80 mg/dL in patients admitted to hospital for ADHF should prompt a close follow-up after discharge.

IC-2
HOSPITAL-BASED HEART FAILURE CARE PROGRAM IN A COHORT OF ELDERLY SPANISH PATIENTS: A COMPARISON WITH PREVIOUS STANDARD CARE

J. Satué Bartolomé[1], A. Pérez Martín[1], J. Marrero Francés[1], J. Belinchón Paraíso[1], S. Gonzalo Pascua[1], P. Talavera Calle[2], A. Zapatero Gaviria[1]

[1]Department of Internal Medicine, [2]Department of Cardiology. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: The aim of this study is to compare clinical profile and changes in management of Heart Failure (HF) patients after starting a Hospital Based HF Care Program.

Material and method: All consecutive patients admitted into our Internal Medicine Department with HF and included into our Hospital HF Care Program from june 2011 to march 2012 were prospectively recruited. Demographic data, cardiovascular risk factors, clinical, biochemical and echocardiography findings, and treatments at discharge were registered in a specific database integrated in our electronic medical record system. Data were compared with a previous cohort of 74 patients admitted in 2007 into our department with a diagnosis of HF and managed with standard care after discharge. Our Hospital HF Care Program starts during index HF admission, and includes educational measures for patients and caregivers, scheduled specific hospital consults in follow up, and telephonic access to specialist after discharge, to optimize treatment and reduce readmission rates.

Results: 48 patients were included to the Hospital Based HF Care Program; 36 were women (75%). Patient's mean age was 78.3 (SD ± 13.7) years. 39% had a previous history of diabetes and hypertension. Left ventricular ejection fraction (LVEF) was registered in 40 patients (84%), being depressed in 8 (20%); Heart failure was attributed to valvular disease in 30 (62%), and hypertensive cardiomiopathy in 10 (20%). On ECG, 27 (56%) patients were in atrial fibrillation. The primary cause of decompensation was acute infection in 15 (31%), arrhythmia in 12 (25%) and dietary or therapeutic transgression in 5 (10%) At discharge, Loop diuretics were prescribed in 83% of cases, ACEIs or ARBs in 58%, beta blockers in 20%, aldosterone antagonists in 33%, thiazides in 8% and digoxin in 41% of patients. 27% of patients were discharged on home oxygen. Main differential characteristics of previous standard care vs Hospital Based HF Care program patients are listed in table 1.

Conclusions: Patients included in our Hospital Based Heart Failure Care Program were slightly younger than previous standard care cohort; they were also usually women with preserved left ventricular ejection fraction, in atrial fibrillation; increase in EF registration, valvular etiology, and arrhythmia as main cause of decompensation are the most reliable differences between the two cohorts. Among therapeutics, aldosterone antagonists and betablockers had an increase in use, but not reaching statistical significance, probably because of the scarce number of patients, his advanced age and comorbidities.

IC-3
ONE-YEAR AND LONG TERM MORTALITY OF PATIENTS WITH ACUTE HEART FAILURE (AHF) MANAGED IN AN EMERGENCY DEPARTMENT

D. Campillo[1], A. Martín[2], E. de las Nieves[3], R. Ruiz[2], R. Merinero[4], I. Portero[2]

[1]Department of Internal Medicine, [2]Department of Emergency. Hospital Universitario Severo Ochoa. Madrid, Spain. [3]Department of Emergency. Hospital Universitario de Móstoles. Madrid, Spain. [4]Department of Statistic. Universidad Complutense. Madrid, Spain.

Objectives: To determine 1-year and 5-year mortality of patients admitted to an Emergency Department (ED) because of acute heart failure and potential clinical predictors of middle and long-term mortality among these patients.

Material and method: This is a prospective observational study conducted in the ED of a referral Hospital in Madrid, Spain, from Dec, 2002 to Feb, 2003. Patients over 14 years old with a final ED diagnosis of AHF were eligible for inclusion. Mortality was assessed

Table 1 (IC-2)

Patients included n (%)	Standard Care 74	Heart Failure Care Program 48	p
Sex, women	53(70%)	36(75%)	0.83
Age, mean (SD)	81.7(6.5)	78.3(13.7)	0.32
Registered EF	47(63%)	40(84%)	0.02
Valvular etiology	18(38%)	30(62%)	< 0.01
Cause of decompensation: arrhythmia	7(10%)	12(25%)	0.03
Aldosterone antagonists at discharge	14(16%)	16(33%)	0.08
Beta blockers at discharge	13(17)%	10(20%)	0.60

in Dec, 2010 by direct telephone interview and by reviewing the Mortality Registry of the Spanish National Institute of Human Statistics. We also evaluated potential variables that could help to predict 1-year mortality. Finally we combined those variables that best performed as individual predictors of mortality to create a multi-variable predictive model of first-year mortality. Results were considered statistically significant if p value of the regression coefficient was < 0.05. Both descriptive and analytical statistics were performed using SPSS 13.0.

Results: 144 patients were included, mean age 77.45 years and 64% of them were female. At 5 years, 72 (50%) of patients included were died. Of these, 25% (n = 36) died in the first year. Predictor factors at ED admission for 1-year mortality that showed the strongest predictive values were: advanced age, disability (OR = 2, both), systolic and/or diastolic hypotension (r = 0.21) and creatinine level over 1.5 mg/dL (r = 0.18) (p < 0.05 for all analyses). Conversely, the initiation of ACEI therapy at the ED decreased this risk (OR > 2). Hypertension, diabetes or COPD, as well as the presence of chest pain at admission, showed only a trend to be associated to 1-year mortality (p < 0.1; 90% confidence level). A logistic regression analysis was performed combining the most powerful variables, and a predictive model for mortality at the first year was generated. Probability values for an individual > 0.5 (probability of death in the first year exceeding 50%) would allow the ED physician to easily identify a high risk group among HF patients. x = (age*0.146)–(gender*1.341)+ (Cr *1.055)–(0.063*DBP)–(1.576*HT)+(1.163*chest pain)–8.104; x = log(p/(1-p)); p = (exp(x))/(1+exp(x)); gender = 0(women) 1(men);Cr = in mg/dl;HT (hypertension) = 0(yes) 1(no);chest pain = 0(yes) 1(no);p = probability of death in the first year.

Discussion: Acute heart failure (AHF) descompensation is the most common cause of hospital admission in patients over than 65 years and the third cause of cardiovascular mortality with a five years mortality around 50%. In our study we observed a 50% mortality rate within five years and 25% in the first year. Although several prognostic scores like the Seattle Heart Failure Model have been developed, limited information is available concerning long-term prognosis of patients with AHF managed in an ED. We have identified easily available clinical variables that are strong individual predictors of 1-year mortality (age, gender, diastolic blood pressure, creatinine level and the presence of chest pain). We also have developed a model combining those variables to assess the risk of 1-year mortality that could be helpful to drive management decisions and to determine patients' prognosis.

Conclusions: We observed no changes in acute heart failure mortality rate in patients attended due to acute heart failure in an Emergency Department even in spite of the performance of optimized AHF treatment schemes. We have identified easily available clinical variables that are strong individual predictors of 1-year mortality and we have developed a model combining those variables to assess the risk of 1-year mortality that could be helpful to drive management decisions and to determine patients' prognosis.

IC-4
OBESITY PARADOX IN HEART FAILURE ELDERLY PATIENTS; A RELATIVE FINDING

A. Casas Vara[1], F. Santolaria[2], A. Fernández Bereciartúa[3], E. González Reimers[2], A. García Ochoa[3], A. Martínez Riera[2]

[1]Department of Internal Medicine, [3]Department of Emergencies. Hospital de Campoo. Reinosa (Cantabria), Spain. [2]Department of Internal Medicine. Hospital Universitario de Canarias. San Cristóbal de La Laguna (Santa Cruz de Tenerife), Spain.

Objectives: Obesity is a serious problem in western world. In USA adults, obesity reached 32%, increasing to 45% in blacks. Obesity is a pivotal feature of the metabolic syndrome as cause of diabetes, hiperlipemia and hypertension, all them cardiovascular risk factors and cause of premature death. However, in patients with certain diseases such as renal failure in dialysis, COPD, cancer, heart failure, coronary disease and in elderly people, overweight (body mass index (BMI) between 25 and 30 kg/m^2) and obesity (BMI > 30 kg/m^2) are associated with a better long term survival than normal weight (BMI between 20 and 25 kg/m^2). This finding sustained by empirical results on diseased and elderly people, is known as obesity paradox.

Material and method: We included, from January 2005 until July 2008, 244 patients hospitalized with heart failure (diagnosed according to Framingham criteria) at the Internal Medicine unit of a country hospital of Cantabria (Tres Mares Hospital at Reinosa); 115 were men and 129 women with an age range of 55 to 100 years (median age and quartiles of 85 and 79-89 years). Fourteen (5.7%) patients died during hospitalization. All patients were followed up by telephone with a median survival of 984 days. We compared survival between heart failure patients and whole population.

Results: Obese patients with a BMI over 30 kg/m^2 showed a better long term prognosis than those with a BMI 25-30 kg/m^2, than those with a BMI 20-25 kg/m^2 and than those with a BMI under 20 kg/m^2 (p < 0.001). We can observe a higher mortality in patients with heart failure than in general population. In this case the mortality is higher in all groups of heart failure patients, obese, overweighed and normal-low weight patients, but especially in those with low weight and old age.

Discussion: Our results confirm the obesity paradox hypothesis in a group of 244 elderly patients hospitalized by heart failure. As many studies have shown, some of them including thousands of patients, obese ones had a better survival, not only compared with those with a low BMI, but also with those with a normal BMI and with those with overweight. However, this better prognosis must be considered a relative finding, because it is so only when survival is compared between obese and non obese heart failure patients, but not if we compare obese heart failure patients with the whole population. In this case mortality is higher in all groups of heart failure patients, obese, overweighed and normal-low weight patients, but especially in those with low weight and old age.

Conclusions: Our results confirm the obesity paradox hypothesis in a group of 244 elderly patients hospitalized by heart failure, but this better prognosis must be considered a relative finding.

IC-6
CONTINUOUS INFUSION OF FUROSEMIDE IN THE TREATMENT OF HEART FAILURE AT HOME

M. Matesanz David, M. Rodríguez Cerrillo, A. Iñurrieta Romero, E. Fernández Díaz, A. Poza Montoro

Department of Home Hospitalization. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: Describe our experience in the treatment of patients with acute heart failure (AHF) using continuous infusion of furosemide administered by the Hospital at Home Unit.

Material and method: Retrospective study including all patients over 75 years old admitted to Hospital at Home (HaH) Unit in 2011 diagnosed with AHF who needed to be treated with intravenous continuous infusion of furosemide administered using an electronic infusion pump. Patients had not improved with intermittent doses.

Results: 55 patients were treated with intravenous furosemide. 11 patients (20%) required continuous infusion. Mean age was 88 years. 62.5% were male. 25% were diagnosed with dyastolic AHF and 75% with systolic AHF. All patients had NYHA class III. 87.5% were diagnosed with atrial fibrillation, 37.5% had chronic renal failure, 75% high blood pressure and 37.5% diabetes mellitus. The initial dose of furosemide was 80 mg in 87.5% of patients. The

maximum daily dose was140 mg. Mean duration of treatment was 6 days (3-12). Two patients developed hypokalemia, it was corrected with oral potassium. One patient experienced a transient increase in serum creatinine. All patients had a good outcome. None of the patients was transferred to hospital.

Discussion: Patients with acute heart failure treated in HaH with intravenous boluses of furosemide had to be transferred to hospital if clinical condition did not improve. The efficacy of continuous infusion allows treating these patients at home.

Conclusions: Treatment of patients with acute heart failure using continuous infusion of furosemide at home is safe and effective.

IC-7
RED BLOOD CELL DISTRIBUTION WIDTH, IN-HOSPITAL COMPLICATIONS AND PROGNOSIS IN A SPANISH COHORT OF ELDERLY PATIENTS WITH ACUTE DECOMPENSATED HEART FAILURE

J. Satué Bartolomé[1], A. Pérez Martín[1], E. Álvarez Santás[2], J. Belinchón Paraíso[1], J. Marrero Francés[1], S. Gonzalo Pascua[1], A. Bermejo Rodríguez[2], A. Zapatero Gaviria[1]

[1]Department of Internal Medicine, [2]Department of Clinical Laboratory. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: A strong association has been recently identified between Red Blood Cell Distribution Width (RDW) and adverse outcomes in patients with heart failure (HF). The aim of this study was to analyze the influence of RDW on in-hospital complications and mortality after discharge in elderly patients with a HF diagnosis.

Material and method: 74 patients aged 70 years old and over, discharged alive with a diagnosis of acute decompensated heart failure from our Internal Medicine Department, were prospectively recruited between February and April 2007. Data collection was carried out during hospitalization and included sociodemographic characteristics, comorbidity (Charlson index), Barthel and Pffeifer scores, cardiovascular risk factors, clinical, hematological, biochemical and echocardiography findings, in-hospital complications and treatments at discharge. RDW was determined on admission and classified as high if it was over the normal upper limit of 15%. Mortality follow up was carried out at 12 and 24 months after discharge through telephonic interview and electronic medical record review.

Results: Mean age was 81.4 (SD 6.5) years; 70% were women. 80% had a previous history of hypertension, 42% of diabetes, 25% of ischemic heart disease (IHD), 30% of dyslipidemia and 20% of chronic kidney disease. Heart failure was attributed to hypertensive cardiomiopathy in 32%, valvular disease in 21% and IHD in 17% of cases. The primary cause of decompensation was acute infection in 43%, hypertensive crisis in 10%, arrhythmia in 10% and dietary or therapeutic transgression in 8% of patients. LVEF was preserved in 74% of patients. In-hospital complications developed in 48% of patients, most of them being respiratory failure (45%), renal failure (26%), delirium (7%) and hyperkalemia (5%) High RDW was found in 47/74 (63.5%) of our patients. It was statistically associated ($p < 0.05$) with male genre, low albumin, low total cholesterol, low relative lymphocyte count and dyslipidemia. No other cardiovascular risk factors, comorbidity, functional status, cognitive status, basal cardiomiopathy or decompensation cause were associated with high RDW. High RDW was statistically associated with in-hospital complications: 40.4% (19/47) patients with high RDW suffered from any complication vs only 7.4% (2/27) patients with normal RDW. Relative Risk (RR) 5.5 95%CI (1.38-21.6) ($p < 0.01$). Two-year crude mortality was 18.9% (14/74 patients). Mortality in patients with high RDW was 21.3% (10/47) vs 14.8% (4/27) in those with normal RDW. RR 1.4 (0.5-4.1)($p = 0.4$). In patients with normal RDW aged over 80 years, mortality was 5.9% (1/17) while high RDW mortality was 27.6% (8/29). Risk difference +21.7% 95%CI (2.0-41.4%) mortality in patients between 70-79 years with normal RDW was 30% (3/10), while high RDW mortality in the same age group was 11.1% (2/18). Risk difference for this strata -18.9% 95%CI (-50.8 to 13.0%). ($p = 0.04$).

Conclusions: In our HF patients, High RDW was related to another prognostic laboratory parameters, and to a higher risk of in-hospital complications. Two-year crude mortality was increased for patients with high RDW, but not reaching statistical significance. We detected an interaction between age and RDW with statistical significance: In the oldest patients, high RDW was significantly associated with increased mortality, but it showed a protective effect in patients between 70 and 79 years. Scarce number of patients can be responsible for this differential association of RDW with mortality influenced by age.

IC-8
ADVANCED HEART FAILURE TREATED WITH SUBCUTANEOUS FUROSEMIDE: DESCRIPTIVE ANALYSIS

J. Galindo Ocaña[1], J. Romero Mena-Bernal[1], J. Castillo Ferrando[2], C. Aguilera González[1], J. Garrido Nieto[1], M. Rincón Gómez[1], A. Fernández López[1]

[1]Department of Internal Medicine, [2]Department of Clinical Pharmacology. Hospital Virgen del Rocío. Sevilla, Spain.

Objectives: Subcutaneous furosemide is an off-label palliative treatment feasible for patients with decompensated advanced heart failure who want to be attended in their homes, thus avoiding hospitalisation. To determine the clinical features of patients attended at home with subcutaneous furosemide because of decompensated heart failure.

Material and method: Cross-sectional study. Inclusion criteria: older than 18 years, heart failure, class III or IV NYHA, treated at home with subcutaneous furosemide (SCF) by a Southern Spanish university hospital at home unit. All episodes of decompensated heart failure (DHF) consecutively attended at home between January 2008 and January 2012 were included for analysis. Qualitative variables were described as number or percentages, quantitative variables were described as mean (SD; range) or median (IQR).

Results: 34 consecutive episodes in 17 patients suffering of decompensated advanced heart failure were included. 11 patients were female (64.7%) and their mean age was 82.94 (7.004). Mean number of hospitalisations in the previous year was 3.294 (2.974; range 0-10), and mean number of emergency departments consults in the previous year was 4.588 (5.466; range 0-23). The mean number of episodes treated with SCF per patient was 2 (1.969; range 1-7), and mean hospital admissions was 1.353 (3.04; range 0-9). Every patient was polypathological, having a mean number of clinical categories of 3.706 (0.772; range 2-5). The mean Barthel Index score was 37.353 (19.455; range 0-70). These patients received a mean number of drugs/patient of 11.563 (5.91; range 3-22). A 50% received ACEI, 25% RAA, 43.8% beta-blockers, 31.3% spironolactone, 18.8% SABA, 25% LABA, 18.8% SAMA, 25% LAMA, 33.8% anticoagulation, 20% aspirin and 10% clopidogrel. These patients received a mean total SCF dose of 932.941 (717.677) mg/episode, and mean daily dose of 161.025 (77.573; range 80-280) mg/day. 8 patients in 20 episodes (58.8%) received a higher than 120 mg/day dose and 7 patients (47.1%) higher than 160 mg/day dose. The mean length of stay per episode was 17.235 (18.863; range 1-69) days, mean number of hospital admissions after the episode was 1.3 (1.636; range 0-4), and mean number of emergency departments consults after was 1.4 (2.459; range 0-8). There were 5 adverse events leading to stop SCF: 3 hematomas, 1 severe local skin infection and one drip removal. At discharge, in 21 episodes patients were followed-up by Primary Care (61.8% of 34 episodes)

and in 2 they were admitted at a hospital ward. 14 died during the period of study (82.4%), accounting for a mean survival time of 191.3 (311.653; range 5.28-1161.49) days.

Discussion: Subcutaneous furosemide is an off-label palliative treatment feasible for patients with decompensated advanced heart failure who want to be attended in their homes, thus avoiding hospitalisation. Clinical essays are needed to establish efficacy and safety of subcutaneous furosemide and allow the subcutaneous route of administration approval.

Conclusions: In the last 4 years, the persons with decompensated advanced heart failure treated with subcutaneous furosemide in our area were mostly female older people who were admitted in multiple occasions to a hospital ward, with high degrees of disability and polymedicated polypathological patients. Subcutaneous furosemide may be a safe feasible alternative for advanced heart failure symptomatic treatment and may avoid numerous hospital admissions in this frail disabled population.

IC-9
ADVANCED HEART FAILURE TREATED WITH SUBCUTANEOUS FUROSEMIDE OR CONVENTIONAL TREATMENT: COMPARISON OF CLINICAL FEATURES BETWEEN BOTH GROUPS

J. Galindo Ocaña[1], J. Romero Mena-Bernal[1], J. Castillo Ferrando[2], C. Aguilera González[1], M. Rincón Gómez[1], M. Bernabeu Wittel[1]

[1]Department of Internal Medicine, [2]Department of Clinical Pharmacology. Hospital Virgen del Rocío. Sevilla, Spain.

Objectives: To compare the clinical features of patients treated with subcutaneous furosemide (SCF) at home because of decompensated advanced heart failure (AHF) with those of patients treated with conventional intravenous route of administration (IVF).

Material and method: Retrospective cohort observational study. Older than 18 years patients with heart failure, treated at home with SCF by a hospital at home unit or on hospital ward with IVF in a southern Spanish university hospital were recruited. All episodes of decompensated AHF consecutively attended at home between January 2008 and January 2012 were recruited. Patients attended on wards were selected randomly to be included. Qualitative variables were compared through Chi-square and binary logistic regression analyses and quantitative variables through parametric (Student's t test) or non-parametric (Mann-Whitney's U for median comparison) analyses.

Results: 34 vs 63 consecutive episodes in 17 vs 27 patients suffering of decompensated AHF were compared (SCF/IVF groups). No sex differences were found (female patients 64.7% vs 58.7%; p = 0.362). Significant differences were found for mean age (SCF 82.94 ± 7.004 vs IVF 81.85 ± 7.156; p = 0.000), mean Barthel Index (SCF 31.912 ± 18.049 vs IVF 43.651 ± 32.518; p = 0.024), mean daily dose (SCF 170.807 ± 71.29 vs IVF 130.422 ± 78.031 mg/day; p = 0.012), median [IQR] number of hospital admissions in the last year (SCF 2 [2.75] vs IVF 2 [4]; p = 0.000), median hospital length of stay (SCF 12 [8] vs IVF 7 [7]; p = 0.001) and number of emergency department consults during the last year (SCF 1 [3.25] vs IVF 4 [4]; p = 0.017). However no differences were found for number of clinical diagnostic categories of polypathological patient (PP) (p = 0.099), NYHA class (p = 0.228), number of hospital admissions in the last year (p = 0.383), hospital readmissions and emergency department consults during the next year (p = 0.941 and p = 0.088 respectively), number of drugs/patient (p = 0.699) at inclusion or at discharge (p = 0.956), mean total dose (SCF 878.824 ± 593.846 vs IVF 891.175 ± 762.195; p = 0.281), or time to die after discharge (p = 0.508). Several qualitative variables differed significantly: % patients with neurologic disease with motor handicaps and severe disability (p = 0.035), advanced dementia (OR 6.154, 95%CI 1.511-25.066; p = 0.008),% symptomatic diabetic retinopathy or neuropathy (OR 0.345; 95%CI 0.117-1.02; p = 0.038),% anaemia (OR 18.881; 95%CI 3.932-90.674; p = 0.000), disabling osteoarthritis (OR 5.6; 95%CI 1.977-15.861; p = 0.001), oxygenotherapy (50% vs 81%; OR 4.25; 95%CI 1.693-10.67; p = 0.002) or anticoagulation (26.5% vs 71%; OR 6.79; 95%CI 2.656-17.360; p = 0.000). Only one patient was treated in a ward with SCF. No differences were found between ward and hospital at home for main symptoms, failure of treatment because agony (14.7% vs 6.3%; p = 0.3), death during stay (p = 0.231), evidence-based treatments (ACEI, RAA, beta-blockers, spironolactone), antiagreggation and other features. Furosemide doses were considerably higher at homes, 51.6% received > 160 mg/day at homes vs 48.4% on wards (OR 0.352; 95%CI 0.145-0.855; p = 0.018). However, time to improve symptoms was much lower on wards, as a 76% of episodes needed more than 8 days to improve at homes with SCF vs a 29.2% at wards with IVF (OR 0.130; 95%CI 0.43-0.394; p = 0.000). Survival time did not differ significantly between the two cohorts. Median survival among SCF treated patients (median [IQR]) was 91.309 [172.8] vs IVF treated patients 83.455 [276.873] (p = 0.937).

Conclusions: Similar clinical features were found between patients with advanced heart failure treated at home with subcutaneous furosemide or on ward with intravenous furosemide. Slight differences with lower age, higher Barthel Index score, higher total furosemide dose per episode, but interestingly no difference in survival time although it was a bit worse among admitted patients.

IC-10
FACTORS ASSOCIATED WITH MORTALITY IN PATIENTS WITH ADVANCED HEART FAILURE TREATED AT HOME WITH SUBCUTANEOUS FUROSEMIDE OR AT WARDS WITH INTRAVENOUS FUROSEMIDE

J. Galindo Ocaña[1], J. Romero Mena-Bernal[1], J. Castillo Ferrando[2], S. García Morillo[1], C. Aguilera González[1], R. Parra Alcaraz[1], M. Bernabeu Wittel[1], A. Fernández López[1]

[1]Department of Internal Medicine, [2]Department of Clinical Pharmacology. Hospital Virgen del Rocío. Sevilla, Spain.

Objectives: To determine which variables are associated with mortality among patients with advanced heart failure treated with parenteral furosemide at home (subcutaneous, SCF) versus on wards (intravenous, IVF).

Material and method: Observational cohort study. Inclusion criteria: older than 18 years, heart failure, class III or IV NYHA, treated at home with subcutaneous furosemide (SCF) by a hospital at home unit or at hospital ward with intravenous furosemide (IVF) in a Southern Spanish university hospital. All patients with decompensated heart failure (DHF) consecutively attended at home between January 2008 and January 2012 were recruited. Hospitalised patients were selected randomly to be included. Clinical data, including comorbidities, functional evaluation by means of the Barthel Index, drug treatments and furosemide doses were considered. Survival Cox regression univariate and multivariate analyses and Kaplan-Meier curves with log-rank test were performed. SPSS 20.0 was used.

Results: 34 consecutive episodes in 17 patients treated with SCF vs 63 random episodes in 27 patients suffering of decompensated advanced heart failure (SCF/IVF groups) were included for analyses. In univariate Cox regression analysis, being attended at home did not show any significant difference in mortality with healthcare at wards (HR 0.990; 95%CI 0.602-1.673; p = 1.003). Mantel-Cox's log rank test showed similar results (p = 0.861). In multivariate Cox regression analyses, Barthel index score showed a significant effect on survival (aHR 0.981; 95%CI 0.965-0.996; p = 0.015), as did cardioselective beta-blocker treatment (aHR 2.79; 95%CI 1.089-

7.147; p = 0.032), adjusted to ward/home treatment (aHR 0.905; 95%CI 0.391-2.094), chronic lung disease (aHR 0.279; 95%CI 0.391-2.094; p = 0.323), chronic kidney disease (aHR 0.629; 95%CI 0.357-1.107; p = 0.108), chronic anaemia (aHR 0.591; 95%CI 0.262-1.330; p = 0.151), disabling osteoarthritis (aHR 1.923; 95%CI 0.787-4.697; p = 0.151) and number of received drugs (aHR 0.982; 95%CI 0.908-1.062; p = 652). ACEI or RAA treatment, spironolactone, anticoagulation, antiaggregation, long or short acting inhaled beta-agonists and long or short acting inhaled muscarinic antagonists or mean dose of furosemide did not influence the model.

Discussion: The limitations of this study, mainly small sample size and being an observational study should be aware. These are very preliminary results, but offer additional information about off-label palliative treatment of symptoms for older patients with advanced heart failure who desire to be attended in their homes in comparison with conventional healthcare standards. 33 hospital admissions were avoided in very old frail disabled patients.

Conclusions: A lower disability measured by the Barthel Index and treatment with cardioselective beta-blockers associated to lower mortality rates among patients with advanced heart failure admitted to hospital wards or hospital at home units.

IC-11
DOSE-EFFECT RESPONSE OF FUROSEMIDE ADMINISTERED BY SUBCUTANEOUS OR INTRAVENOUS ROUTE

J. Galindo Ocaña[1], J. Romero Mena-Bernal[1], J. Castillo Ferrando[2], S. Gutiérrez Rivero[1], M. Bernabeu Wittel[1], C. Aguilera González[1], A. Fernández López[1], M. Ollero Baturone[1]

[1]Department of Internal Medicine, [2]Department of Clinical Pharmacology. Hospital Virgen del Rocío. Sevilla, Spain.

Objectives: To determine the effects of parenteral furosemide dose amount on hospital length of stay and time to symptom improvement among patients with advanced heart failure treated on wards (intravenous route of administration, IVF) or in their homes (subcutaneous route of administration, SCF) by a hospital at home unit.

Material and method: Retrospective cohort observational study. All consecutive cases of advanced (class III or IV NYHA) heart failure treated with subcutaneous furosemide at home during a 4 year period were matched with randomly selected cases treated with intravenous furosemide at ward. Analysed variables were: initial dose, total dose, mean daily dose, time to symptom recovery and length of hospital stay. Correlations and univariate lineal regression analyses were performed to assess association between variables.

Results: 34/63 episodes were treated with SCF/IVF. The mean initial dose of furosemide was 175.294 (70.076) mg in SCF group vs 122.206 (99.085) mg in IVF group. The medians [IQR] of initial dose were 160 [130] and 80.0 [100] mg respectively (p value = 0.000). The mean total dose/episode was 878.824 (593.846) mg in SCF vs 891.175 (762.195) mg in IVF group. The median [IQR] total dose/episode were 720 [645] and 720 [880] mg respectively (p value = 0.666). The mean number of treatment days/episode was 5.441 (3.007) in SCF vs 7.079 (4.916) in IVF group. Mean time to symptom recovery was 17.24 (15.56) days in SCF vs 7.583 (4.462) days in IVF group. The medians [IQR] of time to symptom recovery were 13 [11.5] and 7 [6] days respectively. The medians of length of stay were 12.5 [8] and 7 [7] days respectively. There was a significant difference between medians of daily dose among the SCF/IVF groups 160/103.75 [151/102.095] (p = 0.004). Initial dose of SCF in patients treated at home inversely correlated with length of stay (Pearson coefficient = -0.426; p = 0.006) and these variables were lineally associated (t = -2.667; p = 0.012), as did also inversely with time to symptom recovery (Pearson coefficient = -0.424; p = 0.017), which associated lineally (t = -2.243; p = 0.035). However, total dose/episode did not correlate with length of stay among patients treated with SCF at home (Pearson coefficient = -0.086; p = 0.628). Among hospitalised patients treated with IVF, initial furosemide dose did neither correlate with hospital length of stay (Pearson coefficient = -0.159; p = 0.107) nor with time to symptom recovery (Pearson coefficient = -0.146; p = 0.162), but total dose/episode correlated with length of stay (Pearson coefficient = 0.636; p = 0.000), which associated lineally (t = 6.439; p = 0.000). Moreover, total dose/episode correlated with time to symptom recovery (Pearson coefficient = 0.501; p = 0.000), and they associated lineally (t = 3.930; p = 0.000). Mean daily dose had a similar effect as initial dose on length of stay and time to symptom recovery (SCF t = -2.653; p = 0.012; IVF p = 0.689).

Discussion: These intriguing results may have a simple explanation. As SCF at homes used to be initiated at high doses, and IVF at hospital wards are administered in an increasing way, total doses result finally in similar amounts of furosemide total dose per episode. At home, the highest dose, the shorter time to symptom remission and the shorter length of stay would result. Also, as SCF is usually administered by continuous infusion, it might result in better outcomes, as suggested by Smits and Dormand's essay (JACC. 1996;28:376-82).

Conclusions: These preliminary results show a lineally associated dose-response effect of subcutaneous furosemide in terms of shorter time needed to improve advanced heart failure patients' symptoms and thus in a shorter length of stay. Total dose per each episode did not significantly differ between the two modalities of treatment.

IC-12
HOW TO REDUCE READMISSION IN CONGESTIVE HEART FAILURE (CHF)? GROUP FOLLOW UP VS CONTROL – 2011

E. Zubillaga, A. Eguiluz, K. Leizaola, M. Ibarguren, M. Elola, A. Fuertes, N. Pérez, M. Vaquero

Department of Internal Medicine. Hospital Universitario Donostia UPV/EHU. Guipúzcoa, Spain.

Objectives: To compare Readmission rates of discharged CHF patients (Group Follow up) from the Hospital, followed monthly telephonically by Hospitalists for 6 months and another Group of patients (Group Control) not beeing followed by hospitalists. We expected to reduce readmissions because better pharmacological compliance and non-pharmacological measures and better quality of care provided after better co-management monthly.

Material and method: In 2011, we asked our Medical Record Department to provide us all the 519 CHF patients discharged from July till December 2010. Randomly, 259 of them were followed telephonically monthly during 6 months (Group Follow up), the other 260 patients were Group Control. Each patient was followed by the same Internist. In the Group follow up, 62 patients were excluded because (24 died prior to inclusion, 19 were not available in the provided phone, 16 refused, 3 were non CHF); thus, we surveyed 197 patients monthly. In the Group Control, 39 were excluded for similar reasons. 221 were followed at the end of the 6 month period; they were not followed monthly.

Results: The patients' characteristics are shown in another Poster and were similar in both Groups. Below we express the admissions the 6 months before the study and the following 6 months either with telephonically Follow up or not.

Discussion: After Hospital discharge of CHF patients, the transitional care interventions and continuity of care recommends periodic follow up either by primary physicians or/and co-managed by Hospitalist. The better quality provided and patient well being should follow less readmission for CHF reagudizations.

Conclusions: The monthly telephonic follow up after CHF discharge did not reduce readmissions (p = 0.06) the following 6 months compared with the patients not being followed. There is

Table (IC-12)

	Admission previous 6 months	Readmission next 6 months
Group Follow up (197 patients)	204 admissions	74 admissions. 18 deaths (64% reduction)
Group Control (221 patients)	267 admissions	100 admissions. 17 deaths. (63% reduction)

p = 0.06

always a reduction after discharge comparing with the 6 months before de study.

IC-13
THE WEEKEND EFFECT ON HEART FAILURE ADMISSIONS

R. Barba[1], M. Yebra[1], A. Asenjo[1], D. Joya[1],
C. González de Villaumbrosia[1], J. Marco[3], A. Zapatero[2]

[1]Department of Internal Medicine. Hospital Rey Juan Carlos. Móstoles (Madrid), Spain. [3]Department of Internal Medicine. Hospital Clínico San Carlos. Madrid, Spain. [2]Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: The management of patients admitted on weekends may be compromised because the level of staffing in the hospital is often lower on these periods. This study was conducted to assess what independent influence, if any, weekend admission might have on in-hospital mortality in patients with heart failure (HF).

Material and method: The study included all patients admitted to an acute care hospital of the Public Health Service through an emergency department in Spain between 1st January 2006 and 31st December 2007 with heart failure as the primary reason for admission. We analyzed the clinical data of 257,729. Cases were selected if they were discharged with the diagnosis of heart failure (code DRG 127: Heart failure; DRG 87: Pulmonary edema & respiratory failure, or DRG 544: CHF & cardiac arrhythmia with major CC; DRG-AP.21 version). The relative weight of these DRG was 1.5409, 1.6033 and 3.5968 respectively. We also identify the primary diagnosis of HF using ICD-9-MC codes in the primary diagnosis field: 398.91, 404*, 402.11, 402.91, 428-428.9. The overall mortality according to whether a patient was admitted on a weekend or a weekday was taken into account.

Results: The mean age of the patients was 76.8 years (SD, 11.2); 52.2% of the patients were women. The mean stay was 8.9 days (SD, 7.6). A CCI ≥ 2 was present in 31.1% of the cases. Overall, 22.7% (58.378) of the patients were admitted on weekends, and 199,340 (77.3%) admitted on weekdays. A total of 27,217 (10.6%) patients died during hospital stay. Compared to those seen on weekdays, those seen on weekends had a higher case fatality (11.4% vs 10.3%; OR 1.12 95%CI 1.08-1.15). After adjusting for age, sex, hospital bed size, comorbid conditions, and CCI we found that the odds of death with admission during a weekend were 8.3% higher than during a weekday (adjusted odds ratio [OR] 1.08 95% confidence interval [CI] 1.05-1.11). Analyses of deaths within two days after admission, rather than total in-hospital deaths, generally showed larger relative differences in mortality between weekend and weekday admissions. There was a small increase in mortality among patients admitted do a weekend (3.6% vs 2.9%, OR 1.25 95%CI 1.19-1.32). After adjusted by potential confounder there was a 20% increase in early mortality among patients admitted on a weekend (OR 1.20 95%CI 1.14-1.27).

Discussion: The study demonstrated that HF admissions were more frequent on Monday and least on Sunday, and patient admitted to hospitals via the emergency wards on weekends had an increased risk of dying (8.3%) when compared with patients admitted on weekdays. This excess mortality was independent of age, gender and co-morbidity. An excess of 8.3% in weekend mortality means than 1283 (95%CI 773-1701) HF patients die annually in Spain due to weekend effect.

Conclusions: An increase of in-hospital death was found in patients admitted on weekends compared with weekday even when adjusted for potentially confounding characteristics. Further studies are needed to reveal the possible underlying causes. Quality improvement strategies can then be developed and implemented to standardize care across admission day.

IC-15
ODIMET, KEY TO A NUTRITIONAL STUDY IN HEART FAILURE? CASE-CONTROL SERIES

C. Josa Laorden, M. Matía Sanz, C. Gómez del Valle,
M. Bucar Barjud, B. Amores Arriaga, M. Aibar Arregui,
M. Torralba Cabeza, J. Pérez Calvo

Department of Internal Medicine. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: Malnutrition has a negative prognostic role in patients with acute heart failure (AHF). This phenomenon is being known as "paradoxical effect of obesity" or "the reverse epidemiology of conventional risk factors" in heart failure. ODIMET is a tool designed in web format that allows to calculate nutritional requirements and calories adjusted to every patient. The objective of this study is to evaluate whether this new tool is useful in daily hospital activity.

Material and method: Observational study, case-control series, where we analyzed 20 patients admitted for AHF in Lozano Blesa University Hospital, in Zaragoza, during the period from February to May of 2012, as well as 20 control patients admitted for other pathologies. Patients have been consulted to remember their diet for 24 hours before hospital admission, and analysing them with the program Organizer Metabolic Dietary ODIMET. Both were carried out nutritional test Mini Nutritional Assessment (MNA), which determine the patient's nutritional status. Ultimately, we have analyzed blood parameters, including protein markers: prealbumin and retinol binding protein (RBP). Patients with cognitive impairment were excluded. The statistical analysis has been made with JMP 8 program (ANOVA test).

Results: 47% of the total patients were female (N = 19) and 53% were male (N = 21). The mean age was 77 years, range from 52 to 90 years old. Patients with AHF have a total daily protein intake significantly lower (p = 0.03), with an average of 65 g in cases and 79 g in controls. The consumption of some essential amino acids such as arginine (p < 0.01), histidine (p = 0.0005), methionine (p = 0.009) and threonine (p = 0.0005) were significantly lower in patients with heart failure. No differences were observed in the rest of the essential amino acids or the total consumption daily kilocalories. Patients with AHF have significantly lower prealbumin value than controls (p = 0.028), not so the RBP (p = 0.118). 55% of the cases had a MNA score located in the range of risk of malnutrition, compared with 30% of the controls.

Discussion: Paradoxically, obesity, hypercholesterolemia and hypertension have been associated with less morbidity and mortality in patients with HF. According to recently published literature, patients with HF and obesity have a better long-term prognosis with a higher survival. In this study we found that patients hospitalized for heart failure have a poorer nutritional status than other patients, mainly based on a lower intake of essential amino acids, which determines a protein malnutrition in these patients and the lower values of prealbumin. The organizer dietary ODIMET, commonly used in pediatrics, has become a very useful tool for

assessing the nutritional status of patients admitted to a hospital. It presents a greater interest in those in which malnutrition worsens their survival, as is the case of patients with heart failure. Our approach is to apply the simple survey ODIMET introducing food and dose ingested over 24 hours by a patient, resulting in more than 60 items, which include the amount of amino acids, carbohydrates, fats, vitamins and minerals that consume our patients. With these results, it is easier to approach to their nutritional status, privileged information of their comorbidities and survival.

Conclusions: ODIMET is a new tool that can assess more accurately the nutrition status of patients with heart failure with a simple, easily applicable, reproducible, inexpensive and noninvasive test, thus providing us key information for treatment, evolution and prognosis of these patients.

IC-16
ADVANCED HEART FAILURE IN INTERNAL MEDICINE: THE ROLE OF ESC DEFINITION AND COMORBIDITIES

N. Muñoz Rivas[1], M. Méndez Bailon[1], J. Ortiz Alonso[2], S. Nieto[2], L. Audibert Mena[2]

[1]Department of Internal Medicine. Hospital Universitario Infanta Leonor. Madrid, Spain. [2]Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: To evaluate clinical prognostic value of ESC Advanced Heart Failure Definiton (AHFD) in elderly patients with HF, not preselected by their ejection fraction and other predicting factors of mortality.

Material and method: 270 elderly patients with chronic HF were included in a multidisciplinary HF programme managed by nurses and internal medicine physicians. All patients were evaluated retrospectively if they fulfilled AHFD. We compared baseline characteristic between survivors and non survivors. We used t student test and chi-square ($p < 0.05$). A Kaplan Meier survival mortality curve was performed comparing advanced and non advanced HF patients (ESC 2007 definition).

Results: Mean age was 78 ± 9 years and 58% were women. 54% of them have an ejection fraction < 50%. 45 patients fulfilled ESC AHFD (16%). Clinical characteristics associated to mortality between survivors and non survivors during follow up were, respectively: OARS functional status (10.3 ± 4.3 vs 8.1 ± 1.2; $p = 0.029$), Charlson comorbidity index (2.8 ± 1.6 vs 4.0 ± 2.6; $p < 0.001$), haemoglobine (g/dl) (12.6 ± 1.9 vs 11.9 ± 1.9 $p = 0.02$) creatinine (mg/dl) (1.21 ± 0.51 vs 1.48 ± 0.56; $p = 0.02$) and advanced HF by the ESC 2007 definition (8% vs 54% $p < 0.001$). Advanced HF patients have the lowest time to survival during follow up ($p < 0.001$).

Discussion: ESC AHFD is useful predicting mortality in elderly patients with chronic HF not preselected by their ejection fraction. Other comorbidities (ex. functional status, anemia and renal dysfunction) should be considered in the prognosis of elderly patients with advanced HF.

IC-19
N-TERMINAL PRO BRAIN NATRIURETIC PEPTIDES AND HIGH-MOBILITY GROUP BOX-1 IN HEART FAILURE

I. Francisco[1], A. Armengou Arxé[1], J. Roure Fernández[2], J. Fernández Real[2], L. García Garrido[3], J. Moreno Navarrete[4], A. Castro Guardiola[1], F. García-Bragado Dalmau[1]

[1]Department of Internal Medicine, [2]Department of Cardiology, [3]Department of Endocrinology, [4]IDIBGI. Hospital Universitari Dr. Josep Trueta. Girona, Spain.

Objectives: High mobility group box-1 (HMGB-1) is a nuclear binding protein with a high affinity for the receptor for advanced glycation end products (RAGE). An HMGB1 -RAGE interaction has been implicated in cardiac dysfunction and the complications following ischaemia-reperfusion injuries. Our aim was to analyze the levels of HMGB-1 in patients with heart failure and their relationship with NT-proBNP.

Material and method: Sixty-four consecutive patients at the Heart Failure Unit of the Doctor Josep Trueta University Hospital of Girona from March 2011 to August 2011. Exclusion criteria included descompensation over the last month, neoplastic diseases and immune disorders. Age, sex, smoking, alcohol consumption, cardiovascular risk factors, and current medication were recorded. A transthoracic cardiac ultrasound was performed where no recent study had been undertaken. An LVEF > 45% was considered as preserved. Statistical analyses were performed with SPSS V.15.0 for Windows.

Results: Main baseline characteristics are presented in Table 1. HMGB1 was positively associated with basal glycaemia and triglyceride. HMGB1 negatively correlated with brain natriuretic peptides (Spearman's $r = -0.237$ and $p = 0.059$). HMGB1 did not correlate with aetiology of heart failure or NYHA functional class.

Discussion: This study finds an inverse correlation between HMGB-1 and natriuretic peptides. These results do not concord with results presented by other groups. A possible explanation of this discrepancy may be that HMGB-1 levels are conditioned by factors such as the aetiology of the heart failure, comorbidities and treatments.

Conclusions: The association of Nt-proBNP with HMGB1 in patients with heart failure is not clear, and the role of HMGB1 itself in patients with heart failure remains controversial. The present results lend support to HMGB1 being an inhibitor of brain natriuretic peptide RNA.

Table (IC-19). Some baseline clinical characteristics of patients studied

New York Heart Association classes III to IV	37.5%
Depressed left ventricular ejection fraction	57.8%
Estimated glomerular filtration rate < 60 ml/min	40.7%
HMGB1	2.26 ± 1.19
NT-proBNP (pg/nl)	1,808.19 ± 2,086.82
Basal glucose (mg/dL)	112.81 ± 28.84
Triglyceride	134 ± 55.89

IC-20
IMPACT OF MEDICAL TREATMENT OF HEART FAILURE ON RENAL FUNCTION

J. López Castro[1], L. Cid Conde[2], R. Almazán Ortega[3]

[1]Department of Internal Medicine, [2]Department of Pharmacy. Hospital Comarcal Valdeorras. Barco de Valdeorras (Ourense), Spain. [3]General Subdirectorate of Promotion of Healthy Lifestyles Programs. Dirección Xeral de Innovación e Xestión da Saúde Pública. Santiago de Compostela (A Coruña), Spain.

Objectives: The purpose of this study was to analyze the impact of the drugs used to treat heart failure (HF) on renal function.

Material and method: A descriptive, observational and prospective study was performed including patients with primary or secondary diagnosis of HF, according to clinical and echocardiographic criteria, admitted to either medical or surgical hospital between 1999-2002, in the era of pre-beta-blockers. The sample size was calculated with EPIDAT 2.0. The clinical and pharmacotherapeutic histories were reviewed. The study variables were: demographics (age and sex), services involved, residence,

functional class (FC) NYHA (New York Heart Association), prescribed treatments (antiplatelet agents, oral anticoagulants, nitrates, beta-blockers, calcium channel blockers, digitalis, diuretics (not sparing potassium), spironolactone, angiotensin converting enzyme inhibitors (ACEIs) and angiotensin receptor blockers (ARBs). Were determined the values of creatinine (pathologic > 1.5 mg/dL) and calculated glomerular filtration rate (GFR) according to the formulas for the Modification of Diet in Renal Disease (MDRD) (pathological < 60 mL/min/1.73 m^2). For the construction of the database and statistical analysis was performed using SPSS 15.0.

Results: A total of 384 patients we analyzed, 205 (53.4%) and the mean age was 74.84 years (age range 36 to 95 years). 75% of the patients belonged to the rural population. Most patients had been admitted to the cardiology (51.6%) and internal medicine (39.8%). Most of the patients were placed in the FC II of NYHA prior to hospitalization (39.8%). The laboratory tests showed creatinine rates average 1.34 (95%CI 1.24 to 1.43) and MDRD of 60.20 (95%CI 57.67 to 62.67%). Of the 384 patients evaluated, 26% had creatinine values > 1.5 mg/dL (higher creatinine levels were observed in patients admitted to internal medicine) and 53.9% (28.3% of women and 25.6% of men) showed values of MDRD < 60 mL/min/1.73 m^2. It was found that with increasing age decreases the values of MDRD ($p < 0.05$). The most frequently prescribed drugs were: diuretics not sparing K+ (84.4%), ACEIs (58.9%), antiplatelet agents (44%), nitrates (42.4%), digital (41.9%), anticoagulants oral (30.5%), spironolactone (23.4%), beta-blockers (16.4%), calcium channel blockers (12%) and ARBs (5.5%). Of all the drugs tested, higher creatinine levels (> 1.5 mg/dL) were found with ARBs (38.1%), nitrates (39.3%), beta-blockers and calcium channel blockers (27%), diuretics and antiplatelet agents (25%) and oral anticoagulants, spironolactone and ACEIs (22%). MDRD values < 60 mL/min/1.73 m^2 were higher with ARBs (61.9%), nitrates (59.3%), calcium channel blockers (59%), beta-blockers (51%), diuretics, and antiplatelet drugs (53%) and oral anticoagulants, spironolactone and ACEIs (50%). When comparing patients using ACEIs, ARBs, and nitrates compared to those not employed were found statistically significant differences ($p < 0.05$) in creatinine and MDRD (higher values of creatinine and lower values of MDRD with treatment).

Conclusions: The renal toxicity of some drugs used in the treatment of HF enhance renal impairment (ACEIs, ARBs...). Despite having a favorable prognosis, prevention must be the primary objective. It is advisable to start with low doses and monitoring of renal function at the beginning and during the first weeks of treatment, especially in elderly patients with comorbidities and polypharmacy. We should bear in mind that the sample was selected patients in the pre-beta-blockers. In conclusion, the elderly patients have a higher risk for kidney disease; the most widely used drugs in the treatment of heart failure were diuretics and ACEIs and some drugs used to treat HF affect specify renal function (ACEIs, ARBs and nitrates) compared with those not taking them.

IC-21
THERAPEUTIC COMPLIANCE IN CONGESTIVE HEART FAILURE (CHF): GROUP FOLLOW UP – 2011

U. Errasti, X. Kortajarena, A. Berroeta, M. Del Hierro, A. Aldalur, M. Balenciaga, A. Larrañaga, B. Román

Department of Internal Medicine. Hospital Universitario Donostia UPV/EHU. Donostia (Guipúzcoa), Spain.

Objectives: To answer questions about prescribed therapy, to improve pharmacological compliance and to reinforce non-pharmacologic strategies (diet, exercise, weight control, physical therapy, vaccines); as well as to have a reference physician and his/her telephone number to resolve problems if there were present, and fixing a face to face appointment in the outpatient clinics if necessary.

Material and method: In 2011, we asked our Medical Record Department to provide us all the 519 CHF patients discharged from July till December 2010. After randomization, 259 of them were followed telephonically monthly during 6 months (Group Follow up), and the other 260 patients were Group Control. Each patient was followed by the same Internist. In the Group Follow up, 62 patients were excluded because (24 died prior to inclusion, 19 were not available in the provided phone, 16 refused, 3 were non CHF); thus, we surveyed 197 patients monthly. In the Group Control, 39 were excluded for similar reasons. 221 were followed at the end of the 6 month period; they were not followed monthly.

Results: Data from Group Follow up: the mean age was 80.9 y. (SD 12), being 90 of them men. The BMI was 26.8 (DS4). The 91% of patients had written therapy and 15% of them received long term Chronic Oxygen Therapy. Low salt diet was followed by 77%. The 56% of them walked a minimum of 30 minutes daily. All of them followed prescribed therapy (mostly ACE inhibitors or ARBs, beta-blockers, spironolactones and diuretics). Admission in the previous 6 months and Readmissions the following 6 months were accounted and are shown in another Poster. An enquiry about degree of satisfaction was made and showed: 1 non-satisfied, 40% satisfied, 40% very satisfied, 10% excellent idea, 9% no answer. Several patients would wish to continue more follow ups.

Discussion: Follow up of discharged CHF patients by Hospitalists is considered a good clinical practice to assure quality, improve patient management, avoid co-morbidities, answer medical questions and improve treatment compliance.

Conclusions: The direct and personalized monthly phone call up to 6 months of discharged patients with CHF gives a transitional care and comprehensive follow up and continuity of care with general satisfaction, resolving questions about therapy, having clinical outpatient visits, and avoiding readmissions, and reinforcing good general non-pharmacological measures and therapeutic compliance.

IC-22
RESEARCH OF LIPIDEMIC AND OTHER RISK FACTORS FOR CARDIOVASCULAR DISEASE IN MALES AGED 30 TO 50 YEARS OLD IN THE REGION OF CENTRAL AND WEST MACEDONIA, GREECE

S. Patiakas[1], M. Douska[2], E. Doumpali[2], K. Rousos[3]

[1]Biopathological Laboratory. General Hospital of Kastoria. Kastoria, Greece. [2]Biopathological Laboratory. General Hospital of Filiates. Filiates Thesprotias, Greece. [3]Health Center o f Alexandia. General Hospital of Veria. Veria, Greece.

Objectives: To be researched the lipidemic profil and the other risk factors for cardiovascular disease (CVD) in the middle-aged male population, and to be assessed their role in 10- year risk for development of CVD.

Material and method: Material of the research was 112 male aged 30-50 years old, while the evaluation of the risk of development of CVD at the next decade, in all subjects with the relevant risk factors, was committed with the use of the risk lists "score European low risk ".

Results: 67% of the subjects declared their smoking habit. Obese and over weighted were 24%. The average value of BMI was 29.3 ± 3.6 Kg/m^2, while the systolic and the diastolic blood pressure had average values, respectively, 133 ± 10.1 mmHg and 81.5 ± 9.7 mmHg. Hyperlipidemia was established at 32% of the subjects. Increased Blood Pressure was established at 10%, while increased values of blood sugar were documented at 7% of the examined subjects. The average values of relevant biochemical parameters at the blood sample were: Total cholesterol 218 ± 38.5 mg/dl, HDL 46.5 ± 7.8 mg/dl, LDL 148.6 ± 37.8 mg/dl, triglycerides 133.8 ± 80.2 mg/dl, glucose 92.8 ± 10.6 mg/dl. Finally, the involvement of the

risk factors, separately, to the whole risk of the appearance of CVD was: smoking 49.5%, dyslipidemia 43.5% and increased blood pressure 4.7%.

Discussion: It is proved that the risk of CVD is apparently high at the middle aged males. This fact is concerning, taking into account, that the heart attacks at these ages are having high mortality rate because of the non- existing collateral blood circulation.

IC-23
NATRIURETIC PEPTIDES, OBESITY AND HYPERINSULINEMIA IN PATIENTS WITH HEART FAILURE

I. Francisco Albesa[1], A. Armengou Arxé[1], J. Roure Fernández[2], J. Fernández del Real Lemos[3], L. García Garrido[2], M. Montesinos Costa[4], A. Castro Guardiola[1], F. García-Bragado Dalmau[1]

[1]Department of Internal Medicine, [2]Department of Cardiology, [3]Department of Endocrinology, [4]Department of Clinical Analysis. Hospital Universitari Dr. Josep Trueta. Girona, Spain.

Objectives: Natriuretic peptides (BNP and NT-proBNP) are serum biomarkers for heart failure. Obesity has been associated with reduced levels of natriuretic peptides Obesity is also frequently accompanied by insulin resistance. The objective of the present study was to examine the association between obesity, insulin levels and natriuretic peptides in patients with heart failure.

Material and method: From March to August 2011 we included sixty-four consecutive patients who were visited in the Heart Failure Unit of the Dr Josep Trueta University Hospital in Girona. Descompensated patients were excluded. Age, sex, smoking status, alcohol consumption, cardiovascular risk factors, current medication were recorded. Patients were divided by BMI into underweight and normal weight (BMI < 25) overweight (25 to 30) and obese (> 30). A transthoracic cardiac ultrasound was performed on all patients. Statistical analyses were performed with SPSS V.15.0 for Windows.

Results: There were no differences in sex, age, diabetes, chronic kidney disease, dyslipemia, and treatments received. Hypertension was more prevalent in the obese group. Although without reaching significance, high levels of NT-proBNP were found in overweight and obese patients. Both basal insulin and the HOMA-IR were observed to have a significant direct correlation with NT-proBNP plasma levels.

Discussion: This study demonstrates that serum NT-proBNP is lower in patients with high basal insulin and high HOMA-IR. It is difficult to distinguish the specific contributions of obesity and insulin resistance as both conditions often coexist. The low levels of natriuretic peptides associated with metabolic syndrome may increase susceptibility to left ventricular hypertrophy, and this may explain why heart failure with preserved ejection fraction is more frequent in the obese. Increased visceral adipose may reduce natriuretic peptide levels, which may in turn contribute to continued obesity and insulin resistance.

Conclusions: In addition to obesity, it may well be interesting to take metabolic traits such as insulin levels into account when interpreting natriuretic peptide levels in patients with heart failure.

IC-24
COMPARATIVE STUDY ABOUT ATRIAL FIBRILLATION MANAGEMENT IN PATIENTS ADMITTED TO INTERNAL MEDICINE AND CARDIOLOGY

M. González Gómez[1], M. González García[1], E. Gaspar García[1], P. Mellado Delgado[2], A. Calvo Cano[1], R. Peña González[1], J. Nogales Asensio[2], D. Magro Ledesma[1]

[1]Department of Internal Medicine, [2]Department of Cardiology. Complejo Hospitalario Universitario de Badajoz. Badajoz, Spain.

Objectives: The aim of this study is to compare the clinical characteristics and therapeutic management of patients with atrial fibrillation (AF) getting into the Internal Medicine and Cardiology services, determining the degree of thromboembolism prophylaxis, factors associated with their use and adaptation to clinical guidelines.

Material and method: Based on a previous study in which we review the discharge reports of 100 patients admitted with AF in the Internal Medicine department during the months of August and December 2010, we have compared these with the discharge reports of 100 patients admitted with the same pathology in the Cardiology department during the same period of time.

Results: Most relevant clinical characteristics of both groups are shown in Table 1. We also analyzed heart failure history, ischemic heart disease, thyroid dysfunction and renal failure and found no statistically significant differences. Respect to therapeutic management, cardiologists performed more electrical cardioversions (21 vs 1, $p < 0.001$). The most widely used antiarrhythmic in both services were beta-blockers (Internal Medicine 39%, Cardiology 44%). We use CHA2DS2-VASc scale to determine the anticoagulation need for thromboembolism prophylaxis, and we found that Internal Medicine appropriate prophylaxis was performed in 71% of cases, versus 82% in Cardiology (p 0.067). According to HAS-BLED scale to calculate bleeding risk, 64% of patients admitted to internal medicine were high risk, compared to 35% of cardiology patients ($p < 0.001$).

Discussion: According to clinical guidelines, every patient with CHA2DS2-VASc ≥ 2 should receive oral anticoagulation. In both study populations there is a percentage of patients who don't receive proper thromboembolism prophylaxis (Cardiology: 18% versus 29% of Internal Medicine), finding no significant relation with bleeding high risk, advancing age, score on CHA2DS2-VASc scale or previous thromboembolism history. There is statistically significant association, in both study groups, with AF type, being more anticoagulated patients with persistent/permanent AF that paroxysmal AF (Internal Medicine p 0.038, Cardiology p 0.013).

Conclusions: Despite the proven usefulness of anticoagulation to prevent embolism in patients with any kind AF, even bleeding high risk, there remains a group of patients not receiving adequate prophylaxis. Although patients admitted to Internal Medicine are older and have higher bleeding risk than those admitted to Cardiology, there seems no relationship between these variables and the correct anticoagulation. It has revealed the probable medical belief that paroxysmal AF carries less embolic risk than permanent AF.

Table 1 (IC-23)

	BMI < 25 (n = 21)	BMI from 25 to 30 (n = 25)	BMI > 30 (n = 30)	p

EPIDEMIOLOGICAL AND CLINICAL CHARACTERISTICS OF PATIENTS HOSPITALIZED FOR HEART FAILURE IN INTERNAL MEDICINE AND CARDIOLOGY: ARE THERE DIFFERENCES?

P. Sánchez Junquera[1], M. Ruiz Olgado[2], M. Chimeno Viñas[1], E. Martínez Velado[1], A. de la Vega Lanciego[1], F. Barrieto Rubio[1], P. García Carbó[1], L. Palomar Rodríguez[1]

[1]Department of Internal Medicine, [2]Department of Cardiology. Complejo Asistencial de Zamora. Zamora, Spain.

Objectives: Heart failure (HF) is the final syndrome of numerous cardiopathies and it is the first cause of admission in patients older than 65, which implies a high sanitary cost. In this study we try to analize the epidemiological and clinical differences between patients with HF admitted to an Internal Medicine Department (IMD) or a Cardiology Department (CD).

Material and method: Observational and restrospective study of patients admitted because of HF to Complejo Asistencial, Zamora (CAZA) from November 2010 to March 2011 in IMD and CD. We analyzed the next data: age, sex, length of stay, cause of decompensation and comorbidities: hypertension, diabetes, ischemic cardiopathy, atrial fibrillation and dyslipidemia.

Results: Data from 113 patients were obteined; 55 (27 males) of them admitted to an IMD and 58 (22 females) to a CD. 41 patients (74.5%) in IMD and 22 (37.9%) in CD were over 80 years ($p < 0.005$). See Table 1 and Table 2.

Discussion: The pathologies most frequently associated with HF in patients of both Department were hypertension and atrial fibrillation. Differences between both Department were found in the age, hypertension and ischemic cardiopathy. In IMD the length of stay was higher and the cause of decompensation was more often due to an infection.

Conclusions: 1. Patients admitted in Internal Medicine Department were older and they had higher length of stay and similar comorbidity. 2. Statistically significant differences were found in mean age, length of stay, cause of decompensation and comorbidities as hypertension and ischemic cardiopathy.

IC-26
HEART FAILURE IN INTERNAL MEDICINE AND CARDIOLOGY: DIAGNOSIS AND TREATMENT DIFFERENCES

M. Chimeno Viñas[1], M. Ruiz Olgado[2], P. Sánchez Junquera[1], A. de La Vega Lanciego[1], P. García Carbó[1], E. Martínez Velado[1], J. Soto Delgado[1], M. Mateos Andrés[1]

[1]Department of Internal Medicine, [2]Department of Cardiology. Complejo Asistencial de Zamora. Zamora, Spain.

Objectives: Heart failure (HF) is the most rapidly growing cardiac pathology in industrialized countries, and already the primary cause of hospital admissions of elderly people. There have not been many studies in Spain of the influence of the admission department on diagnostic and therapeutic management. The objective was to analyze whether diagnosis and treatment management of patients admitted with heart failure depending on the admission ward (Internal Medicine versus Cardiology).

Material and method: Observational and retrospective study of patients admitted because of heart failure to Internal Medicine Department (IMD) and Cardiology Department (CD) in Complejo Asistencial, Zamora (CAZA). from November 2010 to March 2011. We analyzed the next data: determination of N-terminal pro-brain natriuretic peptide (NT-proBNP), echocardiogram, treatment (diuretics, angiotensin-converting enzyme (ACE) inhibitors,

ProBNP	12 (21.8%)	37 (63.8%)	0.000
IECA/ARB	36 (69.3%)	42 (75%)	0.131
Beta-blockers	23 (50%)	35 (51%)	0.246
Digoxin	16 (32%)	22 (38.6%)	0.477
Diuretics	45 (90%)	48(84.2%)	0.376
Statins	10 (21.7%)	22 (38.6%)	0.006

angiotensin II receptor antagonists, and beta-blockers, digoxin and statins) and inhospital mortality.

Results: Data from 113 patients were obtained: 55 admitted to IMD and 58 to CD. The inhospital mortality was 1.7% in Cardiology (one patient) and 7.3% (four patients) in Internal Medicine (p = 0.152). Table 1.

Discussion: The diagnostic procedure most commonly employed was echocardiography with significant differences between both Departments. The determination of NTproBNP was significant too. The use of ACE inhibitors, beta blockers, diuretics and digoxin was similar in both Departments. Statins were most commonly prescribed in Cardiology (significant difference). There was also no significant differences in hospital mortality.

Conclusions: 1. Less than half the patients admitted to the Internal Medicine Department have an echocardiogram 2. The NT proBNP is poorly applied in Internal Medicine Department 3. There aren´t significant differences in the treatment management and in hospital mortality in both Department.

IC-28
PROGNOSTIC VALUE OF WORSENING RENAL FUNCTION IN OUTPATIENTS WITH CHRONIC HEART FAILURE

R. Pimentel[1], M. Couto[1], A. Azevedo[2], O. Laszczynska[2], F. Fonseca[1], N. Correia[1], F. Friões[1], P. Bettencourt[1]

[1]Department of Internal Medicine. Centro Hospitalar São João. Porto, Portugal. [2]Department of Clinical Epidemiology and Predictive Medicine. University of Porto Medical School. Porto, Portugal.

Objectives: Renal impairment has long been recognized as a predictor of worse outcomes in acute heart failure patients. More recently, attention has shifted to worsening renal function (WRF). Despite the growing publication record in this area, data from chronic heart failure (CHF) outpatients are scarce. The aim of this study was to assess the prognostic implications of WRF in ambulatory CHF patients.

Material and method: This study is based on a retrospective cohort of patients with CHF and systolic dysfunction, consecutively referred after Jan 2000. Patients under renal replacement therapy were excluded. Serum creatinine and urea at baseline and 6 months later were considered. Patients who did not have lab tests at 6 months (plus or minus 2) were excluded. The final sample included 277 patients. WRF was defined as a change in serum urea or creatinine categories from below to above 60 mg/dl or 1.5 mg/dl, respectively. An absolute 6-month increase in serum urea or creatinine of 20 mg/dl or 0.3 mg/dl, respectively, was also considered. We used the Kaplan-Meier method to estimate survival free of hospitalization for heart failure after the 6-month exposure period and censored at 5 years. Cox regression was used to estimate hazard ratios (HR) and 95% confidence intervals (95%CI) adjusting for age, and 6-month NYHA class, loop diuretic dose and ACEIs dose.

Results: A third of patients had urea > 60 mg/dl and 14% had creatinine > 1.5 mg/dl from baseline. An increase in urea from below to above 60 mg/dl occurred in 17% and 19% had an increase of at least 20 mg/dl. An increase of serum creatinine from below to above 1.5 mg/dl and an increase of at least 0.3 mg/dl affected 8% and 16% of patients, respectively. Of the 277 patients, 66% were alive and free from hospitalization for heart failure at the median follow-up time of 2 years. In comparison with patients with preserved renal function at 6 months, an increase in serum urea from below to above 60 mg/dl or in serum creatinine from below to above 1.5 mg/dl were each associated with a more than double risk of death/hospitalization (adjusted HR: 2.3, 95%CI 1.3-4.1; 2.8, 95%CI 1.5-5.2, respectively). The HR for urea > 60 mg/dl or creatinine > 1.5 mg/dl sustainedly from baseline were 1.6 (95%CI 1.0-2.7) and 1.1 (95%CI 0.6-2.2). An increase of serum urea of at least 20 mg/dl and of creatinine of at least 0.3 mg/dl doubled the risk (HR: 2.0, 95%CI 1.2-3.4; 2.2, 95%CI 1.3-3.7, respectively).

Discussion: Although the relationship between WRF and survival in CHF has already been reported in several multi-centre studies of CHF, our study reinforces this association in ambulatory patients, a population less studied. The definition of WRF we used, based either on urea or creatinine, is arbitrary but follows previous studies, which contributes to comparability and supports its predictive value. Data were analysed only at two defined points during follow-up, and factors that could affect the renal function in the intervening periods such as hospitalizations, medications, dehydration, or exposure to intravenous contrast were not taken into account. Finally, patients who had incomplete data sets at the baseline or follow-up were not included in the analysis, potentially introducing selection bias. The retrospective design is an advantage avoiding changes in practice due to study participation.

Conclusions: In ambulatory CHF patients, WRF was associated with a clinically relevant worse outcome, independently of important confounders, and added prognostic value to renal dysfunction per se.

IC-29
TELEMONITORING IN PATIENTS WITH ADVANCED HEART FAILURE: HEALTH@HOME EXTENSION STUDY PRELIMINARY DATA

J. Galindo Ocaña[1], S. García Morillo[1], A. Martínez García[2], F. Jódar[2], R. Solís López[1], C. Aguilera González[1], A. Fernández López[1], M. Ollero Baturone[1]

[1]Department of Internal Medicine, [2]Technological Innovation Group. Hospital Virgen del Rocío. Sevilla, Spain.

Objectives: To determine clinical features, effectiveness on clinical and healthcare outcomes, quality of life, and satisfaction with the telemedicine platform Health@Home (H@H) in patients with advanced heart failure.

Material and method: Inclusion criteria: older than 18 years-old, informed consent, heart failure of any origin, NYHA class III-IV, being admitted to an internal medicine ward, potential ability to handle a telemedicine platform, absence of terminal cancer or agony. After a training period in the ward, patients were randomly

assigned to telemedicine and hospital at home follow-up or conventional healthcare. Patients were followed up during 4 weeks. Functional evaluation was performed by means of Barthel index for basic activities of daily living and NYHA class. Quality of life was measured through Minnesota Living with Heart Failure (MLHF) and EuroQoL-5D (EQoL-5D) questionnaires at the inclusion time and at the end of follow-up period. Number of hospital admissions and emergency department consults were taken into account in a 6-month period previous to inclusion and in the first month of follow-up. Qualitative data were expressed as numbers/percentages, quantitative data as means (SD) or medians [IQR]. Qualitative variables were compared by means of chi-square and quantitative variables through parametric (Student's t test) or non-parametric analyses (Mann-Whitney's U test for median comparison) when appropriate after Kolmogorov-Smirnov test. SPSS v20.0 was used. A P value of 0.05 was considered for statistical significance.

Results: 19 patients were recruited. 11 patients were assigned to telemedicine intervention (H@H) and 8 to conventional healthcare (control group). 2 H@H patients were lost during follow-up as they showed being not able to handle the devices when applied in their homes. Mean age was 75.5 (10.65) years in control group vs 79.90 (10.53) in H@H group (p = 0.385), mean NT-proBNP was 2696.5 (84.58) vs 6428.4 (5303.33) (p = 0.195), mean initial MLHF was 96.5 (4.11) vs 97.36 (2.73) (p = 0.615), end of study MLHF was 79.71 (28.18) vs 63 (34.74) (p =), ejection fraction percentage was 60.86 (11.84) vs 55.18 (12.54) (p = 0.350), end diastolic left ventricle diameter was 40.31 (5.18) vs 45.45 (7.43) (p = 0.104), the mean number of emergency department consults in the last 6 months was 2.5 (2.62) vs 3 (1.55) (p = 0.640), initial EQoL-5D was 21.25 (9.5) vs 32.27 (12.32) (p = 0.042), end of study EQoL-5D was 53 (23.88) vs 52.86 (30.39) (p = 0.993) for control and H@H groups respectively. No differences were found between groups neither for number of hospital admissions in the last 6 months (median controls 1 [0] vs H@H 1 [1]; p = 0.395), number of hospital admissions during follow-up (0 [0.75] vs 0 [0]; p = 0.6) and number of emergency department consults during follow-up (0 [0] both groups; p = 0.840) nor quality of life measures (initial EQoL-5D p = 0.051; end EQoL-5D p = 1.0; end Minnesota p = 0.318). Patients satisfaction with the H@H platform was good (median score 9 [1.75]), being a 37.5% a score of 10/10, 37.5% 9/10, 12.5% 8/10 and 12.5% 7/10. All patients who ended the study considered easy or very easy to handle the system, with the exception of the 2 patients who were lost because they did not use H@H at home at all. A total amount of 106 alarms were received, of which 25 (23.6%) helped to change treatments and avoided 5 hospital admissions and 22 emergency department consults. The mean number of alarms per patient was 9.64 (9.26), being relevant as decision making tool 2.27 (2). A mean of 0.45 (0.688; range 0-2) hospital admissions and 2 (1.73, range 0-5) emergency consults per patient could be avoided by the system. One patient in the control group died during follow-up.

Conclusions: The H@H system may afford relevant day-to-day clinical information, is well accepted by the patients and their carers and may help avoid hospital admissions and emergency department consults in patients with advanced heart failure.

IC-31
CONGESTIVE HEART FAILURE IN INTERNAL MEDICINE REQUIRING URGENT ATTENTION CARDIOLOGICAL

E. Castelar Delgado, S. García Escudero, P. Dios Díez, S. Aguilar Huergo, F. Estrada Álvarez, J. Llorente García, M. Pérez Panizo, M. de Castro Losa

Department of Internal Medicine. Complejo Asistencial de León. León, Spain.

Objectives: This is a study that analyzes the profile of patients with congestive heart failure requiring urgent attention and even pass Cardiology Service during your stay in Internal Medicine. We analyze morbidity and mortality, cardiovascular risk factors and associated techniques that require such patients from the Cardiology Department.

Material and method: This is a descriptive, retrospective, observational and not controlled study. The sample consisted of those patients who were initially admited in the internal medicine department with a diagnosis of congestive heart failure are discharged from the cardiology Welfare Complex in Leon in 2010.

Results: We analyzed a total of 31 patients of whom 20 were men (64.5%) with a mean age of 75.10 years. As a personal history of cardiac disease highlights before admission in 74.2% and lung pathology in 48.4%, mainly COPD. Toxic habits (9.7% current smokers and 12.9% occasional drinkers). HTA 71.%, DM 32.3%, 35.5% with DL numbers mean LDL 97 (max. 242, min. 37.6). CKD was diagnosed in 29% of patients. However, no evidence of severe hyperkalemia in any case, being the average number of registered potassium 4.42 (max. 5.55, min. 3.2). The average hospital stay for these patients was 13.26 days. Echocardiography was performed in 77.4% of patients, pathological in all cases. The electrocardiogram and chest radiograph in history consisted of all patients, the normal electrocardiogram in 32.3% (10 patients). The chest radiograph was normal in 16.1% of patients and showed signs of congestive heart failure in 71%, cardiomegaly in 6.5% of cases and pleural effusion in 6.5%.

Discussion: The treatment of heart failure includes, according to recent clinical guidelines, available pharmacologic and nonpharmacologic measures. Among the non-drug measures we have cardiac resynchronization as a rare therapy in elderly patients (only one case in our study, a 77 year old patient with dilated cardiomyopathy with severely depressed ejection fraction, functional class NYHA IV.

Conclusions: We realized that the profile of patient admitted to the Internal Medicine Department have an average of old age, with morbidity related to established cardiovascular risk factors and polypharmacy. Exceptionally they required technical approach by the Department of Cardiology and a multidisciplinary heart failure unit, in order to improve our health care assistance and to reduce readmission rates.

IC-36
RELIABILITY OF POINT-OF-CARE POCKET-SIZE ECHOCARDIOGRAPHY PERFORMED BY AN INTERNIST IN A MEDICAL DEPARTMENT

G. Serralta San Martín, L. Soler Rangel, J. Gómez Cerezo

Department of Internal Medicine. Hospital Universitario Infanta Sofía. San Sebastián de los Reyes (Madrid), Spain.

Objectives: To study the usefulness and reliability of point-of-care pocket-size echocardiography at the bedside in the evaluation of cardiac structures of patients admitted to a medical department.

Material and method: Patients admitted to our medical department with standard indications for echocardiography underwent an echocardiography evaluation, performed with a pocket-size ultrasound device, with B-mode and colour flow imaging, by an internist with a previous specific training of 25 hours. Patients were then referred to subsequent high-end echocardiography, performed by an expert cardiologist at the Eco-laboratory. Left ventricular dysfunction, pericardial effusion, valvulopathy and right atrial and ventricular enlargement were assessed in both cases an compared in order to establish the accuracy of the test to detect cardiac structural anomalies.

Results: Nineteen patients were evaluated between January and April 2012, 42% men, median age 72 years. The principal diagnosis was heart failure. Left ventricular dysfunction was present in five

and all patients were well classified. Pericardial effusion was present in one patient and all patients were well classified too. There were four patients with right atrial and ventricular enlargement, but only two were correctly classified, with positive and negative predictive value of 67% and 88% respectively. There were nine patients with significant valvulopathy, eight correctly classified, with positive and negative predictive value of 89% and 90% respectively (e.g. Mitral regurgitation). Global accuracy of the test for detecting any structural anomaly is shown in Table. Global positive predictive value was 89% (95%CI: 0.74-1.03) and negative predictive value was 95% (95%CI: 0.89-1.01).

Discussion: Left ventricular dysfunction, pericardial effusion, valvulopathy and right atrial and ventricular dilatation are important parameters in assessment of cardiac function. Point-of-care pocket-size echocardiography has been used for screening, and can be performed in a few minutes by a trained internist as a complement to physical examination. Data of this study show, in line with other publications, that pocket-size ultrasound performed by internists has good correlation with high-end echocardiography, performed by an expert cardiologist, in the four above mentioned parameters, obtained in a semiquantitative scale. The best accuracy was obtained in the assessment of left ventricular function and pericardial effusion. This may be of high importance in patients with heart failure and in the emergency department.

Conclusions: Point-of-care pocket-size echocardiography examination can be used by internists for the screening of cardiac structures and function in patients admitted to medical department.

Table 1 (IC-36)

	Reference positive	Reference negative
Pocket-size positive	16	2
Pocket-size negative	3	55

IC-39
ANALYSIS OF A SERIES OF PATIENTS ADMITTED TO INTERNAL MEDICINE (IM) WITH HEART FAILURE (HF) AND DEPRESSED LEFT VENTRICULUM FUNCTION (LVEF)

E. Mozos de la Fuente, R. Daroca Pérez, J. Mosquera Lozano, S. García Guerreros, E. Ruiz de la Cuesta Martín, T. Elías Sánchez, M. Núñez Murga, M. Casañas Martínez

Department of Internal Medicine. Hospital San Pedro. Logroño (La Rioja), Spain.

Objectives: The aim of this study was to conduct a descriptive analysis of clinical features, treatment and evolution of patients with heart failure (HF) and depressed left ventriculum function (LVEF) admitted to our hospital in 2010.

Material and method: 31 patients admitted with diagnosis of HF and LVEF < 45% were studied. We evaluated age, sex, comorbidities (hypertension, diabetes (DM), dyslipidemia, smoking, renal failure with Cr > 1.4 mg/dL, and chronic obstructive pulmonary disease –COPD-), etiology, systolic function, New York Heart Association (NYHA) functional class, adequacy of treatment, ECG at admission and evolution.

Results: N = 31 patients. Mean age 81 ± 7 years. Sex: M 71%, F 29%. Mean admission time was 9 ± 7 days. The number of readmissions per patient in 2010 was 2.3 +/-2.5. Prior history: hypertension 71%, atrial fibrillation (AF) 48%, dyslipidemia 45%, ischemic heart disease 42%, renal failure 39%, DM 32%, smoking 26%, COPD 19%. Etiology of HF, 45% ischemic, 23% hypertension, 19% valvular diseases, 10% cardiomyopathy; 3% idiopathic. NYHA Functional class: 3% I, 37% II, 50% III and 10% IV. ECG on admission: 30% sinus rhythm, 7% pacemaker, 63% atrial fibrillation (AF). Pharmacological treatment at admission and at discharge is described in Table 1. Evolution: 77.5% discharge home, 6.5% center for chronic diseases, death 16%. Mortality at the end of 2010 was 25.8%.

Discussion: HF can be classified as systolic HF, with depressed LVEF, or diastolic HF, with preserved LVEF (LVEF > 45-50%). Both types show different characteristics. HF with depressed systolic function has a worse prognosis, with increased mortality and readmissions. Various pharmacological treatments can alter the course, but are often underutilized.

Conclusions: Compared to previous studies (OPTIMIZE, CORONA, EMPHASIS, SHIFT….) our population was older. Incidence of HF with depressed LVEF was higher in men and patients with history of hypertension and ischemic heart disease. Frequency of AF in our patients was higher compared to previous studies. Most subjects elonged to NYHA functional classes II or III, similar to other studies. Mortality was high. The proportion of patients with optimal pharmacological treatment is low.

Table 1. (IC-39)

Treatments	Admissions	Discharges
Spironolactone	12.9%	12.9%
Eplerenone	3.2%	3.2%
ACEI	41.9%	38.7%
ARBs	19.4%	16.1%
Beta-blockers	38.7%	22.6%
Ivabradine	3.2%	3.2%
Digital	29%	29%

IC-40
CLINICAL CHARACTERISTICS AND OUTCOMES OF THE OLDEST OLD HEART FAILURE PATIENTS

M. Camafort Babkowski[1], E. Coloma Bazán[1], J. Milisenda[1], F. Masanes Torán[1], F. Pérez Villa[2], J. Cevallos[2], A. López Soto[1], A. Coca[1]

[1]Department of Internal Medicine, [2]Department of Cardiology. Hospital Clinic IDIBAPS University of Barcelona. Barcelona, Spain.

Objectives: In elderly patients Heart failure is one of the first causes of hospitalizations. Data about the characteristics of the oldest older patients are scarce. We try to evaluate clinical characteristics, and 1-year outcomes, defined as mortality and new hospitalizations, in patients older than 80 years with hospitalized heart failure in internal medicine and cardiology departments of our institution.

Material and method: Retrospective analysis of patients admitted to a Cardiology and Internal medicine departments of a University Teaching Hospital, during the first quarter of 2010. Sociodemographic data, Comorbidities (following PROFUND comorbidity Index), Cognitive status, Clinical echocardiographic and biochemical characteristics, treatments before and after admissions, and outcome (mortality and rehospitalizations one year after hospitalization) were reviewed from the electronic clinical records.

Results: Data from 157 subjects were collected. A 62.4% were women, with a mean age of 86.8 ± 4.63 years (range 80-104 y). Only 12.4% were living in nursing assisted homes, 19.7% had a mild dependency and 37.6% were non dependent. Comorbidities were present as follows: 6.6% were smokers, 84.1%, 31.2% hypertensive, 45.1% diabetics, 47% dyslipidemics, 47%had atrial fibrillation, 41.1% chronic kidney disease, 12.1% atherosclerotic or cardioembolic cerebrovascular disease, 27.4% had COPD, 10.2 had peripheral arterial disease, 53.2% previous Heart failure, and 25%

ischemic cardiomyopathy. 47.5% were pluripathological patients (Profund comorbidity index > 5). 34.4% Presented as "de novo" Heart Failure and 45.2% as a reagudization of a chronic heart failure, 8.3% were hypertensive heart failure, 6.4% presented as pulmonary edema, and 1.3% as cardiogenic shock. 31.8% had no echocardiography, 55.1% had systolic dysfunction and 44.9% had preserved ejection fraction. Only 35.6% received betablockers, 41.5% ACEI or ARB, and only 12.7% Aldosterone antagonists. At one year of follow up 31.65% died in the first year and 46% required new hospitalization, a total of 70.8% of patients presented a bad outcome defined as rehospitalization or death at one year of follow up.

Conclusions: In our study, oldest old heart failure patients are highly comorbid, and present a worse outcome. Unless this worser outcome, those patients were less studied and treated, that younger patients. An intervention to improve management of those patients is needed. New studies should clarify prognostics factors relevant for these patients outcome.

IC-41
NUTRITIONAL ASSESSMENT IN PATIENTS HOSPITALIZED FOR HEART FAILURE

F. Gómez Delgado, L. García Castilla, M. Mantero Castro, R. Martínez Fernández, J. Ampuero Ampuero, A. Jurado Porcel, M. Martín Moreno, M. Montero Pérez-Barquero

Department of Internal Medicine. Hospital Provincial. Córdoba, Spain.

Objectives: To determine the nutritional status and dietary habits in patients hospitalized for heart failure.

Material and method: This is an observational study. The inclusion criteria were consecutively accepted in 30 patients older than 70 years with a diagnosis of heart failure (HF) admitted in the Internal Medicine unit from Reina Sofia University Hospital and gave their consent to participate in the study. Variables of the study: demographic data, anthropometric measurements (height, weight, perimeter: waist, hip and wrist; folds: biceps, triceps and subscapular). The body mass index (BMI), was calculated using the following formula = weight (kg)/height (m^2). It was classified the degree of obesity, following the criteria of the WHO. We applied a food frequency questionnaire for obtain information about the preferences and eating habits of the sick, deficit and excess in the consumption of certain nutrients and the number of calories they consume daily. In all the participants, analytical determinations were carried out are: triglycerides (TG), total cholesterol (TC), high-density lipoproteins (HDL-c), low density lipoprotein cholesterol (LDL-c), albumin, glucose and leukocytes. It was classified the cardiovascular risk by the waist-hip index [very high: 3, high: 2, low: 1]. We established the constitution with the relationship body size-wrist [large: 3, medium: 2, small: 1]. Finally, with the Foulkner equation, we established the fat levels in the patients [low: 1, high: 2]. A descriptive analysis of the sample was made with the SPSS 20.0 program.

Results: Mean age of 83 years, 63% women. The average BMI was 27 kg/m^2. The average values of the folds biceps, triceps and subscapular were 13.5 mm, 13 mm and 16.6 mm, respectively. The average values of the abdominal perimeter were 103 cm, above normal values (88 cm in women and 102 cm in men). In the analytical measurements the average values were: CT 164 mg/dL, HDL-c 35 mg/dL, LDL-c 103 mg/dL, TG 128 mg/dL, uric acid 8 mg/dL, glucose level 137 mg/dL, albumin 4 g/dL, leukocytes 10.34 × 10^3/µL. The average calorie intake was 2,374 kcal/day. In relation to the consumption of fat the average values obtained were: total fat 105 g/day (40 per cent of the total caloric intake), saturated fat of 24 g/day (9 per cent of the total), monounsaturated fats 56 g/day (20 per cent of the total). The consumption of carbohydrates supposed 39% of the daily intake. Proteins were 21% of the total. The average consumption of fiber was 16 g/day. The cardiovascular risk by the waist-hip index was: very high: 48%, high: 41%; low: 10%. The body constitution by the size-wrist relationship was: large 38%, median: 41%, small: 21%. Finally, based on Foulkner equation, fat levels were: low: 61%, high: 39%.

Discussion: The anthropometric data translate into an excess of body fat with a BMI above the reference values and an increase in caloric intake that exceeds the values means recommended (1,500 calories for women and 1,700 calories for men). We also see an imbalance in the consumption of the immediate principles with an excessive consumption of fat. Carbohydrate consumption was lower than the recommended. All of these data have implications for an excess of body fat in 61% of our patients as well as a high cardiovascular risk (4%) and very high (4%) in patients.

Conclusions: Patients admitted to hospital for heart failure have obesity, excessive caloric intake mainly at the expense of fat and a high cardiovascular risk.

IC-42
CLINICAL IMPLICATIONS OF DIFFERENT BIOMARKERS IN ELDERLY PATIENTS WITH HEART FAILURE

I. Sánchez Hernández[1], S. Santana Báez[2], C. Escobar Cervantes[3], J. Santiago Ruiz[1], A. González García[1], N. Ribas Piza[1], J. Castaño Aguado[1], L. Manzano[1]

[1]Heart Failure and Vascular Risk Unit. Department of Internal Medicine. University Hospital Ramón y Cajal. Madrid, Spain. [2]Department of Internal Medicine. University Hospital Gran Canaria Dr. Negrín. Las Palmas de Gran Canaria (Las Palmas), Spain. [3]Department of Cardiology. University Hospital La Paz. Madrid, Spain.

Objectives: To determine the importance of neuroendocrine and inflammatory biomarkers in elderly patients with HF.

Material and method: In this retrospective and observational study performed in patients > 70 years old with HF, TNF-alpha, IL1-beta, IL6, IL18, IL10, Fas (Apo1), BNP and C-reactive protein values were calculated. The relationship between them and the clinical evolution of this population was also determined.

Results: A total of 124 patients (mean age 83 ± 5 years; 32.2% men) were included in the study. With regard to the type of HF, 27% of patients had systolic HF, 54% diastolic HF and 19% valvular disease. Mean follow-up was 2.4 years. Overall, 92% of patients had hypertension, 37% diabetes, 60% atrial fibrillation, and 17% ischemic heart disease. During this period, 20.1% of patients were attended in emergency department for HF, and 40.3% hospitalized for HF. Moreover, 15.3% of patients died during the follow-up. With regard to biomarkers, those patients who were hospitalized for HF showed higher values of IL-6 (9.8 ± 13.1 vs 4.65 ± 5.8; p = 0.003). However patients who died showed higher values of IL-18 (437.1 ± 137.4 vs 299.7 ± 167.2; p = 0.01), C-reactive protein (12.6 ± 19.4 vs 6.1 ± 9.4; p = 0.03), BNP (704.2 ± 428.6 vs 418.5 ± 410.6; p = 0.008) and cystatin C (1.76 ± 0.6 vs 1.45 ± 0.5; p = 0.04), with a trend to lower values of TNF-alpha (1.4 ± 2.5 vs 2.81 ± 4.6; p = 0.07).

Discussion: Neuroendocrine and inflammatory systems are activated in heart failure (HF) patients. Although in the last years there is a growing interest for inflammatory mediators in chronic HF, these have been mainly studied in patients < 70 years old with left ventricular systolic dysfunction. However, data about the importance of these biomarkers in elderly patients with HF are scarce. The main results of this study showed that in elderly patients with HF, the determination of some of these biomarkers may predict which patients will be more likely to die or be hospitalized for HF.

Conclusions: In elderly patients with HF, the determination of biomarkers may be helpful to establish those patients at higher risk of death or hospitalization for HF.

IC-43
TREATMENT WITH AMBRISENTAN IN A COHORT OF PATIENTS WITH PULMONARY ARTERIAL HYPERTENSION

C. González Pulido[1], I. Porras Antrás[1], F. García Hernández[1], R. Hinojosa Pérez[2], J. López Haldón[3], R. González León[1], C. Ocaña Medina[1], M. Castillo Palma[1]

[1]Investigation Group CTS-279. Department of Internal Medicine, [2]Department of Intensive Care, [3]Department of Cardiology. Complejo Hospitalario Regional Virgen del Rocío. Sevilla, Spain.

Objectives: We report our experience in the treatment with ambrisentan in patients with pulmonary hypertension (PH) in a specialized Unit in a third level Spanish Hospital.

Material and method: A retrospective case note review was carried out of all patients diagnosed with PH according to the Dana Point Classification (DPC) and treated with ambrisentan from 2010 to 2012. We analysed the type of PH, functional class at diagnosis as well as the outcomes during follow up.

Results: Thirty patients received ambrisentan (25 women, 83.4%). Median of age at diagnosis was 55.5 years-old (IQR 33.5-67). Diagnosis was chronic thromboembolic pulmonary hypertension in 1 patient and pulmonary arterial hypertension (PAH) in the other 29: 8 (27.6%) idiopathic PAH, 14 (48.3%) connective tissue disease associated PAH (11 scleroderma and 3 systemic lupus erythematosus), 4 (13.8%) congenital heart disease associated PAH, 2 (6.9%) HIV associated PAH and 2 others. 2 patients (6.67%) were in functional class (FC) I, 15 (50%) in FC II, 7 (23.3%) in FC III and 6 (20%) in FC IV at diagnosis. Twenty patients (66.6%) could walk > 325 metres in the 6-minutes-walking test (6-MWT). Diagnosis was confirmed by right heart catheterization in all cases [median (IQR): PCP 12 mmHg (9.25-13), mPAP 50 mmHg (41-56), cardiac output 4 l/m (3.3-5.9), PVR 8.86 Woods U (6-14.3)] and only 2 had a positive vasodilator test. Mean time from diagnoses of PAH to adding ambrisentan was 5 years. Initial treatment was bosentan in 17 cases (53.6%), sildenafil in 5 (16.6%), subcutaneous treprostinil in 5 (16.6%), intravenous epoprostenol in 2 (6.6%) and ambrisentan in 1 (3.3%). Nineteen patients (63.3%) required combination therapy and 11 (36.7%) remained on monotherapy. Initial daily dose of ambrisentan was 5 mg in 86.7% and 10 mg in 13.3%; 5 patients first treated with 5 mg needed to increase the dose to 10 mg after a median of 8 months. The most frequent side effects observed were mild hypertransaminasemia (2 patients), minor bleeding (2), nasal congestion (2) and flushing (1). At the end of follow-up, 23 patients (76.7%) were alive: 20 patients (83.3%) improved or remained stable, 17 (70.8%) were in FC I or II and 14 (58.3%) could walk > 325 metres in the 6-MWT. Seven patients (23.4%) died: 5 due to progression of PAH, 1 for sepsis and 1 for lung cancer.

Discussion: Ambrisentan is a safe and effective treatment for PAH.

Conclusions: PAH is a severe disease with high mortality. Its prognostic has considerably been improved in the last years because of the development of specifics drugs like the endotelin receptors antagonists. In the recent literature, ambrisentan has demonstrated a significant improvement of the functional class and effort capacity, increasing the time until clinical worsening and the survival up to 3 years. Therefore, our data are in agreement to all these findings.

IC-46
PROSPECTIVE STUDY OF HEART FAILURE HOSPITALIZATIONS: CLINICAL AND ANALYTICAL PROFILE AND FACTORS ASSOCIATED WITH LENGTH OF STAY AND HOSPITAL READMISSION

M. Pérez Conesa, M. Martínez Heras, J. Velilla, M. Figueras, E. Jarauta, L. Sáez Comet

Department of Internal Medicine. Hospital Universitario Miguel Servet. Zaragoza, Spain.

Objectives: Determine the clinical profile of heart failure (HF) patients admitted to Internal Medicine (MI) department. To identify prognostic factors associated with readmission for HF.

Material and method: Prospective study of patients admitted to the Internal Medicine Department from February 1st to March 31st 2012, diagnosed with heart failure. We analyzed the following variables: sex, age, principal and associated diagnosis, functional status, physical examination and laboratory tests that included blood tests, chest radiograph, electrocardiogram and echocardiogram, stay and readmissions. The coded variables were analyzed with SPSS 12.0.

Results: Of the 107 admissions with suspected HF, it was confirmed in 81 cases (75.7%) 51.9% were female and mean age 83.01 ± 8.42 years, being significantly higher in women (84.71 years) than men (81.18 years). The average hospital stay was 9.62 ± 7.78 days. The main echocardiography diagnosis were in 27.9% left ventricular dysfunction, diastolic heart failure 14.8%, 13.6% hypertrophic cardiomyopathy, pulmonary hypertension 11.1% and 4.9% severe valvular disease. The most common precipitating factors were infection (44.4%) and decompensated arrhythmia (16%). Functional status (NYHA class) on admission was grade IV (60.5%), grade III (30.9%) and grade II (6.2%). The mean Charlson index admission was 7.28 ± 2.86. 34.5% of patients had 2 or more points of social fragility (own scale: 0-4 points). 46.9% of patients had anemia with Hb < 12 mg/dl and 12.3% Hb < 10 mg/dl. 81.5% of patients have an elevated pro-BNP (> 2000). Most patients improved in the first 48 hours of admission: 73.6% of patients had SO_2 > 90%, 70.5% disappearance of edema and 78.2% disappearance of dyspnea. At discharge, only 8.8% of patients were in grade III-IV of NYHA. More than half of patients (55.6%) had other income in the last 12 months and 16% were early readmissions (last 15 days). When we considered associated variables to hospital admission, we objectify the Charlson index, the scale of social fragility and anemia were associated with higher rates of readmission for HF, such associations being more relevant than those found for ejection fraction (EF) and proBNP.

Discussion: In this series emphasize the high average age (75% were over 79 years) and comorbidity of our patients (almost 75% had scores greater than 5), quite above other series and especially for patients admitted to Cardiology Services. Moreover, despite its "impaired" functional class at admission, therapeutic response was generally favorable and relatively quickly. The high rate of hospital admissions of our patients, however, reveals a high risk of decompensation and poor outpatient control of the disease.

Conclusions: The identification in our setting of anemia, high Charlson index and social fragility as the main factors associated with readmission, to select a subgroup of patients at high risk of decompensation in a proactive monitoring ambulatory likely improve control disease and decrease hospitalization.

IC-47
PREDICTORS OF VENTRICULAR FUNCTION RECOVERY IN PATIENTS WITH HEART FAILURE

F. Cunha[1], C. Paulo[1], S. Silva[1], P. Ramalho[1], P. Lourenço[1], F. Friões[1], A. Azevedo[2], P. Bettencourt[1]

[1]Department of Internal Medicine. Hospital São João. Porto, Portugal. [2]Department of Clinical Epidemiology. Institute of Public Health of University of Porto. Porto, Portugal.

Objectives: Among heart failure (HF) patients with left ventricular (LV) systolic dysfunction, a variable proportion recovers to a normal ejection fraction. Characteristics associated with that recovery are poorly known. We intended to determine the prevalence and the predictors of recovery of LV systolic function in HF patients.

Material and method: We conducted a retrospective cohort study including HF patients with LV systolic dysfunction, admitted to an outpatient HF clinic between 2000 and 2011, who had at least two echocardiograms during follow-up. Clinical, laboratory and echocardiographic data were collected from medical records. Continuous variables were presented as median (interquartile range) and compared using the Mann-Whitney test. Categorical variables were presented as proportions and compared using qui-square test. Logistic regression was used to identify predictors of LV function recovery. The associations were quantified using multivariable-adjusted odds ratios (OR) and 95% confidence interval (CI).

Results: From a total of 295 patients, 201 (68%) were men. The median age was 64 years (31-92). Ischaemic etiology was present in 128 patients (43.4%) and 183 patients (62%) presented a severe systolic dysfunction. Seventy-six patients (25.8%) recovered LV function during follow-up. On univariate analysis, only a younger age (HR: 0.97 [0.95-0.99], p = 0.003), female gender (HR: 0.50 [0.29-0.86], p = 0.013), non-ischemic etiology (HR: 0.47 [0.27-0.82], p = 0.008) and an history of hypertension (HR: 2.18[1.23-3.89], p = 0.008) were associated with that recovery. On multivariate analysis, a younger age (HR: 0.96[0.94- 0.98], p = 0.001), female gender (HR: 0.46[0.26-0.83], p = 0.01) and history of hypertension (HR: 3.25[1.69-6.25], p < 0.001) maintained that association.

Conclusions: In conclusion, only few clinical and demographic variables were associated with LV function recovery. Despite the clinical belief that in non-ischaemic HF the left ventricular function tends to recover more often, in our series that was offset when adjusted for sex and age. Having a higher blood pressure before the development of HF seems to correlate independently with left systolic function recovery.

IC-48
PREDICTORS OF READMISSION FOR HEART FAILURE PATIENTS

L. Pérez Belmonte[1], V. Herrero García[1], M. Blanco Díaz[1], F. Zafra Sánchez[1], M. Platero Sánchez-Escribano[1], P. Medina Delgado[1], M. Loring Caffarena[1], J. Pérez Díaz[1]

[1]Department of Internal Medicine. County Hospital of The Axarquía. Vélez-Málaga (Málaga), Spain.

Objectives: The objective of this study was to know the clinical characteristics of admitted patients with heart failure (HF) and to determinate predictors of readmission in our department over the past 5 years.

Material and method: Retrospective analysis of 681 HF patients admitted between January 2007 and December 2011. Patients were divided into two groups: Readmission group (RG) and group of non-readmission (NRG). Within RG was divided in: readmission within 1 month, between 1 and 6 months, between 6 and 12 months and more than 12 months. We analyzed demographic data, clinic, echocardiography and laboratory variables. We performed a bivariate statistical analysis, comparing the qualitative variables with Chi-squared test and quantitative variables with Student's t-test.

Results: 265 patients (38.9%) were included in the RG, of which 15.4% were within the first month, 23.4% between 1 and 6 months, 23.4% between 6 and 12 months, and 37.8% more than 12 months. They had an average of 3 admissions (2-12). The average hospital stay of RG was higher in two days respect to another group (10 vs 8, p < 0.01). The RG was older (73.2 vs 71.8 years old, p = 0.002) and had fewer foreigners (8.7 vs 17.5%, p = 0.001). However, there were no gender differences with a male/female percentage 60/40. In the RG were more frequent high blood pressure (HBP) (86.8 vs 74.8%, p < 0.0001), diabetes mellitus (DM) (54 vs 38.2%, p < 0.0001), ischemic cardiomyopathy (ICM) (49 vs 46%, p < 0.05), atrial fibrillation (AF) (45.7 vs 36.3%, p < 0.05), chronic obstructive pulmonary disease (COPD) (26.4 vs 19.2%, p = 0.01), anemia (47.9 vs 33.7%, p < 0.001) and chronic kidney failure (CKF) (36.2 vs 21.4%, p < 0.0001). Readmitted patients had higher hospital mortality (11.3 vs 3.1%, p < 0.0001) and worse functional class, 61.1% with NYHA 3 or more compared to 36.8% of NRG.

Discussion: Heart failure is the leading cause of hospitalization and readmission in many hospitals world-wide. It is associated with an important morbid-mortality. Variables like HBP, DM, ICM, AF, COPD, anemia and CKF are readmission's determinants. These factors have been described in previous studies along with systolic dysfunction, although in our study is not a readmission variable, also showing that ventricular ejection fraction does not interfere much in the heart failure prognosis.

Conclusions: Several clinical factors determine the morbi-mortality and prognosis including an older age, associated comorbidity and functional class. All these factors are detectable at the time of hospital admission.

IC-49
BOSENTAN IN THE TREATMENT OF A COHORT OF PATIENTS WITH PULMONARY ARTERIAL HYPERTENSION

E. Montero Mateos[1], A. León Guisado[1], F. García Hernández[1], A. Herruzo Avilés[2], F. López Pardo[3], R. González León[1], C. Ocaña Medina[1], M. Castillo Palma[1]

[1]Investigation Group CTS-279 Collagenosis. Department of Internal Medicine, [2]Department of Intensive Care, [3]Departament of Cardiology. Hospital Virgen del Rocío. Sevilla, Spain.

Objectives: Evaluate the response to bosentan in an specialized unit in pulmonary hypertension (PH) of a third level hospital.

Material and method: We analyzed data collected from a protocol in patients diagnosed with PAH according to the Dana Point's Classification, using for it clinical, laboratory and haemodynamic information.

Results: Sixty-eight patients were treated with bosentan (80.9% women, mean age at diagnosis 51.7 years-old). Diagnosis was chronic thromboembolic PH in 4 patients (5.9%), veno-occlusive pulmonary disease in 1 (1.5%), neurofibromatosis associated PH in 1 (1.5%) and arterial pulmonary hypertension (HAP) in 62 (92.6%): 20 idiopathic (32.2%), 33 connective tissue disease associated PAH (53.2%), 7 congenital heart disease associated cardiopathy (11.3%) HIV associated PAH (3.2%). Mean evolution time before starting bosentan was 0.86 ± 1.46 years. At baseline, functional class (FC) was I 11.1%, II 44.4%, III 26.7% and IV 17.8%, mean value of systolic pulmonary arterial pressure (PAP) estimated by echocardiogram was 70 mmHg and mean distance covered in the 6 minutes walking test (6MWT) was 387.9 meters. Diagnosis was confirmed by right heart catheterism in all cases, with the following mean values: median PAP 48.6 ± 15.1 mmHg, PCP 11.7 ± 4 mmHg, PVR 9.5 ± 6.6 Woods U, CI 2.7 ± 1 l/minute/m2, RAP 11.5 ± 12 mmHg. Bosentan

was the initial treatment in 40 patients in monotherapy (58.8%) and associated in 2 (2.9%), 23 patients (11.8%) required combination therapy. Bosentan was replaced with other endothelin receptor antagonist (ERA) in 7 patients (16.7%). At the end of follow-up 35 patients (51.5%) were alive: 19 patients (54.3%) improved or remained stable, FC was I 2 (2.9%), the IInd 25 (36.8%), the IIIrd 22 (32.4%) and the IVth 18 (26.5%) and mean distance covered in 6MWT was 408 meters. Thirty three patients (48.5%) died during follow-up: progression of PAH (16, 48.5%), infection (4, 12.1%), sudden death (3, 9.1%), toxic multifactorial hepatitis (1, 3%) and unknown (9, 27.3%). Mean survival 9.00 (5.31-12.69) years (Kaplan-Meier method was performed to estimate survival).

Discussion: PAH is a serious disease whose prognosis has improved dramatically in recent years by the development of new drugs. ERA are a mainstay of treatment. In studies, bosentan resulted in a significant improvement in FC, exercise capacity, time to clinical deterioration and survival, and was the first drug that was shown to increase survival in FC II. Analysis of our data reinforces the evidence.

Conclusions: Bosentan is a safe and effective treatment for PAH.

IC-50
USEFULNESS OF POCKET-SIZE BED-SIDE ULTRASOUND FOR DIURETIC MANAGEMENT OF ELDERLY PATIENTS WITH ACUTE HEART FAILURE

L. Soler Rangel, G. Serralta San Martín, J. Gómez Cerezo

Department of Internal Medicine. Hospital Universitario Infanta Sofía. San Sebastián de los Reyes (Madrid), Spain.

Objectives: To evaluate the clinical usefulness of assessing the congestive state by a pocket-size point-of-care ultrasonography in the treatment with diuretics of elderly patients admitted for acute heart failure to a medical department.

Material and method: Twenty-one consecutive older than 80 patients admitted with acute heart failure underwent a cardiopulmonary limited ultrasound examination using a pocket-size echography device, by interpretation of subcostal IVC diameter (< 12 mm, 13-17 mm or > 17 mm), and collapse (none, < 50% or > 50%) and protocolized multiple intercostal views in each patient in order to detect the comet-tail artifact, which is indicative of interstitial pulmonary edema. Each patient was then classified as having or not interstitial edema (IE = yes/no), and having high, normal of low central venous pressure (CVp = H/N/L) and a theoretical algorithm pointed diuretics management (increase, decrease, maintain). A different physician classified the same patient also in these categories attending to usual clinical practice (pulmonary auscultation and assessment of elevated jugular venous pressure and hepatojugular reflux) and collected the real diuretics management. This evaluation was made at the internal medicine ward, after 12-24 hours of on treatment initiated in the emergency room. We analysed how many patients changed their classification, and therefore their treatment, because of ultrasound examination.

Results: We studied 21 patients, 13 women and 8 men, median age 86. The etiology of heart failure was ischemic in 6, valvular in 4, dilated myocardiopathy in 2 and hypertensive in 9. Ejection fraction was preserved in 12 cases. Data obtained with ultrasonography changed classification in 9 cases. Two of them had a different diagnosis: one neumonia and one pulmonary fibrosis. In 5 cases that were classified clinically as having interstitial edema and right congestion, ultrasound reclassified patients in no-edema and deplective state, which should drive to low or remove diuretics. In the 2 other cases, clinical examination classified the patients as no interstitial edema and no right congestion, and ultrasound revealed tail-comet artifact in all points examinated, which should drive to increase dose of diuretics.

Discussion: The lack of specificity of many of the signs of heart failure, especially in elderly individuals makes difficult to interpret signs of decompensated heart failure in the acute setting in these patients, and many of them are given exceeding dose of diuretics, which can drive to a hypoperfusion state and dehydration leading to hypotension and renal dysfunction. The presence of the comet-tail artifact detected by bed-side performed echography can be a more objective sign of left congestion, and the measure of inferior vena cava diameter and collapse can assess the state of right congestion and deplective state. This test changed classification in many patients in our study. Pocket-size ultrasonography, performed by an internist, may be a complement to physical examination, improving the evaluation and management of patients with acute heart failure, providing a better adjusted dose of diuretics.

Conclusions: Performation of a pocket-size point-of-care ultrasonography improves evaluation and treatment of congestive state in elderly patients admitted for acute heart failure.

IC-51
CARDIORENAL SYNDROME IN PATIENTS WITH ACUTE DECOMPENSATED HEART FAILURE-CLINICAL AND PATHOPHYSIOLOGICAL CHARACTERISTICS

C. Florescu, C. Barsan, C. Cojocaru, R. Musetescu

Department of Cardiology. Craiova Cardiology Center. Craiova, Romania.

Objectives: CRS type 1 occurs when acute decompensated heart failure results in activation of hemodynamic and neurohormonal factors leading to an acute drop in glomerular filtration rate and the development of acute kidney injury. Our objectives are to examine the impact of this problem and to describe clinical and pathophysiological profile of these patients.

Material and method: We included in our study 24 consecutive, unselected patients admitted in our cardiology clinic in one year, in whom diagnosis of cardiorenal syndrome was established after admission.

Results: Patients clinical characteristics: Age: 58-81 years. Gender: Males/females: 17/7 (70.84% vs 29.16%). Smoking: 10 (41.66%). Males/females: 7/3. Obesity: 8 (33.33%). Males/females: 5/3. Dislipidaemia: 14 (58.33%). Males/females: 9/5. Comorbidities: Diabetes Mellitus: 11 (45.83%), Metabolic syndrome: 6 (25%), Hypertension: 18 (75%), Anemia: 15 (62.5%). Previous use of drugs: Antiinflammatory agents: 5 (20.83%), Diuretics: loop diuretics: 20 (83.33%), thiazides: 5 (20.83%), ACEI/ARB: 22(91.66%), Aldosteron receptor antagonists: 19 (79.16%), Betablockers: 20(83.33%). History of heart failure or impaired left ventricular ejection fraction: 24 (100%). Prior myocardial infarction: 10 (41.66%). NYHA functional class: Class III: 11 (45.83%). Class IV: 13 (54.16%). Severe atherosclerotic vascular disease: 9 (37.5%). Low systolic blood pressure at admission: 7 (29.16%). Low serum sodium: 10 (41.66%). Elevated cardiac troponines: 8 (33.33%). Elevated CPK-MB: 4 (16.66%). Elevated hs CRP: 15 (62.5%). Chronic kidney disease: 14 (58.33%). Creatinine > 2 mg/dl: 5 (20.83%). Creatinine > 3 mg/dl: 3 (12.5%). Intrahospital mortality: 4 (16.66%). Readmission in first month: 5 (20.83%).

Conclusions: CRS identifies patients at the limits of hemodynamic compensation and most susceptible to increased morbidity and mortality. Risk factors for renal dysfunction in heart failure are hypertension, diabetes, severe vascular disease, elderly age and past history of heart failure, renal disease or both.

IC-52
COMORBIDITIES IN PATIENTS WITH UNDERLYING HEART DISEASE IN A SPECIALTY HOSPITAL OF THE SSPA

G. Ruiz Villena, M. Guzmán García, M. Escobar Llompart, R. Aranda Blázquez, E. Sánchez Relinque, V. Lechuga Flores, V. Manzano Román, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: Nowadays, is usual that patients with ischemic heart disease associate comorbidities independently of traditional cardiovascular risk factors. Our study seeks to know what are the most frequent comorbidities present in patients with acute coronary events in our center.

Material and method: Descriptive study including patients admitted for decompensated heart pathology in our center during 2011 in Cardiology Service. Study variables: Age, sex, toxic habits, comorbidity, between another factors.

Results: Total patients enrolled, 392. Average age: 65.039 ± 1.2035. Male: 57.653%. Toxic habits: tobacco (22.959%) or alcohol (8.163%). Associated disorders: Diabetes mellitus (42.09%), COPD (8.418%) or chronic renal failure (6.378%).

Discussion: Most patients with underlying heart disease in our center are men aged over 65 with significant consumption of tobacco showing high comorbidity, depending mainly from diabetes and COPD.

Conclusions: It is important to carry out a comprehensive approach to these patients pathologies. The assistance to underlying pluripathological patients it's nowadays, even more frequent, where the work of the Internal Medicine Physicians who performs a comprehensive patient assessment is essential for proper care.

IC-53
CLINICAL PROFILE OF RENAL FUNCTION IN PATIENTS WITH HEART DISEASE INFLUENCE OF IONIC CHANGES IN THE OUTCOME AND AVERAGE HOSPITAL STAY IN A SPECIALTY HOSPITAL OF SAS

G. García Domínguez, S. Romero Salado, M. Guzmán García, R. Aranda Blázquez, G. Ruiz Villena, E. Sánchez Relinque, O. Mera Gallardo, F. Gómez Rodríguez

Department of Internal Medicine. Hospital de Puerto Real. Cadiz, Spain.

Objectives: Determine the influence of renal profile of patients with heart disease in the outcome and average hospital stay in our center.

Material and method: We included patients admitted with heart disease in the Universitary Hospital Puerto Real (Cádiz) in 2011. Variables studied: creatinine serum levels, urea, sodium (Na), potassium (K), renal function by Cockcroft-Gault, average hospital stay. The results were analyzed based on the characteristics of a descriptive study.

Results: Been seen that 30.07% of the patients (392 patients) in the present study, presents serum creatinine levels greater than 1.3 mg/dl or creatinine clearance less than 50, and 47.02% presents BUN levels above 40 mg/100 ml mean + 5.15 - 0.66 versus 5.076 ± 0.3878, but if we consider patients with serum levels greater than 2.5 mg/dl, we observe an average of 5.23 ± 1.02. Hyponatremia (values below 135 mg/dl) the 14.32% of patients, although no alterations in the average days of stay (4.73 ± 0.84). Presented hypokalaemia (values above 5 mg/dl) in 11.084% and hyperkalemia in 9.157% with a corresponding mean of 4.96 ± 4.837 + 0.92 and -1.2 respectively, presenting no changes in the average stay established.

Discussion: In patient with heart diseases, increasingly, there is often a pathology associated where you have to take account of renal function and Na and K alterations. In our study, 30% had renal function alterations, but the presence of hyponatremia and hypokalemia was not associated with increased length of hospital stay.

Conclusions: We perform a comprehensive assessment of patient with heart disease, paying attention to the pathology associated. The presence of altered renal function is common in patients with heart disease and was not associated with increased length of stay. The work of the Internal Medicine physician in this clinical setting is critical for proper patient care.

IC-54
INDICATIONS FOR ANTICOAGULATION IN PATIENTS WITH ATRIAL FIBRILLATION AND HEART FAILURE. ARE WE GOING IN THE RIGHT DIRECTION?

M. Hernández Meneses, A. Conde Martel, A. Martín Plata, S. Alonso, S. Santana, M. Serrano

Department of Internal Medicine. Hospital Universitario Dr. Negrín. Las Palmas de Gran Canaria (Las Palmas), Spain.

Objectives: This study analyzes the implementation of clinical practice guidelines in our environment, in order to know the adherence to anticoagulation (ACO) indications in hospitalized patients with heart failure (HF) and atrial fibrillation (AF).

Material and method: We reviewed discharge reports of 212 hospitalized patients with HF and AF, during the period between May 2011 and April 2012. We collected demographic data, medical history, comorbidity factors and history of AF specifying treatment with antiplatelet and/or anticoagulation before admission and at discharge. We calculated the CHADS2 and CHADS2vasc, as thrombotic risk score, and scale HASBLED about the risk of bleeding. We collected patients with ACO and patients who did not have anticoagulant therapy, being indicated, and the characteristics of them. To evaluate the relationship between categorical variables it was used chi-square test and to evaluate continuous variables relationship, student t-test or Mann-Whitney U-test.

Results: Out of 212 patients studied, hospitalized with HF and AF, 43% (91) were male and 57% (121) female, mean age 82 years (SD: 9 range 48-100). Comorbilities associated were Hypertension 87.3% (185), type 2 diabetes 49.5% (105), ischemic heart disease 30.2% (64) and stroke 20% (43). The average score of the Barthel index was 70 points (SD: 36 range 0-100). Almost all patients 62.7% (133), had heart failure with preserved ejection fraction. CHADS2 mean score was 3.8 points (SD 1.4, range 1-6), CHADS2vasc 4.5 points (SD: 2.2, range 1-9) and HASBLED score was 3.5 (SD 1.7, range 1-9). In our series more than 90% had indication to anticoagulation, according to the guidelines. Before hospital admission, 42% (89) were taking anticoagulation drugs, 19.1% (17) of them had double treatment with antiplatelet and anticoagulation drugs. After admission, 43% (91) kept treatment with ACO, 23% (21) with double therapy. Otherside, 36.3% (66) of all patients were receiving antiplatelet therapy, a trend which continued to rise, given that 39.7% (81) of them followed this treatment. Before admission 12.6% (23) of patients and after discharge 18% (37) did not receive any antithrombotic treatment. Only in 19.8% (24) it was specified the reason to not use anticoagulation therapy in patients who did not take it. There were no significant differences in the scales CHADS2, CHADS2vasc and HASBLED between patients with and without ACO. However, patients who did not have anticoagulation treatment were, significantly, older than who did (mean age 83 vs 79 years, p = 0.007), and they had poorer functional status, measurement by Barthel index (63.9 vs 79.2, p = 0.02). Any patient with Barthel index 0 did not receive treatment with ACO.

Discussion: It is well known the strong impact on the scientific medical community that the complying new guidelines of ACO in AF have. This is accentuated, if it is possible, by the appearance, and

even marketing, of new oral anticoagulants drugs. These reasons are made us review physician adherence guidelines regarding anticoagulation use in the patient type hospitalized in internal medicine. These results showed poor adherence to the guidelines; the trend of anticoagulation in our area is low, being indicated in almost all patients, but less than half did receive ACO. Elderly, pluripathology and poor functional status could explain these results.

Conclusions: In patients with heart failure and atrial fibrillation: old age, comorbidities and low functional status, call for a thorough and conscientious management of anticoagulation indications. In fact, these factors determine the physicians therapeutic decision, despite CHADS2, CHADS2vasc, and HASBLED scores. In conclusion, in our environment we did not prescribe anticoagulation according to guidelines. Less than 50% of patients which it is indicated, did not receive anticoagulant therapy.

IC-55
DECOMPENSATED HEART FAILURE REGARDING BLOOD PRESSURE IN AN INTERNAL MEDICINE DEPARTMENT

F. Gioia[1], I. Said Criado[1], E. Cortés Varón[1], S. Chamorro Tojeiro[1], J. Santiago Ruiz[1], M. Yebra Yebra[2]

[1]Department of Internal Medicine. Hospital Ramón y Cajal. Madrid, Spain. [2]Department of Internal Medicine. Hospital Rey Juan Carlos. Móstoles (Madrid), Spain.

Objectives: To describe basal and semiological characteristics, therapeutic strategies and clinical outcomes recopilated in a small sample of older inpatients diagnosed of heart failure and admitted to the department of Internal Medicine of Ramon and Cajal Hospital at Madrid.

Material and method: We selected thirty two patients managed as decompensated heart failure (HF), during 1st semester of 2010, excluding those with severe valve disease and whose clinical course did not agree with heart failure. We collected their basal characteristics, blood tests and treatment, focusing on treatment in the first 12 hours according to systolic blood pressure (SBP) and outcomes related to them. We sorted patients by blood pressure in 4 groups: low pressure (SBp < 85), normal systolic pressure (SBP between 86 and 105 or SBP between 106 and 139) and higher blood pressure (SBP > 140). We measured percentage of deaths, hospitalization-time and time from first attendance to death (if happened) in days. When collected the whole database, we calculated rates and means using SPSS 15.0.

Results: Thirty two patients were selected, 65.6% women, averaged 82 years old. Most of them (93.8%) had hypertension, chronic renal insufficiency 56.3% (mean creatinine 1.72) and atrial fibrillation 62.5%. Signs and symptoms were orthopnea (71.9%), jugular ingurgitation (31.3%), edemas (68.8%) and lung crepitation (78.1%). Mean SBP at attendance was 133.2 mmHg (± 30.5). Among therapeutic strategies in the first 12 hours, 3 patients were managed with only fluids (9.4%), 2 were treated with volume expansion plus furosemide (6.3%), 65.6% with furosemide and 15.6% with furosemide plus vasoactive drugs (Dopamine). After the first 6 to 8 hours after the treatment started, blood pressure (BP) did not change too much, being SBP 129 (± 28.3). Serum creatinine after 12-24 hours of treatment was 1.77 (closed to the first determination). We also found an average of 11.57 (± 10) days of hospitalization. We recorded 5 deaths (15.6% from total), all of them had chronic renal failure. Initial levels of serum creatinine of deceased were 2.36 mg/dl and 1.6 mg/dl among survivors. Four of 5 deceased had HF with preserved ejection fraction. All death patients had systolic BP between 86 and 139 (80% between 86 and 105) while among those who lived, 3.7% had SBP 86-105 and 48.1% had SBP 106-139. All deaths had impaired renal function 12 to 24 hours after admittance, while survivors had only 27.3%. Intravenous dose of furosemide at the first 6 hours was, on average, 40 mg (maximum 80 mg). Other treatments used: intravenous digoxin 18.8%, non-invasive mechanical ventilation 3.1% and intravenous nitrites 9.4%. Mean of hospitalization time was shorter in those with SBP > 140 (8 days), and it increased progressively: SBP 106-139 (10.5 days); SBP 86-105 (16 days) and 22 days in those with lower SBP at the time of attendance. From those patients with SBP 86-105, 75% had renal impairment while this impairment was present only 42.9% among the group with SBP 106-139.

Discussion: Recommendations about management of HF do not include clear statements for older patients with decompensated HF and normal BP (SBP 85-139) whose management is more difficult than those presented in guidelines. In that context, we focused on those therapeutic strategies used in clinical practice during the first hours of treatment, when doubts about the final diagnosis of the patient are present, describing outcomes of these patients, both deaths and impairment of renal function. Our results show that BP may be determinant in the clinical course of our patients.

Conclusions: Management of older normotensive (SBP > 85 mmHg) patients with decompensated HF, impaired renal function and normal BP is difficult, and current guidelines do not give specific recommendations.

IC-56
PHARMACOLOGICAL TREATMENT AS PREDICTOR OF OUTCOME IN THE OLDEST OLD HEART FAILURE PATIENTS

M. Camafort Babkowski[1], J. Gómez Ruiz[1], A. Jerez Lienas[1], E. Sacanella Meseguer[1], F. Pérez Villa[2], J. Cevallos[2], A. López Soto[1], A. Coca[1]

[1]Department of Internal Medicine, [2]Department of Cardiology. Hospital Clinic IDIBAPS University of Barcelona. Barcelona, Spain.

Objectives: In elderly patients Heart failure is one of the first causes of hospitalizations. Data about the characteristics of the oldest older patients are scarce. We try to evaluate clinical characteristics, and define the predictors of 1-year outcomes, defined as mortality and new hospitalizations, in patients older than 80 years with hospitalized heart failure in internal medicine and cardiology departments of our institution.

Material and method: Retrospective analysis of patients admitted to a Cardiology and Internal medicine departments of a University Teaching Hospital, during the first quarter of 2010. Sociodemographic data, Comorbidities (following PROFUND comorbidity Index), Cognitive status, Clinical echocardiographic and biochemical characteristics, treatments before and after admissions, and outcome (mortality and rehospitalizations one year after hospitalization) were reviewed from the electronic clinical records.

Results: Data from 157 subjects were collected. A 62.4% were women, with a mean age of 86.8 ± 4.63 years (range 80-104 y). Only 12.4% were living in nursing assisted homes, 19.7% had a mild dependency and 37.6% were non dependent. Comorbidities were present as follows: 6.6% were smokers, 84.1%, 31.2% hypertensive, 45.1% diabetics, 47% dyslipidemics, 47% had atrial fibrillation, 41.1% chronic kidney disease, 12.1% atherosclerotic or cardioembolic cerebrovascular disease, 27.4% had COPD, 10.2 had peripheral arterial disease, 53.2% previous Heart failure, and 25% ischemic cardiomyopathy. 47.5% were pluripathological patients (Profund comorbidity index > 5). 34.4%.At one year of follow up 31.65% died in the first year and 46% required new hospitalization, a total of 70.8% of patients presented a bad outcome defined as the combination. Only 35.6% received beta blockers, 41.5% ACEI or ARB, and only 12.7% Aldosterone antagonists. Only aldosterone antagonists showed a significant difference as for mortality, with a 23.3% of mortality in those untreated vs a 0% in those treated (p 0.039).

Conclusions: Oldest old heart failure patients are highly comorbid, and with a worse outcome. Those patients were less studied and treated, for different reasons as frailty and adverse effects, in our study treatment with aldosterone antagonists was related to a reduction in mortality. These findings deserve new studies.

IC-57
PREDICTORS OF OUTCOME IN THE OLDEST OLD HEART FAILURE PATIENTS: BIOLOLOGICAL DATA

M. Camafort Babkowski[1], C. Cardozo Espinola[1], M. Navarro López[1], F. Pérez Villa[2], J. Cevallos[2], A. López Soto[1], A. Coca[1]

[1]Department of Internal Medicine, [2]Department of Cardiology. Hospital Clinic IDIBAPS University of Barcelona. Barcelona, Spain.

Objectives: In elderly patients Heart failure is one of the first causes of hospitalizations. Data about the characteristics of the oldest older patients are scarce. We try to evaluate clinical characteristics, and define the predictors of 1-year outcomes, defined as mortality and new hospitalizations, in patients older than 80 years with hospitalized heart failure in internal medicine and cardiology departments of our institution.

Material and method: Retrospective analysis of patients admitted to a Cardiology and Internal medicine departments of a University Teaching Hospital, during the first quarter of 2010. Sociodemographic data, Comorbidities (following PROFUND comorbidity Index), Cognitive status, Clinical echocardiographic and biochemical characteristics, treatments before and after admissions, and outcome (mortality and rehospitalizations one year after hospitalization) were reviewed from the electronic clinical records.

Results: Data from 157 subjects were collected. A 62.4% were women, with a mean age of 86.8 ± 4.63 years (range 80-104 y). Only 12.4% were living in nursing assisted homes, 19.7% had a mild dependency and 37.6% were non dependent. Comorbidities were present as follows: 6.6% were smokers, 84.1%, 31.2% hypertensive, 45.1% diabetics, 47% dyslipidemics, 47% had atrial fibrillation, 41.1% chronic kidney disease, 12.1% atherosclerotic or cardioembolic cerebrovascular disease, 27.4% had COPD, 10.2 had peripheral arterial disease, 53.2% previous Heart failure, and 25% ischemic cardiomyopathy. 47.5% were pluripathological patients (Profund comorbidity index > 5). 34.4%. At one year of follow up 31.65% died in the first year and 46% required new hospitalization, a total of 70.8% of patients presented a bad outcome defined as the combination. Regarding to systolic dysfunction, CKD, and biological data only BNP (p 0.038), higher Potassium levels (p 0.005) and higher creatinine ($p < 0.005$) levels were associated with higher rates of readmission or death.

Conclusions: Oldest old heart failure patients are highly comorbid, and with a worse outcome. In our study BNP levels were related to a worse prognosis as in younger population, but only creatinine and potassium levels showed a significant association to a worse outcome. This finding deserves new studies.

IC-58
DIFFERENTIAL CHARACTERISTICS BETWEEN OLDEST OLD HEART FAILURE PATIENTS WITH SYSTOLIC VERSUS DIASTOLIC DYSFUNCTION

M. Camafort Babkowski[1], M. Domènech[1], C. Sierra Benito[1], F. Pérez Villa[2], J. Cevallos[2], A. López Soto[1], A. Coca[1]

[1]Department of Internal Medicine, [2]Department of Cardiology. Hospital Clinic IDIBAPS University of Barcelona. Barcelona, Spain.

Objectives: In elderly patients Heart failure is one of the first causes of hospitalizations. Data about the characteristics of the oldest older patients are scarce. We try to evaluate clinical characteristics, and define the predictors of 1-year outcomes, defined as mortality and new hospitalizations, in patients older than 80 years with hospitalized heart failure in internal medicine and cardiology departments of our institution, asnd differences between those with systolic and those with dyastolic dysfunction,.

Material and method: Retrospective analysis of patients admitted to a Cardiology and Internal medicine departments of a University Teaching Hospital, during the first quarter of 2010. Sociodemographic data, Comorbidities (following PROFUND comorbidity Index), Cognitive status, Clinical echocardiographic and biochemical characteristics, treatments before and after admissions, and outcome (mortality and rehospitalizations one year after hospitalization) were reviewed from the electronic clinical records.

Results: Data from 157 subjects were collected (62.4% women) with a mean age of 86.8 ± 4.63 years (80-104 y). 12.4% were living in assisted homes. 37.6% were non dependent, and 19.7% had a mild dependency. Comorbidities were present as follows: 6.6% smokers, 84.1% hypertensive, 31.2% diabetics, 45.1% dyslipidemia, 47% atrial fibrillation, 41.1% chronic kidney disease, 12.1% cerebrovascular disease, 27.4% COPD, 53.2% previous Heart failure, and 25% ischemic cardiomyopathy. 47.5% had a Profund comorbidity index > 5. 31.8% had no echocardiography, 55.1% had systolic dysfunction and 44.9% had preserved ejection fraction. Patients with preserved ejection fraction were more likely to be women (75% vs 46% in systolic dysfunction p 0.003), to have lower serum creatinine (1.3 vs 1.6 mg/dL in systolic dysfunction; $p = 0.02$), and they were less likely to receive aldosterone antagonists (7% vs 19%; $p = 0.05$). There was a non-statistically significant trend towards more rehospitalizations in the systolic dysfunction group (68% vs 51%) and higher mortality in the diastolic dysfunction group (30% vs 21%).

Conclusions: In our study, oldest old heart failure patients are highly comorbid, and present a worse outcome. Patients with diastolic dysfunction were more often women and they had lower serum creatinine. Their prognosis, however, was as bad as that of patients with systolic dysfunction.

IC-59
ECHOCARDIOGRAPHY IN HEART FAILURE: ARE WE DOING WELL?

A. Romero Alegría, J. Martín Oterino, P. Miramontes González, E. Puerto Pérez, N. Cubino Bóveda

Department of Internal Medicine. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca, Spain.

Objectives: To identify patients diagnosed with heart failure in our department of Internal Medicine in Salamanca (and of those who were recently diagnosed) To observe how many of them had an echocardiogram during hospital stay.

Material and method: This is a retrospective review of patients with heart failure who has been admitted to our department (Internal Medicine in Universitary Hospital of Salamanca) for two years. All patients who discharge summary was the diagnosis of heart failure from January, 1st 2009 to December, 31th 2010 were eligible for inclusion in the study. Data obtained include if the diagnosis of heart failure was prior or new, if they had previous echocardiogram and which had been made during hospital stay.

Results: Table 1.

Discussion: All major heart failure guidelines recommend echocardiography as an essential first line investigation in the evaluation of suspected heart failure. Retrospective studies

Table 1 (IC-59). Results

	Total	Heart Failure	Heart Failure (new diagnosis)	Prior echocardiogram	Echocardiogram during hospital stay
2009	1051	108 (10.27%)	38 (35.18%)	35 (32.41%)	6 (5.55%)
2010	1273	137 (10.76%)	43 (31.39%)	50 (36.49%)	7 (5.11%)

suggest that patients with a clinical diagnosis of heart failure who have had an echocardiogram have a better outcome than those who have not, presumably due to more appropriate evidence based management. Echocardiography is uniquely suited to characterize anatomical and functional abnormalities in patients at risk of developing heart failure, suspected of having heart failure, and with symptomatic heart failure. Furthermore, echocardiography can provide prognostic information and assist in the management of patients with acute, chronic and end-stage of heart failure. Echocardiogram let us know the presence or absence of left ventricular systolic dysfunction, the presence and severity of valvular dysfunction and key haemodynamic features such as diastolic filling patterns and pulmonary artery pressure. In our series, we see that less than a half of the cases had echocardiograms done and most of them were present prior to admission. So, treatment is not guided as either the systolic or diastolic dysfunction and our patients are discharged from hospital without knowing whether there is structural heart disease.

Conclusions: 1. The number of echocardiograms performed in MI is too low. 2. We have to do an echocardiogram, during hospital stay, in all cases of suspected heart failure to confirm the clinical diagnosis, identify the etiology and guide further investigation and therapy.

IC-62
DESCRIPTIVE STUDY OF PHARMACOLOGICAL MANAGEMENT OF ATRIAL FIBRILLATION (AF) AND HEART FAILURE (HF) IN PATIENTS ADMITTED TO AN INTERNAL MEDICINE DEPARTMENT (IMD)

M. Gallego Villalobos[1], N. Morán Suárez[2], E. Capín Sampedro[3], D. Pérez Martínez[1], J. Ferreiro Celeiro[1]

[1]Department of Internal Medicine. Hospital San Agustín. Avilés (Asturias), Spain. [2]Department of Internal Medicine. Hospital Nuestra Señora de Covadonga. Oviedo (Asturias), Spain. [3]Department of Cardiology. Hospital General de Asturias. Oviedo (Asturias), Spain.

Objectives: Describe the type of drugs used for heart rate control, the use of platelet antiaggregants and anticoagulants in HF patients admitted to an IMD.

Material and method: We reviewed the discharge summaries of patients admitted to the Heart Failure Unit in an Internal Medicine Department between the period of October 1, 2010 till March 31, 2011.

Results: We reviewed 214 discharge summaries, of those 119 patients presented AF (55% of patients) and the mean age was 81.3 years. Heart rate control was achieved using digoxin (54.62%), beta-blockers (45.38%), and non dihydropyridine calcium channel antagonists (16.81%). With respect to antithrombotic management, 47.06% used antiplatelet therapy, 65.54% anticoagulants, 17.24% used both, whilst 8.4% were not treated.

Discussion: AF is the most common cardiac arrhythmia in clinical practice. In our study, more than 50% of patients had AF, the high prevalence is due to the elderly age of patients admitted for HF. Heart rate control is one of the objectives to minimize symptoms and associated morbidity. We found digoxin to be the most commonly used drug, this may be explained by the relative contraindication of beta-blockers and calcium antagonists in heart failure patients. With respect to antithrombotic management despite being recommended in nearly all patients, only 65% were observed to be treated, probably due to factors such as elderly age, high degree of dependence, and the lack of studies in patients over 80 years.

Conclusions: 1. Age and heart failure are risk factors for atrial fibrillation. 2. Digoxin was the most commonly used drug for rate control.3. Only 65% of patients used anticoagulants.

IC-63
DIFFERENCES AMONG PATIENTS WITH ATRIAL FIBRILLATION (AF) ADMITTED FOR HEART FAILURE WITH OR WITHOUT ACCOMPANYING THYROID DISORDERS

M. Gallego Villalobos[1], N. Morán Suárez[2], H. Gómez Rodríguez[2], J. Ferreiro Celeiro[1], E. Capín Sampedro[3]

[1]Department of Internal Medicine. Hospital San Agustín. Avilés (Asturias), Spain. [2]Department of Internal Medicine. Hospital Nuestra Señora de Covadonga. Oviedo (Asturias), Spain. [3]Department of Cardiology. Hospital General de Asturias. Oviedo (Asturias), Spain.

Objectives: To assess whether there are differences in patients with AF admitted with HF who had thyroid disorders or not.

Material and method: We reviewed the discharge summaries of patients admitted to a Heart Failure Unit in an Internal Medicine Department between the period of October 2010 till March 2011. We included patients who had AF, whom were then divided into two groups, those who had thyroid disorders and those that did not.

Results: We reviewed 214 discharge summaries, of those patients 119 were found to be in AF and the mean age was 81.3 years. There were 21 patients with thyroid disorders, of which 14 were women (67%), 18 hypertensive (85.7%), 5 diabetic (23.8%) and 7 had ischemic heart disease (33.3%). The other 98 patients without thyroid disorders, 45 were women (46%), 82 hypertensive (83.7%), 37 diabetic (37.8%) and 41 had ischemic heart disease (41%). We found no significant difference with respect to sex ($p = 0.08$), age ($p = 0.201$), diabetes mellitus ($p = 0.225$), hypertension ($p = 0.817$), and ischemic heart disease ($p = 0.471$).

Discussion: In our study most were elderly patients, with an average age over 80 years. Thyroid disorders are present in a high percentage of patients almost 20%. However we found no statistically significant differences with respect to demographic and clinical characteristics of patients. It seems appropriate to assess thyroid disorders in patients with AF and in particular patients admitted with HF.

Conclusions: 1. There is a high prevalence of AF in patients with HF. 2. There are no epidemiological differences between patients with or without thyroid disorders. 3. Due to the elderly age of patients, there were concomitant diseases also associated with age such as hypertension, DM or ischemic heart disease.

Table 1 (IC-64)

	Age/ women %	FC III-IV	PAPm	CI	PVR (WU)	PRAm	Sat O2 Ao/ Sat O2 AP	Survival 1, 3, 5 years

IC-64
PULMONARY HYPERTENSION ASSOCIATED TO CONGENITAL HEART DISEASE WITH LEFT-TO-RIGHT SHUNT. IS IT ALWAYS BETTER THE DEFECT CLOSURE? PULMONARY HYPERTENSION REGISTRY (REHAP) DATA

M. Castillo Palma[1], M. Rodríguez Puras[2], C. Jiménez López-Guarch[3], J. Oliver Ruiz[4], L. Dos[5], J. Segovia[6], M. Lázaro Salvador[7], P. Escribano Subías[3] and the REHAP Investigators

[1]Department of Internal Medicine, [2]Department of Cardiology. Hospital Virgen del Rocío. Sevilla, Spain. [3]Department of Cardiology. Hospital 12 de Octubre. Madrid, Spain. [4]Department of Cardiology. Clínica Nuestra Sra. de la Paz. Madrid, Spain. [5]Department of Cardiology. Hospital Vall d'Hebron. Barcelona, Spain. [6]Department of Cardiology. Hospital Universitario Puerta de Hierro Majadahonda. Majadahonda (Madrid), Spain. [7]Department of Cardiology. Complejo Hospitalario de Toledo. Toledo, Spain.

Objectives: Pulmonary arterial hypertension associated with congenital cardiopathy (PAH-CC) develops in a subgroup of patients (pts) with left-to-right shunt after a period of time that depends on the defect characteristics (size and localization). There are few clinical and prognostics data of the subgroup of pts in which PAH is diagnosed after the surgical or percutaneous defect closure. The Spanish registry of pulmonary hypertension (REHAP) was started in 2007 and take in all the PAH forms, including pts with (PAH-CC). Objective: to analyze the clinical and prognostics characteristics of patients with PAH-CC after the defect closure, without residual shunt, and compare them with the larger and better known group of patients with Eisenmenger syndrome.

Material and method: REHAP registry is based on voluntary reporting of adult (> 14y) pts. diagnosed of PAH from Jan/98 to Apr/12, which include PAH-CHD. Cardiac catheterism is mandatory to include pts except in the Eisenmenger Physiology. 38 centers reported cases but the 4 larger reference centers of PAH and CC included 75% of the pts that were stratified in two groups of the new classification: 1) Eisenmenger; 2) PAH after the defect closure, without residual shunt. Pts were censored to death/transplantation. Comparative analysis of demographic, clinical, hemodynamic and survival data between groups and Kaplan-Meier curves were done.

Results: 298 pts were included (18% the total REHAP cohort). Differences among the 2 groups are depicted in table 1.

Conclusions: 1) REHAP is the first HAP-CC registry in our country and is one of the largest in Europe. 2) The pts with corrected defect have less PAPm, but worse right ventricular function: less cardiac index and O2 saturation in pulmonary artery and higher medial right atrial pressure. 3) Survival is significantly better in Esienmenger group. 4) Very strict criteria should be established to decide defect closure in pts with left-to-right shunt because an incorrect decision can induce an extreme bad prognosis (p: 0.015).*

IC-66
ADDING DRONEDARONE + DABIGATRAN + DEFIBRILLATION, SAFELY AND EFFECTIVELY CARDIOVERTS ATRIAL FIBRILLATION AND MAINTAINS SINUS RHYTHM. DDD PROCEDURE

R. Nicolas, B. Seoane, L. Castelo, S. Penedo, C. Pellicer, V. Ramos, F. de la Iglesia

Department of Internal Medicine. Hospital Universitario A Coruña. A Coruña, Spain.

Objectives: Dronedarone is the only anti arrhythmic decreasing deaths in Atrial Fibrillation (AF). Dabigatran is superior to warfarin in reducing strokes in AF. Leaving aside the outcomes of death and stroke, it is not known if the combined use of Dronedarone + Dabigatran + Defibrillation is safe and effective in promoting electrical cardioversion of AF and improving symptoms associated with AF.

Material and method: Retrospective analysis of prospectively collected data from a cohort of 33 consecutive patients with persistent AF. Patients were pretreated with Dronedarone + Dabigatran and electrically cardioverted. Primary outcome: change in the severity of symptoms attributable to AF as determined by the Canadian Cardiovascular Society Severity of AF Scale (CCS-SAF) and exercise capacity. Symptoms, 6 min walk test and LVEF were measured before and 6 months after cardioversion.

Results: The majority of patients (median age of 70) had comorbidities including hypertension, diabetes, and COPD. Cardioversion was not preferentially offered to younger patients with fewer comorbidities. Although we included elderly patients with multiple comorbidities requiring treatment with oral anticoagulants, antiarrhythmics, and other cardiovascular drugs, no major adverse effects, such as major bleeding, or proarrhythmia occurred. Minor bleeds, however, occurred in 2% of patients. Adequate rate control pending electrical cardioversion was achieved in the majority of patients. 14% of patients cardioverted to sinus rhythm (SR) while on treatment with dronedarone, without electrical cardioversion. Electrical cardioversion while on treatment with dronedarone had a 95% efficacy rate. Average follow-up was 6 months, with 80% of patients maintaining SR. Duration of persistent AF was associated with an increased risk of recurrent AF. We observed a significant improvement in symptom scores (particularly dyspnea and fatigue) in all patients that were previously severely symptomatic. Some patients who had "asymptomatic" AF felt much better after successful cardioversion. After restoration of SR, there was a significant improvement in the distance walked in 6 min. There was also an increase in LV Ejection Fraction in those patients with previous systolic dysfunction.

Discussion: This is the first clinical report of the combined effect of Dronedarone + Dabigatran + Defibrillation for conversion of AF demonstrating a significant symptom improvement without relevant adverse effects.

Conclusions: This investigation produced three novel findings concerning the combined use of Dronedarone, Dabigatran and Defibrillation: First, it is a logistically simple, safe and effective procedure to cardiovert persistent AF and maintain SR. Second, starting dronedarone while anticoagulation is achieved was useful for rate control previous to electrical cardioversion. Third, there was a clear clinical improvement in AF related symptoms more evident in dyspnea and fatigue amelioration, but also in palpitations perception. There was an increase in the distance

walked in a 6-minute walk test in more symptomatic patients. Given that better anticoagulants and antiarrthythmic drugs have became recently available we advocate to preserve sinus rhythm as a preference, and try cardioversion at least once when AF is first diagnosed.

IC-67
PREDICTORS OF HOSPITALIZATION DECISION AND MANAGEMENT OF ACUTE HEART FAILURE

J. Gómez Verdú[1], S. Valero Cifuentes[1], I. Cerezo Gracia[2], F. Alonso Cano[2], I. Fontes Manzano[2], J. Bauset Navarro[2]

[1]Department of Internal Medicine, [2]Department of Emergencies. University General Hospital Reina Sofia. Murcia, Spain.

Objectives: To determine the prevalence of Acute Heart Failure (AHF) in the Emergency Department (ED) and investigate the presence of predictors of mortality, readmission and re-visits in these patients.

Material and method: Epidemiological observational retrospective by reviewing case histories. We selected all patients attending in the first quarter of 2011 with a diagnosis of AHF. Variables: Framingham criteria; destination (hospilatization or discharged home); systolic, diastolic and mean blood pressure; value of NT-proBNP in the emergency admission; value of troponin in emergency admission; sodium ion value of emergency admission; hospital stay; hospital mortality; readmission in patients discharged home from the ED (admission for the same reason within the following 72 hours); readmission in patients hospitalized (readmissions for the same reason during the first 30 days after discharge); visits to emergency services in all patients within 90 days after initial assistance.

Results: ED of University General Hospital Reina Sofía (Murcia) receives about 280 emergencies per day. The first quarter of 2011, we assisted 25,131 emergencies, 251 of which (1%) were diagnosed with acute heart failure. In our series, 205 (82.7%) patients fulfilled Framingham diagnostic criteria for the diagnosis of AHF (two major or one major and two minors). So, 38 (15.3%) patients who were diagnosed as AHF, failed to meet the Framingham criteria for diagnosis. There are 8 missing cases in which we could not perform the review. 61 (24.5%) patients were discharged home after an initial emergency healthcare (outpatient), 11 (4.43%) were transferred to Media Care Hospital, and 168 (67.74%) were hospitalized. Hospitalized patients stayed in hospital an average of 11.08 days, with a mortality of 7.9%. Of the patients hospitalized, 18 (10.11%) were readmitted for AHF within 30 days after discharge. Three of patients who were not hospitalized (4.92%) consulted again by AHF within the first 72 hours after discharge. Of all patients, both hospitalized and discharged home, 62 (25.94%) were attended again due to AHF within 90 days after discharge. Prognostic factors associated with mortality were hyponatremia (Na < 135 mEq/l) (OR 5, 53, 95%CI: 2.04-15, p = 0.001), diastolic blood pressure less than 68 (p = 0.045) and mean blood pressure less than 88 (p = 0.044). No statistically significant difference was observed for the variables studied in the number of readmissions, and readmissions reconsultations.

Conclusions: The prevalence of AHF in our study is low. we think that it could increase whether we select patients also include AHF as secondary diagnosis. One in four patients treated in ED will be discharged home, and less than 5% of them return to consult for the same reason within 72 hours. Hospitalized patients (70%, similar to other series) remain in the hospital an average of 11 days, with a mortality around 10% and a readmission rate of 10%. Of the total patients, 25% consulted again by AHF within the first 3 months.

IC-68
MONOCYTOSIS AND DESCOMPENSATED CHRONIC ISCHEMIC HEART FAILURE

R. Ramírez Montesinos, L. Tikhomirova, C. Bidegain, O. Araujo, P. Villavicencio, A. Martínez, J. Márquez, E. Pedrol

Department of Internal Medicine. Sant Pau i Santa Tecla Hospital. Tarragona, Spain.

Objectives: Inflammation is strongly associated with cardiovascular disorders. Peripheral monocytosis is related to acute heart failure (HF) and left ventricular dysfunction after myocardial infarction. The objectives of this study were to establish the possible association between peripheral blood monocytosis and chronic HF due to ischemic etiology. Secondary objective was to evaluate possible differences between hospitalizations for ischemic and non ischemic heart failure.

Material and method: A transversal retrospective study attending to medical records of all patients (407) admitted in our centre for HF between December 2007 and October 2008 was retrospectively reviewed. Once exclusion criteria, patients with age < 18 or > 80 years, hematologic disorders, active or chronic infection or known terminal disease were excluded. Finally 89 patients were analized. Those who required more than one hospitalization only the first one was evaluated. Clinical information, blood tests, ejection fraction and requirement of new hospitalization, death for cardiovascular cause or death for any cause in the following 4 years) were recorded. Etiology and comparison between those with ischemic heart failure (IHF) and non ischemic (NIHF) cause was performed. Data were analysed using SPSS 20.0 for MAC.

Results: Patients hospitalized for HF were predominantly men (57.3%); 76.4% had hypertension (HT), 46.1% diabetes mellitus (DM), 16.9% smoke, 40.9% had anemia, 6.7% liver insufficiency and 22.7 renal insufficiency. On physical examination they presented 89 ± 29 beats/min, 140/76 ± 28/16 mmHg, 23 ± 5 resp/min and 91 ± 6% Hb oxygen saturation. According to the etiology 43% was ischemic, 39.5% valvular, 54.7% arrythmogenic, and 50.6% hypertrophic/hypertensive. Comparative results of IHF and NIHF showed difference between sex (males 55.1% vs 44.9 p < 0.05). Prevalence of HT was higher in IHF (86.5% vs 67.3% p 0.041), but not differences were found in DM (54.1% vs 40.8%), smoke (24.3% vs 12.2%) anemia (38.9%vs 42.9%), liver insufficiency (5.4% vs 6.1%), renal insufficiency (27% vs 20.4%), or exploration data (88 ± 22 vs 88 ± 29 beats/min, 24 ± 5 vs 23 ± 5, 141/76 ± 28/16 vs 140/74 ± 28/15 mmHg or 92 ± 5 vs 91 ± 7) p NS respectively for all of them. On laboratory test, both acid uric and GOT were significant higher in IHF (8.08 ± 1.98 vs 6.93 ± 2.46 mg/dl and 52.88 ± 57.79 vs 27.72 ± 24.71 U/I, p = 0.038 and p = 0.012 respectively). The rest of laboratory test (hemoglobin, lymphocytes, total cholesterol, triglycerides, albumin, bilirrubin, urea, creatinine, GPT and LDH showed no significant differences). Neither comparison of peripheral monocyte account between IHF with NIHF nor comparison between IHF plus any other etiology with NIHF showed differences (761 ± 295 vs 785 ± 289 cell/mm^3 and 729.40 ± 304.37 vs 785.63 ± 289.33 cell/mm^3 P NS in both cases). IHF showed too significant lower ejection fraction (59 ± 14% vs 49 ± 14%, p = 0.012), and was correlated with higher death for cardiovascular causes (24.3% vs 8.2% p = 0.038) with no differences in death for any cause (21.6% vs 22.4% p NS). They were no difference in readmission related to HF between IHF and NIHF (21.6% vs 12.2% p NS).

Conclusions: Patients hospitalized for ischemic heart failure has lower ejection fraction than to hose with non ischemic heart failure. Ischemic heart failure is correlated with higher incidence cardiovascular death. Peripheral monocytosis is not related to chronic heart failure due to ischemic etiology in our series.

IC-69
CHARACTERIZATION OF PATIENTS PRONE TO READMISSION TO HOSPITAL DUE TO HEART FAILURE

R. Ramírez Montesinos, L. Tikhomirova, P. Villavicencio, O. Araujo, A. Martínez, C. Bidegain, M. Díaz, E. Pedrol

Department of Internal Medicine. Sant Pau i Santa Tecla Hospital. Tarragona, Spain.

Objectives: Heart Failure (HF) represents almost 25% of all cause of mortality and hospitalizations in Spain. Decompensated patients who require admision to Internal Medicine Services are frequently related to any infectious disease. The objective of our series was to characterize patients ingressed in our hospital with HF diagnosis in order to assess possible differences between patients hospitalized at least one time previously (H) and those with no history of previous hospitalization (NH). The finally was to identify patients prone to hospital readmission and think about possible prevention measures.

Material and method: Descriptive transversal study of patients admitted in our hospital with HF between December 2007 and October 2008 were retrospectively reviewed. Medical records of 407 patients were evaluated. Exclusion criteria were age younger than 18 and older than 80 years, active infection or known terminal disease. Finally 89 patients were analized. Demographic (age, gender), clinical (risk factors, physical examination, laboratory test, ejection fraction), and death due to cardiovascular o due to any cause in the following 4 years were collected. Data were compared between HF previously hospitalized at least one time and no previous HF hospitalization using SPSS 20.0 for MAC.

Results: Patients admitted for HF were predominantly men 57.3%; 76.4% had hypertension (HT), 46.1% diabetes mellitus (DM), 16.9% smoke, 40.9% had anemia, 6.7% liver insufficiency and 22.7 renal insufficiency. On exploration heart rate was 89 ± 29 beats/min, 140/76 ± 28/16 mmHg, 23 ± 5 resp/min and 91 ± 6% Hb oxygen saturation. According to the etiology, 54.7% was arrythmogenic, 50.6% hypertrophic/hypertensive, 43% ischemic and 39.5% valvular. Comparing results between H and NH there were no differences between gender (males 58.5% vs 56.2%), HT (82.9% vs 70.8%), (DM 53.7% vs 39.6%) smoke (9.8% vs 22.9%) anemia (45% vs 37.5%), renal insufficiency (30% vs 16.7%) p NS in all of them. Liver disease was more frequent in patients previously hospitalized (12.2 vs 2.1) p = 0.058. Attending to the etiology there were no difference valvular (41% vs 38.3%), arrythmogenic (53, 8% vs 55.3%, hypertrophic/hypertensive (48.7%vs 52.2%), diastolic dysfunction (10.3% vs 10.9%). Anyway ischemic HF showed a tendency to be significant higher in those HF with previous hospitalizations (53.8% vs 34%) p = 0.06. There were no difference in examination: 94.6 ± 33.51 vs 83.51 ± 22.73 beats/min, 23.63 ± 4.52 vs 23.23 ± 5.22, 145/78 ± 33/16 vs 135/74 ± 21/16 mmHg, and 92.8 ± 4.6 vs 90.8 ± 7.2% on pulsioximetry, pNS in al of them). On laboratory test only urea was higher in previously hospitalized (72.74 ± 51.89 vs 50.70 ± 26.60 mg/dl p = 0.014). No differences were shown respect to the rest of biochemical parameters evaluated (GOT, GPT, total bilirrubin, LDH, creatinin, cholesterol, tryglicerids, albumin and acid uric, p NS). On hemogram, hemoglobin, lymphocytes, and monocytes levels were significant lower in patients previously hospitalized for HF (11.61 ± 2.04 vs 12.51 ± 2, 12, 1353 ± 690.27 vs 1730.11 ± 740.65 and 684.87 ± 299.02 vs 830.38 ± 272.95 p = 0.045, p = 0.016 and p = 0.019 respectively). No differences on ejection fraction (53.72 ± 16.92% vs 54.82 ± 13.73%) were observed. Cardiovascular mortality was higher in those HF with previous hospitalizations (27.5% vs 6.2% p = 0.007), but not mortallity for any cause (30% vs 16.7%) p NS.

Conclusions: According to our series, no data on clinical information or physical examination can differentiate patients with HF who required previously hospitalization. Some haemathologic manifestations (lower hemoglobin, monocytes and lymphocytes) could mark patients who required hospitalizations before. Those patients present, as expected higher cardiovascular mortality.

IC-70
HEART FAILURE WITH PRESERVED EJECTION FRACTION, ARE THERE DIFFERENCES IN TERMS OF SERVICE INCOME?

J. Lebrón Ramos, M. Villena Ruiz, R. Quirós López, M. Núñez Rodríguez, D. Urdiales Castillo, A. Aguilar López, M. Martín Escalante, J. García Alegría

Department of Internal Medicine. Hospital Costa del Sol. Marbella (Málaga), Spain.

Objectives: To analyze the differences among patients admitted for the first time Heart Failure with Preserved Ejection Fraction in terms of their stay in Internal Medicine and Cardiology.

Material and method: The study includes patients in first admission with heart failure (HF) with left ventricle fraction of ejection (LVEF) > 50% in the period from 1st January, 1997 till the 31st of December 31, 2001. We analyze two groups, depending on the income in Internal Medicine (IM) or Cardiology (C), with special attention to demographic variables, comorbidity, therapeutic and, finally, prognostic. The maximum follow-up time was 14 years.

Results: A total of 231 patients join the hospital, but only 130 do so in the cardiology department (56.3%). This average of age was higher in patients admitted to Internal Medicine (71.9 vs 67, p <0.001). In both groups, the amount of women that join were similar, 58%. Among the comorbidities, hypertension was more prevalent in those admitted to IM (72.3% vs 57.7%, p = 0.02), as well as COPD (16.8% vs 6.2%, p = 0.01) and kidney failure (56.4% vs 40.8%, p = 0.02). There were no differences among groups in the prevalence of diabetes, dyslipidemia, ischemic heart disease, cerebrovascular disease, atrial fibrillation and stroke. Decompensation with respiratory infection was more frequent in IM (28.7% vs 10.8%, p < 0.001), while in Cardiology, it was ischemic heart disease (8.5% vs 2%, p = 0.04) and rapid atrial fibrillation (29.2% vs 13.9%, p = 0,007). In treatment, there were no differences in the use of diuretics, antiplatelet therapy, ACE inhibitors, ARBs, digoxin, calcium channel blockers and statins among groups. It was a larger proportion of patients receiving beta-blockers in Cardiology (54.6% vs 17.8%, p < 0.001). During the follow-up (average 81.3 months (95% CI 74.8-87.8)) patients admitted in IM readmitted 2.7 times, compared to 2.08 in Cardiology, no significant differences. At the end of follow-up, mortality was higher in IM (82.2% vs 56.2%, p < 0.001). Table 1 shows the variables included in the multivariate analysis adjusted by age and gender for the total sample.

Conclusions: Patients hospitalized for HF with preserved LVEF in IM are older, with higher prevalence of hypertension and renal failure compared to those who enter Cardiology. Revenue in Cardiology in a greater proportion of decompensation caused by atrial fibrillation and ischemic heart disease. On the other hand, Respiratory infection is the main factor in IM. The main difference in treatment is the increased use of beta-blockers in Cardiology. The long-term mortality is lower in patients with first admission in Cardiology.

Table 1 (IC-70). Variables associated with mortality in multivariate analysis

	Odds Ratio	95%CI	p
Age	1.01	1.00-1.03	0.03
Cardiology Admission	0.66	0.46-0.93	0.01
Diabetes	1.52	1.09-2.12	0.01
Kidney Failure	1.57	1.10-2.24	0.01
Treatment with beta-blockers	0.57	0.39-0.82	0.003
Treatment with statins	0.49	0.31-0.78	0.003

IC-73
MULTIDISCIPLINARY APPROACH OF THE CARDIORENAL SYNDROME

M. Poveda García[1], M. Esteban Moreno[2], S. Muñoz Troyano[3]

[1]Department of Internal Nephrology, [2]Department of Internal Medicine, [3]Department of Cardiology. Complejo Hospitalario de Especialidades Torrecárdenas. Almería, Spain.

Objectives: The term cardiorenal syndrome (CRS) has been applied to these interactions, but the definition and classification have not been clear. To include the vast array of interrelated derangements, and to stress the bidirectional nature of heart-kidney interactions, we present a new classification of the CRS with 5 subtypes that reflect the pathophysiology, the time-frame, and the nature of concomitant cardiac and renal dysfunction. Our purpose was to study the existence of CRS in a cohort of patients admitted for heart failure in a general hospital.

Material and method: Retrospective study in 50 patients with heart failure. The sample calculation was performed on a universe of 983 discharged patients from the Internal Medicine department of Torrecárdenas hospital from January 2011 until April 2011. We analyzed clinical and epidemiological variables (eg age, sex, cardiovascular risk factors and toxic habits). The data were analyzed by using SPSS 18.0 statistical package.

Results: The following variables were studied: age 64 ± 5 years, sex 32 males/28 females (66%). We study the comorbidity: 48% of patients with diabetes mellitus, 59% arterial hypertension, 45% dyslipidemia and 37% were smokers. 42% of patients had Cardiorenal syndrome type 1 (acute CRS is characterized by a rapid worsening of cardiac function, leading to acute kidney injury). Of these patients, 15% required renal replacement therapy. 68% of patients had Cardiorenal syndrome type 2 (Type 2 CRS is characterized by chronic abnormalities in cardiac function causing progressive cronic kidney disease). Analyzing therapeutic antihypertension families: 80% ACE inhibitors, 73% angiotensin 2 receptor antagonists and 69% diuretics. 9% had heart failure refractory to treatment with CKD (stage 3) to require weekly ultrafiltration techniques with good results.

Conclusions: A reduced glomerular filtration rate (GFR) is generally associated with a worse prognosis in patients with heart failure (HF), whether present at baseline or developing during therapy for HF. In our study we found high prevalence of CRS in patients hospitalized for heart failure. The management should be based on the individualization of treatment and the multidisciplinary approach.

IC-74
PROGNOSTIC FACTORS AND VERY LONG-TERM SURVIVAL AFTER INITIAL DIAGNOSIS OF HEART FAILURE

R. Quirós López, V. Núñez Rodríguez, D. Urdiales Castillo, A. Aguilar López, M. Marcos Herrero, A. Blázquez Puerta, M. Martín Escalante, J. García Alegría

Department of Internal Medicine. Hospital Costa del Sol. Marbella (Málaga), Spain.

Objectives: To assess very long-term mortality and prognostic factors in patients with heart failure with preserved ejection fraction (ICFEP) against heart failure with systolic dysfunction (ICDS).

Material and method: Retrospective cohort study of patients with first admission for heart failure during the period between 01.01.1997 and 31.12.2001, classified according to ejection fraction (LVEF) increased (ICFEP) or lower (ICDS) of 50%, followed until December 31, 2011.

Results: On a total of 400 incident cases of heart failure, 231 patients (57.7%) had ICFEP. They were older (69.1 vs 66.3 years, $p < 0.001$), predominantly female (58.5% vs 30.8%, $p < 0.001$), history of hypertension (64.1% vs46.7%, $p < 0.001$) and atrial fibrillation (22.9% vs 14.8%, $p = 0.03$) for the group with ICDS. Mean follow-up was 76.8 months (95%CI 71.9 to 81.7), with a maximum of 168 months. At 14 years, mortality was greater in the ICDS (78.1% vs 67.5%, $p = 0.02$). After performing a multivariate analysis the variables associated with mortality in ICFEP included age, diabetes mellitus and chronic renal failure. Treatment with statins and β-blockers was associated with better prognosis. Among patients with ICDS predictors of mortality were age and presence of diabetes mellitus, while treatment with beta-blockers improved survival.

Conclusions: A high proportion of patients with heart failure have ICFEP. Mortality in these patients over the long term is very high, although somewhat lower in the ICFEP regarding the ICDS. Age, diabetes mellitus and chronic renal failure is associated with poor prognosis in patients with LVEF > 50%, while the use of statins improves it. In systolic dysfunction are age and the presence of diabetes-related variables over the very long term prognosis. B-blockers improved survival in both groups.

IC-75
CARDIOVASCULAR RISK FACTORS IN PATIENTS ADMITTED FOR HEART FAILURE

I. Domínguez Quesada[1], V. Martínez Mateo[2], J. Plaza Carrera[2], L. Oriente Frutos[1], M. Galindo Andúgar[1], J. Castellanos Monedero[1], L. Rodríguez Rojas[1], A. Martín Castillo[1]

[1]Department of Internal Medicine, [2]Department of Cardiology. Complejo Hospitalario La Mancha Centro. Alcázar de San Juan (Ciudad Real), Spain.

Objectives: To analyze the differences between the inpatients with congestive heart failure (CHF) in our hospital and their cardiovascular risk factors (CVRF).

Material and method: Retrospective descriptive study that included patients admitted to our hospital for exacerbation of heart failure from January to February 2010. Different factors were included as personal history and echocardiogram results (when it was performed during admission or within the last six months). Analysis with PASW statistic 18 (SPSS inc.).

Results: 49 patients were included in the study. The specialty in charge was Internal Medicine in 40 patients (80%), Cardiology in 3 patients (6%), Neumology in 6 patients (12%) and Intensive Care Unit (ICU) in 1 patient (2%). The mean age was 80.6 years and the median stay was 12.5 days. Regarding to the personal history, the most frequent CVRF was the arterial hypertension in 32 patients (64%) followed by diabetes mellitus type 2 in 21 patients (42%), dyslipidemia in 14 patients (28%), smokers in 4 patients (8%) and ex-smokers in 4 patients (8%). Besides, there were chronic renal disease in 20 cases (41.5%) and chronic obstructive pulmonary disease in 15 (31%). The most usual treatment were the angiotensin-converting enzyme inhibitors (ACEI) in 69% of the patients, followed by digoxin in 42.9%, beta-blockers in 24.4%, spironolactone in 21.4%, amiodarone in 7.1%, ACEI + angiotensin II receptor blockers in 4.9%, digoxin + beta-blockers in 4.8% and eplerenone in 2.4%. Echocardiography was performed in 67.3% of patients with preserved left ventricular ejection fraction (LVEF) in 22 inpatients (66.7%) and decreased LVEF in 11 cases. When we divided the patients into two groups in accordance with the LVEF, the presence of CVRF and the treatment are similar between both groups with no statistically significant difference. However, the inpatients with decreased LVEF had a longer staying with statistically significant difference ($p = 0.01$).

Discussion: It is remarkable the small percentage of former smokers and current smokers, a percentage that may be influenced by the number of old women. Hypertension appears to be the most common risk factor.

Conclusions: In our study we found no differences between the patients with preserved and decreased LVEF except for the stay at the hospital.

Table 1 (IC-76). Baseline characteristics

Hypertension	92% (n = 46)	Coronary heart disease	18% (n = 9)
Chronic kidney disease	44% (n = 22)	Creatinine	1.20 ± 0.38
Diabetes	52% (n = 26)	Renal clearance (MDRD)	54.11 ± 20.56
Atrial fibrillation	60% (n = 30)	Potassium	3.96 ± 0.35

IC-76
SAFETY AND TOLERABILITY OF SPIRONOLACTONE IN ELDERLY PATIENTS WITH HEART FAILURE AND PRESERVED EJECTION FRACTION

A. González[1], J. Santiago[1], N. Ribas[1], M. Yebra[2], I. Barbolla[1], M. Pumares[1], M. Moralejo[1], L. Manzano[1]

[1]Department of Internal Medicine. Hospital Ramón y Cajal. Madrid, Spain. [2]Department of Internal Medicine. Hospital Rey Juan Carlos. Móstoles (Madrid), Spain.

Objectives: To evaluate the safety and tolerability of spironolactone in patients with heart failure and preserved ejection fraction.

Material and method: We included 50 consecutive patients evaluated in our clinic who met criteria for heart failure with preserved ejection fraction (HFPEF) (using a diagnostic protocol based on clinical and echocardiographic parameters and brain natriuretic peptide) and who were being treated with spironolactone before December 2009. Patients with severe or moderate to severe valvular disease were excluded. We analyze the number of hospital admissions, the emergency room visits, the number of deaths and the need to discontinue the drug or reducing the dose until December 2011. We classify the causes of suspension into 4 groups: 1) Kidney failure, 2) Hyperkalemia, 3) Gynecomastia/Breast Pain, 4) Other/Unknown; and the causes of dose reduction in 3 groups: 1) Kidney failure, 2) Hyperkalemia, 3) Other. Emergency room visits and hospital admissions were divided into those that occurred due to renal failure and/or hyperkalemia, heart failure and other causes. We used the chi square test for comparing proportions. Continuous variables are expressed as mean ± standard deviation and qualitative variables as percentage.

Results: The mean age of patients was 81.4 years. 66% of patients were women. The rest of the baseline characteristics are shown in Table 1. 30% were on ACEI, 34% on ARBs, and 98% on loop diuretics treatment. The mean duration of treatment with spironolactone was 25.40 ± 16.70 months. 42% (n = 21) of patients required discontinuation of treatment with spironolactone, 11 of them because of worsening renal function, 4 by hyperkalemia and 6 by unknown cause. However, in half of the patients requiring discontinuation, the drug could be introduced again (n = 10). Moreover, 14% (n = 7) of cases required a dose reduction, without having to stop the treatment, due to high levels of potassium or due to renal impairment. The need to discontinue the drug was significantly higher among patients with chronic kidney disease (p = 0.03). There were 80 hospital admissions, 39 due to heart failure, 4 secondary to hyperkalemia and 37 due to other causes. There were 152 emergency room visits, 40 caused by heart failure, 4 due to hyperkalemia/renal impairment and 108 related to other causes. During the monitoring period, 17 patients died (34%). No death was attributed to hyperkalemia.

Discussion: The benefits of aldosterone antagonists in patients with systolic dysfunction have been widely observed. However, it could also be useful as diuretic drug in patients with HFPEF. This study, based on a cohort of elderly patients with very close monitoring, suggests that the use of spironolactone in elderly is safe even in those who have some degree of renal impairment and in those who are treated with ACE inhibitors or ARBs.

Conclusions: The use of spironolactone in elderly people with HFPEF-in a closely monitored settings- is safe and well tolerated.

IC-78
IMPROVED SURVIVAL OF PATIENTS WITH HEART FAILURE TREATED WITH BETA BLOCKERS, WHEN THE BENEFIT BEGINS?

R. Quirós López[1], V. Núñez Rodríguez[1], M. Villena Ruiz[2], D. Urdiales Castillo[1], A. Blázquez Puerta[1], J. Lebrón Ramos[1], M. Uribe Pérez[1], J. García Alegría[1]

[1]Department of Internal Medicine. Hospital Costa del Sol. Marbella (Málaga), Spain. [2]Department of Internal Medicine. USP Hospital de Marbella. Marbella (Málaga), Spain.

Objectives: To assess the prognostic benefit of beta-blockers in heart failure (HF) after the initial diagnosis, analyzing their benefit on prognosis and the time in which it appears.

Material and method: Retrospective cohort study of patients with first admission for heart failure during the period between 01.01.1997 and 31.12.2001, followed until December 31, 2011. Analysis of epidemiological variables, comorbidity, treatment and prognosis. Subsequently, Kaplan-Meier analysis of the impact on survival of beta-blockers during follow-up period.

Results: A total of 400 incident cases of heart failure were included, with a mean age of 67.9 years (95%CI 66.8 to 69.1), female gender in 46.8%. Highlighted in the personal history: hypertension in 56.8%, diabetes mellitus in 40.5%, dyslipidemia in 17.8%, ischemic heart disease in 23.3% and renal failure in 46.3%. 43.5% of patients had atrial fibrillation. The ejection fraction (LVEF) was 52% (95%CI 50-54), with 42.3% of patients with left ventricular systolic dysfunction. Regarding treatment, antiplatelets in 59.5%, loop diuretics in 95.8%, potassium-sparing, 45.3% in 86% ACE inhibitors, ARBs in 22.5%, calcium-antagonist in 33.3%, 49.3% beta blockers, digital accounted for 48.3% and finally 22.5% statins. After performing a multivariate analysis adjusted for age and gender, variables related with mortality were age, diabetes mellitus, lower creatinine clearance and a lower LVEF. However, the use of b-blockers improved the prognosis of patients, OR 0.71 (95%CI 0.54-0.91). The Kaplan-Meier analysis showed a decrease in mortality in patients treated with beta-blockers from the first year of treatment (log rank test: 0.013), maintaining this protective effect for a maximum follow-up period of 14 years and average of 76.8 months (95%CI 71.9 to 81.7).

Conclusions: In patients with heart failure at initial diagnosis the use of beta blockers provides survival benefit early, from 12 months of treatment. This survival benefit is maintained during evolution of heart failure.

IC-80
ATRIAL FIBRILLATION IN PRESERVED EJECTION FRACTION HEART FAILURE PATIENTS, A FREQUENT ASSOCIATION, WITH A WORSE PROGNOSIS?

V. Uribe Pérez[1], M. Villena Ruiz[2], R. Quirós López[1], D. Urdiales Castillo[1], A. Aguilar López[1], A. Blázquez Puerta[1], J. García Alegría[1]

[1]Department of Internal Medicine. Agencia Publica Hospital Costa del Sol. Marbella (Málaga), Spain. [2]Department of Internal Medicine. USP Hospital de Marbella. Marbella (Málaga), Spain.

Objectives: To analise the heart failure long-term prognosis con with preserved ejection fraction (ICFEP) depending on the presence of atrial fibrillation (AF).

Material and method: Retrospective cohort study of patients with first admission for heart failure with LVEF higher or same as 50%, between January 1st 1997 and December 31st 2001. Demographic variants, comorbidity, treatment and long-term prognosis with a maximum period of 14 months follow-up are analised.

Results: During the time of the study, 231 patients were checked in, out of which a 51.9% showed atrial fibrillation (permanent in 94.2% of the cases). Within the overall group of heart failure with LVEF preserved patients, the amount of preserved atrial fibrillation was higher than diabetes mellitus (41.6%), ischemic heart disease (17.7%), renal failure (47.6%). In the analysis per group (AF vs sinus rhythm), there were no differences regarding age (68.6 vs 69.7, p = 0.49) or gender (60% vs 56.8% feminine, p = 0.68). The dyslipidemia was less frequent in the AF group (11.7% vs 28.8%, p = 0.02), as in the case of the ischemic heart disease (10.8% vs 25.2%, p = 0.006). There are no records of differences among groups in the hypertension, diabetes, renal failure and COPD prognostic. The valvular dysfunction was more frequent in AF patients (43.3% vs 31.5%, p = 0.07). Chart 1 shows the main differences in the treatment administered. Finally, there were no differences in the long-term prognosis among the group (a maximum of 14 months follow-up, average 76.8 months, 95%CI: 71.94-81.77), with a mortality rate of 63.3% in the AF group, compared to the 72.1% in sinus rhythm, p = 0.16.

Conclusions: Heart failure with LVEF preserved and atrial fibrillation patients show a similar clinical profile to those in sinus rhythm. Atrial fibrillation does not affect the long-term prognostic of these patients.

Table 1 (IC-80). Difference among groups in the treatment

	Atrial fibrillation Group	Sinus rhythm Group	p
Loop diuretics	97.5%	91.9%	0.07
ACE inhibitors	82.5%	79.3%	0.61
Beta-blockers	33.1%	44.1%	0.10
Digital	78.3%	18%	0.001
Anticoagulants (acenocumarol)	77.5%	23.5%	0.001
Antiplatelets	41.7%	70.3%	0.001
Calcium-antagonist	36.7%	49.5%	0.06

Inflammation and autoimmune diseases

IF-1
DESCRIPTIVE ANALYSIS OF A COHORT OF 140 PATIENTS WITH CHRONIC FATIGUE/CF IN THE HOSPITABLE SPECIALIZED UNIT OF THE CAMP OF TARRAGONA - HSUCFCT

R. Qanneta[1], M. Poveda Elices[2], S. Castro Oreiro[2], A. Castel Riu[3], J. Aguilar Naranjo[4], E. García Romero[5], R. Fontova Garrofé[2]

[1]Department of Internal Medicine, [2]Department of Rheumatology, [3]Department of Psychology, [4]Department of Physical Medicine and Rehabilitation, [5]Nurse Manager of Cases. Hospital Universitari Joan XXIII. Tarragona, Spain.

Objectives: The HSUCFCT is an initiative based on the creation and promotion of unit of managing interdiscipline of patients with Chronic Fatigue. We describe our experience from June 2010 untill May 2012.

Material and method: A descriptive observational study including patients who have been attended for asthenia in the HSUCFCT. We were collected epidemiological and clinical characteristics as well as accompanying disorders and associated comorbidity phenomena (ADACP). It has been realized the statistical descriptive and comparative analysis by means of the chi-squared test with the program SPSSPC v 11.5 for Windows.

Results: Of the total of 140 patients: 83.5% were women (117/23) and the mean age of onset of symptoms was 42.5 years (min 9/max 76). 54.3% (76 p) are patients with a specialized job. 38.5% (54 p) were on sick leave at the time of the visit, 32.8% (46 p) were still working and 28.5% (40 p) with disability status. As a possible precipitating factor 27.8% include stressful life event, 14.2% infectious cause, 8.5% toxic exposure and 7.2% physical trauma. 42.8% (60 p) do not remember any factor. The onset was insidious in 73.6% (103 p) and suddenly in 26.4% (37 p). The evolution course has been continuous in 74.3% (104 p) and in outbreaks in 25.7% (36 p). 100% of the patients complain of musculoskeletal symptoms, recurrent headache in 82.8%, sleep disruption in 80.7%, cognitive symptoms in 80% and autonomic symptoms in 53.6%. As ADACP: 82% of patients have Sicca syndrome, fibromyalgia in 55%, dyslipidaemia in 39.3%, rhinosinusitis in 37.2%, dysthymia in 22.2%, irritable colon in 19.3%, multiple chemical sensitivity in 18.5%, autoimmune tiroiditis in 15.7%, lactose intolerance in 13.6%, urinary incontinence in 11.4%, sleep snoring in 8.6%, myofascial syndrome in 6.4%, nickel allergy in 6.4%, restless legs syndrome in 5.7%, coeliac disease in 3.6%, bladder hyperactive in 2.8%, interstitial cystitis in 2.2%, plantar fasciitis in 2.2% and Raynaud's phenomenon in 2.2%. 81 patients (57.8%) were diagnosed as having chronic fatigue syndrome-myalgic encephalomyelitis CFS-ME (6 patients with a family history) according to the Fukuda´s criteria 1994. However 37 patients (26.4%) were diagnosed of Secundary Chronic Fatigue while 11 patients (7.8%) were received the diagnosis of idiopatic chronic fatigue. 11 other patients (7.8%) were considered as having fibromyalgia without a clear component of CF. Respect to patients diagnosed of secundary chronic fatigue: 24.3% (9 p) are associated to incomplete Sjögren syndrome according to the American European Consensus 2002, 18.9% (7 p) to psychiatric disorder, 13.5% (5 p) to statin-induced myopathy, 13.5% (5 p) to rheumatic polymyalgia, 8.1% (3 p) to liver cirrhosis, 8.1% (3 p) to pituitary microadenoma, 5.4% (2 p) to sleep apnea syndrome, 5.4% (2 p) to ischemic cardiopathy and 2.7% (1 p) to Guillain-Barré syndrome. 59 patients (42.1%) were evaluated for cognitive behavioral therapy and exercise program regulated. 77 patients (55%) were received antidepressants, 38 p (27.1%) NSAIDS, 18 p (12.8%) Prednisone, 12 p (8.5%) antioxidants, 6 p (4.2%) Hydroxychloroquine, 1 p anti-TNF and other 1 p intravenous immunoglobulins.

Discussion: CFS-ME affects mainly young women and determines functional limitation. It is difficult to reach an accurate diagnosis. Some patients diagnosed with CFS-ME have symptoms commonly observed in primary Sjögren's syndrome, leading to speculation that the two disorders share common pathophysiological features.

Conclusions: The HSUCFCT is a model of management centered on the integral valuation of all the pathological processes and diagnostic/therapeutic procedures.

IF-2
EXPERIENCE IN CRYOGLOBULINEMIA AT FUENLABRADA UNIVERSITY HOSPITAL

R. Calderón Hernáiz, D. Rejas Velásquez, R. Martín Díaz, E. Madroñal Cerezo, J. Ruiz Ruiz, I. Perales Fraile, A. Zapatero Gaviria, J. Canora Lebrato

Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: Cryoglobulinemia is a rare disease, with an estimated prevalence of 1 per 100,000. More than 90% of the cases have a

known predisposing condition. However, there is still areas of uncertainity about how to treat this disease (duration and combination of immunosupresors, biologic therapies…). Our objective is to analyze all cases of cryoglobulinemia diagnosed in the Internal Medicine Service of Fuenlabrada University Hospital (FUH), describing predisposing conditions, clinical course, complications and treatments received.

Material and method: Retrospective descriptive study of cryoglobulinemia cases diagnosed in the Internal Medicine Service of FUH, since its opening in 2004.

Results: During this period we detected 5 cases of cryoglobulinemia: two type I and three type II. Most were healthy woman (4/5) of mean age at diagnosis (range 51-63 years), without known viral infection or cancer (there was only one case of breast cancer treated years earlier with no evidence of disease). The most common finding was palpable purpura in lower extremities (4/5). Two cases had also sensory-motor polyneuropathy. None of the patients had renal failure, although we detected one case of hematuria: renal biopsy was impossible due to coagulopathy. There were no cases of alveolar hemorrhage or CNS involvement. We detected one case of HCV infection (genotype 1) and other of HBV. It was common to find low C4 (4/5) with standard C3. The autoimmunity study performed in all patients revealed three cases of positive ANA (high title but intermittent in time) without diagnosis criteria for SLE, one of them also had antiRo and anticardiolipins antibodies but not diagnosis criteria for Sjögren or antiphospholipid syndrome. The skin biopsy performed in four patients showed leukocitoclastic vasculitis in all of them. Only one patient had endoneural vasculitis. Four patients were treated: one of them only with oral steroids for a month, the remaining with bolus of methylprednisolone followed by oral steroids (between 1-1.5mg/kg/d) for a variable time (between 5 and 16 months). The most refractory was infected with HCV: she also received 14 sessions of plasmapheresis, and because of persistence of outbreaks and poor tolerance to the treatment it was necessary to use azathioprine and methotrexate. She received no antiviral treatment due to comorbidity, high viral load, liver fibrosis and type of cryoglobulinemia (I) not typically associated with HCV infection (accessed with the Digestive Service). However, the patient infected with HBV received antiviral treatment with a significant clinical improvement. Clinical remission and negative cryoglobulins were reached in all cases. The mean follow-up time was 11.6 months. There were no deaths in our series.

Conclusions: Despite being a rare disease we found many cases of cryoglobulinemia in FUH. Most occur in middle-aged women and palpable purpura is the most common finding. Only two cases in our study had a predisposing condition (HCV and HBV infection). It is usual to find low C4 with normal C3. There is limited evidence about the treatment of cryoglobulinemia; in many cases the strategies are based on personal experience and expert opinions. There is also no data on maintenance of immunosupressive agents. The only case of viral infection that was treated in our series had a favorable outcome. Rituximab was not used in any case.

IF-4
ANTICOAGULATION TREATMENT WITHDRAWAL IN PATIENTS WITH PRIMARY APS WHEN APL BECAME NEGATIVE

E. Coloma Bazán, P. Moreno Lozano, C. Donate López, R. Cervera, G. Espinosa

Department of Autoimmune Diseases. Hospital Clínic de Barcelona. Barcelona, Spain.

Objectives: Recommended treatment for patients with primary antiphospholipid syndrome (APS) after a thrombotic event is long-term anticoagulation. Few patients with APS and previously positive antiphospholipid antibodies (aPL) may become negative over time. It is still not exactly known how to treat these patients whose aPL become negative. We described a group of APS patients with negative aPL during follow-up after anticoagulation therapy was discontinued.

Material and method: Eleven patients with primary APS and previously positive aPL that became negative during follow-up were included. Anticoagulation or antiaggregation therapy was discontinued when APA became persistent negative during follow-up.

Results: Ten (90%) patients were female. All patients except one (IgG anticardiolipin antibodies [aCL] below 40 GPL) fulfilled classification criteria for APS. Seven (64%) patients had deep venous thrombosis and 4 (40%) had recurrent miscarriage. Lupus anticoagulant (LAC) was the aPL most frequent (82%). Two patients had both LAC and IgG aCL. As a whole group, no new thrombotic episode was observed after a median follow-up period of 20 months. In those patients with previous thrombosis no new thrombotic episode was observed after a median follow-up period of 18 months.

Conclusions: Anticoagulation could be discontinued in those patients with primary APS and persistent negative APA. However, more extensive studies are required to confirm these results.

IF-6
RISK FACTOR IN COLON CROHN'S DISEASE SURGERY: SMOKING HABIT

R. Lana[1], N. López Palacios[2], A. Lérida Urteaga[1], E. Urcelay[3], J. Mendoza[3], J. Mendoza[2]

[1]Department of Internal Medicine, [2]Department of Digestive Diseases, [3]Department of Immunology. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: To analyze the tobacco influence in bowel surgery rate of CD patients. A secondary objective was to investigate whether smoking will affect surgery rates, depending on the location.

Material and method: Medical records of CD patients diagnosed at a single center in Madrid, Spain, between 2005 and 2009, were retrospectively reviewed. The primary outcome was the occurrence of non-perianal CD-related surgery, defined as the need for bowel resection or drainage of non-perianal abscesses. Smokers were compared with nonsmokers at the time of diagnosis. Smokers included smokers at the time of diagnosis or less than 5 years without smoking at the time of diagnosis. Multivariate analysis (Cox proportional hazard model) includedage at diagnosis, sex, location, behavior, perianal disease and treatment prior to surgery (immunosuppressive, anti-TNF) as covariates.

Results: We included 400 patients (49% women) with mean follow-up of 12.0 ± 8.7 years, and average age at diagnosis of 31.9 ± 14.6 years. 40% of patients were smokers at diagnosis, and 29% had perianal involvement. Behavior: inflammatory (62%), stricturing (17%) and penetrating (21%). Location: ileum (37%), colon (17%), ileocolonic (30%) and upper gastrointestinal tract (18%). Thirty seven percent of patients required surgery, with median time from diagnosis to surgery of 1 year [range 0-29]. 41% had immunosuppressive and/or biological therapy, before surgery or until the end of follow-up. Tobacco was not associated with an increased need for surgery in the overall population or in the subgroup of terminal ileum CD. However, in the group with isolated involvement of the colon, smoking was associated with the need for surgery [HR 20.3 (95%CI 2.2 to 183.8) p = 0.007].

Conclusions: The consumption of tobacco at the time of diagnosis seems to be associated with an increased likelihood of needing surgery in colonic CD. Consumption of tobacco was not associated with higher surgery rates in CD when other intestinal locations are affected.

IF-7
AUTOIMMUNE INFLAMMATORY MYOPATHIES: A DESCRIPTIVE STUDY OF CASES IN A TERTIARY HOSPITAL

A. Callejas Díaz, S. Mellor Pita, S. de la Fuente Moral, A. Ramos Sánchez, J. Vargas Núñez, M. Yebra Bango

Department of Internal Medicine. Hospital Universitario Puerta de Hierro Majadahonda. Majadahonda (Madrid), Spain.

Objectives: To compare the epidemiological, clinical, prognostic, diagnostic and therapeutic management of patients diagnosed with autoimmune inflammatory myopathy in our hospital with that described in the literature.

Material and method: A cross-sectional study recruiting all patients who had been diagnosed with autoimmune inflammatory myopathy, polymyositis (PM) and dermatomyositis (DM) and coded as ICD-9 in hospital discharge reports, covering the period from January 1st 1995 to May 31st, 2011 was carried out. Epidemiological, clinical, major additional diagnostic tests, initial treatment and the evolution of the disease to date were gathered. These data were compared with that available in the literature.

Results: In total, 30 patients were included; 17 were classified as DM and 13 PM. There was a male predominance and a mean age of 56 years, with a range from 16 to 92 years. The mean age at diagnosis of DM was 48 years, while in PM was 66 years. 17 cases were classified as idiopathic, 5 associated with autoimmune disease and 10 associated with malignancy, being the most frequent lung and colon adenocarcinoma, with 4 and 3 cases respectively. There were 2 cases associated both with autoimmune disease and neoplasia. The mean age of patients with associated neoplasia was 63.1 years. In 3 patients the disease was disseminated at diagnosis. The initial symptom was muscle weakness in most patients (18) and appeared over time in 29 of them, accompanied by myalgia in 17 cases. Cutaneous manifestations appeared in all cases of DM, being the initial symptom in 13 patients. 13 patients presented constitutional syndrome and 6 patients had interstitial lung disease. The creatine phosphokinase (CPK) was elevated in 26 patients, being higher in patients with cancer (6889 IU/L versus 3485 IU/L). 19 of 27 patients had positive ANA and 7 of the 19 specific antibodies of inflammatory myopathies. All patients were treated with glucocorticoids, for periods from 8 months to 12 years. The initial response was good in 20 patients, poor in 7 patients and non-assessable in the remaining 3 patients. Immunosuppressive treatment was required in 21 patients, azathioprine and methotrexate being the most used. Specific treatment of neoplasia, when associated with the disease did not improve the outcome in any of the patients. In these patients, the clinical outcome of the myopathy was similar to that without neoplasia because the response to the treatment was similar in both groups.

Discussion: The difference in age at diagnosis, which is clearly higher in PM than in DM, probably as a result of the peak incidence of DM in children under 20 years, should be noted. Unlike that described in the literature in our series males were more frequent and there was a greater association of DM with autoimmune diseases, systemic lupus erythematosus (SLE) being the most frequent. The PM was associated with cancer with a clearly higher than usual frequency. The age at diagnosis is 10 years higher in patients with neoplasia than in patients without malignancy which is in agreement with that previously described. The mean levels of CPK were higher in patients with associated malignancies. The ANA were positive in a lower percentage than that reported in other series in the literature and anti Jo-1 was not present in any patients. The response to treatment of the autoimmune disease is not influenced by the presence of poor prognostic factors or by the presence of neoplasia.

Conclusions: In our series of autoimmune inflammatory myopathies there is a higher prevalence of males and more cases associated with neoplasia and autoimmune diseases such as SLE. Patients with cancer had higher levels of CPK and this group did not respond worse to treatment.

IF-8
IMMUNE SUPPRESSANT TREATMENTS IN A DAY HOSPITAL BELONGS TO AN AUTOIMMUNE UNIT OF INTERNAL MEDICINE DEPARTMENT

P. Fanlo Mateo, E. Bidegain Garbala, M. López de Goicoechea, P. Prol García, M. Cia Lecumberri, J. Ibáñez Olcoz, J. Elejalde Guerra, C. Pérez García

Department of Internal Medicine. Complejo Hospitalario de Navarra-B. Pamplona (Navarra), Spain.

Objectives: The aim of this study was to analyse the number of admissions to a Day Hospital belongs to an Autoimmune Unit, the type of immune suppressant treatments that had been prescribed, most frequent autoimmune diseases that received treatment in the Day Hospital and possible adverse effects of these treatments.

Material and method: We performed a retrospective study of 110 admissions to our Day Hospital belongs to the Internal Medicine Department of Complejo Hospitalario de Navarra of Pamplona during the year 2011. All patients had been diagnosed of Autoimmune Disease and were referred by an internist to our Day Hospital to receive immune suppressant treatment.

Results: 110 admissions to the Day Hospital were analysed. The average of admissions per month was 9.16. 39 (35.45%) admissions were due to the administration of subcutaneous adalimumab, 40 (36.36%) admissions due to intravenous injection of cyclophosphamide, 28 (25.45%) admissions due to intravenous injection of immunoglobulins, and 3 (2.7%) admissions due to intravenous administration of infliximab. The average dose of adalimumab was 40 mg per week, the average dose of cyclophosphamide was 837,5 mg per month (minimum dose: 500 mg, maximum dose: 1,000 mg), average dose of infliximab was 200 mg and the average dose of immunoglobulins was 28.75 g (minimum: 20 g, maximum: 45 g). Main autoimmune diseases were 29 (26.36%) admissions for treatment of systemic vasculitis, 39 (35.45%) for uveitis, 16 (14.54%) for inflammatory myopathies, 6 (5.45%) for systemic sclerosis, 4 (3.6%) for SLE and 16 (14.54%) for other diseases such as Behçet's disease and Job's syndrome. There were not any adverse effect during the infusion period, no treatment had to be stopped due to secondary effect and there weren't any infection during the period of treatment.

Discussion: Inpatient treatment is an expensive way of caring patients. Nowadays, day hospitals are an useful and effective option to treat several diseases such as infections and mental disorders. Autoimmune disorders need periodic infusions of immune suppressants. In our study nine admissions per month were referred to our day hospital. The most frequent treatment was cyclophosphamide followed by adalimumab. Systemic vasculitis and uveitis were the most frequent autoimmune disease that were admitted. We report no adverse effect or infection during the treatment in the day hospital, consequently the use of day hospital is an alternative to outpatient in the treatment of autoimmune disorders.

Conclusions: We can conclude saying that Day Hospital could be a useful tool for prescription of immune suppressants in Autoimmune Units of Internal Medicine Departments as a result of the lack of adverse effects and complications of immune suppressants reported in our study.

IF-9
INSULIN RESISTANCE, ENDOTHELIAL DAMAGE AND C3 CONVERTASE, TRIPLETS WALKING HAND IN HAND

A. Rodríguez Guerrero, M. Fabregate Fuente, R. Fabregate Fuente, C. Martínez, S. Tello Blasco, J. Sabán Ruiz

Endothelial Pathology Unit. Hospital Universitario Ramón y Cajal. Madrid, Spain.

Objectives: The aim of the study was to investigate the correlation between serum C3 convertase levels and HOMA model.

Material and method: Population: 369 patients from the endothelial pathology unit, who had serum C3 determinations in their first visit. Patients with type 1, LADA and MODY diabetes were excluded. C3 convertase was measured by nephelometry (mg/dl), glucose by an HITACHI autoanalyzer and insulin levels (uU/mL) by immunometric assay (Immulite DPC). HOMA (Homeostasis Model Assessment) score: fasting insulin (uU/ml) × fasting plasma glucose (mmol/L)/22.5. Statistical analysis: Continuous variables described as mean (SD: standard deviation). Pearson's correlation coefficient. Multivariate limear regression. Comparison between groups: student's t-test. Normality assessed by Kolmogorov-Smirnov test. Levene test for Equality of Variances. Anova test for the analysis of variance. Alpha = 0.05.

Results: Population: aged 55 (14.6) range 17 to 90 years, 58.5% males, 53% hypertensives, 20% smokers, 25% diagnosed with hyperglycemia. C3 serum levels ranged from 65 to 236 mg/dl. Mean 133.3 (SD: 25.7). No significant differences were found in C3 levels between males and females. C3 levels were not correlated to age. Insulin resistance HOMA score: 2.5 (1.84), range: 0.4 to 11. C3 was significantly correlated to insulin resistance ($r = 0.37$; $p < 0.001$) in our whole population. Being significant in males ($r = 0.30$; $p < 0.001$) and in females ($r = 0.43$; $p < 0.001$). Dividing in to tertiles according to age (cut-off points: 48.0, 61.0 y.o.), we also found statistical significance with $p < 0.001$ in both genders, except for men over 61 y.o. with borderline significance. Linear correlation between C3 and HOMA remains statistically significant after adjustment by BMI, sex and age (standardized B coefficient, $\beta = 0.358$, $p < 0.001$).

Discussion: The C3 convertase/ASP system (acylation stimulating protein) has been recognized as a regulator of the lipid metabolism and glucose uptake (Cianflone et al. 2003). The impaired postprandial fatty acid metabolism plays a key role in the pathogenesis of Metabolic Syndrome (MS) (McGarry 2002, Sniderman et al. 1998), contributing to insulin resistance (IR) (Roden et al. 1996) and endothelial dysfunction (Van Oostrom et al. 2007). The pathophysiological role of C3 in the MS and diabetes remains unclear (Van Oostrom et al. 2007). The C3 was found to be a strong marker of insulin resistance in elderly Italians (Muscari et al, 2007). The C3 as an acute phase reactant has been associated with atherosclerosis (Onat et al. 2005). However, it has not been studied to date the independent association of C3 complement factor with the development of complete MS and IR.

Conclusions: High levels of C3 convertase are linearly correlated with increased risk of insulin resistance in the overall population of our study in both sex. C3 come forward as a self-reliant predictor of insulin resistance, independent of other factors that classically can influence over the insulin resistance such as age, gender and BMI.

IF-12
ANTIPHOSPHOLIPID ANTIBODIES ASSOCIATED WITH INFECTIONS

P. Fanlo Mateo[1], I. Aoiz Jauregui[2], M. Carrasquer Pirla[1], M. Cia Lecumberri[1], I. Elejalde Guerra[1], J. Ibáñez Olcoz[1], G. Tiberio López[1], C. Pérez García[1]

[1]Autoimmune Unit. Department of Internal Medicine. Complejo Hospitalario de Navarra-B. Pamplona (Navarra), Spain. [2]Department of Haematology. Complejo Hospitalario de Navarra-A. Pamplona (Navarra), Spain.

Objectives: Antiphospholipid antibodies (aPL) have been detected on several infections, without knowing their pathogenic mechanism. A molecular mimicry between infectious peptides and aPL, has been proposed as a possible theory of the pathogenic mechanism. The aim of this study, was to analyse how three infections, EBV, Coxiella burnetii, toxoplasmosis could induce the production of aPL.

Material and method: We performed a retrospective review of ten cases, during 3 years in the Internal Medicine Department of Complejo Hospitalario de Navarra-B of Pamplona. 4 patients were diagnosed of Coxiella burnetii infection, 3 of EBV infection and other 3 of Toxoplasmosis infection.

Results: 4 patients suffered from Coxiella burnetti infection, all were men, from 23 to 83 years old. The liver was the main organ affected in 3 of them, but the other presented heart disease and adenopathies. Those who had liver infection, only 2 of them induced the production of lupus anticoagulant (LA) and just one produced anticardiolipin antibodies (aCL) and β2 glycoprotein I (β2GPI). The patient with heart affection induced the production of LA, and died during the study. No trombotic events were reported. After 1 to 6 months, aPL were all negative. 3 patients presented Toxoplasmosis infection, 2 were men, from 32 to 42 years old. Two presented uveitis and the other had pericarditis. 2 induced the production of LA and just one produce aCL. Only the patient with cardiac toxoplasmosis and positive LA, presented a retinal arterial thrombosis. After 12 months he had negative antibodies. 3 patients were collected with EBV infection, 2 were men, from 26 to 45 years old. 2 had affected the skin, lung and spleen and the other one suffered from hepatitis. One patient with skin and lung manifestations, induced the production of the three types of aPL, (LA, aCL, β2GPI). This patient surprisingly, didn't produce any thrombotic events and after a month had negative antibodies. The patient with hepatitis, induced the production of LA, and after a month it was negative. The patient with skin and spleen infection, induced the production of LA and β2GPI, and at the moment, they still remain positive. 7 patients received, acetylsalicylic acid 100 mg/day as treatment. The patient with retinal thrombosis was treated with anticoagulant doses of low molecular weight heparin (LMWH). The patient with Coxiella burnetti cardiac infection, which died during the study, was treated with prophylactic doses of LMWH. Only the patient with EBV infection and the production of the three antibodies didn't received treatment, because of the negativation of the antibodies one month later.

Discussion: In our 10 cases, only one suffered a thrombotic event. In contrast, the patient with the three positive antibodies (aPL, aCL, β2GPI) didn't present any thrombotic complication. After reviewing current literature, we found that the viral infections have a greater preponderance to thrombosis, rather than bacterial or parasitic infection. But in our series, only the patient with Toxoplasmosis presented the thrombotic manifestation.

Conclusions: Although many infections, could induce the production of aPL, few cases show manifestations of antiphospholipid syndrome (APS). It isn't still clearly determined the pathogenic role of aPL associated with certain infections.

IF-14
PREVALENCE OF SUBCLINICAL ATHEROSCLEROSIS IN PRIMARY ANTIPHOSPHOLIPID SYNDROME

I. Márquez Gómez[1], E. Rivera Sánchez[2], V. Buonaiuto[1], A. Espejo Gil[1], A. Jiménez Recio[1], M. Camps García[1], E. de Ramón Garrido[1], R. Gómez Huelgas[1]

[1]Department of Internal Medicine, [2]Department of Radiology. HRU Carlos Haya. Málaga, Spain.

Objectives: To know the prevalence of subclinical aterosclerosis evaluated by measuring carotid intima media thickness (IMT) in primary antiphospholipid syndrome.

Material and method: All the patients included were diagnosed with APS (Sydney criteria) and followed in the consultation of systemic autoimmune diseases unit in a tertiary level hospital. After obtaining informed consent, all demographic data, classics vascular risk factors (hypertension, smoking, hyperlipidemia,

diabetes, obesity), as well as homocysteine and C reactive protein levels and clinical and analytical data for the APS activity of all the participants were collected. Carotid Doppler ultrasound examinated the common carotid artery and the carotid bifurcation (1-2 cm). In each study, we evaluated the IMT and atheroma plaques. Subclinical atherosclerosis was defined as IMT greater than 0.9 mm and plaque as IMT more than 1.2 mm. The interobserver variability was examined in every one in 5 patients.

Results: Descriptive, cross-sectional study which included 52 patients with APS, 19 males and 33 females; average age: 43.65 years (26-71). Thrombosis 76.9%: 40.4% venous thrombosis (TV), 28.8% arterial thrombosis (TA), 13.5% both TA and TV, and 21.2% obstetric manifestations (MO). 1.9% with thrombosis and MO. 50% of patients with TV had pulmonary embolism. In those patients with TA, stroke: 19.2%, transient ischemic attack: 15.4% and coronary involvement: 9.6%. Related to antiphospholipid antibodies (aPL), Lupus anticoagulant: 71.2% and persistent 86.5%; aCLG: 63.5% and persistent in the 90.4%; the aCLM: 17.3%. Anti B2 G positive at 52%, persistent and at high levels in 38% of cases and the antib2M in the 26.9%. The more prevalent classics cardiovascular factors were 30% smokers; 38.5% had hypertension and 28.8% dyslipidemia, the most common of which being the mixed dyslipidaemia in 17.3% and 26.9% hyperhomocysteinemia. The 34.6% received antiplatelet, anticoagulation 40.4% and 17.3% combined treatment. The IMT medium in our series was 0.87 mm; 30.8% presented thickening of the intima greater than 0.9 mm and 9.6% plaque. We found statistical association between IMT and age in years ($p < 0.01$), male sex ($p < 0.05$), arterial events ($p < 0.05$), coronary events ($p < 0.04$), dyslipidemia ($p < 0.01$), diabetes ($p < 0.01$), B2GPI G ($p < 0.04$) and plaque ($p < 0.02$). Multivariate analysis showed a connection between IMT and male sex (OR 7.84; 95%CI 0.90-68.36), age in years (OR 1.08; 95%CI 1.00-1.18) and dyslipidemia (OR 17.16; 95%CI 2.31-127.50).

Discussion: The prevalence of preclinical atherosclerosis and its association with cardiovascular risk factors in APS patients is little studied and its results may differ from different publications.

Conclusions: In our study, we found prevalence of subclinical atherosclerosis in 40% being statistically significant with dyslipidemia, age and male sex. We found no links with the APS nor with aPL in the multivariate analysis, probably due to the small sample size.

IF-15
LYMPHOPENIA IN ELDERLY IN-HOSPITAL PATIENTS

F. Gili, M. Rubio-Rivas, F. Formiga, R. Pujol

Department of Internal Medicine. Hospital Universitario de Bellvitge. Hospitalet de Llobregat (Barcelona), Spain.

Objectives: To assess the prevalence and features of in-hospital elderly patients with lymphopenia.

Material and method: 50 consecutive in-hospital patients have been included. Lymphopenia was considered < 1,100 × 10^9/l.

Results: 26 males (52%), mean age 84.23 (SD 6.17). Cardiopulmonary disease was the main diagnosis in 36 patients (72%). Mean Pfeiffer 2.73 (SD 2.3) and Barthel 65.9 (SD 29.09).

Discussion: Infections seems to be more likely in lymphopenic patients. Calcidiol levels tends to be lower as well. A greater number of hospital admission in the last year and a greater likelyhood of death have been found.

Conclusions: Lymphopenia is a frequent disorder (32%) related with infections, number of admissions and death, and lower calcidiol.

Table 1 (IF-15). Features of patients with lymphopenia

	Mean (SD)/number (%)
CD4/CD8 (× 10^9/l)	244.67 (SD 129.51)/194.47 (SD 94.59)
Ratio CD4/CD8 (% inverted ratio)	1.26 (33.3%)
Lymph B (× 10^9/l)	52.77 (SD 40.86)
Hypergammaglobulinemia	6 (40%)
Hypogammaglobulinemia	1 (6.7%)
Autoimmune disease	1 (6.7%)
Cancer	2 (13.3%)
Hepatopathy	2 (13.3%)
HBsAg +/AntiHBc +/HVC +	1 (6.7%)/2 (13.3%)/1 (6.7%)
ANA +/RF +	8 (50.2%)/2 (13.4%)

Table 2 (IF-15). Univariate between groups

	With lymphopenia (n = 16)	Without lymphopenia (n = 34)	Significance
Age (years)	83.63 (SD 5.98)	81,77 (SD 15.96)	0.656
Sex(male)	7 (43.75%)	19 (55.88%)	0.423
Infections 5 last years	-	-	-
Pulmonary	11 (73.33%)	10 (30.3%)	0.018
Urinary	7 (46.67%)	6 (18.18%)	0.131
Gastrointestinal	3 (20%)	0	0.026
Albumin (g/l)	34 (SD 4.79)	33.11 (SD 6.20)	0.618
Calcidiol (nmol/l)	27,94 (SD 11,12)	31,36 (SD 18.17)	0.510
Calcidiol insufficiency (< 50 nmol/l)	15 (100%)	27 (93.1%)	0.540
Calcidiol deficiency (< 30 nmol/l)	8 (53.3%)	17 (58.6%)	0.737

Hospital length of stay (days)	17,15 (SD 8.49)	17,69 (SD 19.66)	0.926
Death	3 (21.43%)	2 (6.90%)	0.309

IF-17
USEFULNESS OF INTRAVENOUS CYCLOPHOSPHAMIDE IN TREATMENT OF SEVERE AUTOIMMUNE DISEASE. EXPERIENCE OF AN INTERNAL MEDICINE SERVICE-AUTOIMMUNE DISEASE UNIT

B. Lacruz Escalada[1], P. Fanlo Mateo[1], M. López Mancha[2], M. Mellado Ferreiro[1], M. Areses Manrique[1], E. Bidegain Garbala[1], J. Ibáñez Olcoz[1], C. Pérez García[1]

[1]Department of Internal Medicine, [2]Department of Pharmacy. Complejo Hospitalario de Navarra B. Pamplona (Navarra), Spain.

Objectives: To evaluate the number of patients that were treated with intravenous cyclophosphamide (CYC), dose, number of pulses, autoimmune diseases, flare-up, remission, and secondary effects.

Material and method: We retrospectively evaluated the number of patients who received intermittent pulses of CYC in the period from November 2007 to February 2012 at Internal Medicine Service Department of Complejo Hospitalario de Navarra-B. Intravenous CYC was administrated following international established and approved protocols for autoimmune diseases. We studied the following data: number of patients, age and sex, average dose of CYC and number of pulses per patient, type of autoimmune disease, flare-up, remission and secondary effects.

Results: We reported 22 patients treated with intravenous pulses of CYC. The average dose was 790.90 mg (min dose: 500 mg, max dose: 1,000 mg) with an average pulses of 4.9 pulses per patient (min: 1, max: 13). Patients had a mean age of 52.72 years (23-72). 14 patients were women and 8 were men. Principle disorders were: 13 systemic vasculitis, 4 lupus (SLE) and antiphospholipid syndrome (APS), 2 systemic sclerosis, 1 antisynthetase syndrome, 1 retroperitoneal fibrosis and 1 Sjögren's syndrome. CYC was infused in 19 patients due to a flare-up of their disease as a first choice treatment in that moment, while 3 patients received CYC due to the failure or intolerance of previous treatments (one patient with lupus membranous nephropathy with no remission with azathioprine, other with retroperitoneal fibrosis resistant to steroids and tamoxifen and another with polyarteritis nodose with intolerance to steroids). In the group of patients with systemic vasculitis (13 patients) 9 had a pulmonary flare, 2 had a renal flare, one had a cutaneous disease and the other one suffered from mesenteric ischemia. The types of flares up in SLE patients were: 2 active lupus nephritis, one haematologic flare (anemia and neutropenia) and one aseptic meningitis. Both patients with systemic sclerosis suffered from pulmonary fibrosis, the patient with antisynthethase syndrome was also affected by pulmonary fibrosis and the patient with Sjögren's disease presented cervical myelopathy. After treatment with pulses of CYC, 12 patients didn´t achieve remission, whereas 9 patients achieved remission and 1 patient is still in treatment. In six patients pulses of CYC had to be stopped due to secondary effects. In 3 patients CYC produced gastrointestinal intolerance, in one cutaneous rash and in 2 patients CYC produced neutropenia. Two patients died during their treatment due to the severity of their disease.

Discussion: CYC is one of the most powerful immunosuppressive treatments used in patients with severe autoimmune disease in Internal Medicine Departments. CYC could be administrated in daily oral dose or intermittent pulses. Although CYC is very effective has adverse effects such as infections, bladder toxicity and neutropenia. All our patients received intermittent pulses of CYC intravenously every three or four weeks, we chose this way of administration due to the long-bladder complications of daily oral therapy. All patients received bladder protection with MESNA and prophylaxis for Pneumocystis jirovecii infection with trimethoprim-sulfamethoxazole. In our experience the main indication was the treatment of flare of systemic vasculitis and the main organ affected was the lung. The treatment was satisfactory nearly in fifty per cent of the cases treated. Two patients died but not because of the treatment with CYC. The two main secondary effects were gastrointestinal and neutropenia. We didn't report any opportunistic infection or cystitis.

Conclusions: Currently intravenous cyclophosphamide is still an useful and secure treatment for severe systemic autoimmune disease in Internal Medicine Departments.

IF-18
IMMUNOGLOBULINS IN A COUNTY HOSPITAL, IS IT WORTH IN TIME OF CRISIS?

R. Hurtado García[1], C. Reyes Herrera[1], V. Herrera[1], I. González Cuello[1], B. Martínez López[1], R. Bonilla[2], A. Acedo[3], J. Custardoy[1]

[1]Department of Internal Medicine, [2]Department of Pharmacy, [3]Department of Haematology. Hospital Vega Baja de Orihuela. Orihuela (Alicante), Spain.

Objectives: The aim of this study was to determine the use or intravenous immunoglobulin (IVIG) in terms of consumption, indications, medical prescribers and a clinical follow up of patients treated with IVIG, through an assessment of the justification and the rationale of the use.

Material and method: The study was conducted at the Hospital Vega Baja in Orihuela (Alicante). This hospital has about 380 beds. This is a retrospective study of the use of IVIG from January 1st 2011 to April 30th, 2012. The ratio of patients was reported by the application of the IVIG in the pharmacy department. The clinical records of patients were retrospectively reviewed. They were divided into two categories according to the indication by which IVIG was prescribed: A. Authorized in Spain by the Agencia Española de Medicamentos y Productos Alimentarios (AEMPS). B. Not authorized in Spain but scientifically accepted in the medical literature.

Results: The number of patients who were prescribed an IVIG in this period was 30; two patients were excluded because of missing data. 14 of the 28 remaining were men (50%) and 14 women (50%). With an average age of 54 years old. The groups were divided as follows: 6 in group A (21.42%) and 22 in group B (78.57%). In 18 cases of 28 the Neurology service was prescriber (64.28% of total), 94.1% of whom belonged to group B. In 2 cases of 28 the IVIG was used for Hematology Service (7.14%), 100% of whom belonged to group A. 8 cases of 28 were treated by internists (37.5% belonged to group A and 62.5% belonged to group B). The mean therapeutic session was 5.61 per patient. At least 18 patients were taking other immunosuppressive agent; prednisone (64.285) was the most frequent drug. With regard to the side effects they have not been described during the use of IVIG. Only one patient in the sample died during the follow-up.

Discussion: The price of the vials of IVIG is between 223€ to 400€. The use of IVIG is known in clinical situations in which the indications are not approved as in our sample which is up to 78% of cases. Several studies on its rational use have been carried out; however, we have asked the same questions for 25 years. Note that in Neurology IVIG is widely used for myasthenia gravis and multiple sclerosis, literature has shown an improvement in symptoms. More importantly, there are some bureaucratic difficulties when trying to use this therapy with off-label drugs. Finally, as in other studies, the off-label use in IVIG prescriptions is mostly covered by the Neurology service. We stress the importance of establishing protocols for a rational use of IVIG among internal medicine and pharmacy department.

Conclusions: In our sample, most were IVIG guidelines for off-label use. No side effects in the use of IVIG were reported, the mortality rate in the sample was very low. There is still a loophole in the use of IVIG for the indications supported by scientific literature but not approved by health authorities. This

leads to a greater off-label use, with the legal problems involved. It is important to mention that the departments of internal medicine should work in collaboration with the pharmacy department in order to develop the protocols of IVIG treatment and to ensure its effectiveness and cost-effectiveness. The approval of those indications could be raised with the AEMPS, as the use of the IVIG has been sufficiently justified by scientific evidence.

IF-20
SARCOIDOSIS- STATISTICAL ANALYSIS OF INTERNAL MEDICINE AND PNEUMOLOGY CONSULTATION IN DISTRICT HOSPITAL

L. Oliveira[1], M. Oliveira Ferreira[1], C. Melo[1], D. Ferreira[2], N. Cardoso[1], A. Duarte[1]

[1]Department of Internal Medicine, [2]Department of Pneumology. Centro Hospitalar de Médio Ave- Unidade de Famalicão. Vila Nova de Famalicão, Portugal.

Objectives: Characterize the sarcoidosis patients followed in Internal Medicine and Pneumology Consultation of District Hospital.

Material and method: Retrospective study of individual clinical files of patients diagnosed with sarcoidosis followed in Internal Medicine and Pneumology Consultation of our hospital. Statistical analysis was carried out with the support of Statistical Program for Social Sciences (SPSS), version 20.

Results: The sample consists of 27 patients, with average age of 47, 89 ± 13.73 years. The feminine gender was most prevalent (59% of sample). In Women, the age most affected was 41 to 50 years and in men was 31 to 40 years. Regarding smoking habits, the majority were non smokers (78% of cases). At admission, 86% had symptoms related to the organ involved by sarcoidosis. The most observed symptoms were erythema nodosum (33%), dyspnea (22%), dry cough (19%) and asthenia (19%). Extra-thoracic manifestations were found in 67% of cases. The lung was the most involved organ (52% of cases). The angiotensin converting enzyme was increased in 37% of the sample. Among the patients who underwent bronchoalveolar lavage, 60% had lymphocytosis greater than 15% and 22% had increasing CD4/CD8 ratio. The diffusing capacity for carbon monoxide was normal in 44% of cases and 33% of sample was not screened. The predominant radiological type was I (37%), followed by type III (26%) and type II (22%). The radiological types 0 and IV were 7% of cases. The skin biopsy was more held (22% of cases), followed by lymph nodes biopsy (15% of cases). On chest radiograph, bilateral hilar strengthening was more common (17 cases). On CT scan, 82% of sample has hilar and mediastinal lymphadenopathy and 48% of sample has micronodular pattern. The corticosteroid therapy was held in 16 patients. Concerning disease activity, 63% of patients had active disease and 37% of patients had remission. Pulmonary fibrosis was the most common complication, present in 30% of sample.

Discussion: Although relatively small sample, this results are according to what is described in the scientific literature.

Conclusions: Sarcoidosis is a multisystemic granulomatous disorder of unknown etiology, with many clinical presentations. It affects individuals worldwide, people of all racial groups, sex and age, although it commonly strikes young people with slight female preponderance. Many patients do not require therapy and their conditions will spontaneously improve. Although corticosteroids are used for symptom relief and remain the mainstay of therapy, their efficacy in this disease is unclear. Due to the significant heterogeneity in prevalence, disease presentation, severity and prognosis, sarcoidosis is a challenging diagnosis.

IF-21
INFLAMMATORY ACTIVITY ASSESSMENT BY F18-FDG-PET/CT IN PATIENTS WITH SARCOIDOSIS

J. Mañá[1], C. Gámez[2], A. Fraga[1], M. Rubio[1], M. Labori[1], F. Martínez[3], L. Rodríguez-Bel[2], R. Pujol[1]

[1]Department of Internal Medicine, [2]Unitat PET-IDI, [3]Department of Radiology. Hospital Universitari de Bellvitge. L'Hospitalet de Llobregat (Barcelona), Spain.

Objectives: To assess the presence of inflammatory activity using FDG-PET/CT in patients with sarcoidosis.

Material and method: A prospective study was undertaken of 36 whole-body F18-FDG-PET/CT scans performed in 32 patients with biopsy-proven sarcoidosis. Patients characteristics included: 19w/13m, 29-69y, diabetes: 1, chronic.

sarcoidosis: 19 (3 to 23 y), neurosarcoidosis:1. Prolonged fasting was required. In 10 scans patients received corticosteroids. Positive findings were classified as thoracic and/or extrathoracic, measuring SUVmax in all active lesions. Thoracic findings in the CT were classified as typical or atypical. The left myocardial FDG uptake was quantified on a scale of 0-4, with grade 0 being no apparent activity, grades 1-2-3 physiological pattern with diffuse activity (3 > liver) and grade 4 abnormal.

Results: Indications included (36 scans): 1) assessment of presence of pulmonary activity in chronic fibrotic pulmonary sarcoidosis (14), 2) monitorization of response to corticosteroids (3, as the second PET), 3) characterization of mediastinal lymph nodes (7), 4) detection of occult activity sites (3), 5) assessment of presence of inflammatory activity in systemic sarcoidosis (6, a second PET in 1), 6) staging in cancer patients with previously known sarcoidosis (1) and 7) detection of occult primary malignancy (2). PET/CT showed pulmonary activity in 11/14 patients with chronic fibrotic pulmonary sarcoidosis. The 3 second PET scans after corticosteroid therapy showed a significant reduction in pulmonary uptake. Positive findings were seen in 30/36 scans (83%): 12 thoracic, 2 extrathoracic and 16 both. The most common positive sites were mediastinal lymph nodes (24), lung (17) and abdominal lymph nodes (12) with ranges of SUVmax of 3 to 44.Eight scans showed occult sites in abdominal lymph nodes, muscle, skin and spleen. Left ventricular FDG uptake was present in 29 scans: physiological pattern in 28 (grade 3 in 14) and grade 4 in 1. In 26/36 (72%) PET scan changed the management of the patient, guiding biopsy/other tests (13) or corticosteroids (13).

Discussion: FDG-PET/CT appeared to be a sensitive method to detect inflammatory activity in sarcoidosis. It seems to be useful in the assessment of residual activity in fibrotic pulmonary sarcoidosis and may help to therapeutic decisions. In addition, it is a valuable tool to detect occult activity sites identifying extrathoracic involvement (> 60% patients) and may be used to guide biopsies.

Conclusions: FDG-PET/CT is useful to detect residual activity in chronic pulmonary sarcoidosis. In addition, it is of value in identifying occult sites in systemic disease and may be used to guide biopsy.

IF-22
CHRONIC SARCOIDOSIS. A DESCRIPTIVE STUDY OF 41 PATIENTS

M. Labori, A. Fraga, M. Rubio-Rivas, J. Mañá, R. Pujol

Department of Internal Medicine. Hospital Universitario de Bellvitge. Hospitalet de Llobregat (Barcelona), Spain.

Objectives: To report the clinical, radiological, lung function features and follow-up of 41 patients with chronic sarcoidosis.

Material and method: Retrospective assessment of 41 patients with chronic sarcoidosis. Chronic sarcoidosis was defined as

persistence of disease activity for more than 5 years since the diagnosis.

Results: 26 (63%) patients were females, the mean age at diagnosis was 46 years (range 8-77) and all the patients were Caucasian. At diagnosis, 5 (13%) patients showed radiological stage 0, 12 (30%) stage I, 12 (30%) stage II, 7 (18%) stage III and 3 (8%) stage IV. Extrathoracic organ involvement at diagnosis and during the follow-up time was as follows: 21 (51%) had specific skin lesions (9 maculopapular lesions, 7 plaques, 4 scar sarcoidosis, 4 subcutaneous nodules and 3 lupus pernio), 12 (29%) spleen, 12 (29%) salivary/lacrymal glands, 10 (24%) peripheral lymph nodes, 10 (24%) ocular, 7 (17%) hypercalcemia, 4 (10%) neurological and 4 (10%) erythema nodosum (Löfgren's syndrome). SACE level at diagnosis was increased in 24/35 (69%) patients. After 5 years, radiological stages had evolved as follows: stage 0 in 10 (28%) patients, stage I in 4 (11%), stage II in 8 (22%), stage III in 8 (22%), and stage IV in 6 (17%). Impairment in pulmonary function tests (< 80% of predicted values) at diagnosis (and after 5 years) were as follows: FVC in 24% (30%) of patients, FEV1 41% (37%), and DLco 27% (42%). 35 (85%) patients were treated with corticosteroids. 11 (27%) patients also received other immunosuppressant drugs either alone or associated with corticosteroids (methotrexate, azathioprine or hydroxycloroquine). 3 (7%) patients died because of sarcoidosis.

Discussion: Chronic sarcoidosis has a wide variety of clinical and radiological manifestations. Extrathoracic involvement may be extensive and emphasises the systemic nature of the disease. Interestingly, 13% of patients had only extrathoracic involvement (stage 0). Stages III and IV at onset were present in only 26% of patients and after 5 years in 39%. Occasionally, patients with Löfgren's syndrome may evolve to chronic disease. The number of patients with lung function – FVC and FEV1 - impairment remained relatively stable after 5 years. However, the number of patients with decreased DLco increased after 5 years. Long-term immunosuppressive therapy is usually required. Death is uncommon.

Conclusions: Chronic sarcoidosis is a systemic disease with heterogeneous clinical and radiological manifestations. After 5 years, the majority of patients have remained with relative clinical stability, with mild lung functional deterioration.

IF-23
INFLAMMATORY BOWEL DISEASE (CROHN'S DISEASE) AND CONCOMITANT AUTOIMMUNE DISEASE: CLINICAL REASONS FOR COMMON INFLAMMATORY PATHWAYS

G. de Luna, P. G. Vasco, G. Fraile, V. Gómez, J. Nava

Department of Internal Medicine. Hospital Ramón y Cajal. Madrid, Spain.

Objectives: To describe any clinical association between Crohn' disease (CD) and autoimmune disease.

Material and method: We designed a retrospective study (1988-2012) in the internal medicine department, reviewing the electronically data files searching the next keywords: CD and diagnosis of autoimmune disease (or immunologic dysfunctional disease) of any kind, after, before or coexisting with knowledge IBD. Patients could have been treated with any immunosuppressive therapy.

Results: 89 patients were analyzed. Of them, 8 cases (female:male ratio 1.66) had got during following-up any coexistence of autoimmune diseases (isolated, sequential or in combination): multiple sclerosis (n = 1), sarcoidosis (n = 1), Sjögren's syndrome (n = 2), psoriasis (n = 2), nodous erythema (n = 2), antiphospholipid syndrome (n = 1), thrombotic thrombocytopenic purpura (n = 1), anterior optic neuritis (n = 1) and osteoarticular symptoms (bilateral sacroiliitis and arthritis n = 2; one HLA-B27+). The median age of CD diagnoses was 26.37 years (SD 11.36), and of autoimmune disease was 24 years (SD 8.48). Then, the average accumulated incidence of autoimmune disease was 14.6% in 24 years. Half of patients had terminal ileum affection and surgical resection should be performance in 3 cases. Therapeutic agents were corticoids (n = 5), sulfazalazine/mesalazine (n = 4), methotrexate (n = 1), plasmapheresis (n = 1) and mercaptopurine (n = 1).

Discussion: Inflammatory bowel disease (IBD), multiple sclerosis and autoimmune diseases are chronic inflammatory entities, which show acute and recurrent flares and/or indolent evolution. Cytokines are essential molecular signals that regulate migration and other leucocytes functions. So they are the main factors in inflammation pathways up and down regulation, which could be related to different autoinflammatory and autoimmune diseases. In some patients seems that autoimmune manifestations can onset before that the CD, although these median of age differences could be artifact, due to the fact that relation between CD and autoimmune disease was distributed in three equal parts (coincidence, after or before IBD diagnosis). IBD and autoimmune entities share common inflammatory pathways confluence in T lymphocyte (Th17,STAT3). Dysregulation of STAT3 pathway has therefore been implicated in the development of chronic autoimmune diseases, as well as, a number of malignant and neurodegenerative diseases. It suggests common risk factors that favour these associations, opposite to a multiorganic, systemic affection, aimed in a unique molecular mechanism.

Conclusions: Coexistence of IBD and autoinflammatory disease is a rare clinical association, but it does possible to find it in day-by-day clinical practice, due to its common molecular inflammatory pathways.

IF-24
HOSPITALIZATION AS PRECIPITATING FACTOR FOR ACUTE GOUTY ARTHRITIS

P. Demelo Rodríguez, B. Andrés del Olmo, D. Gaitán Tocora, I. Muñoz Betegón, E. Trigo Esteban, C. Muñoz Delgado, A. García Escobar, J. García Castaño

Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: Primary objective in our study was to evaluate whether hospitalization itself could play a role in development of episodes of acute gouty arthritis. As secondary objectives, we analyzed clinical features of these patients, evaluating average age, duration of stay and whether they were previously diagnosed with hyperuricemia or gout.

Material and method: We revised medical records of all patients who suffered an acute gouty arthritis attack during their stay for a period of 14 months (January 2011 to February 2012) in our hospital. We excluded those patients who had symptoms before their admission. We collected data about all known precipitating factors (trauma, surgery, drugs, etc), epidemiological features (age, sex), personal history of hyperuricemia or gout, service of hospitalization, and average stay.

Results: Clinical records of 43 patients were revised from both medical and surgical departments in our hospital. 31 patients (72.1%) were men, with a mean age of 73.16 (SD 14.54). 20 patients (46.5%) had personal history of hyperuricemia or gout, but only 9 (45%) of them were receiving antihyperuricemic therapy. In most cases (67.4%) precipitating factor was not clear. The most frequently known cause was surgery (14.0%) and pharmacological cause (9.3%). The average stay was 15.35 days (SD 12.87). Most cases were registered from Gastroenterology (25.6%), Cardiology (25.6%) and Internal Medicine (20.9%) departments.

Discussion: Hyperuricemia is a very common condition, with a high prevalence and incidence in our environment. Hyperuricemia is known as a necessary condition to develop gout (monosodium

urate crystal deposition disease), although other circumstances are known to be necessary to develop an acute attack of gouty arthritis. These circumstances include trauma, surgery, drugs, diet, dehydration, among others. Recent studies point hospitalization as a precipitating factor to develop an attack. In our study, we evaluated all new cases of gouty arthritis in hospitalized patients during more than a year to analyze precipitating factors. Some of the circumstances mentioned before were present (especially surgery and drugs), but in most cases (67,4%), precipitating factor was not clear. Although one limitation of our study was that is hard to determine if some other factors (dehydration, diet changes not reported by patients, etc) could influence the apparition of these attacks, we can interpret the high rate of unclear cases as point for hospitalization being a precipitating factor itself. We found gouty arthritis to be much more frequent in male than female, and almost half of cases appeared in patients with a previous diagnosis of hyperuricemia or gout.

Conclusions: Hospitalization can be considered as a precipitating factor itself for development of an acute attack of goutyarthritis. In our study, almost half of patients who suffered acute gouty arthritis were not previously diagnosed with hyperuricemia or gout.

IF-26
CALCINEURIN INHIBITORS IN A COHORT OF PATIENTS WITH ANTISYNTHETASE-ASSOCIATED INTERSTITIAL LUNG DISEASE. AN OBSERVATIONAL STUDY

A. Labirua Iturburu[1], A. Selva O'Callaghan[1], X. Martínez Gómez[2], E. Trallero Araguás[1], M. Juanós Iborra[1], I. Pinal[1], M. Labrador Horrillo[1], M. Vilardell Tarrés[1]

[1]Department of Internal Medicine, [2]Department of Preventive Medicine and Epidemiology. Vall d'Hebron General Hospital. Barcelona, Spain.

Objectives: To assess the effect of calcineurin inhibitors (tacrolimus or cyclosporine) for treating patients with interstitial lung disease (ILD) associated with antisynthetase autoantibodies.

Material and method: Sixty patients with antisynthetase autoantibodies were identified in our myositis cohort of 179 patients. The medical records of 15 patients with antisynthetase autoantibody-associated ILD treated with tacrolimus/cyclosporine (4 as first-line therapy and 11 for refractory disease) between 1980 and 2011 were retrospectively reviewed. Fifteen patients with antisynthetase autoantibody-associated ILD who were not treated with calcioneurin inhibitors during the same period were included as a comparison cohort. Serial pulmonary function test were used to assess the clinical response. Comparisons were performed using the Fisher's exact test and Mann-Whitney test.

Results: Patients had received tacrolimus/cyclosporine for an average of 18 (IQR 12-29) months. In treated patients, median age at onset of ILD was 42.3 (IQR 32.4-56.8) years and median duration of lung disease before administration of calcineurin inhibitors was 11 (IQR: 5-49) months. Median duration of follow-up was 24 (IQR 12-32) months. A more than 10% increase in FVC and/or FEV, or stabilization was observed in 12 (80%; 95%CI: 52-96) patients who received calcineurin inhibitors (4 [100%] as first-line therapy and 8 [72%] refractory cases), and in 10 (66%; 95%CI: 38-88) patients in the comparison cohort (p = 0.68).

Discussion: The clinical course of ILD, a common feature in patients with inflammatory myopathies, especially in those with antisynthetase syndrome, is heterogeneous and varies from asymptomatic forms to chronic or rapidly progressive lung disease. The immune mechanism that underlies antisynthetase-associated ILD is uncertain, although some authors have reported a predominance of CD8+ activated T cells in bronchoalveolar lavage or lung tissue. Therefore, T-cell targeted therapies such as calcineurin inhibitors (tacrolimus/cyclosporine) might be of benefit in these patients. Our data are consistent with the results of other reports showing the benefit of calcineurin inhibitor therapy in patients with ILD associated with antisynthetase antibody syndrome.

Conclusions: Calcineurin inhibitors seem to be a good therapeutic option for managing ILD associated with antisynthetase autoantibodies, not only in refractory cases but also as a first line treatment.

IF-27
ADULT STILL´S DISEASE: CASES REVIEW IN A GENERAL HOSPITAL

I. Pérez Hernández[1], C. López Calderón[1], A. Hidalgo Conde[1], M. de Haro Liger[2], M. Abarca Costalago[1], P. Valdivielso Felices[1]

[1]Department of Internal Medicine, [2]Department of Reumathology. Complejo Hospitalario Virgen de la Victoria. Málaga, Spain.

Objectives: To describe the epidemiological, clinical and blood test characteristics of the patients diagnosed of Still´s disease in our hospital since year 2000.

Material and method: A retrospective study of the patients diagnosed of Still´s disease in the 2000-2011 period was done. All the clinical features were analyzed, the same as laboratory tests, including haemogram, biochemistry, autoimmunity and ferritin, at the onset of the disease and along this period. Biopsies were also reviewed.

Results: Since year 2000, ten cases of Still´s disease have been diagnosed. The onset of all of them was at adult age. Five of them were women and the mean age was 32.9 years. They were Caucasian except an African one. At the moment of the diagnosis, eight patients had fever and nine of them arthritis (poliarticular form) and in seven the last of the pain was more than two weeks. A skin rash could be seen in six and adenopaties in five. Only one biopsy was performed and showed reactive linphadenitis with a mix pattern (paracortical expansion, follicular hyperplasia, hystiocitosis and eosinophylic infiltrate). Six patients had sore throat and two suffered from pleuritis and pericarditis. In the blood test there were high ferritin levels in all patients with a mean of 4,039.6 ng/ml. Only one of them had positive Antinuclear Antibodies (ANA) and Rheumatoid factor in two, without low levels of complement. The mean value of RCP was 184.5 mg/ml and 60% had leucocytes levels higher than 10.000 (mean neutrophils of 82%). All but one had hypertransaminemia (AST 144 UI/ml; ALT 162.2 UI/ml) and just in four there was hepato or hepatoesplenomegalia. Blood cultures were negative at diagnosis, the same as HIV, HCV and Salmonella serology. One patient had a chronic infection of HBV and another one had a positive Parvovirus IgG serology. Chronic infection of EBV and CMV was present in 50% and 60% respectively. For treatment, all of them needed NSAID to control the symptoms but eight of them needed steroids and even metotrexate in two to control the disease.

Discussion: Adult Still´s disease is an inflammatory disease of unknown etiology. To consider the diagnosis is needed to exclude other illnesses, inflammatory, infectious or malignant and many criteria have been used to do it as the Yamaguchi ones. The prevalence is low as we could have seen in our study, only ten patients in the last eleven years and we have to think of it in fever of unknown origin. In the analysis is common to see leukocytosis and neutrophilia, acute reactants elevation and abnormalities in hepatic profile with just a small hepatomegalia. Ferritin levels are very important as they help to diagnose and control the treatment effects. The response to NAIDS alone is very poor in our patients, the same as in other series and just one patient did not need another therapy such as steroids or even metotrexate to control the symptoms.

IF-28
CRYOGLOBULINEMIC VASCULITIS IN ADULTS: DIFFERENCES BETWEEN HIGH AND LOW LEVELS OF IGG

P. Guisado Vasco[1], G. de Luna Cardenal[1], I. Muñoz Roldán[2], R. Calderón Hernáiz[3], G. Serralta Sanmartín[4], M. Patiño[5], J. Canora Lebrato[3], G. Fraile Rodríguez[1]

[1]Department of Internal Medicine. Hospital Universitario Ramón y Cajal. Madrid, Spain. [2]Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain. [3]Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain. [4]Department of Internal Medicine. Hospital Universitario Infanta Sofía. Madrid, Spain. [5]Department of Internal Medicine. Hospital Universitario de Móstoles. Madrid, Spain.

Objectives: Cryoglobulinemic vasculitis (CV) could be or not associated to chronic viral infections (mainly HCV +). However, independently from the underlying cause, CV usually has a chronic course, with flares and remissions. These flares are ethiopathogenic linked to B-cells activity and immune complex tissue damage. Polyclonal hypergammaglobulinemia IgG could be an indirect measure of this B-cell activity. Objectives: to study if there is any kind of clinical differences between high or low levels of IgG in CV in the autoimmune diseases Group of Madrid-Castilla La Mancha.

Material and method: A multicentric and retrospective study of consecutive patients with final diagnosis of CV was designed taking data from 4 centers of Madrid (Jan/1994-Mar/2012). The data were divided in two cohorts: high and low levels of IgG, selecting a cut point of 1800 mg/dl. The categorical variables were analysed using the χ^2 of Pearson test (or Fisher exact test where indicated) and continuous variables were compared using the Mann-Whitney or t-student for independent samples. A Kolmogorov-Smirnov test was firstly made to check the normal distribution of the continuous variables. p significance were < 0.05 for all statistical analyses, using the SPSS 18.0 version.

Results: Data of 56 patients were available for this analysis approach. Cohort 1 (IgG ≤ 1,800 mg/dl) included 39 patients; cohort 2 (IgG > 1800) had 17 cases. The following variables were analized: HCV (+), fever, asthenia, arthralgias, arthritis, weakness, myalgias, sicca syndrome, Raynaud's phenomenon, skin ulcers, purpura, distal cyanosis, livedo reticularis, dizziness, sickness, headache, nistagmus, any potential associated lung disease, arterial hypertension onset or worsening, renal insufficiency (and range of proteinuria) and nervous system. Of all of them, it was found a more frequent affection of peripheral nervous system (symmetric polyneuropathy) (Fisher test p = 0.022) in cohort 1. Crioglobulins turned negative also more frequently in cohort 1 (χ^2 p = 0.014). Recurrence, remission and mortality showed non-significance differences between both groups. Level of IgG did not influence on monoclonal antibodies therapy (Fisher exact test, p = 0.42). It wasn't found any statistical significance in Mann-Whitney and t-student test (ERS, C-reactive, serum creatinine, proteinuria range, plasma compounds of blood, ANA, C3/C4, age, months to diagnosis or total dose of cyclofosfamide or corticoids).

Discussion: Our results are limited by two main factors: low number of events in each cohort and a retrospective study design. The symmetric polyneuropathy observed in group 1 is just a statistic effect (event in group 2, n = 1). HCV (+) is not related to higher levels of IgG (retrospective design). Immune complex tissue deposition and low levels of complement factors still remain being the main pathophysiological events in CV. These data should be validated in larger cohorts of patients (prospective or larger retrospective studies).

Conclusions: Tissue damage, clinical manifestations and laboratory data in CV does not seem to be related to serums level of polyclonal IgG.

IF-29
CRYOGLOBULINEMIC VASCULITIS IN ADULTS. MAIN CLINICAL FEATURES AND SOME OUTCOMES RATES

P. Guisado Vasco[1], J. Navas[1], O. López[2], I. Perales Fraile[3], L. Soler Rangel[4], J. Ríos[5], J. Canora Lebrato[3], G. Fraile Rodríguez[1]

[1]Department of Internal Medicine. Hospital Universitario Ramón y Cajal. Madrid, Spain. [2]Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain. [3]Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain. [4]Department of Internal Medicine. Hospital Universitario Infanta Sofia. Madrid, Spain. [5]Department of Internal Medicine. Hospital Universitario La Paz. Madrid, Spain.

Objectives: Cryoglobulinemic vasculitis (CV) is a systemic vasculitis involving medium and small-sized vessels mediated through immune-complex reaction. The manifestations could be so heterogeneous, affecting wide range of organs and systems. Objectives: to assess the main clinical features of CV patients in the group of autoimmune diseases of Madrid-Castilla La Mancha.

Material and method: It was designed a multicentric and retrospective study of consecutive patients with final diagnosis of CV in 4 centers of Madrid (Jan/1994-Mar/2012).

Results: 59 patients were finally included for descriptive analysis, with female:male ratio 1.34. The median age of patients was 61.8 yrs (SD 16.91), with a delayed between clinical diagnosis and onset of symptoms of 9.56 months. HVC (+) were found in 69%; HVB (+) in 6.8%. The frequencies of cryoglobulinemic types were: type I (21.4%), II (55.4%) and III (23.2%). 11% had any kind of cancer. The general complains include headache (6.8%), fever (> 38ºC) in 16.9%, weakness (59.3%), arthalgias (40.7%). The more frequent cutaneous signs were Raynaud's phenomenon (10.3%), purpura (49.2%) or any other manifestation of vasculitis (27.1%). It was detected pulmonary infiltrates in 6.8% of cases, without any alveolar hemorrhage. New onset renal insufficiency was detected 20.3% of cases (nephrotic range, 6.9%; non-nephrotic proteinuria, 20.3%; hematuria, 18.6%), and arterial hypertension (39%). Symmetric polyneuropathy was detected in 27.1% of cases. Median IgG levels were 1,505.95 mg/dl. ANA were positives in 32%; ANCA, were negatives in all cases. The global mortality rate reached 23.78% (directly causes by CV 8.33%). Almost a third has got complete remission after different treatments schemas (22% reached negativization of crioglobulins). Recurrences happened in 13.47%. Of the total cases, 11.9% developed B-cell non-Hodgkin lymphoma.

Discussion: CV in adults is not only associated to chronic viral infections (HCV, HBV): more than 20% have not got any of them. The patients' illness complaints are wide, mostly affecting skin. Some of them could affect organ (renal, peripheral nervous system), even with severe damage. Mortality directly related to CV does not reach 10%, being the main causes of death the comorbidities and therapy adverse reactions.

Conclusions: CV has a wide range of clinical manifestations, which lead to a delayed in diagnosis of several months. Global mortality is more due to comorbidities and treatment side effects than to crioglobulinemia.

IF-30
RHUPUS: A CASE SERIES OF PATIENTS WITH RHUPUS AND SJRHUPUS

S. Hammami[1], M. Younes[2], S. Mahjoub[1], N. Bergaoui[2]

[1]Department of Internal Medicine. EPS F Bourguiba Monastir Tunisia. Monastir. [2]Rheumatology. EPS F Bourguiba, University of Monastir. Monastir.

Objectives: Among the clinical manifestations of systemic lupus erythematosus (SLE) is an arthropathy, which is usually nonerosive.

In many cases the joint involvement is mild. A subset of patients have deforming, nonerosive Jaccoud's arthropathy, and a minority (< 5%) have an arthropathy with clinical findings similar to rheumatoid arthritis (RA) that has been called "rhupus." We report our series of five patients Objectives: To analyse the clinical features and pathogenesis of overlapping features of rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE), termed 'Rhupus syndrome'.

Material and method: Patients meeting American College of Rheumatology criteria for RA and SLE.

Results: Five women, with rhupus arthropathy: Patients meeting American College of Rheumatology criteria for RA, SLE. Patients were between the ages of 28 and 52 years at the disease onset. The diagnosis was RA in 3 patients at the beginning. They developed SLE after an average of 2.3 years (range: few yrs to 3 years). Two patients have a history of familial lupus. All patients had a symmetrical small joint polyarthritis and features of SLE such as rash, photosensitivity (n = 5), oral ulceration (n = 2), serositis (n = 4), cytopenia (n = 4), and biopsy proven lupus nephritis (n = 1). Four had hypocomplementemia. Autoantibodies were characteristic of the two diseases: all patients had antibodies to double stranded DNA, four had rheumatoid factor and two had anti-CCP antibodies, four had antibodies to Ro (SS-A), antibodies ti La (SS-B) and anti Sm-RNP for two patients respectively. There was also an overlap of systemic lupus, RA and Sjögren termed "Sjrupus" (n = 3). Antiphospholipid syndrome (n = 2) and scleroderma (n = 1). Hematopoietic system manifestations were prominent in this population. Two patients developed macrophagic activation syndrome, with febrile pancytopenia, hyperferritinemia, hypertriglyceridemia with a rapidly deteriorating course with progressive pancytopenia and death despite immunosupressive therapy.

Conclusions: Most of the Rhupus syndrome patients firstly presented with RA and showed less SLE associated severe damages. Sex hormone factor might be associated with the incidence of the disease. The coexistence of auto-immune rheumatic disease may be partially explained by the interplay of environmental factors with gene that predispose to autoimmunity. Our study suggests that genetic factors do have a role in the development and expression of overlap of systemic lupus. The use of intravenous Immunoglobulin may be efficacious in macrophagic activation syndrome.

IF-31
RHEUMATOID ARTHRITIS WITH SYSTEMIC LUPUS ERITHEMATOUS: THE CHARACTERISTICS OF RHUPUS SYNDROME

M. Fernández Blest[1], J. Calvo Catala[2],
I. González-Cruz Cerverella[2], C. Campos Fernández[2], A. Rueda Cid[2]

[1]Department of Internal Medicine, [2]Department of Rheumatology and Bone Metabolism. Hospital General Universitario de Valencia. Valencia, Spain.

Objectives: Describing the characteristics of seven patients with Rhupus syndrome with their clinical presentation and the treatment they received in these patients evaluated in the outpatient of our hospital.

Material and method: We present the clinical, serological and radiographic characteristics of seven patients with Rhupus syndrome in where we described the clinical presentation and the treatment they received in these patients evaluated in the outpatient. The diagnosis of SLE and RA were performed following the clinical criteria of the American College of Rheumatology (ACR). The patients should meet the clinical criteria of one of these diseases and later meet the criteria of the other.

Results: We included seven patients, three women and four men with a median age of 58.14 years at the time of diagnosis. Six patients (85.7%) debuted with RA, meeting the criteria for SLE after. The seventh patient (14.3%), first met the criteria for SLE and then, when he had rheumatoid nodules, met the criteria for RA, having characteristic radiographic lesions in hands, even the rheumatoid factor and the anti-citrullinated protein antibodies (anti-CCP) were all negative. The rheumatoid factor was positive in 6 patients and the anti-CCP in 5 of them. All the patients had ANA and Anti-DNA antibodies positive. In three patients, the anti-Ro and anti-La antibodies were positive. Four patients showed leukopenia while three of them had thrombopenia. All patients presented with arthralgia and/or arthritis. The rheumatoid arthritis was the only extra articular manifestation of RA. Two patients had skin manifestations which are typical of SLE. None of the patients had renal or neurological impairment. The following treatment used was: Dolquine (4 patients), methotrexate (4 patients), leflunomide (2 patients), azathioprine (1 patient) and adalimumab (1 patient), 5 of them had associated glucocorticoid treatment.

Discussion: The simultaneous manifestation of SLE and RA is very rare but it has been documented and defined as SRh. Panush et al have reported an incidence of 0.09% among 7,000 newly diagnosed patients in one year. Aside from clinical manifestations and the serologic evidence of SLE, for patients with SRh, there is also radiographic evidence of erosive arthropathy. Among patients diagnosed with SRh in our outpatient clinic, articular manifestations are the most frequent. There were just a few severe articular manifestations associated with the underlying disease: only one patient had rheumatoid nodules as an extra articular manifestation of RA and neither had renal or neurologic impairment from SLE. The finding of elevated values of anti-CPP antibodies in some patients with SRh supports the idea that for some patients this overlap syndrome may represent a true concordance of the two diseases rather than an atypical arthropathy of SLE. Almost without exception, the treatment is directed to the particular clinical manifestation and is not predicated with a definitive diagnosis. Many of the patients with SRh, develop the initial manifestations of RA or SLE and after that they develop the other disease over the course of years of evolution. In our study, the finding of positive anti-dsDNA and anti-CPP is evidence that supports the concordance of SLE and RA.

Conclusions: There are patients with findings that are suggestive of RA or SLE, but do not fulfill ACR criteria for this diagnosis. A few of them will ultimately fulfill diagnostic criteria for another systemic rheumatic disease, when this occurs; the patient has an overlap syndrome which is called Rhupus syndrome.

IF-32
FOLLOW-UP OF PRIMARY IMMUNODEFICIENCIES IN AUTOIMMUNE DISEASES UNIT

I. Piñero de Paz, H. Gómez Rodríguez, A. Martínez Zapico,
N. Morán Suárez, S. de la Villa Martínez, D. Colunga Argüelles,
R. Gómez de la Torre, J. Díaz López

Department of Internal Medicine. Hospital Universitario Central de Asturias. Oviedo (Asturias), Spain.

Objectives: Development and follow-up of patients with primary immunodeficiencies, in a tertiary hospital, with reference to clinical presentation, progress and follow-up after treatment.

Material and method: All primary immunodeficiency patients (PI) followed in the autoimmune disease unit since 2007 were included. All of them had a well documented (PI) according to clinical manifestations and biological data, and criteria the European Society of Immunodeficiencies, excluding partial immunoglobulin deficits. A database with demographic criteria: age, sex, clinical impairment, biological data, treatment, has been designed.

Results: Seventeen PI patients were included, 65% women, mean age 36 years old (range 17 to 75 years), 16 with B cell immunodefi-

cience (BCID) and only one with T cell immunity deficience (TCID). In BCID: 2 cases with X-linked agammaglobulinemia (XLAGM), and 14 with common variable immunodeficiencie (CVID). In BCID the initial forms of presentation have been: respiratory infection 10 (62.5%); major sinusitis and multiple ear infections in 8 patients (50%), 6 of them have simultaneous respiratory and sinusitis and ear infections. One of the patients suffers S. pneumoniae parameningeal infection, and 3 multiple pneumococcal bacteremic. One patient has a bacteremic genitourinary infection. Associated autoimmune disorders were observed in 5 patients (31%): autoimmune hematologic disorders in 3 (all thrombocytopenia), 1 chronic diarrhea celiac like disease and 1 an optic neuritis. Non-Hodgkin´s lymphoma was observed in 1 patient. All patients with BCID have been treated with immunoglobulins (IVIg) in relation to the decline of B cell memory (MB cell) (igD- CD27+), lower Ig levels and diminished response to pneumococcal and tetanus vaccination. Adverse reactions to IV ig infusions were observed in 3 cases (18.75%), and all of them minor (flushing and fever in 2 cases and headache in one fever. Mean level of Ig G at diagnosis were 2.58 g/L (range 0.33 to 4.7 g/L). Mean levels after IVig were 8.37 g/L, (range 5.64 g/L to 14.1 g/L). Mean B cell memory (IgD- CD27 +) at diagnosis was 1.86% (0 to 9%). In CIVD lower percentage of MB cell were associated with all type of clinical manifestations. The Bruton disease presents the lower percentages of B cell memory. Delayed diagnosis has been: 417 weeks mean, maximum: 1,440 weeks and minimum: 0 Follow-up mean: 218 weeks, maximum: 1,440 weeks. All patients B cell IP continue IVig infusions without disease progression.

Discussion: The usual form of (IP) presentation It's has been CIVD: heterogenous group disorders characterized by decreased immunoglobulin production. This syndrome describes a group of immunological disorders of unknown etiology with impaired antibody response. Clinical manifestation is recurrent sinopulmonary infections by encapsulated bacteria, autoimmmune diseases, lymphoproloferative, granulomatous or neoplastic disorders and intestinal dysfunction. The onset of symptoms was usually 25 years.

Conclusions: CIVD is the most common IP in our unit of autoimmune disease. Their varied forms of presentation which include involvement of: respiratory, hematological, autoimmune, gastrointestinal and granulomatous disease, appear to be associated with lower MB cells count. Repetiton bacteremic pneumococcal alert to the presence of BCID. Replacement IVIg is specific treatment CIVD in cases with lower MB cells count, has changed the outcome of disease. Adverse reactions to IVig infusions were minor. No patient has needed to withdraw the infusions. Avoid delayed diagnosis may be prevented complications linked to MB cell count.

IF-33
SWEET´S SYNDROME: RETROSPECTIVE STUDY OF CLINICAL AND HISTOLOGIC FEATURES OF 11 CASES

B. Galve Valle[1], E. Calvo Begueria[1], J. Pérez Lorenz[1], L. Martínez González[1], M. Mallen Díaz de Terán[1], Y. Gilaberte Calzada[2], C. Martínez Huguet[1]

[1]Department of Internal Medicine, [2]Department of Dermatology and Venereology. Hospital General San Jorge. Huesca, Spain.

Objectives: Sweet's syndrome (SS) is an uncommon disorder characterized by the abrupt onset of erythematous papules and plaques that histologically exhibit diffuse dermal neutrophilic infiltration and edema. There are usually associated constitutional symptoms such as fever, neutrophilia, elevated serum inflammatory markers, and associated disorders. The aim of this study was to describe the clinical, epidemiological profile the aetiopathogenic, developmental and therapeutic features of patients diagnosed with Sweet's syndrome in our Hospital, and to compare their findings with those published in the literature.

Material and method: Retrospective descriptive study, collecting data from patients histologically diagnosed with Sweet's syndrome in the Hospital San Jorge (Huesca, Spain), between 2005 and 2012. All patients met the diagnostic criteria. Collected variables included: age, gender, morphology and distribution of lesions, associated symptoms and disorders, therapy) and histologic features, as well as laboratory abnormalities.

Results: 11 patients were included, 5 women and 6 men, with a mean age of 68 years. All of them meet the 2 major criteria, 6 patients 3 minor and 5 patients only 2 of them. 6 patients (53%) associated malignancy (4 solid tumors, being the more frequent breast cancer, and hematological malignancy 2 of them), 3 patients presented bacteremia (E. coli and S. aureus germs), 2 thyroid gland diseases, and 1 AIDS who was on antiretroviral treatment. ESR and C-reactive protein were increased in 100% of the cases. Leukocytosis was present in 7 patients, 4 of them with neutrophilia. 7 patients (63%) presented anemia, 3 thrombocytosis and 2 thrombocytopenia. 7 patients had systemic involvement; 2 of them of the bone marrow, 2 liver enzymes elevation, 1 renal insufficiency and in 2 lymphadenopathy. 100% of the cases were treated with oral corticosteroids with good response, even though most of them had been previously treated with antibiotics or 4 anti-inflammatory drugs. 2 patients with hematological malignancy received treatment of hydroxyurea. The average length of the treatment was 3 months and recurrent only occurred in one case.

Discussion: Sweet's syndrome is an uncommon but not rare disease that occurs predominantly in middle-aged women. In our study mean age of 68 years and 65% were man. Although most cases are idiopathic, the possibility of para-neoplastic process or associated systemic diseases must be carefully excluded. Special attention must be paid to screening of haemoproliferative processes. In our study, 35% of patients presented bacteremia, 53% associated malignancy, 25% thyroid gland diseases, and 10% AIDS who was on antiretroviral treatment. The treatment of choice is systemic corticosteroids, with such a good response that constitutes a diagnostic criterion. In our study, 100% of the cases were treated with oral corticosteroids with good response. Otherwise, the antibiotic treatment are ineffective but in our study while only in 35% of cases presented bacteremia, to 85% of patients take in antibiotic.

Conclusions: Sweet's syndrome usually is idiopathic. Nevertheless, and extensive examination is mandatory in order to rule out associated malignancy or systemic disease.

IF-34
BILATERAL UVEITIS AS MANIFESTATION OF SYSTEMIC SCLEROSIS. REPORT OF THREE CLINICAL CASES

P. Fanlo Mateo[1], S. Clemos Matamoros[1], I. Elejalde Guerra[1], A. Belzunce Manterola[2], M. Etxebarría Lus[1], H. Heras[2], A. Villanueva Fortún[1], C. Pérez García[1]

[1]Department of Internal Medicine, [2]Department of Ophthalmology. Complejo Hospitalario de Navarra B. Pamplona (Navarra), Spain.

Objectives: To describe three cases of systemic sclerosis with bilateral anterior uveitis.

Material and method: To review medical histories and current literature.

Results: Case 1: a 34 year-old woman with no previous medical history, was referred to our Multidisciplinary Consultory of Uveitis due to several flares of bilateral anterior granulomatous uveitis during 3 years. The patient presented a constitutional syndrome associated with diffuse arthralgia and Raynaud's phenomenon. Screening for infectious and autoimmune disease was negative. Thoracic radiography showed a pattern of bilateral basal fibrosis.

Chest CT scan was requested and demonstrated lung nodules without lymphadenopathy. A bronchoscopy was performed and the biopsy confirmed the existence of patched alveolar septal fibrosis. The patient presented skin lesions similar to livedo reticularis in her thighs years ago. Skin biopsy showed reticular dermis fibrosis, capillary and perivascular mild chronic inflammation, suggestive of scleroderma or morphea. Early scleroderma pattern was found in capillaroscopy study. Treatment with pulses of cyclophosphamide was initiated with clear improvement of uveitis. The patient was diagnosed of systemic sclerosis with pulmonary involvement (pulmonary fibrosis), ocular affection (uveitis), skin disease and Raynaud´s phenomenon. Case 2: A 37 year-old male patient was referred to Internal Medicine consultory because of recent onset of Raynaud's phenomenon. The patient had a previous history of recurrent bilateral anterior uveitis 6 years ago and idiopathic chronic interstitial lung disease. Laboratory analysis detected positive antinuclear antibodies with anticentromere pattern. Capillaroscopy study showed giant capillaries and capillary tortuosities. The diagnosed of systemic sclerosis with Raynaud´s phenomenon, dermal, ocular and pulmonary affection was established. Case 3: A 63 year-old woman with CREST syndrome diagnosed in 1997 with posterior systemic involvement with severe cutaneous arterial destructive form, esophageal involvement, pulmonary hypertension and fibrosis was referred to Multydisciplinary Uveitis Unit due to blurred vision, ophthalmological examination revealed bilateral anterior uveitis associated with macular edema. The patient was in treatment with methotrexate and intravenous pulses of infliximab with lack of response. Treatment with intravenous pulses of abatacept was initiated, achieving complete remission of ocular involvement. Bilateral anterior uveitis and macular edema secondary to severe CREST syndrome with systemic involvement was diagnosed.

Discussion: Systemic sclerosis (SSc) is a multisystemic connective tissue disease of unknown etiology that predominantly affects skin, musculoskeletal system, gastrointestinal tract, lungs and kidney. Ocular involvement has been documented and some ocular manifestation in SSc are well known such as keratoconjunctivitis sicca and eye lid changes. Ocular manifestations such as conjuntivitis, episcleritis, glaucoma, xeroltafmia, keratitis, strabismus and retinal abnormalities are described. The association between uveitis and SSc is unusual but due to the low prevalence of this association, few cases are reported, consist only in sigle case reports or small number of case series. In two of our 3 cases, uveitis was the onset symptom of SSc and in the other case, uveitis started years after the SSc diagnosis.

Conclusions: In some cases, inflammatory eye disease, uveitis, could be the onset manifestation of SSc and could be developed after years of diagnosis. Therefore a promptly diagnosis of SSc-related uveitis may set up a properly treatment of this disease.

IF-35
CRYOGLOBULINEMIA ASSOCIATED WITH AUTOIMMUNE SYSTEMIC DISEASE

R. Calderón[1], G. de Luna[2], I. Muñoz[3], A. Llanos[4], J. Navas[2], O. López[3], J. Canora[1], G. Fraile[2]

[1]Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain. [2]Department of Internal Medicine. Hospital Universitario Ramón y Cajal. Madrid, Spain. [3]Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain. [4]Department of Internal Medicine. Hospital Universitario Infanta Sofía. Madrid, Spain.

Objectives: Cryoglobulinemia (CM) is a rare disease and almost 90% of cases have a known predispossing condition: viral infections, lymphoproliferatives syndromes, autoimmune systemic diseases (ASD)... Sjögren syndrome is the most frequent ASD associated with CM (typically type III). Our objective is to analyze all cases of CM associated with ASD diagnosed in the Internal Medicine Service of several hospitals of Madrid and to compare them with those not associated.

Material and method: Retrospective descriptive multicenter study of cases of CM diagnosed in the Internal Medicine Service of several hospitals of Madrid since 1994 to 2012. We compare two groups: CM associated with ASD (A) and CM not associated to ASD (B). χ^2 was used for cathegorial variables (or exact Fisher test when indicated) and U-Mann-Whitney or t-student for continuous variables. p significance was < 0.05 for all statistical analysis, using the SPSS 18.0 version.

Results: We diagnosed 59 cases of CM, 19 of them with ASD (4 Sjögren, 2 AR, 2 sarcoidosis, 2 SLE, 1 systemic sclerosis and 8 unespecified vasculitis). CM type II was the most frequent in both groups (11 in group A and 20 in B). Only 3 cases of CM type III were detected in group A. Patients with ASD were mostly women and a high percentage of them (68.42%) were associated with HCV infection. HBV infection was infrequent (5.2%) and up to 26% of cases had malignances. The most common presentation was asthenia and malaise without fever in both groups. Dry syndrome, arthralgyas, myalgias and palpable purpura were most frequent in group A ($p < 0.05$). Raynaud phenomenon was detected in 15.7% of patients of group A and in 7.5% of group B. Urine sediment alterations and renal failure were infrequent in our series (15.7% in A and 22.5% in B), as well as the SNC involvement. There were no differences in the presence of sensorio-motor polyneuropathy between the two groups (36.8% in A and 22.5% in B) (p 0.24). No case of alveolar hemorrhage was detected. The most common findings were high levels of rheumatoid factor and C4 in both groups, with low C3 patients with ASD and normal levels in those without ASD ($p > 0.05$). The 100% of patients with ASD were treated with corticoids: some of them with bolus of methylprednisolone but most of them with oral steroids ($p < 0.05$). Cyclophosphamide was rarely used, but when used, it was in the bolus form and not for maintenance. Some patients received immunoglobulins or plasmapheresis sessions. Only 9 of the total series were treated with rituximab with a similar distribution in both groups and despite the high association with HCV infection, antiviral drugs were rarely used. Four patients with ASD developed non-Hodgkin lymphoma B (two of them with Sjögren's syndrome). Outcome was generally favorable although complete remission with negative cryoglobulins was not achieved in all cases.

Conclusions: Although the CM type III is typically associated with autoimmune diseases, we have not confirmed this association in this series. Sjögren's syndrome is the most related ASD (excluding vasculitis) and association with HCV infection is common: both conditions coexist in many patients. The presentation, clinical course and therapeutic approach do not differ from other types of CM but it has significantly more arthralgyas, myalgias, dry syndrome and palpable purpura. Oral steroids are more used in patients with CM associated with ASD, probably because of the existence of a known ASD before the onset of symptoms.

IF-37
ADULT ONSET STILL´S DISEASE: REVIEW OF 14 CASES OF A SINGLE CENTER

A. Martínez Zapico[1], L. Caminal Montero[1], L. Trapiella Martínez[2], H. Gómez Rodríguez[1], C. Suárez Cuervo[1], A. Fidalgo Navarro[1], J. Bernardo Cofiño[1]

[1]Department of Internal Medicine. Hospital Universitario Central de Asturias. Oviedo (Asturias), Spain. [2]Department of Internal Medicine. Hospital Cabueñes. Gijón (Asturias), Spain.

Objectives: Adult onset Still´s disease (AOSD) is a rare systemic inflammatory disorder of unknown etiology that is responsible for

significant cases of fever of unknown origin. The clinical presentation of AOSD is heterogeneous, and the spectrum of differential diagnoses is wide. The diagnosis is a challenge and there is no specific test. The annual incidence of ASD is estimated to be 0.16 cases per 100,000 persons and only few reports of the disease had been made in our country. To describe the clinical characteristics, treatment and outcome of a series of patients with AOSD in an academic hospital in Spain.

Material and method: Between 1994 and 2012, only 14 patients were found with AOSD in the Autoimmune Disease Unit and the hospital discharge databases. All of them fulfilled the Yamaguchi criteria giving significant value to the increased serum ferritin. Specific clinical features, laboratory tests, treatment and outcome were retrospectively recorded.

Results: All patients were diagnosed in the Internal Medicine department. The mean age was 31 years (16-51 years). Five were male (35.7%) and 9 female (64.3%). Clinical manifestations were similar to those previously described. The follow-up was 8 years (1-19 years). Two patients died, one by a heart attack and another from pneumonia. All of them were treated with high-dose corticosteroids (0.5-1 mg/kg/day) and immunosuppressive drugs usually methotrexate or azathioprine. There were recurrences in 50% of cases. Three patients were treated with anti-TNF biological therapy. A reactive hemophagocytic syndrome (most serious complication of the disease) was diagnosed in 3 patients.

Discussion: In our series the most relevant information for the diagnosis was the fever and the laboratory hyperferritinemia. We used routinely high-dose corticosteroids and immunossupressive, and biological agents were required only in three patients (21%) because disease recurrence.

Conclusions: Our patients had relatively severe disease with 14% mortality. Nevertheless the prognosis is good although there is loss in the patient follow-up mainly by referral to health centers (almost 50%). Hyperferritinemia levels are not part of Yamaguchi criteria and therefore are not included in the diagnosis of disease. However, in our entire series of patients had elevated ferritin important to diagnosis and monitoring possible to determine the response to treatment. Thus, their inclusion in a future diagnostic criteria of the disease would be important.

IF-39
EPIDEMIOLOGICAL AND CLINICAL CHARACTERISTICS IN PATIENTS WITH GUILLAIN BARRÉ SYNDROME

S. Araújo Fernández, R. Puerta Louro, H. Enríquez Gómez, L. Novoa Llamazares, A. Arca Blanco, M. Rodríguez Arias, J. Álvarez Otero, J. de la Fuente Aguado

Department of Internal Medicine. Povisa Hospital. Vigo (Pontevedra), Spain.

Objectives: To determine the incidence and analyse the clinical and epidemiological characteristics of patients who develop Guillain Barré syndrome (GBS).

Material and method: We performed a retrospective study of the hospital discharges in with diagnosis include GBS, between January 1, 2002 and April 30, 2012. The following variables were recorded: age, sex, date of admission and season, average stay, existence of previous triggering, clinical features and variants of GBS.

Results: Were included 29 patients, 16 women (55.2%), mean age 52 ± 18 years (age ranged 13-79). The incidence was 2.2/100,000, being the summer season when more cases were diagnosed (41.4%). The average stay was 32 ± 36 days. In most patients (62%) did not detect a previous triggering, while a few days before 24% presented gastrointestinal disorders and 13.8% respiratory infection. The most common clinical presentation was lower extremities weakness, arreflexia (62%), upper limb weakness (17.2%), tetraparesis (13.8%) and oculomotor abnormalities (6.9%) with areflexia in 62% of cases. Finally, 48.3% patients developed tetraparesis and 10.3% oropharyngeal weakness. Paresthesias appeared in 65.5% of cases, pain in 20.7%, and dysautonomia (tachycardia, hypertension and constipation) were documented in 20.7% of cases. Of the 29 cases, acute motor axonal neuropathy was presented in 13 patients, motor and sensory axonal neuropathy in 10, demyelinating polyneuropathy 5 cases (17%) and 1 case Miller Fisher syndrome.

Discussion: Guillain Barré syndrome is defined as an ascending and progressive muscular weakness with arreflexia, which progresses over a few days to a few weeks. It can occur at any age and in both genders. In our series had an incidence of 2.2/100,000, slightly higher than what is stated in the literature. It showed a higher incidence in the summer months. Only 31% of cases had a previous infectious process. The most common manifestations were the weakness in lower limbs and paresthesias followed by weakness in upper limbs. Another remarkable date in our study was the high number of cases of acute motor axonal neuropathy and axonal neuropathy acute motor and sensory, in contrast with previous reports in which the most common variant was the demyelinating.

Conclusions: GBS occurred more frequently in the summer months and concomitant with previous reports, the most common presentation was lower limb weakness and paresthesias. However, in our series acute motor axonal neuropathy was the most frequent variant of GBS.

IF-40
TEST PERFORMANCE OF ULTRASONOGRAPHY FOR GIANT-CELL ARTERITIS IN A TERTIARY HOSPITAL OF CASTILLA-LA MANCHA (SPAIN)

I. Mora Escudero[1], A. Gato Díez[1], E. Palazón García[2], T. Segura Martín[2], A. Sedano Casas[1], O. Ayo Martín[2], J. García García[2], L. Sáez Méndez[1]

[1]Department of Internal Medicine, [2]Department of Neurology. Hospital General de Albacete. Albacete, Spain.

Objectives: 1. To determinate the diagnostic performance of color duplex ultrasonography (CDU) for giant-cell arteritis (GCA) in our hospital. 2. To analyze the epidemiologic and clinic characteristics of patients with GCA. 3. To identify the best set of predictors for a positive temporal artery biopsy, and 4. To identify which patients could be avoided the temporal artery (TA) biopsy.

Material and method: Retrospective study of patients with suspected GCA, from 2008 to 2011 in the University Hospital Complex of Albacete. The following data were collected: demographic features, fever, new headache, polymyalgia rheumatic, amaurosis, jaw claudication, hemoglobin, erythrocyte sedimentation rate, C-reactive protein, corticoid administration, TA biopsy, final diagnosis and treatment. Diagnostic performance of CDU was determinate for the halo sign, stenosis, or occlusion. CDU results were compared with TA biopsy findings and the American College of Rheumatology (ACR) research criteria for diagnosing ACG and weight sensitivity and specificity of CDU were calculated. Statistical analysis was performed with the SPSS software package.

Results: 72 patients with suspected GCA were studied. TA biopsy was realized in 26 of them, with positive result for GCA in 15 patients. In patients with TA biopsy the mean age was 74.2 years, a female predominance was observed (73.1%) and new headache was the most frequent clinical finding (61.5%). The 44 patients without TA biopsy had an alternative diagnosis or the condition resolved without corticoid administration. In this group of patients, CDU was normal in 93.2% of cases. When CDU was compared with TA biopsy, the sensitivity was 86.6% ($p < 0.05$), the specificity was 63.3%, the positive predictive value (PPV) was 76.5, the negative predictive value (NPV) was 77.8, the positive likelihood-ratio (LR+) was 2.38 and the negative likelihood-ratio (LR-) was 0.20. When

CDU was compared with ACR classification criteria for GCA results were: sensitivity 83.3%, specificity 75%, PPV 88.2, NPV 66, LR+3.33, LR-0.22. In patients with bilateral CDU findings the specificity was 90.9% compared with TA biopsy and 87.5% compared with ACR criteria. 80.8% of patients with TA biopsy showed 4 or more clinical data for ACG.

Discussion: Our series show higher sensitivity and lower specificity than other series published. However there are considerable heterogeneity between the studies, attributable to different ultrasound techniques, operator experience, and the range in numbers of patients recruited to each study. Our centre has a high-quality duplex machine and neurologist-vascular with relevant practical experience, which would explain the high sensitivity. Although our study is retrospective, it is interesting that in the group of patients without TA biopsy, 93.2% had normal CDU. In these patients, with low clinical suspicion of GCA, CDU was useful to avoid TA biopsy. In addition, the high sensitivity showed by this technique make it a very interesting screening study of GCA.

Conclusions: In our setting is verified the CDU utility in the diagnosis of GCA. In patients with low suspected of GCA and CDU negative, and in patients with high suspicion of GCA and positive CDU probably TA biopsy is unnecessary. We must be quick in the diagnosis and treatment of GCA about potential complications if not treated early, so the CDU can be very useful in this regard. CDU should be included in the guidelines as initial study of all patients with suspected of GCA.

IF-41
AORTITIS REVEALED BY 18F-FDG PET/CT SCAN AS CAUSE OF FEVER OF UNKNOWN ORIGIN: TWO CASES

J. Goiri, R. Rodríguez, A. Martínez-Berriotxoa, I. Les, M. Egurbide

Department of Autoimmune Diseases-Internal Medicine. Hospital Universitario Cruces. Barakaldo (Vizcaya), Spain.

Objectives: To describe two patients with fever of unknown origin due to aortitis demonstrated by fluorine-18-fluorodeoxyglucose (18F-FDG) positron emission tomography (PET)/CT scan.

Material and method: Review of the clinical records of two patients with aortitis diagnosed in the Service of Internal Medicine of Cruces University Hospital (Barakaldo, Spain).

Results: Case 1: a 65-years-old white female with no antecedents was referred with fever of more than three months duration, weight loss, polyarthralgia and back pain. No temporal artery abnormalities were present and physical examination was unremarkable. Laboratory tests revealed increased erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) and moderate normocytic anemia; cultures were negative and immunological and thyroid function tests were normal. Mantoux test was negative. Echocardiography showed no signs of infectious endocarditis. Chest and abdominal CT-scan and magnetic resonance imaging (MRI) of the spine revealed no findings. Bone marrow biopsy, immunophenotype and cultures were non-diagnostic, and temporal artery biopsy was negative. 18F-FDG PET/CT imaging showed active inflammation of the aorta and its main branches. The patient was treated with IV pulse methyl-prednisolone and low-dose oral prednisone and methotrexate, with progressive improvement. Case 2: A 72-years-old white female with antecedents of essential hypertension and non-obstructive nephrolithiasis presented with fever of four weeks duration, weight loss and lower back pain. Physical examination was unremarkable and no temporal artery abnormalities were present. Laboratory tests revealed increased ESR and CRP, and mild normocytic anemia; blood cultures were negative and immunological and thyroid function tests were normal. Mantoux test was negative. Echocardiography ruled out infectious endocarditis, and spinal MRI showed no findings other than degenerative lumbar changes. Uncomplicated right nephrolithiasis and unspecific aortic wall changes were found on chest and abdominal CT-scan. 18F-FDG PET/CT imaging revealed active aortitis. Fever disappeared after IV pulse methyl-prednisolone, and progressive improvement was achieved with low-dose oral prednisone and methotrexate.

Discussion: The clinical presentation of large-vessel vasculitis varies across a wide spectrum of symptoms and clinical signs, ranging from ischemic manifestations to pyrexia of unknown origin and constitutional or unspecific (i.e. back pain) symptoms, as in the two patients we report. Demonstrating appropriate inflammatory vessel wall involvement is the standard diagnostic criterion, but biopsy is almost impossible in most cases and diagnosis and follow-up are usually supported on noninvasive diagnostic imaging techniques. Recent publications have highlighted the use of 18F-FDG PET/CT scan as a moderately sensitive, noninvasive diagnostic test for large-vessel vasculitis, particularly in those cases in which first-line imaging techniques (i.e. CT-scan or MRI) are non-diagnostic. In our two cases, the initial comprehensive study was negative, and 18F-FDG PET/CT scan revealed the presence of aortitis as the cause of fever of unknown origin.

Conclusions: 18F-FDG PET/CT scan is a useful noninvasive diagnostic test for diagnosis of large-vessel vasculitis, particularly in those cases with unspecific symptoms and/or in which first-line imaging techniques are non-diagnostic.

IF-42
A DESCRIPTIVE STUDY OF PULMONARY SARCOIDOSIS: RADIOGRAPHIC STAGE AND EXTRAPULMONARY MANIFESTATIONS

P. Fanlo Mateo, A. Villanueva Fortún, S. Clemós Matamoros, M. López de Goicoechea Sáiz, B. Lacuz Escalada, M. Abinzano Guillén, G. Tiberio López, C. Pérez García

Department of Internal Medicine. Complejo Hospitalario de Navarra-B. Pamplona (Navarra), Spain.

Objectives: Pulmonary affectation is over 90 percent of patients with sarcoidosis and the stage is based on the chest radiograph. The aim of this study was to describe radiographic stage and extrapulmonary manifestations of the 21 pulmonary sarcoidosis cases presented in our department.

Material and method: We performed a descriptive study of 21 pulmonary sarcoidosis cases admitted to the Internal Medicine Department of Complejo Hospitalario de Navarra-B of Pamplona from January 2001 to May 2012.

Results: In our 21 thoracic sarcoidosis cases, 11 (52.38%) were females and 10 (47.62%) were males. The mean age was 53.28 years old (19-85). Radiographic stages distribution was as follows: 10 (47.62%) cases showed a radiologic stage I, and the other 7 (33.33%) expressed stage II, 3 cases (14.28%) showed radiologic stage III and only 1 (4.76%) showed radiologic stage IV. As regards the organs involved, 6 (28.57%) had thoracic affectation as unique manifestation and surprisingly, 15 (71.42%) had also extra thoracic manifestations and 13 of them had stage I or II. The Lofgren syndrome was the most frequent extra thoracic manifestation (5 cases, 23.80%) followed by muscle and nervous system affection (3 cases each, 14.28% each). Cutaneous involvement was presented in 2 (9.52%) and one of those also had liver affectation. Exocrine glandular affectation was seen in 1 (4.76%) case and only one case had liver involvement (4.76%). The serum angiotensin converting enzyme (ACE) level could only be determined in 19 (90.47%) of the 21 cases. The mean ACE level was 52.36 U/L, being the serum ACE reference levels in our laboratory 8-52 U/L. The lowest ACE level was 7 U/L and the highest 147 U/L being the media level 44 U/L. We founded that 9 cases (47.36%) showed an ACE level beyond 52 U/L and among these ones, 77.77% had a radiologic stage I or II. Furthermore 10 cases (52.64%) showed a normal ACE level (under

52) and among these 80% had a radiologic stage I or II. Calcium levels were measured in all our patients and only one of them was founded to be beyond the higher calcium reference level (10.9 mg/dL). After reviewing the medical histories we founded that the tuberculin skin test was only accomplished in 7 (33.33%) of 21 cases, resulting positive 5 (71.42%) of them. As regards the treatment, 18 (85.72%) of them received corticosteroids and 3 (14.28%) of them received nonsteroidal antiinflammatory drugs (NSAIDs). During the study period, 5 patients died. They were aged 72-88 years old and 3 out 5 (60%) showed radiologic stage III or IV. Three of them died due to infectious complication (2 pneumonia and 1 tuberculosis), other patient after thyroid operation and the other one because of colon cancer.

Discussion: Though sarcoidosis usually presents in patients between 10 and 40 years of age, in our study the mean age was higher, probably because our population is characteristically older. As it is described in related literature, sarcoidosis affects females slightly more frequently than males and radiographic stages I and II are much more frequent than radiographic stages III and IV. The most frequent clinical manifestations were thoracic features associating extrathoracic symptoms at the same time. Those patients generally presented mild stages (I and II). Being Lofgren syndrome the most frequent extra thoracic manifestation. An unexpected founding was that though eye lesions are one of the usual abnormalities, none of our cases had eye involvement. Finally we founded that higher levels of ACE didn't correlate with more severe radiographic stages. Sarcoidosis cases that died during our study period were characteristically older and exhibited a more serious radiographic stage. The main cause was respiratory infection.

Conclusions: In patients with pulmonary sarcoidosis, clinicians should rule out other possible extra thoracic manifestations in early radiologic stages.

IF-43
OMALIZUMAB FOR THE TREATMENT OF THE ASTHMATIC COMPONENT OF CHURG-STRAUSS

I. Aomar Millán, L. Gallo Padilla, J. Callejas Rubio, R. Ríos Fernández, N. Ortego Centeno

Systemic Diseases Unit. Department of Internal Medicine. Hospital de Especialidades San Cecilio. Granada, Spain.

Objectives: To analyze the characteristics and development of two patients diagnosed as having Churg-Strauss, who received treatment with omalizumab to control the asthma.

Material and method: We analyze the clinical evolution for 29 and 11 months respectively from two patients diagnosed with Churg-Strauss and treated with omalizumab to the persistence of respiratory symptoms.

Results: Patient 1: 67 years-old man diagnosed in 2008, with a good development of vasculitis after receiving immunosupressive treatment, although he had persistence of asthma, high IgE (1,500 Ku/l) and eosinophilia (18%-1490/µl), so he needed treatment with high doses of corticosteroids. In December 2009 a treatment based on the administration of 150 mg/sc of omalizumab every 15 days was started, getting an excellent response, with no data of vasculitis up to now. The asthma was controlled without corticosteroid treatment, marked decrease of IgE (271KU/l) and with no eosinophilia. Patient 2: 47 years-old woman diagnosed in 2006, who had multiples acute asthmatic exacerbations, needing high corticosteroids doses and salbutamol. In May 2011 a treatment with omalizumab 150 mg/sc every month was started, getting a drastic decrease of the asthmatic crisis, and allowing a reduction of the corticosteroids doses. She is currently stable, with no data of vasculitis activity and IgE 149 KU/l (previous of 471 KU/l) and normal eosinophils.

Discussion: Omalizumab is an anti-IgE recombinant humanized monoclonal antibody, that inhibits the degranulation of mast cells and basophils, and reduces the tisular and circulating eosinophils by inhibiting its apoptosis. It is indicated for the treatment of severe persistent allergic asthma with high levels of IgE. There is a lot of controversy about Churg-Strauss. Some authors propose it to be used for the asthmatic component and the refractory forms without response to the conventional treatment, since the IgE might participate in the mechanisms of peripheral eosinophilia in this kind of patients. Other authors state that it can trigger vasculitis outbreaks by direct effect in the development of Churg-Strauss, or exposing "frustrated forms" of the disease in asthmatic patients, in which treatment with corticosteroids is reduced to initiate omalizumab. None of our patients showed vasculitis data, but they had an improvement of the asthmatic component after a medium monitoring of 29 and 11 months respectively.

Conclusions: although there is controversy about the use of omalizumab in Churg-Stauss, we think that, in selected cases with severe cortico-dependent asthma, it may be a good therapeutic alternative.

IF-44
RETROSPECTIVE STUDY OF ADULT-ONSET STILL´S DISEASE: OUR EXPERIENCE

E. Gaspar García, F. Olgado Ferrero, M. González García, M. González Gómez, J. Bureo Dacal, L. Nevado López-Alegría, J. Izquierdo Hidalgo, G. García García

Department of Internal Medicine. Complejo Hospitalario Universitario de Badajoz. Badajoz, Spain.

Objectives: The present study analyzed clinical and laboratory features, treatment and prognosis of patients with adult-onset Still´s disease (AOSD).

Material and method: Retrospective study of patients who had been diagnosed of AOSD from 1997 to 2011 in the city of Badajoz (Spain). All of patients fulfilled the diagnostic criteria of AOSD proposed for Yamaguchi.

Results: A total of 7 patients with a diagnosis of AOSD who had been followed-up in our department were retrospectively evaluated. Of 7 patients, 5 (71.4%) were male. The mean age of patients was 37.0 year ± 23.7 at the time of diagnosis (range 12-74). The characteristics of clinical manifestations were found as follows: fever was present in all patients; typical evanescent maculopapular rash could be seen in 5 (71.4%) patients; arthritis 6 (85.7%); sore throat 4 (57.1%), lymphadenopathy just 1 (14.3), hepathomegaly 2 (28.6%), splenomegaly 1 (14.3%), pleural 28.6% and pericardial effusion 14.3%. The mean values of laboratory findings were: leukocytosis with a mean value of 17,414.29 ± 8,608.02 was present in 85.7% of the cases; Four of patients had high ferritin values (> 500 ng/ml) and the mean value of ferritin was 12,216 ng/ml; C reactive protein level of 230.5 mg/dl; erythrocyte sedimentation rate of 75.8 mm/h; elevation of aspartate aminotransferase (GOT) was present in 4 (57.1%) patients and alanine aminotransferase (GPT) was elevated in 5 (71.4%) patients. Negative results of tests for rheumatoid factor (RF), antinuclear body (ANA) and blood cultures were seen in all of patients were seen. Corticosteroids (usually prednisone) were given as initial treatment after diagnosis in 3 (42.9%) patients. Just one patient received nonsteroidal antiinflamatory drug (NSAIDs) as a single medication. One patient received azatrioprine and other patient MTX in addition to corticosteroids during the follow-up.

Discussion: Adult-onset Still´s disease is s a rare systemic inflammatory disorder. Clinical features include fevers, sore throat, a salmon-colored rash typically found on the trunk, arthritis or arthralgias, lymphadenopathy and a number nonespecific hematologic findings like leukocytosis or liver abnormalities. Has

been associated with markedly elevated serum ferritin, so in a patient with compatible symptoms should lead to suspicion of AOSD in the absence of a bacterial or viral infection. A few sets of criteria have been proposed to classify AOSD, those of Yamaguchi being the most commonly used like in our study. The clinical course can be variable, since complete resolution until persistently active disease. The principal options for treatment are NSAIDs, glucocorticoids, biologic agents and disease-modifying antirheumatic drugs. Our results are similar to those described in the literature. Cause for hospital admission of all patients was fever and was not always easy to reach a diagnosis, requiring a large number of tests. Many patients required two or three consultation or admissions to be diagnosed. We have just included patients who have been followed by Internal Medicine department. The evolution of each of the patients has been variable and only two patients had severe outbreaks of the disease, mainly characterized by joint pain who responded well to intensive treatment.

Conclusions: Because no pathognomonic test could be used for this disease, diagnosis of AOSD depends of clinical features, laboratory findings and exclusion other causes. For this, it must be considered like cause of fever of unknown origin.

IF-46
RISK FACTORS AND PREVALENCE OF VASCULAR THROMBOSIS IN PATIENTS DIAGNOSED WITH OBSTETRIC ANTIPHOSPHOLIPID SYNDROME

A. Escandell[1], E. Lluch[1], L. Mico[1], Y. Mira[2], J. Fernández[1], V. Vila[3], V. Martínez[3], G. Herrero[4]

[1]Department of Internal Medicine, [2]Hemostasis Unit, [3]Investigation Center La Fe, [4]Department of Obstetrics. Hospital Universitari i Politècnic La Fe. Valencia, Spain.

Objectives: The antiphospholipid syndrome (APS) is a procoagulant state due to the presence of antiphospholipid antibodies which may manifest clinically by thrombotic disease, or by obstetric morbidity (fetal death, miscarriages, pre-eclampsia and prematurity), with usual therapeutic approach different in each case. The incidence of vascular thrombosis in patients with obstetric APS is considered very low, although the data available in the literature are scarce. Antithrombotic prophylaxis in this group of patients who present with obstetric APS may prevent the occurrence of vascular thrombotic events. The aim of our study was to investigate the prevalence and possible risk factors for the development of vascular thrombosis in patients with obstetric APS.

Material and method: We studied 20 pregnant women diagnosed with obstetric APS (according to the classification criteria of Sydney, 2006). The clinical variables investigated were: the criteria responsible for the diagnosis of obstetric APS, the type of thrombotic event (deep vein thrombosis, myocardial infarction, stroke), family history of premature cardiovascular and/or autoimmune disease, the presence of classical cardiovascular risk factors and treatment of patients. We determined the following analytical parameters in blood: lipid levels (total and fractionated cholesterol, triglycerides), glucose, urea and creatinine, fibrinogen, lipoprotein a (LPa), plasma viscosity, uric acid, CRP (uCRP), antiphospholipid antibody pattern (AAF) and markers of endothelial injury (circulating endothelial cells (CEC), interleukin 6 (IL-6), von Willebrand factor, vascular endothelial growth factor (VEGF) and tissue factor). For the study we used SPSS version 19.0.0. Continuous variables are expressed as mean and standard deviation and categorical variables as percentages. The comparison between dichotomous variables was tested by the chi square statistical method and the quantitative with the t test.

Results: The mean age of patients studied was 38.5 (SD 6.1) years. With regard to obstetric pathology: 51.7% had presented previous misscarriages, fetal deaths 31%, 6.9% pre-eclampsia and 7% prematurity. Thrombotic events were present in 30% of patients. The prevalence of classic cardiovascular risk factors was: smoking 35%, obesity 20%, dyslipidemia 15%, hypertension 10% and diabetes mellitus 5%. Only in 2 cases there were a family history of early cardiovascular disease and in 3 cases of autoimmune disease. As for emerging cardiovascular risk factors, there were no significant differences between the group of patients with or without thrombosis. Regarding the AAF there was no predominant pattern in the study group. Markers of endothelial damage showed no statistically significant differences between patients with and without thrombosis. Only 55% of patients (11) receiving treatment with anti-aggregating and/or anti-coagulants at the time of the interview.

Discussion: According to our results, up to 30% of patients with obstetric APS associated with vascular thrombosis. The prevalence of reversible cardiovascular risk factors could potentially increase the risk of thrombosis due to antiphospholipid antibodies, therefore it could raise the need for prophylactic antithrombotic treatment in this patient group. We found no statistically significant differences in terms of markers of endothelial damage, as the expression of inflammatory vascular involvement in APS obstetrician.

Conclusions: 1. This is a group of patients, women of childbearing age diagnosed with obstetric APS, being the most frequent pathology miscarriages. 2. Thrombosis was present in 30% of the cases. 3. The classic cardiovascular risk factors should be investigated routinely in these patients, adapting the treatment of cardiovascular risk level. 4. Almost half the patients received no antithrombotic treatment. 5. No significant relationship between markers of endothelial damage and the occurrence of thrombotic events, failing to complete the study with a larger volume of patients soon.

IF-48
HENOCH-SCHOLEIN PURPURA IN ADULTS. A REVIEW OF 16 CASES ADMITTED IN AN INTERNAL MEDICINE DEPARTMENT

A. Laso Ortiz, A. Garre García, A. Hernández Molina, A. Cascales Vallejo, G. Poza Cisneros, M. Molina Boix

Department of Internal Medicine. Hospital Universitario Virgen de la Arrixaca. El Palmar (Murcia), Spain.

Objectives: Henoch-Scholein purpura (HSP) is a small size vessel vasculitis characterized by purpura, abdominal pain and arthritis that typically affects children but can also occur in adults, usually with a worse prognosis and higher incidence of renal disease. The objective of this review is to analyze adult patients who were admitted to the Internal Medicine Department with a HSP diagnosis during a five year period (2007-2011).

Material and method: Medical records from patients older than 15 years admitted with HSP diagnosis at our department from January 2007 to December 2011 were reviewed. HSP diagnosis was made according to the 2006 International Consensus Conference Diagnostic Criteria. Renal involvement was defined as the presence of hematuria or/and proteinuria. We studied: sex, age, previous episodes of HSP, co-morbidities, antecedent infection, clinical manifestations, laboratory findings (hemoglobin, leucocytes, platelet count, creatinine, proteinuria, hematuria, ESR), skin and/or renal biopsies, treatment and outcomes.

Results: Sixteen patients were diagnosed of HSP with ages ranging from 16 to 85 (mean 49), half of them older than 55 years old. 12 were male. Four patients had a previous HSP episode with a mean of 10.7 years between them. Seven patients, all older than 55 years old, had any co-morbidity. Twelve patients had an

antecedent infection (7 respiratory, 3 tonsillar, 2 urinary). Skin biopsy was made in 14 patients showing leukocytoclastic vasculitis with IgA deposit in 11. Nine patients, 6 younger than 55 years/old, had abdominal pain. Eight patients, 6 younger than 55 years, had articular manifestations. ESR was elevated (> 30 mm/h) in 11 patients, 8 patients had leukocytosis (> 10,000 cells/mm), 2 had thrombocytosis (> 400,000 cells/mm^3) and one had anemia (Hb < 12 g/dL). Five patients, 3 older than 55 yrs old, had renal involvement with nephrotic proteinuria in two and renal failure (creat > 1.2 mg/dl) in 3. Renal biopsy was made in two patients showing Ig A deposit. 13 patients received steroids, one ibuprophen, one azathioprine, and two patients didn't receive any treatment.

Discussion: This series of adult patients with HSP show a greater prevalence in males as previously reported. A small percentage had a previous episode of HSP with a long mean time interval between them. Leukocytoclastic vasculitis was confirmed by skin biopsy in all patients with a first episode and most of them showed Ig A deposit. We found a greater frequency of antecedent infection, most of them respiratory tract infection. Gastrointestinal and musculoskeletal manifestations were more common in younger patients. ESR was elevated in most of the patients. Renal involvement was less common than in other series due perhaps to the low number of patients, a greater number of younger patients and admission in a general internal medicine, non-nephrological department. As other series, nearly all patients received corticosteroids and only one needed immunosuppression.

Conclusions: 1. HSP should be considered in every adult patient with suspected cutaneous vasculitis, even in the very elderly. 2. Gastrointestinal and articular manifestations occur most often in younger patients and renal involvement is more common in older adults.

IF- 49
SPONDYLOARTHRITIS - A CASUISTIC OF AN IMMUNO-MEDIATED DISEASES UNIT

M. Jone, I. Amorim Ferreira, C. Favas, J. Delgado Alves

UDIMS - Systemic Immuno-Mediated Diseases Unit. Hospital Professor Fernando Fonseca. Amadora, Portugal.

Objectives: This retrospective study was performed to characterize the population with the diagnosis of spondyloarthritis in an auto-immune diseases unit created about three years ago, concerning to demographic characteristics, disease manifestation and treatment.

Material and method: It's a retrospective analysis of clinical records at UDIMS – Systemic Immuno-Mediated Diseases Unit, from July 2009 to March 2012. We included patients with the diagnosis of spondyloarthritis (SpA), namely ankylosing spondylitis (SA), enteropathic arthropathy, seronegative spondyloarthritis and psoriatic arthritis.

Results: We currently follow 58 patients, 31 males and 27 females, with a mean age of 48 years and a mean disease duration of 8.3 years. The diagnosis is as follows: 39 (67.3%) with ankylosing spondylitis, 2 (3.4%) with enteropathic arthropathy, 7 (12%) with seronegative spondyloarthritis and 10 (17%) with psoriatic arthritis. The positivity for HLA B27 is 58%. 29 patients have exclusive axial involvement; 6 patients have exclusive peripheral involvement, with the remaining patients having mixed axial and peripheral involvement. The most frequent extra-articular manifestation is uveitis, especially anterior granulomatous uveitis (15% of the patients). 55% of patients are being treated with TNF-alpha blockades: 13 with etanercept, 12 with adalimumab, 5 with golimumab and 2 with infliximab. 12 patients needed to switch between biologic drugs, mainly because of cutaneous drug reactions (5), uveitis (1) and 6 because secondary failure. One patient had a central venous thrombosis, possibly related with golimumab, and another had tuberculosis reactivation and pulmonary vasculitis possibly related with adalimumab. 87% of the patients under biologic therapies have absolute changes in BASDAI score superior to 2 points and/or relative changes in BASDAI superior to 50%. The patients with no biologic drugs (26 patients, 45%) are currently under exclusively non steroid anti-inflammatory (NSAI) drugs (15), sulfasalazine (4) and sulfasalazine with hydroxicloroquine (3). There are 4 patients with psoriatic arthritis with exclusive peripheral involvement are under methotrexate and prednisone.

Discussion: The most common spondyloarthritis amongst our patients is ankylosing spondylitis, followed by psoriatic arthritis. Our patients have predominantly axial involvement and the most common extra-articular manifestation is uveitis. Only two severe adverse events were registered. More than a half of the patients are treated with biologic therapies with a good profile of efficacy and safety.

Conclusions: Concerning to the prevalence of positivity to HLA B27, our study showed a lower prevalence than what's describe in literature: 58% in our study versus 70-75% in literature. The rate of severe adverse events under biologic therapy was very low (2 patients, 6%). The prevalence of each diagnosis (SA, enteropathic arthropathy, seronegative spondyloarthritis and psoriatic arthritis), the incidence of extra-articular manifestations and the percentage of patients treated with TNF-alpha blocker therapies (55%). Of those, 87.5% achieves criteria of disease remission, also as it's described.

IF-50
ATYPICAL CLINICAL MANIFESTATIONS OF GIANT CELL ARTERITIS: ON CALL EXPERIENCE FROM A TERTIARY HOSPITAL

C. Voulgari, S. Siasiakou, M. Korogiannou, K. Vendra, T. Loukopoulos, S. Pagoni

3rd Department of Internal Medicine. Athens Regional Hospital G. Gennimatas, University Medical School. Athens, Greece.

Objectives: The typical manifestations of giant cell arteritis are familiar in everyday clinical practice. However, the challenge lies in recognizing atypical cases that lack the more specific manifestations or reflect vasculitis in less frequently involved territories. Among atypical clinical manifestations, dry cough has been recently reported. However, literature data are scarce and contain mostly sporadic and single case reports.

Material and method: The objective of this study was to determine the frequency of dry cough in patients with giant cell arteritis. Clinical data were collected from 18 patients with giant cell arteritis. Relationships between dry cough and other clinical manifestations or biological data were analyzed. Dry cough of recent appearance was found at initial presentation of giant cell arteritis in 3 patients (16.6%). In 1 case, dry cough was isolated. The patients sought attention because of chronic dry cough associated with fever of unknown origin. In all cases, dry cough was associated with typical clinical manifestations of giant cell arteritis. Significant correlations were found between inflammatory biomarkers and presence of dry cough. The mean CRP was 153.8 ± 35.1 mg/L in patients with dry cough and 94 ± 22.2 mg/L in patients without dry cough ($p = 0.013$).

Results: Diagnosis of giant cell arteritis should always be considered in elderly patients with an unexplained elevation of inflammatory markers and chronic dry cough. In our study, dry cough in giant cell arteritis was not correlated with other clinical manifestations of this vasculitis, including pulmonary manifestations, but was significantly correlated with inflammatory biomarkers.

IF-51
PULMONARY HYPERTENSION IN THE GENERAL HOSPITAL. TEN YEARS OF OUR WORK

B. Cervantes Bonet, A. Barnosi Marín, M. Esteban Moreno, S. Domingo Roa, C. Maldonado Úbeda, B. Hernández Sierra, A. García Peña, L. Díez García

Department of Internal Medicine. Complejo Hospitalario Torrecárdenas. Almería, Spain.

Objectives: Pulmonary hypertension is a difficult condition. It is present in various diseases and it is confers a worse prognosis and severity.

Material and method: A retrospective study of patients admittied in the Systemic Autoimmune Diseases and Pulmonary Hypertension Unit with diagnosis of pulmonary hypertension from January 2001 until December 2010. We analized the main clinical and echocardiographic variables.

Results: 21 patients were objectived with pulmonary hypertension: 52.58 ± 14.6 years, 71.4% female/28.6% male. The following variables were studied: etiology (38.1% idiopathic, chronic thromboembolism 30%, 14.3% collagen diseases, congenital diseases 9.5%, LVH 4.8% and others etiologies 4.8%); functional class at the time of diagnosis (4.8% I-NYHA, 33.3% II-NYHA, 52.4% III- NYHA, 9.5% IV-NYHA) and the performance status at the time of the study (11.7% I-NYHA, 29.4% II-NYHA, 47.05% III-NYHA, 11.7% IV-NYHA). The average distance covered in the walk test at diagnosis was 405 m and the average at the end of the study was 323 m. The right heart catheterization was performed in all patients, which were positive vasoreactivity in 23.8%. The mean mPAP 46.36 mmHg, CI 2.5 and RPT l/min/m^2 874.27 Dynas. The mean PSP echocardiographic diagnosis was 97.9 mmHg and 85.4 mmHg monitoring. The treatment used was: 15% calcium antagonists, 57.1% bosentan, 61.9% sildenafil, 14.3% inhaled iloprost, 14.3% treprostinil and 9.5% epoprostenol. The mortality rate was 28.6% over 10 years.

Conclusions: Although advances in treatment have greatly improved the survival of these patients but the pulmonary hypertension remains a serious disease that causes high mortality.

IF-52
UTILITY POCKET ULTRASOUND (VSCAN) IN THE ASSESSMENT OF PULMONARY HYPERTENSION

A. Barnosi Marín, B. Cervantes Bonet, G. López Lloret, M. Esteban Moreno, G. López Martínez, L. Díez García

Department of Internal Medicine. Complejo Hospitalario Torrecárdenas. Almería, Spain.

Objectives: To assess the utility of pocket echocardiography and Color Doppler in pulmonary hypertension and to compare the findings with conventional echocardiography.

Material and method: A prospective study of 15 patients admitted in general hospital with diagnosis of pulmonary hypertension whom were subjected to pocket echocardiography (VSCAN) and to compare the results with conventional echocardiography. We study the validity of V. Scan GE. We analized right atrial (RA) and ventricular (RV) size, right ventricular hypertrophy (HRV), valvular dysfunction (VD), tricuspid regurg area (TRA), displacement of the tricuspid annulus (DTA, paradoxical movement of interventricular septum (PMIVS) and distention inferior vena cava (DIVC). The difference between these techniques (ultrasound pocket versus conventional ultrasound) was performed by assessing the level of agreement and we used the Cohen's Kappa (K) and the Pearson correlation coefficient (PC).

Results: In a sample of 15 patients we found: 10 female (86.7%)/5 male (13.3%) and age 40.2 ± 12.2 years. The levels of agreement were: PMIVS: Kappa 0.72 ($p < 0.05$); DIVC: Kappa 0.80 ($p < 0.05$); HRV: Kappa 0.62 ($p < 0.05$); RA size: Pearson 0.82 ($p < 0.01$); TRA: Pearson 0.73 ($p < 0.05$); DTA: Pearson 0.76 ($p < 0.05$).

Conclusions: The pocket ultrasound may be useful as a screening test in pulmonary hypertension. It can detect indirect echocardiographic signs suggestive of pulmonary hypertension. In connection with conventional echocardiography, ultrasound pocket has limitations, but it can help improve early diagnosis of PAH.

IF-53
TREATMENT OF AUTOIMMUNE HEMATOLOGICAL DISEASES WITH RITUXIMAB

L. González González[1], L. Álvarez Pequeño[2], C. Loureiro[2], P. Vilaoa[3], B. Moure[1], C. Vázquez Triñanes[1], B. Sopeña[1]

[1]Department of Thrombosis and Vasculitis, [2]Department of Hematology, [3]Department of Pharmacy. Complejo Universitario de Vigo. Vigo (Pontevedra), Spain.

Objectives: Rituximab (RTX) is a humanized chimerical monoclonal antibody specific for CD-20 antigen. CD-20 antigen is a suitable target for immunotherapy since their antibody binding antiCD-20 causes a rapid depletion of B lymphocytes. RTX could be an effective therapeutic option in patients with autoimmune haematological disease refractory to other treatments it also could avoid splenectomy. The objective of this study is to evaluate RTX efficacy and tolerance in patients with autoimmune haemolytic anemia (AHA) and immune thrombocytopenic purpura (ITP) refractory to conventional treatments in a series of patients with long follow-up.

Material and method: All adult patients (> 16-years-old) treated with RTX for autoimmune cytopenias in our hospital from January 2004 to June 2011 were included in the study. Medical history, previous treatments, clinical evolution and analytical results were collected. The RTX regimen was 375 mg/m^2 every 1 week (MABTHERA®, Roche) except one patient who received 1 g/15 days (two doses).

Results: During this period of time 37 patients were included (54% women) with a median age of 63 years. All patients had received more than three treatments (including splenectomy in 8) before RTX. ITP was diagnosed in 25 patients receiving RTX after failed first-line treatments with therapeutic response in 16 of them (64%) and an average free-disease period of 23 months. In the 5 patients (20%) with ITP plus a related autoimmune disease the RTX response was 100%. RTX was administered to 11 patients with refractory AHA with a complete response to RT in 7 patients (64%) with a mean free-disease time of 25 months. 4 patients had AHA plus another autoimmune disease, showing all of them response to RTX and good control of other non-hematological manifestations. Two of AHA patients had been diagnosed with autoimmune hepatitis with complete biochemical resolution after RTX. One patient with simultaneous ITP/AHA had complete and permanent response. Overall, the administration of RTX was well tolerated, however, 4 patients had non-serious infections and other 4 patients (10%) developed tumors during the follow-up period (mean 12 months).

Discussion: The reported efficacy of rituximab in other autoimmune disorders provided a rationale for investigating rituximab therapy in AHA and ITP with encouraging results. The mechanism of action of RTX in autoimmune diseases should be further investigated, it has been postulated that this is unlikely to be the result of a drop in the autoantibody level and that a mechanism of Fc-receptor saturation of reticuloendothelial cells by opsonized CD-20 cells may be involver to justify the initial phase of response. In our study the response rate in both entities was 64% similar to other studies including five or more patients reveals that RTX is effective in treating AHA and ITP with an overall response rate ranging from 40% to 100%. Patients with other autoimmune diseases showed a 100% response. RTX may provide an effective

alternative to splenectomy and/or chemotherapy. In our experience RTX was very well tolerated and no significant infusion-related or late events were registered.

Conclusions: RTX was an effective treatment in patients with autoimmune haematologic diseases refractory to first-line treatments. The response was excellent in the context of autoimmune diseases. This study has detected some patients with malignancies after treatment.

IF-54
COMMON VARIABLE IMMUNODEFICIENCY CLASSIFICATION BASED ON IMPAIRED B CELL MEMORY DIFFERENTIATION WITH CLINICAL OUTCOME

R. Gómez de la Torre[2], A. Echeverría de Carlos[2], L. Tricas[2], J. Díaz López[1], L. Caminal Montero[1], L. Molinos[3], E. García Carús[1], H. Suárez Casado[4]

[2]Department of Immunology, [1]Department of Internal Medicine, [3]Lung Unit. Hospital Universitario Central de Asturias. Oviedo (Asturias), Spain. [4]Department of Internal Medicine. Hospital Carmen y Severo Ochoa. Cangas del Narcea (Asturias), Spain.

Objectives: Follow-up patients with common variable immunodeficiency (CVID) in a tertiary hospital with reference a classification based on impaired B cell memory and correlation with clinical aspects.

Material and method: 47 patients (25 females, 22 males) ranging 19-81 years (50+-14.3) have been included in the study. All of them had well documented CIID according international criteria (European Society of Immunodeficiencies)). Most of them were treated monthly with immunoglobulins infusions (IVIG) and were free of any serious infection when tested. Patients were grouped according to the quantification of peripheral MB cell (Piqueras criteria) in MB0: 16 patients, with almost no memory B cells, MB1: 15 patients, with defective switched memory (IgD- CD27 +) but normal unswitched memory (IgD+ CD27 +) B cells and MB2: 16 patients, with normal memory B cells. The groups were tested by χ^2. Finally we used clinical data base with demographic data.

Results: Laboratory data at diagnosis: MB0 group median level of IgG = 4.7g/L, B cells = 10%, IgD+CD27- = 95%, IgD+. CD27+ = 2.5%, IgD-CD27+ = 0.4%. MB1 group: median level of IgG = 4.55 g/L, B cells = 13%, IgD+ CD27- = 68%, IgD+ CD 27+ = 24%, IgD-CD27+ = 5%. MB2 group: median level of IgG = 5.1g/L, B cell = 8%, IgD+CD27- = 16%, IgD+CD27+ = 16%, IgD-CD27+ = 19% Clinical data: MB0 group respiratory infection in 68.75%, splenomegaly in 25%, cytopenias in 18.75%, granulomatous in 12.5%, gastrointestinal in 25% and osteoarticular in 6.25%. MB1 group respiratory infection in 60%, splenomegaly in 13.3%, granulomatous in 0%, gastrointestinal in 13.3% and osteoarticular in 13.3%. MB2 group respiratory infection in 25%, splenomegaly in 6.25%, cytopenia in 6.25%, granulomatous in 6.25%, osteoarticular in 0%. Group MB0 have statistically significant less unswitched and switched memory B cells and level serum immunoglobulin than the other groups. Moreover, group MB0 don't respond to pneumococcal vaccination. All patients included are alive.

Discussion: CVID is a heterogeneous syndrome characterized by hipogammmaglobulinemia and recurrent respiratory infections, often lead structural damage in the form of bronquiectasis. MB cells are responsible for a rapid efficacies onset of production antibodies. MB cells can be subdivided in three subsets according Piqueras classification: MB0, MB1, MB2. Clinical studies related MB defects to an increased incidence of splenomegaly, lymphoid proliferation, autoimmune cytopenias, respiratory, intestinal and granulomatous disease.

Conclusions: The main finding of this study is that patients with CVID with the most severe alteration in MB count presented the most severe clinical phenotype with higher prevalence in: respiratory, gastrointestinal, granulomatous, autoimmune disease. In group MB0 the patients don't respond to toxoid tetanic and anti-pneumococcal vaccination.

IF-55
CAPILLAROSCOPIC FINDINGS AND PATTERNS IN 3 SPANISH HOSPITALS

L. Sáez Comet[1], J. Todolí Parra[2], P. Fanlo Mateo[3], J. Velilla Marco[1], J. Fernández Navarro[2], M. Cía Lecumberri[3], M. Pérez Conesa[1]

[1]UEAS. Department of Internal Medicine. Hospital Universitario Miguel Servet. Zaragoza, Spain. [2]Department of Internal Medicine. Hospital Universitario La Fe. Valencia, Spain. [3]Department of Internal Medicine. Complejo Hospitalario de Navarra. Pamplona (Navarra), Spain.

Objectives: To describe capillaroscopic findings in patients studied in three Internal Medicine Services in Spain. To find out differences in the capillaroscopic classification between the three centers.

Material and method: Databases of capillaroscopic studies performed in Hospital Universitario Miguel Servet de Zaragoza (May'08 to May'12), Hospital Universitario La Fe de Valencia (Oct'03 to May'12) and Complejo Hospitalario de Navarra (Jan'10 to May'11) were reviewed. Repeated capillaroscopies were excluded. Data included were age, gender, Raynaud's phenomenom, service of origin, ramified capillaries, dilatation, disorganization, microhaemorrages, capillary loss and giant capillaries. Capillaroscopic pattern was grouped in inespecific changes, connective tissue

Table 1 (IF-55). Capillaroscopic findings (all data in%)

	Total	HUMS Zaragoza	H. La Fe Valencia	CHN Navarra
Ramifications	43.2%	58.6%	32.5%	Not available
Dilated capillaries	35.3%	37.8%	21.5%	91.8%
Giant capillaries	33.2%	40.9%	15.0%	82.7%
Capillary disorganisation	21.5%	29.6%	18.9%	Not available
Microhaemorrhages	39.3%	43.2%	67.3%	29.5%
Capillary loss	24.6%	22.2%	23.1%	51.8%

Table 2 (IF-55). Capillaroscopic patterns in each centre (all data in%)

	Inespecific	Connective tissue pattern	Scleroderma pattern
HUMS Zaragoza	46.7%	28.5%	22.1%
H. La Fe Valencia	72.3%	13.4%	11.4%
CHN Pamplona	27,6%	11.2%	60.2%

disease pattern and scleroderma pattern. The later group was classified into early, active or late pattern. Chi square test was used to compare qualitative variables and one way ANOVA to compare quantitative variables.

Results: 1,298 capillaroscopic studies were included, 655 from Zaragoza, 545 from Valencia and 98 from Pamplona. Mean age of patients was 46.8 years, and 1037 (79.9%) were women. 1046 patients (80.6%) referred Raynaud's phenomenon. 916 (70.6%) patients came from the own Internal Medicine services, 182 (14.0%) from Rheumatology services and 112 (8.6%) from Vascular Surgery services. The main capillaroscopic findings are shown in table one. The classification of the capillaroscopic pattern in each centre is shown in table two.

Discussion: Differences observed between the 3 centres can be explained by the previous selection of patients who underwent capillaroscopic exploration.

Conclusions: We describe different frequencies of capillaroscopic patterns in the 3 centres. Scleroderma pattern was more likely to be found in Navarra's patients, connective tissue disease pattern in Zaragoza's patients and unspecific changes in Valencia's patients.

IF-59
CROHN'S DISEASE SUSCEPTIBILITY: TLR9 AND IL23R

J. Mendoza[1], R. Lana[2], A. Lérida Urteaga[2], N. López Palacios[1], E. Urcelay[3]

[1]Department of Digestive Diseases, [2]Department of Internal Medicine, [3]Department of Immunology. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: Crohn's disease (CD) shows a complex aetiology with environmental factors and multiple genes involved. Nowadays, up to 70 CD susceptibility loci have been described; however, a high proportion of disease heritability remains unexplained. Genetic interactions could contribute to elucidate part of that missing heritability. Epistasis between polymorphisms in TLR9 and variants in CARD15 and IL23R has been described as modulating CD susceptibility in the German population. We aimed at replicating those interactions in our independent CD samples from the Spanish population, and at corroborating the statistically significant interactions in patients showing ulcerative colitis (UC), the other clinical form of inflammatory bowel disease.

Material and method: Nine single nucleotide polymorphisms (SNPs) located in the CARD15 (rs2066844 = R702W, rs2066845 = G908R and rs2066847 = 1007fsinsC), IL23R (rs1004819, rs7517847 and rs11209026) and TLR9 (rs352162, rs187084 and rs5743836) genes were genotyped in 416 CD patients and 547 unrelated healthy controls. Some of those SNPs were also genotyped for replication purposes in an additional set of 122 CD and 452 UC patients and in 307 controls. Genetic interactions were evaluated using chi-square tests in TLR9/CARD15 and TLR9/IL23R stratified tables. This study conforms to the principles of the Declaration of Helsinki of the World Medical Association (www.wma.net). A written informed consent was obtained from all the participants in the study.

Results: A significant interaction between the polymorphism rs352162 in TLR9 and rs7517847 located in IL23R was observed and replicated in CD patients, but not in controls or UC patients. Carriage of the minor allele of IL23R rs7517847 confers a strong protective effect towards CD development when present in TLR9 rs352162_CC homozygous individuals: p = 0.0003 OR = 0.44 95%CI 0.27-0.71. Genetic interactions were not observed between TLR9 and CARD15 variants.

Conclusions: We confirmed the presence of epistasis between TLR9 and IL23R polymorphisms affecting CD susceptibility in the Spanish population.

IF-60
THE NATURAL HISTORY OF CROHN'S DISEASE IS MODIFIES FOR THE THIOPURINE IMMUNOSUPPRESSANTS

R. Lana[1], N. López Palacios[2], A. Lérida Urteaga[1], E. Urcelay[3], J. Varade[3], J. Mendoza[2]

[1]Department of Internal Medicine, [2]Department of Digestive Diseases, [3]Department of Immunology. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: To determine whether the use of thiopurine immunosuppressants (IS) decreases CD intestinal surgery rates.

Material and method: Retrospective medical records of CD patients diagnosed at a single center in Madrid, Spain, between 2005 and 2009. The primary outcome was the occurrence of non-perianal CD-related surgery defined as the need for bowel resection or drainage of non-perianal abscesses. We compared patients treated for at least 6 months with the appropriate dose of IS (2.5 mg/kg azathioprine and 1.5 mg/kg mercaptopurine) with those not receiving IS (or biological) until intestinal surgery or the end of follow-up. Multivariate analysis (Cox proportional hazard model) was performed with age at diagnosis, sex, location, behavior, perianal disease, smoking or duration of immunosuppressive therapy to surgery (or during follow-up without surgery) as covariates.

Results: We included 300 CD patients (49% women), the mean age at diagnosis was of 33.47 ± 15.2 years and classified depending of the location: 39.9% ileal, 16.6% colonic, ileocolonic 27% and 16.6% upper gastrointestinal tract. Behavior at diagnosis: 62.3% inflammatory pattern, 17.3% stenotic and 19% penetrating. Twenty per cent of the cohort had perianal disease at diagnosis and 38.8% were smokers at diagnosis. Overall the mean follow-up time was 12 ± 8.7 years. Forty one per cent had IS treatment at any time of the follow-up, with a mean duration of treatment of 6.3 ± 4.6 years. In the final regression model, the use of IS was associated with a reduced need for surgery during follow-up [0.658 (HR) (95%CI 0.525 to 0.825)], this effect increases with the duration of treatment.

Conclusions: The use of IS reduces the risk of no perianal first surgery in CD patients, this effect increases with the duration of treatment.

IF-61
DESCRIPTIVE STUDY IN A SERIES OF PATIENTS WITH IDIOPATHIC AND SECONDARY PULMONARY HYPERTENSION IN AN INTERNAL MEDICINE CONSULTING ROOM

J. Vicario Bermúdez, M. Gracia Sánchez, J. Caballero Castro, M. Villanueva Gimeno, M. Vidal Marín, F. Lerín Sánchez, S. Zabala López, A. Garzarán Teijeiro

Department of Internal Medicine. Hospital Obispo Polanco. Teruel, Spain.

Objectives: The PAH has been defined as the increase in the pulmonary pressure (PPD) middle higher or equal to 25 mmHg in rest calculated by right cardiac catheterism (CCD). Pulmonary pressure of 25 mmHg is the cardinal measure. This value has been used to select the patients at all the controlled tests of random distribution and registers of PAH, The recent evaluation of the information has showed that the normal limit of 20 mmHg. The importance of a normal PAP between 21 and 24 mmHg is not clear, that is why a major research in epidemiologic studies is required. We do not have a certainly definition for pulmonary hypertension during exercise calculated by right pulmonary catheterism. In the pathology of primary or idiopathic PAH ("Clinical guidelines practices of diagnostic and therapeutic procedures in pulmonary hypertension", Clinical Cardiology April 2011), the principal aim of

our studies we have found principally pathological injuries that affect the distal pulmonary arteries (< 500 um of diameter). They are characterized by abnormal cells growth of different layer of vessels, fibrotic changes of intima layer artery, cell proliferation on adventicial layer with important vascular inflammatory infiltration. Usually the pulmonary veins are not affected. The lowest prevalence of the PAH and the PAHI was 15 cases and 5.9 per million of adult population respectively. The lowest incidence estimated was 2.4 cases per million of adult population per year. The estimate prevalence was 15 cases per million of adult population per year. The PAHI correspond to sporadic diseases without any family procedents or know cause factor.

Material and method: Descriptive study made in a series of 9 patients followed at the Internal Medicine consulting room in Obispo Polanco Hospital in Teruel (Spain) between 2007-2011 (during 5 years) with Pulmonary Arterial Hypertension (PAH) with Pulmonary Systolic Pressure (PSP) determined by transesophageal echocardiogram (EET). The 55.5% of group (5 patients) of group of 9 patients of initial study are men with ages around 45-76 years old, and 44.5% of group (4 patients) are women with ages around 40-83 years old. The 88.8% of group (8 patients), were treated with Bosentan and the 11.1% of group (1 patient) was treated with two drugs, Bosentan and Sildenafilo. The 44.5% of study (4 patients) showed a severe PAH and the 55.5% (5 patients) moderate PAH with PSP calculated with ETT and associating with Cor Pulmonale and right heart failure controlled with medical treatment. One patient death at the end of five years of study secondary failure with the highest PSP found of 110 mmHg. The total number of patients the 66.6% (6 patients) were diagnosed of associated autoimmune disease (scleroderma was the mostly frequency), 2 patients (22.3% of study) were associated with thromboembolic pulmonary disease and 1 patient (11.1% of study) was associated with deficient C protein.

Results: Scleroderma (Autoimmune Disease) is the mostly associated disease in our group with pulmonary hypertension. Severe pulmonary hypertension associated the higher number of complications in the study and failure of medical treatment (right heart failure and cor pulmonale). The patient who died had the most elevated pulmonary hypertension of 110 mmHg.

Discussion: There is an association between pulmonary hypertension, autoimmune disease, failure drug treatment and morbidity-mortality?

Conclusions: The patient with higher pulmonary hypertension associated most complications, failure medical treatment and elevated morbidity.

IF-63
SARCOIDOSIS IN PATIENTS DIAGNOSED IN INTERNAL MEDICINE AND PULMONOLOGY

E. Pardo Magro[1], S. González García[1], A. Sanz Cabrera[2], R. Pérez Palacio[1], R. Morales Gómez[1], M. García García[2], I. Gallego Parejo[1], D. Magro Ledesma[1]

[1]Department of Internal Medicine, [2]Department of Pulmonology. Complejo H. Universitario de Badajoz. Badajoz, Spain.

Objectives: Sarcoidosis is a multisystem disease of unknown etiology, characterized histologically by the presence of noncaseating granulomas in involve organs. The objective is to describe clinical, diagnostic procedures and therapies used in patients with sarcoidosis diagnosed in Internal Medicine and Pulmonology in our hospital.

Material and method: We retrospectively analyzed discharge reports and reviews in consultation of patients with the diagnosis of sarcoidosis in our department or in the respiratory medicine department in the period between 2003 and 2011. For data analysis, we used SPSS version 15.0.

Results: We studied 117 patients, 54 belonged to the Internal Medicine and 63 to Pulmonology. The median age of patients at diagnosis was 42 years. 60% were women. At diagnosis, 30% were asymptomatic while 31% had respiratory symptoms (cough and dyspnea). The rest of patients had extrapulmonary symptoms. Radiological pattern more objectified in our patients was I with 35% followed by II with 30%. Twelve of thirty three asymptomatic patients had a chest radiography in stage I. The diagnostic methods more frequently used were mediastinoscopy (28.8%) and transbronchial biopsy (20.2%). A total of 60 patients had high serum ACE while 20 of them weren´t analyzed and 37 were negative. Among the extrapulmonary manifestations, 23% had cutaneous manifestations, 11.4% had Lofgren syndrome, and 6% neurosarcoidosis. Only 2 patients presented uveoparotidea fever and 1 patient presented cardiac involvement. Up to 53.5% of patients were not treated, while 42.1% received therapy with steroids and 4.4% received combined therapy of steroids and immunosuppressants. The progress of these therapies was favorable in 89.3% of patients, opposed to the cured (16%) by clinical and radiological stability.

Discussion: The clinical manifestations of sarcoidosis may involve a single organ or be systemic. Within the systemic symptoms, one can experience fever, fatigue, malaise and weight loss. Pulmonary sarcoidosis may cause dyspnea and dry cough. Regarding extrapulmonary manifestations, the symptoms include: uveitis, scleritis, erythema nodosum, sicca syndrome, skin lesions and peripheral limphadenopathy. The diagnosis of sarcoidosis is based on clinical suspicion and confirmed by histological demonstration of noncaseating granulomas, excluding other diseases. Once diagnosed, treatment is not always required and the prognosis depends on the organic damage of this disease.

Conclusions: The median age at diagnosis was 42 years. There was a large number of asymptomatic patients at the diagnosis, many of them having stage I radiological pattern. ACE was positive in 50% of patients. The diagnostic method more frequently used was the mediastinoscopy and more than 50% of patients did not require treatment at the diagnosis. These findings are similar to the data that are described in the literature.

IF-64
TEACHING AND TRAINING DEVELOPED BY SYSTEMIC AUTOIMMUNE DISEASES UNITS (UEAS) IN DEPARTMENTS OF INTERNAL MEDICINE IN SPAIN

L. Pallarés[1], R. Pérez Álvarez[2], M. Ramos-Casals[3] and the Board of Directors of the Group of Autoimmune Diseases[4]

[1]Department of Internal Medicine. Hospital Son Espases. Palma de Mallorca, Spain. [2]Department of Internal Medicine. Hospital do Meixoeiro. Vigo (Pontevedra), Spain. [3]Department of Autoimmune Diseases. Hospital Clínic. Barcelona, Spain. [4]GEAS-SEMI, Spain.

Objectives: To evaluate the structure and activities related to teaching and training of systemic autoimmune diseases units (UEAS) integrated in Spanish Internal Medicine Departments.

Material and method: Systematic evaluation using a questionnaire containing the main data on patient care, teaching and research in systemic autoimmune diseases (SAD). The questionnaire was sent to all members of the Spanish Group of Autoimmune Diseases (GEAS-SEMI) through the mailing group list in February 2012. UEAS was defined as a functional healthcare structure in which specific circuits have been established to provide targeted care to patients with SAD.

Results: By March 31, 2012, information had been collected from 56 UEAS integrated in Spanish Internal Medicine Departments. About 90% of UEAS conducted monographic hospital sessions centered on SAD, with a frequency varying from weekly to monthly. Half the UEAS have organized specific meetings to provide updates

on knowledge of SAD and 75% have participated in meetings discussing SAD in the last 3 years. About 70% of UEAS have residents: the total number of residents trained in one year was 374, which is roughly equivalent to a mean of 10 residents trained per year per centre. Seventy per cent (254) of residents were doing internal rotations: 117 (46%) were specializing in Internal Medicine and 137 (54%) in other specialties. In addition, an annual mean of 120 of external residents from other hospitals were taught by 13 UEAS (33%), of which 106 (88%) came from Spanish and 14 (12%) from foreign hospitals. 36% (20) of UEAS have postgraduate (Ph.D) teaching capacities, with doctoral theses related to SAD being carried out in 13 (23%) UEAS. Of the 56 UEAS, 37 (66%) have one or more of staff who are university professors, coming from 27 universities. More than half of the 190 UEAS internists (53%) are university professors: 51 are associate professors, 18 teaching assistants, 12 lecturers/full professors and 6 other types of teacher.

Conclusions: Nearly 400 medical residents per year receive training in Spanish UEAS, including SAD residents and those from other specialties, and residents from the same hospital and from other hospitals. This teaching activity, together with undergraduate and postgraduate teaching activities, is sufficient to formulate proposals on a definition of accreditation levels of Spanish UEAS in order to assess their capacity to teach the subject of SAD in Internal Medicine.

IF-67
IMMUNOMODULATORY EFFECT OF ATORVASTATIN IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

A. Ramos[1], S. Rosado[1], M. Citores[1], K. Alkadi[1], M. Yebra Bango[1]

[1]Department of Internal Medicine. Hospital Universitario Puerta de Hierro Majadahonda. Majadahonda (Madrid), Spain.

Objectives: In the field of SLE there is a growing interest in developing personalized immunosuppressive therapy to improve the individual response and to minimize adverse effects of treatment. Recently has been proposed that statins besides their cholesterol-lowering effects, have immunomodulatory properties that might reduce disease activity, which would make them potential candidates for the treatment of SLE. The Cylex Immune Cell Function Assay (Immuknow®) designed to measure the net state of immune function and it was recently approved by the U.S. Food and Drug Administration (FDA) to help monitor the immune status of solid-organ transplant patients for better individualization of therapy. This assay measures the activity of CD4+ T cells by assessing the intracellular concentration of adenosine triphosphate (ATP) from circulating CD4+ T cells after in vitro stimulation with phytohemagglutinin (PHA). However its utility in the management of autoimmunity disease patients remains to be determined. The aim of the study was to evaluate whether immune function, determined by the Immuknow® assay after a therapeutic intervention with statins in SLE patients.

Material and method: Nineteen female patients with SLE (≥ 4 ACR 1997 criteria) with a mean age of 44 years (range 27-64) were enrolled. None of the patients had received statin therapy previously to the beginning of the study and in any case the treatments they are taking for their disease have been changed over the time of the study. The patients received atorvastatin (20 mg/day) during eight weeks. Data collected in the basal and in the end of treatment visit, includes demographics, clinical parameters, SLE activity (assessed by SLEDAI) and inflammatory markers. Immune responses were measured using the Immuknow® assay according to the manufactured instructions. Concentrations of soluble inflammatory and anti-inflammatory cytokines (IL-2, IL-6, TNF, IL-4, IL-10), adhesion molecule (sVCAM-1) and growth factors (VEGF, endothelin-1) were assessed in patient serum by ELISA.

Results: It was observed that an 8 weeks treatment with atorvastatin, significantly decreased the concentration of ATP after PHA in vitro stimulation in SLE patients (228.30 ± 103.63 ng/ml pre-statin vs 164.95 ± 61.14 ng/ml post-statin; p = 0.012). We also found a decrease in disease activity, patients after atorvastatin intake showed a lower SLEDAI score (1.68 ± 2.06 SLEDAI pre-statin vs 1.58 ± 1.92 SLEDAI post-statin) and an increase in complement C3 level (104.74 ± 25.92 mg/dl pre-statin vs 108.41 ± 23.47 mg/dl post-statin), although these differences were not statistically significant. In the same way, analyzing soluble inflammatory markers, we observed a significant decrease in the VEGF concentration (318.22 ± 267.13 pg/ml pre-statin vs 282.25 ± 236.67 pg/ml post-statin; p = 0.015).

Discussion: Statins are widely used to treat patients with hyperlipidemia. However, accumulating evidence suggests that statins possess a variety of biological properties including immunomodulatory and anti-inflammatory effects. We reported that administration of 20mg/day of atorvastatin for 8 weeks significantly reduced in vitro ATP production, suggesting that SLE patient cellular immune status measured by Immuknow® assay is immunomodulated. In the same way, our results suggest that the effect of atorvastatin in SLE patients may involve inhibition of VEGF secretion and an attenuation of lupus activity.

Conclusions: The results of this preliminary work evidence the immunosuppresive effect of atrovastatin in patients with SLE, but further studies would be necessary.

IF-68
RESEARCH IMPACT OF SYSTEMIC AUTOIMMUNE DISEASE UNITS (UEAS) IN SPANISH INTERNAL MEDICINE DEPARTMENTS: DEVELOPMENT OF RESEARCH PROJECTS, SCIENTIFIC PUBLICATIONS AND NATIONAL REGISTERS OF PATIENTS WITH AUTOIMMUNE DISEASES

L. Pallarés[1], R. Pérez Álvarez[2], M. Ramos-Casals[3] and the Board of Directors of the Group of Autoimmune Diseases [4]

[1]Department of Internal Medicine. Hospital son Espases. Palma de Mallorca, Spain. [2]Department of Internal Medicine. Hospital do Meixoeiro. Vigo (Pontevedra), Spain. [3]Department of Autoimmune Diseases. Hospital Clinic. Barcelona, Spain. [4]GEAS-SEMI, Spain.

Objectives: To evaluate the research activity carried out by Systemic Autoimmune Disease Units (UEAS) integrated in Spanish Internal Medicine Departments.

Material and method: Systematic evaluation using a questionnaire containing the main data on patient care, teaching and research in systemic autoimmune diseases (SAD). The questionnaire was sent to all members of the Spanish Group of Autoimmune Diseases (GEAS-SEMI) through the mailing group list in February 2012. UEAS was defined as a functional healthcare structure in which specific circuits have been established to provide targeted care to patients with SAD.

Results: By March 31, 2012, information had been collected from 56 UEAS integrated in Spanish Internal Medicine Departments. Sixty-six per cent of UEAS have initiated or are developing SAD-related research projects in the last 3 years, with a total of 131 lines of research (76 from the Unit itself and 55 (42%) in collaboration with other specialties). These research lines have generated 233 research projects, including 71 (30%) competitive projects (44 within-Unit and 27 in collaboration with other centers), 81 (35%) clinical trials and 81 (35%) non-competitive projects. UEAS research activity has generated 748 scientific publications in the last 3 years; 586 (78%) in international journals and 162 (22%) in Spanish journals. These publications have been generated by 33 (59%) out of the 56 UEAS. The UEAS have also generated 72 book chapters, 43 clinical guidelines and 53 clinical protocols in SAD. 70% of the UEAS have participated actively in collecting patients for inclusion in GEAS

patient registries (lupus, scleroderma, ANCA-vasculitides, Sjögren syndrome, Behçet disease, antisynthetase syndrome, biological therapies, capillaroscopy and vascular risk in SAD).

Conclusions: Bringing together the management of patients with SAD in dedicated UEAS in Internal Medicine Departments has enabled the creation of knowledge and skills centers with proven experience whose research output is strong and highly competitive.

IF-69
MESENTERIC PANNICULITIS: HETEROGENEOUS AND INFREQUENT

E. Esteve[1], A. Tapiz[1], A. Flor[1], R. Pérez[1], L. Fernández[3], M. Royuela[1], O. Valencoso[2]

[1]Department of Internal Medicine, [3]Department of Family Medicine, [2]Department of Radiology. Althaia-Xarxa Assistencial de Manresa. Manresa (Barcelona), Spain.

Objectives: To look through an infrequent pathology, which has been associated to many other pathologies, with different kind of appearances and evolution, which is also important to be considered in the differential diagnosis of the abdominal pain.

Material and method: Three cases of mesenteric panniculitis. Case 1: male, 48 years old. History of Raynaud's phenomenon developed during 7 years with negative capillaroscopy and immunological studies. Admitted because of a diffuse abdominal pain of a few hours of evolution, fever is added later. Abdominal CT with abdominal fat infiltration compatible with mesenteric panniculitis, no changes on the rest. Good evolution with symptomatic treatment. Case 2: male, 59 years old. Without notable history. Admitted because of a long standing fever and lumbar pain, during the admission at the hospital he is diagnosed as aortic endocarditis from streptococcus bovis, severe aortic failure, colonic tubular adenoma and probable spondylodiscitis. Favorable evolution with an antibiotic treatment. 15 days after the admission he shows diffuse and acute abdominal pain. All the examinations are negative except for the abdominal TC which shows mesenteric panniculitis. Negative immunological test. Very good improvement with a corticoid treatment. Case 3: male, 68 years old. History of a recent laparoscopic cholecystectomy after an episode of cholecystitis and a tubular colonic adenoma. Admitted because of an acute epigastralgia, TC shows mesenteric panniculitis. Immunological tests and neoplasia hides negatives. Take a treatment with corticoids and the recovery of the symptoms.

Results: Three cases of mesenteric panniculitis without a clear etiologic association, one case with Raynaud phenomenon history and the other two had showed recent pathological process. Two of them needed corticoid treatment. Favorable evolution in all of them.

Discussion: The mesenteric panniculitis is defined as an aseptic and specific inflammation of the mesenteric fat. It's associated to a multiple concomitant etiologies or pathologies, it can be an independent pathological entity, or even a casual and asymptomatic finding after the abdominal TC. It is described regarding neoplasias, lymphoma, sarcoidosis, medicines, abdominal traumatism,previous abdominal surgery, fibrosing inflammatory diseases or systemic diseases. It is predominant in males and middle ages, as in the cases below. It should be considered in the differential diagnosis of abdominal pain, it can be associated to fever or toxic symptoms. We could also palpate an abdominal mass. The abdominal TC shows suggestive images and or induce to the diagnosis. Initially, the treatment is conservative and symptomatic; if there is no improvement it will require only corticoids, or corticoids with immunosupressives or colchicine. Prognosis was favorable as in the cases described below. Due to the possibility of a subsequent appearance of neoplasms or systemic diseases, it is important monitoring the patient.

Conclusions: Mesenteric panniculitis is an uncommon condition whose exact cause remains unclear. This finding should be a challenge for any doctor. A clue to find the underlying entity in which it can be associated with.

IF-72
CELIAC DISEASE: A SYSTEMIC INFRADIAGNOSED DISORDER

M. Barrientos, B. Mora, N. Aldezábal, L. Acevedo, N. Matskiv, E. Bello, L. Álvarez-Sala, E. Donis

Department of Internal Medicine 2B. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: Celiac disease is an immune mediated systemic disorder characterized by malabsorption after ingestion of gluten in genetically susceptible individuals. It occurs in 1% of general population, and has a wide spectrum of gastrointestinal and extra-intestinal manifestations. Objectives: review characteristics of celiac disease in patients diagnosed in our hospital, in the last six years. Identify clinical and analytical patterns that force us to rule out celiac disease.

Material and method: A descriptive study was performed on patients diagnosed of celiac disease between 2006 and 2011. We reviewed medical records of this population and we analyzed clinical, analytic and histological characteristics, associated diseases, family history of the disease, HLA DQ and gluten free diet compliance and responses. SPSS v.18.0 was used for data analysis.

Results: From 2006 to 2011, 62 patients were diagnosed of celiac disease, with a mean age of 34 years (range 0.8-90). They were stratificated in 3 groups: 1-patients < 10 years old (33.9%); 2-individuals between 11 and 20 years old (only 2 patients); 3-patients > 20 years (62´9%). In first group the diagnosis was mainly based on clinical features (delay in linear growth 52.4% followed by diarrhea 33.3%) and small bowel biopsy, that was performed in 90% of individuals and was positive in 100% of them. In third group the main age was 54 years, with 64.1% female. The most prevalent symptom was diarrhea (66.7%) followed by weight loss (35.95%) and abdominal pain (23.1%). Between laboratory abnormalities we found iron deficiency as the most common (51.3%), followed by folic deficiency (23.1%), hypoproteinemia (17.9%), vitamin D deficiency and vitamin B12 deficiency (15.4%). Serologic testing were obtained in more than 75% of patients and were positive for antigliadin antibodies in 72.7% and for transglutaminase antibodies in 60%. We found a statistically significant association between iron, vitamin B12 and folic acid deficiency with positive transglutaminase antibodies. Small bowel biopsy was taken in 82.1% and was positive in 81.3% of patients. The most frequently associated patologies to celiac disease were: osteoporosis/osteopenia (35%), enteric infections (15.4%), autoimmune disease (12.8%) and dermatitis herpetiformis –like rash (10.3%). The dietary adherence was similar in children and adults (93.9% and 93.1% respectively), but in these last the good response to it was lower (74% vs 88% in children).

Discussion: According to previous reviews about celiac disease, gastrointestinal manifestations remain the guiding symptom to the clinical suspicion. In our review, we have observed that laboratory abnormalities are the mainstay of diagnostic suspicion in adult population, being the most common in this group iron deficiency, followed by folate and vitamin B12 deficiency. All of them are correlated with positive transglutaminasa antibodies. A clinical response to gluten-free diet was observed in most cases.

Conclusions: 1) In population under 10 years, diagnosis of celiac disease was based on digestive manifestations or growth delay together with positive biopsy, supported by the response to gluten free diet. 2) In adult population, gastrointestinal symptoms were

predominant clinical manifestations, and bone disorders were the most common pathology associated, probably related to major prevalence in more than 50-year age people. 3) In case of unexplained iron deficiency, or folate and B12 deficiency, especially if there are digestive symptoms associated, it is important to have a high index of suspicion for celiac disease and to amplify the study with serological studies.

IF-73
TEMPORAL ARTERITIS IN OUR ENVIRONMENT

S. González[1], M. Pérez[1], G. Morales[1], A. Rubio[2], R. Peña[1], M. Sánchez[1], D. Magro[1], E. Pardo[1]

[1]Department of Internal Medicine, [2]Department of Pathology. Complejo Hospitalario Universitario de Badajoz. Badajoz, Spain.

Objectives: To determine the characteristics of patients with suspected giant cell arteritis at the University Hospital of Badajoz to whom underwent biopsy of the temporal artery.

Material and method: Retrospective descriptive study conducted from the database of the Department of Pathology University Hospital of Badajoz of temporal artery biopsies performed between 2000 and 2011. A protocol was designed to collect data with regard to the main symptoms associated with the disease and laboratory abnormalities and pathological data. We also analyzed the treatment or not administration. Statistical analysis was performed using SPSS 15.0.

Results: We analyzed forty-seven patients belonged to different departments of our hospital complex, all included in the database of the Pathology Department of the temporal artery biopsies between 2000 and 2011. Of these patients, 15 were men and 32 women. The average age observed was 73 years. The most common symptoms were: headache (observed in 53.2% cases), fever (25 patients) and constitutional syndrome (53.2%). On the other hand, the most frequently observed laboratory abnormalities were: elevated erythrocyte sedimentation rate (ESR) in 40 patients in the sample, the presence of anemia in 66% of cases and elevated C-reactive protein (PCR), observed in 18 of 29 patients in which such determination was made. In our sample, thirteen patients were diagnosed with polymyalgia rheumatic although the association between this disease and giant cell arteritis was observed only in 12.8% of cases. Of the temporal artery biopsies performed, only 9 showed findings suggestive of giant cell arteritis. 68% of the biopsies were reported as doubtful for the diagnosis of temporal arteritis. Moreover, the clinical diagnosis of giant cell arteritis was made in 49% of cases, 9 of them with compatible biopsy and 4 with equivocal pathological findings for temporal arteritis. However steroid treatment was prescribed in 70% of patients in our sample. Only 7 cases steroid therapy was associated with acetylsalicylic acid (ASA). Of the 40 patients who showed an elevated ESR, 22 were diagnosed with temporal arteritis. In the same way, positive or inconclusive biopsy for diagnosis of temporal arteritis is always observed in patients with ESR values above 90 mm/1st hour.

Discussion: Temporal arteritis is a rare disease in our environment. The guiding symptoms include headache, fever and constitutional symptoms in elderly patients, in which is observed anemia and elevated ESR. In some cases establishing empirical steroid treatment despite negative or equivocal results of histological studies, since the absence of compatible discoveries not exclude this ill because the affectation of the temporal artery is patched.

Conclusions: A high clinical suspicion justifies the introduction of steroid treatment. But new diagnostic means more profitable should be generalized as doppler ultrasonography of the temporal artery.

IF-75
GUILLAIN BARRÉ SYNDROME: MANAGEMENT, TREATMENT AND EVOLUTION

S. Araújo Fernández, R. Puerta Louro, H. Enríquez Gómez, L. Novoa Llamazares, M. Rodríguez Arias, J. Álvarez Otero, J. de la Fuente Aguado

Department of Internal Medicine. Povisa Hospital. Vigo (Pontevedra), Spain.

Objectives: To describe the laboratory tests, treatment and outcome of patients admitted for a Guillain-Barré syndrome (GBS) in our hospital.

Material and method: We performed a retrospective study of the hospital discharges in with diagnosis include GBS, between January 1, 2002 and April 30, 2012. The following variables were recorded: age, gender, diagnostic test, treatment and need for mechanical ventilation, relapse, comorbidities, and death.

Results: A total of 29 patients of which + 16 were women (55.2%). The age ranged between 13-79 years with a mean of 52 ± 18.5 years. Samples of the cerebrospinal fluid were taken in all patients except 1, showing albumin-cytological dissociation in 86.2% of cases. Neurophysiological findings were 44.8% pure motor axonal polyneuropathy, 34.5% a sensory-motor axonal polyneuropathy and only 17.2% demyelinating polyneuropathy. Ganglioside antibodies (anti-GM) were positive in 1 of 7 patients. Lumbar MRI was performed in 27 patients, demonstrating findings consistent with GBS in 58.6% of cases. Of the 29 patients, 23 (79.3%) were treated with immunoglobulin, 1 (3.4%) with plasmapheresis and in 2 cases (6.9%) were used immunoglobulins and plasmapheresis. Five patients (17.2%) needed mechanical ventilation. Regarding evolution, 24 patients (82.8%) recovered without sequelae, 3 had a relapse and there were 2 patients who did not obtain their data by removal. Five patients (17.2%) died. The diagnosis of GBS was concomitant with SLE in 1 patient and with sarcoidosis in another one.

Discussion: GBS is defined as an ascending and progressive muscular weakness with areflexia, which progresses over a few days to a few weeks. It can occur at any age and in both genders. The cerebrospinal fluid findings and the imaging test are similar to those in other series. However, the electrophysiological findings differ greatly from those previously described because, in our series, the pure motor axonal polyneuropathy is more common than demyelinating polyneuropathy. In previous studies, anti-GM was positive in one third of the patients, but in our serious was positive only in 1 patient. This data would not be valuable because in our series anti-GM were only requested in 7 patients. With regard to treatment, due to lack of experience in our centre with plasmapheresis, almost 80% of cases were treated with immunoglobulin and only 1 patient was treated with plasmapheresis starting because it presented a deficit of IgA. Previous studies have shown that the use of immunoglobulin is as effective as plasma exchange and association of both does not increase the benefit. However, a study of 2010 explains that in the axonal variant, plasma exchanger could be higher than immunoglobulin. Although in our series dominates axonal pathology, which is correlated with increase severity of disease, evolution and mortality did not differ from previous studies in which most often dominates the demyelinating polyneuropathy.

Conclusions: Unlike previous studies published, in our series pure motor axonal polyneuropathy was the most common neurophysiological finding, however the measurement of the antibody was inappropriately low. MRI was a diagnosis aid in more than 50% of cases. The most common treatment was immunoglobulins presenting a favourable evolution in most of the cases. Mortality was similar to previous studies.

IF-79
EFFECTIVENESS OF ANTI-TNF THERAPY IN HIDRADENITIS SUPPURATIVA

I. Aomar Millán[1], J. Callejas Rubio[1], M. Fernández Pugnaire[2], M. Gutiérrez[2], M. García Morales[1], R. Ríos Fernández[1], N. Ortego Centeno[1]

[1]Systemic Diseases Unit. Department of Internal Medicine, [2]Department of Dermatology. Hospital de Especialidades San Cecilio. Granada, Spain.

Objectives: Hidradenitis suppurativa (HS) is a chronic recurrent inflammatory disease that affects skin areas where apocrine glands predominate. To assess the severity and activity classification have the three stages of Hurley and a scoring system based primarily on the number of affected areas and injuries. In severe or recurrent cases with conventional treatment, anti-TNF may be a therapeutic option Objective: to analyze the characteristics and clinical course of two patients suffering from HS treated with anti-TNF by lack of response to conventional therapy.

Material and method: Patient 1: a 37-year man with history of epilepsy and mild cerebral palsy, diagnosed in 1995 HS, with frequent and severe relapses in the past year. In the presence of extensive lesions in the groin and axillary regions and bilateral gluteal and failed standard therapy (retinoids and tetracyclines), started treatment with etanercept 50 mg sc/week, with very good response after the first three months of follow-up from an stage III to stage I of Hurley. Patient 2: a 33-year woman with recurrent hidradenitis affects in right underarm, and pubic inframammary region since 2007, with poor response to surgical treatment, retinoids and courses of antibiotics. In November 2010 we started treatment with adalimumab 40 mg sc every two weeks with good response after one year follow up moving from stage III to stage II.

Discussion: HS is characterized by painful subcutaneous nodules that may progress to abscess formation and suppurative fistulous tracts with hypertrophic scarring. They are located at the level of groin, axilla, and intertriginous areas submammary folds and buttocks. In mild cases, treatment consists of surgery, antibiotics and retinoids, alone or in combination. In severe or recurrent cases with standard treatment, described the response to treatment with anti-TNF-alpha, as in the cases presented. The duration of treatment is not well established, with frequent recurrences in case of suspension.

Conclusions: The anti-TNF should be considered an alternative to the treatment of severe HS. Lesions often recur to suspend them so they must be considered as a second or third line of treatment to be administered indefinitely to the risk of side effects and high cost.

IF-83
EPIDEMIOLOGICAL CHARACTERISTICS OF SARCOIDOSIS PATIENTS IN OSONA (1983-2011)

C. Loste Andreu[1], C. Azuaje Tovar[1], X. Pla Salas[1], P. Roura Poch[2], G. Lucchetti[1], J. Brugés Terradellas[1]

[1]Department of Internal Medicine, [2]Department of Epidemiology. Consorci Hospitalari de Vic. Vic (Barcelona), Spain.

Objectives: Sarcoidosis is multisystemic inflammatory disease that is characterized histologically by noncaseating granulomas. No recent studies in Catalonia that value the epidemiology, diagnosis and outcome. To know the current incidence and to evaluate the epidemiological profile of sarcoidosis in the Osona's area. To describe type of clinical presentation, diagnosis methods, delay in the diagnosis, radiologic pattern, treatment, and the mortality.

Material and method: We reviewed the cases of sarcoidosis of Consorci Hospitalari de Vic, between 1983-2011. The diagnosis of the sarcoidosis was based on clinical, radiological, bronchoalveolar lavage and histopathological criteria. The study is descriptive and retrospective.

Results: 54 patients were diagnosed of sarcoidosis with incidence of 2.08 for 100,000 inhabitants/year. 37 (68.5%) were women with a mean age 51 ± 13.8 years and 17 (31.5%) were male, with a mean age 41 ± 14.5 years. (p = 0.016). Comorbility was: HTA 19 (35.2%), smokers 16 (29.6%), DM-2 5 (9.3%), others 9 (16.6%). There were 5. (9.2%) with organ-specific autoimmune disease. The most frequent presentation form was Löfgren syndrome 18 (33.4%), respiratory symptoms 14 (25.9%), general syndrome 9 (16.6%), erythema nodosum 4 (7.4%) and miscellaneous 7 (12.9%). There was one case of Heerfordt syndrome. Analytical findings: the mean of PCR was 33.9 (3.10-128), VSG 34.19 (1-87), ECA 128 (17-483). ANA's were positive in 4 cases (7.4%). Tomographic findings at the time of the diagnosis were: stage I 35.2%, stage II 40.7%, stage III 3.7%, stage IV 5.6% and stage 0 14.8%. Gammagraphic-Ga was done in 17 (31.5%), was positive in 94.1% of them. Bronchoalveolar lavage recount: Lymphocytes 45 ± 20%, Neutrophils 5 ± 3-4%, Macrophages 50 ± 19.7%. Biopsy was transbronchial in 20 (36%), skin 11 (20.3%), muscle 10 (18.5%), ganglionar 7 (13%), mediastinoscopy 3 (5.6%), open lung biopsy 2 (3.6%), others (5.6%). Delay in diagnosis was about 6 months (0.4-51). 11 patients died (20.4%) and 4 of them were related with sarcoidosis (7.4%). Hospital readmission was in 38.8% of cases. Radiologic findings worsened only in 5 cases. The treatment was corticoids 44 (81.5%), methotrexate 6 (11.1%), azatioprine 5 (9.3%), hidroxicloroquine 4 (7.4%), infliximab 3 (5.5%), ciclosporine 2 (3.6%). One case was associated with the adverse effect of a tumor necrosis factor inhibitor: etanercept.

Conclusions: The incidence of sarcoidosis was higher than previously published in an area of Catalonia. Like has been published before, the findings in our review, shows: sarcoidosis was more common in women. And the presentation was in older age than men. HTA was the most related comorbility. Löfgren syndrome was the most frequent presentation form. Stage II was the most common. Diagnostic delay mean was of 6 months. Transbronchial biopsy was the main diagnostic method. The most common treatment was with Corticoids. The trend of radiological evolution was to stability or to improvement with a low sarcoidosis-related mortality. Furthermore, we report one case of sarcoidosis associated with etanercept, and another case with Heerfordt syndrome presentation.

IF-84
PREVALENCE AND CLINICAL FEATURES OF BEHÇET DISEASE IN A COHORT OF 123 PATIENTS WITH UVEITIS

J. Lozano Herrero[1], A. Sánchez Guirao[1], M. Herranz Marín[1], E. Mompeán Conesa[1], A. Climent Albadalejo[2], E. Díaz Guía[3], C. Marín Silvente[1], F. Herrero Huerta[1]

[1]Department of Internal Medicine, [2]Department of Rheumatology, [3]Department of Ophthalmology. Hospital General Universitario J.M. Morales Meseguer. Murcia, Spain.

Objectives: To assess the prevalence of Behçet disease (BD) in a cohort of patients with uveitis and to describe the clinical features and course of their ocular and extraocular manifestations.

Material and method: Retrospective observational study of a cohort of 123 uveitis patients, followed-up in our Uveitis Unit from January 2008 to April 2012. All patients underwent a full systemic review, ocular examination, and systematic standard baseline investigations which included blood and urine analyses, VDRL test for syphilis, a chest X-ray and tuberculin skin test. Other determinations such as HLA B51, autoantibodies or specific radiological test were performed selectively according with clinical history. Diagnosis of BD was made in patients who fulfilled the International Study Group criteria. Information on the patient's

sex, age at onset of uveitis, clinical features, complications and systemic treatment was collected.

Results: Diagnosis of BD was made in 12 of 123 patients with uveitis (9.75%). Sex ratio was 1:1 and median age at presentation 34 years (17-42). Uveitis was the first manifestation of BD in 10 of 12 patients. Clinical presentation was chronic or recurrent in 10, severe in 10 and bilateral in 6 subjects. We found 2 panuveitis, 6 posterior uveitis, 3 intermediate uveitis and 1 anterior uveitis. Main ocular features were 7 retinal vasculitis, 7 vitritis, 3 pars planitis and 2 iridociclitis. The most severe complications were 4 macular edema, 1 retinal detachment, 1 glaucoma, 1 central retinal vein thrombosis, 1 choroidal neovascularization, 1 pseudo orbitary tumor and 1 optic neuritis. Oral ulcers were present in all subjects and genital ulcers in half of them. Other extraocular manifestations were 6 patients with cutaneous lesions (3 erythema nodosum, 2 pseudofolliculitis, 1 purpura, 1 urticaria), 4 patients with arthralgias and/or arthritis, 3 patients with neurologic involvement (2 psicosis and 1 migraine headache), 1 patient with thrombosis (bilateral pulmonary thromboembolism) and 1 patient with diarrhea. Two patients referred a history of pathergy, but none of the subjects were tested for a pathergy test. HLA–B51 was tested in all patients, resulting positive in 5 of 12 patients. Regarding the treatment, steroids were used in 9 patients, requiring intravenous bolus only in 1 of them. Among immunosuppressant the most common used was cyclosporine A (83%, 10 patients). Others were azathioprine (5 patients), methotrexate (4) and biologic agents such as adalimumab (3) and infliximab (1).

Discussion: BD is a chronic relapsing inflammatory multisystemic vasculitic disease with a wide spectrum of clinical presentations. Eye involvement occurs in approximately 70% of the patients and is associated with a high risk of blindness. The disease can affect the anterior and/or posterior segments of the eye, and the main manifestations include iridocyclitis, hypopyon, mild to moderate vitritis, posterior or panuveitis with occlusive retinal vasculitis, optic neuropathy and macular edema. Medications such as corticosteroids and immunosuppressive agents are used to reduce inflammation in patients with posterior or panuveitis. Novel biologic drugs such as tumour necrosis factor (TNF)-alpha-antagonists have been introduced in the treatment of ocular BD with very promising results.

Conclusions: 1. Nearly 10% of patients of our series were diagnosed with Behçet disease. 2. Most patients presented with severe uveitis as the first manifestation. 3. Early diagnosis and treatment are essential in order to prevent disease-related complications, such as blindness in the case of uveitis Behçet. 4. Multidisciplinary Units composed of internists, rheumatologists and ophthalmologists are essential for adequate management of this disorder.

IF-86
ANTIPHOSPHOLIPID SYNDROME (APS): DESCRIPTION OF 32 CASES FULFILLING SYDNEY'S CRITERIA

D. Colunga[1], S. Colunga[2], H. Gómez[1], L. Caminal[1], R.G. de la Torre[1], B. Díaz[1]

[1]Department of Internal Medicine, [2]Department of Cardiology. HUCA. Oviedo (Asturias), Spain.

Objectives: To describe the clinical and epidemiological characteristics of the patients with diagnostic of APS, attended at the Unit of Autoimmune Diseases of the HUCA, in Asturias from May 2006 up to Diciembre-2010, including only those patients who fulfill Sydney 2008's diagnostic criteria, and to review the results of the laboratory tests used.

Material and method: Retrospective review of computerized reports of 48 patients recorded in the database of the Unit with the diagnosis of APS. We recorded: Age, sex, kind of APS (primary or secondary), clinical diagnostic criteria (arterial thrombosis, venous thrombosis, pregnancy morbidity), laboratory diagnostic criteria (kind of positive antiphospholipid antibody) and treatment given (anticoagulants, antiplatelet agents, hidroxicloroquine).

Results: 48 patients were registered by APS's diagnosis of which 32 were fulfilling Sydney's criteria. Middle Age to the diagnosis 38.8 year, 21 women (65.6%) vs 11 males (34.4%). 25% as presenting secondary APS to another autoimmune systemic disease, 100% SLE, all of them women. The diagnostic criteria were including arterial thrombosis in 11 patients (34.37%, 7 of them, 63.6% in SNC), venous thrombosis in 19 (59.4%), and pregnancy morbidity in 9/21 women, 5/9 as the only clinical criterion. The laboratory criteria patients were including a positive lupus anticoagulant (LA) test in 15/32: as the only criterion in 5/15; a positive ELISA testing in the case of anticardilipin antibody (ACL) IgG test in 15/32 patients and IgM 10/32; the ELISA testing for anti-beta2glicoprotein-I IgG was positive in 16/32 patients and for IgM one in 6/32. Only 3 patients fulfill the diagnostic laboratory criteria for all antiphospholipid antibodies (aPL), two of them were women and with diagnosis of secondary APS. It was possible to confirm the treatment of 31 patients: 23/31 patients were treated by oral anticoagulants, one of them by Rivaroxaban, only in 2 of them associated to antiplatelet agents, 9/31 they were taking hidroxicloroquine, 7 of them with secondary APS.

Discussion: Many studies on APS do not fulfill the criteria for Sydney's diagnosis, usually because of testing for aPL is performed at one time point only, without confirmation by subsequent testing at least 12 weeks apart, and with an "over-diagnosis" of the syndrome. Thus, the research conclusions might be erroneous if applied to patients who really meet diagnostic criteria for APS.

Conclusions: 1) Two thirds of the patients registered in our database like APS were fulfilling the criteria. 2) The syndrome, even if diagnosed fulfilling Sydney's criteria, is more prevalent in women at the young age. 3) The venous thrombo-embolic disease remains also the most frequent diagnostic clinical criterion (59.4%). 4) LA, ACL IgG and anti-beta2glicoprotein-I IgG were the most prevalent tested antibodies, the last one even more than the first one in patients with thrombo-embolic disease. 5) 74.2% of the patients receive oral chronic anticoagulation, antiplatelet agents are reserving for the treatment of women with pregnancy morbidity. 5) The Sydney criteria should be used in clinic practice to prevent "over-diagnosis" of APS and more extensive workshops using them should be made for research purposes with clinical warranties.

IF-87
POPULATION-BASED STUDY OF INCIDENCE A ND PREVALENCE OF UVEITIS IN THE SOUTH OF SPAIN

E. de Ramón Garrido[1], F. Rosales Villalobos[2], A. Chinchurreta Capote[3], L. Echevarría Lucas[4], F. Borrás Rubia[5], A. Delgado Fernández[6], M. Jódar Márquez[7], M. Del Río Pardo[8]

[1]Department of Internal Medicine. Hospital General. Málaga, Spain. [2]Department of Ophthalmology. Complejo Hospitalario Virgen de la Victoria. Málaga, Spain. [3]Department of Ophthalmology. Hospital Costa del Sol. Marbella (Málaga), Spain. [4]Department of Ophthalmology. Hospital de la Axarquía. Vélez-Málaga (Málaga), Spain. [5]Department of Ophthalmology. Hospital Materno Infantil. Málaga, Spain. [6]Department of Ophthalmology. Hospital Comarcal de Antequera. Antequera (Málaga), Spain. [7]Department of Ophthalmology. Hospital Comarcal de Ronda. Ronda (Málaga), Spain. [8]Department of Ophthalmology. Hospital Civil. Málaga, Spain.

Objectives: Population-based retrospective epidemiological study of incidence and prevalence rates of Uveitis in a well defined geographical area in the south of Spain.

Material and method: Medical records of all patients diagnosed of uveitis, from 1/05/2012 to 30/04/2012, in the six public hospitals of Malaga province, in the south of Spain, that provided a practically complete collection of uveitis cases in this area, was reviewed. Ophthalmologists, in charge of the patients care, obtained data from medical records using precoded forms, including information of socio-demographic (age, sex, ethnicity) and clinical characteristics (age at diagnosis, time from diagnosis, anatomic and clinical classification, clinical course, and complications. All patients received information about study and signed consent.

Results: In this time, 196 incident and 589 prevalent uveitis patients were diagnosed, with more females than males (55.6% and 58.4% vs 44.4% and 41.6%, respectively). The raw incidence and prevalence rates were 12.1/100.000 (95%CI: 10.5-13.9) and 36.2/100,000 (95%CI: 33.4-39.3), population, respectively. The mean age at the time of disease diagnosis was 40.3 ± 19.2 years, and at the time of study was 45.7 ± 18.3 years, and mean follow-up time was 66.9 ± 82.6 months. There were 92.5% whites, 3.2% Hispanics and 2.9% from the north of Africa. Clinical course was acute in 33.8%, recurrent in 50.4%, and chronic in 15.6% cases. Anatomic classification was, anterior in 68.9%, intermediate in 6.6%, posterior in 7.1%, and panuveitis in 17.0% cases. Related to clinical classification, 41.6%, were idiopathic, 11.0%, were specific ophthalmologic forms of uveitis, 34.0%, were uveitis associated with known systemic diseases, and 13.4%, were infectious (herpetic, 6.6%, toxoplasmosis, 2.2%). Mean visual acuity (VA) of right eye was 0.77 ± 0.30 and of left eye was 0.76 ± 0.31. There were 13.9% patients with VA < 80% of at least one eye, 2.2% with AV ≤ 0.1 in both eyes, and 0.5% with VA < 0.05 in both eyes. Most important complications were, cataract (28.9%), glaucoma (12.4%), cystoid macular edema (9.0%), retinal detachment (1.9%), retinal neovascularization (2.5%) and vitreous haemorrhage (2.2%), and 238 (40.4%) patients had at least one of these complications. Only cataract, cystoid macular edema, and any type of complication were more frequent in prevalent than incident cases.

Conclusions: In this well defined geographical area of the south of Spain, frequency and characteristics of uveitis are similar to those referred in other countries of the western word. It is a rare disease of unknown etiology, with recurrent or chronic inflammatory course, who frequently develop severe complications.

IF-88
AGE EFFECT IN ETIOLOGY AND CHARACTERISTICS OF UVEITIS

M. Del Río Prado[1], F. Rosales Villalobos[2], L. Echevarría Lucas[3], A. Chinchurreta Capote[4], F. Borrás Rubia[5], A. Delgado Fernández[6], M. Jódar Márquez[7], E. de Ramón Garrido[8]

[1]Department of Ophthalmology, [8]Department of Internal Medicine. Hospital General. Málaga, Spain. [2]Department of Ophthalmology. Complejo Hospitalario Virgen de la Victoria. Málaga, Spain. [3]Department of Ophthalmology. Hospital de la Axarquía. Vélez-Málaga (Málaga), Spain. [4]Department of Ophthalmology. Hospital Costa del Sol. Marbella (Málaga), Spain. [5]Department of Ophthalmology. Hospital Materno Infantil. Málaga, Spain. [6]Department of Ophthalmology. Hospital Comarcal de Antequera. Antequera (Málaga), Spain. [7]Department of Ophthalmology. Hospital Comarcal de Ronda. Ronda (Málaga), Spain.

Objectives: Evaluation of the relationship of age at diagnosis with the clinical characteristics (anatomic and clinical classification, clinical course, and complications) or uveitis in a well defined geographical area in the south of Spain.

Material and method: Medical records of all patients diagnosed of uveitis, from 1/05/2012 to 30/04/2012, in the six public hospitals of Malaga province, in the south of Spain, that provided a practically complete collection of uveitis cases in this well defined geographical area, was reviewed. Ophthalmologists, in charge of the patients care, obtained data from medical records using precoded forms, including information of socio-demographic (age, sex, ethnicity) and clinical characteristics (age at diagnosis, time from diagnosis, anatomic and clinical classification, clinical course, and complications. All patients received information about study and signed consent.

Results: Age distribution at time of diagnosis of 589 patients registered was: younger than 16 years (children and adolescents [CA]), 12.5%, older than 16 years and younger than 60 years (middle age [MA]), 70.9%, and older than 60 years (older [O]), 16.6%. In CA group, there were more frequent females, chronic clinical course, intermediate anatomical classification, and association with known systemic diseases, as well as less complications, more time of follow-up en better visual acuity. In the O group, there were more frequent anterior anatomical classification, idiopathic forms and development of complications, cataract and glaucoma ($p < 0.05$). Factors related with the presence of complications at logistic multivariate statistical model were: O group of age at diagnosis, panuveitis, chronic forms and longer time of follow-up.

Conclusions: Uveitis have different characteristics related to the age at presentation. Complications development are more frequent in older patients with panuveitis, chronic evolution and longer duration of the disease.

IF-89
ASSOCIATION OF 25-HYDROXYVITAMIN D DEFICIENCY WITH SELECTED CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

K. Alkadi Fernández[1], S. Mellor Pita[1], S. Rosado García[1], F. Granado Lorencio[2], C. Jiménez Ortiz[3], M. Yebra Bango[1]

[1]Department of Internal Medicine, [2]Clinical Biochemistry, [3]Department of Neurology. Hospital Universitario Puerta de Hierro Majadahonda. Majadahonda (Madrid), Spain.

Objectives: Epidemiological studies suggest that systemic lupus erythematosus (SLE) patients have a higher cardiovascular (CV) risk which is not explained by traditional cardiovascular risk factors. Low serum levels of25-hydroxyvitamin D [25(OH)D] are associated with CV risk factors and a higher frequency of CV disease in the general population. The aim of this study is to determine serum vitamin D level in SLE patients and its relationship with cardiovascular risk factors, inflammatory markers, clinical parameters, activity of the disease and markers of subclinical CV disease.

Material and method: 28 SLE patients (> 4 ACR 1997 criteria) were recruited from outpatient clinics between April and June 2011. Data collected included demographics, SLE activity (measured by SLEDAI) disease damage (measured by SLICC/ACR), CV risk factors, inflammatory markers and markers of subclinical CV disease. 25(OH)D measured by Ultra-high performance liquid chromatography, was defined as deficient serum 25(OH)D < 25 nmmol/l, insufficient 25-75 nmmol/l, and normal > 76 nmmol/l. Arterial stiffness was assessed by measuring the carotid-femoral pulse wave velocity (PWV) by Doppler velocimetry and carotid atherosclerosis was determined by evaluating the intima media thickness (IMT) and carotid plaque using B-mode ultrasound scanning.

Results: The median age of the 28 SLE patients included was 40.5 years. The mean of 25(OH) D concentration in our patients was 41.89 ± 19.88 nml/L, with 3 patients presenting normal 25(OH)D concentration (10.71%), 17 patients (60.71%) had insufficient levels and 8 patients (28,57%) deficient levels. A positive correlation between 25 (OH)D levels and HDL levels was observed ($r = 0.375$, $p = 0.049$). Patients with insufficient and deficient 25(OH)D levels were found to have significantly higher hsPCR ($p = 0.04$) and D

dimer concentrations (p = 0.004). No differences were detected between 25(OH)D and the other cardiovascular risk factors studied (Hypertension, smoking, diabetes mellitus, dislipemia, family history of CV disease and metabolic syndrome). However, we observed that patients with a higher number of cardiovascular risk factors present lower 25(OH)D (not statistically significant). The patients with active disease (SLEDAI > 4), photosensitivity, and renal disease tended to have lower vitamin D levels. No association was found between arterial stiffness, assessed by PWV, increased IMT or the presence of carotid plaque and the concentration of 25(OH)D in the serum of SLE patients included in our study.

Discussion: This study shows an association between CVD risk factors (HDL cholesterol, D Dimer and hsPCR) and low 25(OH)D levels as well as lower 25(OH)D levels in patient with higher SLEDAI. These findings have also been described in the literature. No association has been found between 25(OH)D level and subclinical atherosclerosis assessed by PWV and IMT. There are contradictory results in the literature regarding the association between 25(OH)D and subclinical atherosclerosis. This could be due to the different number of patients in each study and the method use to measure subclinical CV disease.

Conclusions: Vitamin D levels are low in women with SLE and significant associations exist with selected CV risk factors. Future studies are needed to determine whether vitamin D levels can predict subclinical atherosclerosis in patients with lupus.

IF-90
BIOLOGICAL DRUGS USE IN PRIMARY IMMUNODEFICIENCIES

P. Romero Gallego-Acho, E. Rodríguez Castellanos, A. Robles Marhuenda, J. Guilloth Alfaro, E. Nadal, A. Gil Aguado, F. Arnalich Fernández

Department of Internal Medicine. Hospital Universitario La Paz. Madrid, Spain.

Objectives: To analyze our experience in the use of biologic agents in patients with primary immunodeficiency antibodies.

Material and method: Retrospective analysis of 8 patients over 18 years, diagnosed with primary antibody deficiency, by WHO classification, followed by Internal Medicine. The mean age of patients was 23 years, all of whom were male. The time evolution of the disease was on average 10.2 years.

Results: We present 8 patients that have received biological drugs for various indications and other immunosuppressive drugs, mainly steroids, azathioprine. The rate of infection was lower along the use of biological drugs (median follow up 1.2 years) than along the treatment with other immunosuppressants. There was only one episode of serious infection that required hospitalization, a patient with X-linked agammaglobulinemia who presented a herpes zoster, while being trated with steroids and certolizumab for inflammatory bowel disease (IBD). The perceived quality of life was better when using biological agents than previously to it. Four patients received anti.TNF for the treatment of IBD refractory to standard treatment. One of them, an X-linked agammaglobulinemia, received infliximab, adalimumab and certolizumab. Three chronic granulomatous disease received infliximab and adalimumab. For all the cases, the disease control was adequate, although some of them needed to change the anti.TNF and one of them the use of adjuvant agranulocitoapheresis Another 2 patients with common variable immunodeficiency (CVI) and autoimmune thrombocytopenia received rituximab with an excellent evolution. Another CVI received rituximab for a transverse myelitis with resolution of the spinal pathology. A lymphoid interstitial pneumonitis got a total resolution after the use of antiCD20.

Discussion: The development of knowledge and the care process of patients with primary immunodeficiencies have improved the life expectancy and quality of life. In the last years, biological drugs have been introduced for the treatment of various autoimmune diseases profile.

Conclusions: Our experience can open the prudent use of biological drugs for patients with PID, always under close monitoring and appropriate prescription.

IF-91
POLYARTERITIS NODOSA IN THE INTERNAL MEDICINE DEPARTMENT - A STATISTICAL STUDY

M. Gonçalves, L. Castro, S. Freitas, G. Alves, J. Cotter

Department of Internal Medicine. Centro Hospitalar do Alto Ave. Guimarães, Portugal.

Objectives: (i) Identify patients with polyarteritis nodosa according to the ACR (American College of Rheumatology) criteria, who were under supervision in the Autoimmune Diseases Outpatient Care, Internal Medicine Department; (ii) describe their clinical condition; (iii) assess their response to therapeutics and their clinical progress. This study took place between October 2003 and January 2011.

Material and method: 1) Retrospective assessment of patients with polyarteritis nodosa, who were followed from October 2003 to January 2011 in Autoimmune Diseases Outpatient Care in the Internal Medicine Department. 2) Diagnosis of Polyarteritis nodosa according to the 1990 criteria of the American College of Rheumatology. 3) Analyzing the patients' clinical history and filling in a form specifically designed for this study. 4) Inserting the results in the database and analyzing them (statistics). 5) Variables under study: number of cases, gender, race, current age, age when the first symptoms occurred, age at the time of the diagnosis, time elapsed between the first symptoms and the diagnosis, follow-up time in autoimmune diseases outpatient care, registered diagnose criteria, clinical manifestations, factors of poor prognosis, therapy applied, registered comorbidity, development.

Results: Six cases were analysed, with the average age of 47 years (27-61), all female Caucasian subjects. They were under supervision for an average of 46 months (13-86). The first symptoms were detected at the average age of 41 years old (25-55) and the diagnosis was carried out at the average age of 44 years old (26-55). Registered diagnosis criteria: ponderal weight loss greater than 4 kg (83%); livedo reticularis (100%); myalgia or muscular weakness (100%); mono or polyneuropathy (67%), diastolic blood pressure above 90 mmHg (50%); urea above 40 mg/dl or creatinine above 1.5 mg/dl (50%); HBsAg or Ab (17%); angiographic changes (50%); biopsy which shows signs of vasculitis (33%). Most frequent clinical manifestations: fever (17%); asthenia (100%); weight loss (83%); arthritis (33%); arthralgia (83%); muscular weakness (83%); myalgia (100%); livedo reticularis (100%); Raynaud's phenomenon (50%); proteinuria (33%); HTN (83%); peripheral neuropathy (67%); cerebral vasculitis (33%); lymphocytic alveolitis (17%); optic papillitis (17%). Registered comorbidity: dyslipidemia (50%); obesity (17%); osteoporosis (17%); diabetes mellitus type II (50%); spontaneous abortion in the first quarter (17%); depressive syndrome (50%). All patients underwent induction therapy with corticosteroids (100%) and cyclophosphamide (83%), but only four patients were administered corticosteroids (33%) and azathioprine as maintenance therapy and they responded well and remained stable. The patient with positive HBsAg underwent a treatment with lamivudine and adefovir after he was administered corticosteroids and cyclophosphamide due to a high HBV viral load. Factors for a poor prognosis for four patients: age over 50 years (33%) and neurological involvement (50%).

Discussion: Since the sample is too small, it is not possible to accurately: (1) compare the results we gathered with the ones described in the literature; (2) relate the factors of poor prognosis with the clinical development.

Conclusions: We were able to draw the following conclusions about our patients: (1) 100% Caucasian females; (2) Average age when the first symptoms appeared: 41 years old; (3) Main clinical manifestations: livedo reticularis and Raynaud's phenomenon, arthralgia, arthritis, myalgia and muscular weakness, ponderal weight loss > 4 kg, peripheral neuropathy, HTN and renal involvement. (4) 67% of the patients show factors of poor prognosis; (5) Six patients underwent induction therapy with corticosteroids and/or cyclophosphamide; (6) Four patients were undergoing maintenance therapy (azathioprine); (7) The patient HBsAg positive was administered antiretroviral therapeutics; (8) Four patients responded well to the therapeutics.

IF-92
THROMBOTIC THROMBOCYTOPENIC PURPURA IN SYSTEMIC LUPUS ERYTHEMATOSUS: PRESENTATION AND CLINICAL OUTCOME IN A SINGLE CENTER EXPERIENCE

L. Boix, F. Mitjavila, C. Contra, F. Gili, O. Capdevila, M. Rubio, M. Labori, M. Pestaña

Department of Internal Medicine. Hospital Universitario de Bellvitge. Hospitalet de Llobregat (Barcelona), Spain.

Objectives: Describe the clinical presentation, response to therapy and outcomes of thrombotic thrombocytopenic purpura associated with systemic lupus erythematosus in a tertiary university hospital.

Material and method: This is a retrospective observational study of a series of 4 patients diagnosed of thrombotic thrombocytopenic purpura and systemic lupus erythematosus admitted to the department of Internal Medicine of a tertiary university hospital between January 2003 and June 2011. Demographic, clinical and treatment related data, including the number of plasmapheresis sessions performed, and outcome data were recorded.

Results: All patients were young women under 40 years. In 50% the diagnosis of SLE was established an average of 5.5 years after the onset of TTP. In the remaining 50%, TTP and SLE presented simultaneously. All of those who presented simultaneously had renal involvement with diffuse proliferative lupus nephritis diagnosed on the renal biopsy in one of them. Only one of the four patients had neurological symptoms with seizures. ADAMTS-13 was measured in only one patient, and it was within normal range. All patients received high dose corticosteroids and an average of 9.75 sessions of plasmapheresis. 2 patients (50%) received immunosuppressive therapy (1 patient sodium mycophenolate, 1 patient iv cyclophosphamide). The patients presenting TTP and SLE simultaneously received more plasmapheresis sessions (4 vs 15.5). The outcome in our patients was excellent with a 100% of complete remission. None of them recurred, after a mean follow-up period of 4 years (1-8). None of the patients died.

Discussion: Thrombotic thrombocytopenic purpura (TTP) is a syndrome characterized by the clinical pentad of severe thrombocytopenia (< 50.000/mm^3), microangiopathic haemolytic anaemia, neurological symptoms, renal dysfunction and fever. Autoimmune inhibition or genetic mutation of the metalloprotease that cleaves von Willebrand factor multimers (ADAMTS-13) contributes to its pathogenesis. TTP is a rare but often fatal complication of systemic lupus erythematosus (SLE), and causes high mortality in the absence of early therapeutic interventions. Its prevalence is between 1% and 4% and the prognosis in the few published studies so far is worse than in idiopathic or acquired TTP. Diagnosis is often difficult because of their clinical and biological similarities.

Conclusions: Despite being described in the literature as a fatal association with a high mortality in our small series the prognosis was very good with a complete remission of the PTT flare of 100%, no recurrences and no mortality during the follow up period. This can be explained by an early diagnostic suspicion and prompt treatment and plasmapheresis initiation. Although the number of patients presented is limited, we recommend to rule out PTT in any SLE patient presenting with microangiopathic haemolytic anaemia and thrombocytopenia in order to initiate plasmapheresis as soon as possible to improve prognosis.

IF-94
INFLAMMATORY BOWEL DISEASE ASSOCIATED WITH VENOUS THROMBOEMBOLISM

C. Vázquez Triñanes[1], A. Argibay Filgueira[2], A. Rodríguez Gómez[2], R. Lorenzo Castro[2], J. Gómez Sousa[2], M. Freire Dapena[1], A. Rivera Gallego[1], B. Sopeña Pérez-Argüelles[1]

[1]Department of Thrombosis and Vasculitis, [2]Department of Internal Medicine. Complejo Universitario de Vigo. Vigo (Pontevedra), Spain.

Objectives: To establish the prevalence of inflammatory bowel disease (IBD) in a prospective cohort of patients with venous thromboembolism (VTE) and to describe the clinical and analytical characteristics in these patients and their prognosis, after a long clinical follow-up.

Material and method: From January 1, 2002 to May 1, 2012, 702 patients with VTE were prospectively included in the computerized database of the Thrombosis and Vasculitis Unit of the Hospital Xeral de Vigo, a tertiary care hospital which attends a population of more than 300,000 inhabitants. All patients with IBD were selected for the study and their clinical and analytical data were analyzed using the SPSS statistical program, version 18.0. Descriptive statistics including the percentage, mean ± DS and interquartile range were used.

Results: The prevalence of IBD in patients with VTE was 1.7%. The 12 patients with IBD and VTE had a mean age of 55 ± 14 years (range 35-80) and 75% were male. Proximal deep venous thrombosis was diagnosed in 11 patients (92%), in 1 of them without pulmonary embolism (PE) (PE was not investigated in 4 patients). One patient had PE without deep venous thrombosis. Five out of 12 (42%) had Crohn disease, 3 with ileal and 2 with colonic involvement. Seven out of 12 (58%) had ulcerative colitis, 4 sigmoiditis and 3 pancolitis. Eigth out of the 12 patients (67%) were diagnosed of VTE during a flare-up of IBD. Other risk factors for VTE were present: rest in 5 (42%), arterial hypertension in 4 (33%), smoking in 2 (17%), hypercholesterolemia in 2 (17%), cancer in 1 (8%) and surgery in 1 (8%). At least 1 of these risk factors was present in 9 patients (75%), 2 in 7 patients (58%), 3 in 2 patients (17%) and 4 in 1 patient (8%). Factor V Leyden, factor II mutation and protein C, protein S and antithrombin III deficiency were negative in the 3 patients tested, in the same way that ACLA and LA in 4 patients. Patients were treated with anticoagulation during an average of 1 year. Eight out of the 12 patients (67%) had active bleeding at the time of VTE diagnosis but no major bleeding was recorded even after anticoagulation. However, 2 received lower level of anticoagulation. The mean follow-up was 42.6 months (range 1-120). Two patients died by causes other than VTE. Three out of 10 patients (30%) had a recurrence of VTE (2 during new flare-up of IBD and 1 after a trauma) 3.3 years on average (range 2-4) after the first episode.

Discussion: According to a recent review of the literature, patients with IBD have a two- to four-fold increased risk of recurrent venous thrombosis, with a peak incidence of venous thrombosis when having a flare up of the disease. However, more studies are needed to evaluate these patients because some questions remain unresolved, for example: if other risk factors for thrombosis are present or if anticoagulation is safe during flare ups.

Conclusions: The prevalence of IBD in the cohort of patients with VTE is low. Patients with ETV and IBD usually have proximal deep

venous thrombosis. Most ETV occur during a flare-up of IBD and, in the majority, at least 1 known risk factor for thrombosis is present Major bleeding is not associated with anticoagulant therapy even during a flare-up of IBD.

IF-95
HLA-B27-ASSOCIATED UVEITIS

C. Vázquez Triñanes[1], A. Martínez Vidal[2], B. Maure Noia[1], A. Sousa Domínguez[2], A. Soto Peleteiro[2], M. Freire Dapena[1], A. Rivera Gallego[1], B. Sopeña Pérez-Argüelles[1]

[1]Department of Thrombosis and Vasculitis, [2]Department of Internal Medicine. Complejo Universitario de Vigo. Vigo (Pontevedra), Spain.

Objectives: To asses clinical features and prognosis of HLA-B27-associated uveitis and to evaluate differences between patients with or without ocular complications, with or without an associated systemic disease as well as gender differences.

Material and method: Consecutive patients referred for HLA-B27 typing from January 1, 2006 to December 31, 2011 were selected from the database of the Clinical Analysis Department of the Complexo Hospitalario Universitario de Vigo, a tertiary care hospital which attends a population of more than 300,000 inhabitants. Medical records of HLA-B27 positive patients were reviewed and adult patients with at least 1 episode of uveitis evaluated by an Ophthalmologist were included in the study. Patients were grouped by the presence of ocular complications, the association with a systemic disease and sex. Data were analyzed using the SPSS program, version 18.0.

Results: 1,802 patients were referred for HLA-B27 typing and 292 (16.2%) were positive, 264 of which were adult patients (90.4%). 40 (15.2%) had at least 1 episode of uveitis with a mean age of onset of 39.2 years (range 15-62) and 57.5% were male. The mean follow-up was 7.8 years (range 1-21). 92.5% were anterior, 2.5% posterior and 5% no specified by the Ophthalmologist. 60% were recurrent, with 4.4 episodes of uveitis on average during a mean follow-up of 8.8 years. 12.5% were bilateral, of which 80% were recurrent. 5% were chronic, none of them associated with systemic disease. 57.5% were associated with a systemic disease: 65.2% ankylosing spondylitis (AS), 13% undifferentiated arthritis (UA), 4.3% reactive arthritis (RA), 4.3% psoriatic arthritis (PA), 8.7% inflammatory bowel disease (IBD) and 4.3% Wegener disease. In 7 patients (18.4%) uveitis were diagnosed after HLA-B27 typing (5 AS, 1 RA and 1 PA). In 9 (23.7%) HLA-B27 was typed at the onset of uveitis and in 22 (57.9%) uveitis was diagnosed before HLA-B27 typing (with a mean delay in diagnosis of 27.3 months, range 2-156). 52.5% of patients had complete response to topical corticosteroids and 20% (8patients) required a biological drug: 1 because of chronic steroid-dependent uveitis and 7 because of their systemic disease. 25% of patients had at least 1 ocular complication: 1 cystoid macular edema, 1 glaucoma, 5 cataract, 6 synechaie. Patients with ocular complications compared to those without were more frequently recurrent or chronic (100% vs 53.3%, $p < 0.05$) and treated with a biological drug (40% vs 13.3%, $p < 0.05$). Patients associated with a systemic disease compared to those no associated were more frequently treated with biologic drugs (30.4% vs 5.9%, $p < 0.05$). Female patients compared with males were more frequently acute and non recurrent (52.2% vs 21.7%, $p < 0.05$). No other differences were detected.

Discussion: Few series of patients with HLA-B27-associated uveitis with a long follow-up have been published. As in other studies, in our series HLA-B27-associated uveitis was often acute, anterior and recurrent and had good prognosis. Some of the published series found a higher prevalence of associated systemic disease in males, but this was not confirmed in the present work. In a recent study, men have a previous diagnosis of HLA-B27 more often than women when uveitis was diagnosed and have more ocular complications, but in the present series this difference was not significant. However, women had more frequently acute non recurrent uveitis, which were not associated with complications.

Conclusions: HLA-B27 uveitis is usually acute anterior and recurrent, with complete response to topical corticosteroids, good prognosis and, in more than half of patients, associated with systemic disease. There is an important delay in diagnosis of HLA-B27 uveitis. The association with systemic disease does not mean a worse ocular prognosis, however, biological treatment is associated with more frequent complications of uveitis.

IF-96
MARKERS OF LIVER FUNCTION AS SIGNS OF SYSTEMIC DISEASES

G. Chosnis, A. Rachioti, K. Tsamis, P. Karamitrou, K. Vasileiadis, C. Karampampa, E. Louka, M. Rapti

Department of Internal Medicine. General Hospital of Livadeia. Livadeia, Greece.

Objectives: The central role of liver in metabolism, energy homeostasis, immune defense and detoxifying protection of the organism, as well as its anatomical and functional position, vascular specificity, correlation with adjacent organs have as a result its participation in multiple immunological syndromes.

Material and method: 130 patients treated in the period 2010-2011 with symptoms of hepatocellular necrosis: High levels of Bil, Ast, Alt, Alp, g-GT, ESR, Low levels of Alb, Chol, APTT, PT, INR, weight loss, jaundice, fever, arthralgias, sarkopenia, anorrhexia, abdominal pains, pruritus.

Results: See Table.

Conclusions: 1. It is perceived the need of differential diagnosis between liver disease and liver expression by systemic diseases. 2. Ultrasound elastography plays important role in the diagnosis of NAFLD. 3. The presence of fever, high ESR and arthralgias is correlated with autoimmune diseases. 4. Fever is the most common symptom among systemic diseases with hepatic impairment. 5. High precentage of acute viral hepatitis patients developed vasculitis.

Table 1 (IF-96)

Thyrrhoid impairment - 3	Idiopathic inflammatory bowel diseases (Crohn's, Ulcerative colitis, PSC) - 15
Celiac disease - 6	Granulomatous diseases (Hodgkin's, Brucellosis, EBV, CMV, Drugs) - 20
Addison's diseases - 3	Sarcoidosis - 3
Wilson's diseases - 1	Tuberculosis - 2
Ischemic hepatitis (heart failure - renal impairment) - 17	HIV (pneumocystis carinii, leishmania, cryptococcus, histoplasma) - 1
Haematological diseases (MDS, haemoglomunopathy) -7	Vasculitis (HBV) - 20
Autoimmune hepatitis type I (MS, SLE) - 2	NAFLD - 30

IF-97
FEVER OF UNKNOWN ORIGIN PRESENTING AS INTERSTITIAL LUNG DISEASE AND ANCA-ASSOCIATED VASCULITIS: CLINICAL AND LABORATORY ASSOCIATIONS IN A TERTIARY COHORT STUDY

C. Voulgari, S. Siasiakou, E. Alexaki, S. Avgeri, X. Drakou, S. Pagoni

3rd Department of Internal Medicine. Athens Regional Hospital G. Gennimatas, University Medical School. Athens, Greece.

Objectives: ANCA-associated vasculitides i.e. polyangiitis (granulomatosis Wegener's), microscopic polyangiitis and Churg–Strauss syndrome are characterized by pauci-immune necrotizing vasculitis of small blood vessels. Despite the common association with ANCA, these disease entities differ significantly in their clinical features and underlying pathophysiology. Interstitial lung disease and ANCA-associated vasculitis, particularly microscopic polyangiitis, are frequently associated.

Material and method: The study was designed to investigate the incidence of patients with interstitial lung disease in a cohort of patients with ANCA-associated vasculitis, originally presented in the Emergency Room and investigated as fever of unknown origin, their defining characteristics and overall outcomes. For this reason, we included patients with final diagnosis of ANCA-associated vasculitis who also had interstitial lung disease. We recorded patient demographics, diagnostic tests, treatment, and clinical complications.

Results: Interstitial lung disease was observed in 6.9% (n = 5) of the studied patients with ANCA-associated vasculitis (n = 72); constitutional symptoms were present in all patients (n = 5), whereas respiratory symptoms including a dry cough and progressive dyspnoea were also common (n = 4). Other clinical features included arthritis/arthralgia (n = 3), scleritis (n = 3), rash (n = 2), and peripheral neuropathy (n = 2). All had MPO-ANCA and a clinical diagnosis of microscopic polyangiitis. Sepsis was present in all patients, whereas 2 presented pulmonary hemorrhage.

Discussion: There is a uniquely association between interstitial lung disease and microscopic polyangiitis, and specifically with anti-MPO-ANCA. This particular antibody or its evoked response is critical for development of interstitial lung disease. In cases of fever of unknown origin and interstitial lung disease, presence of vasculitis should be ruled out as an underlying disorder, in view of other potential organ involvement and possible therapeutic interventions.

IF-98
PROGNOSTIC IMPLICATION OF CLINICAL, SEROLOGICAL AND MICROVASCULAR ASPECTS OF PATIENTS WITH PRIMARY BILIARY CIRRHOSIS AND AUTOIMMUNE SYSTEMIC DISEASES

J. Taján[1], B. Marí[1], C. Tolosa[1], E. Oviedo[1], M. Amengual[2], J. Oliva[3], C. Simeón[4], V. Fonollosa[4]

[1]Department of Internal Medicine, [2]Laboratory of Immunology, [3]Statistic Unit. Hospital de Sabadell. Barcelona, Spain. [4]Department of Internal Medicine. Hospitals Vall d'Hebron. Barcelona, Spain.

Objectives: 1. To identify the incidence of connective tissue diseases (CTD) associated to patients with primary biliary cirrhosis (PBC) in our health reference area; 2. To describe the major characteristics of patients with PBC and Systemic Sclerosis (SSc), and 3. To evaluate the clinical, biological and micro-vascular aspects of patients with both diseases.

Material and method: From January 1990 to May 2011, 97 cases of PBC were diagnosed at the Parc Taulí Hospital, with a reference area of 389,758 inhabitants. This report is a cross-sectional study of PBC patients diagnosed following the American Association of the Study of Liver Disease criteria. Extra-hepatic signs of CTD were thoroughly investigated in 74 patients, as well as a full immunological investigation and nailfold capillaroscopy (NC).

Results: The average age of the cohort at the time of the study was 64 years (range: 29-96) with a female predominance (94%, female:male ratio: 15:1). 11.3% of PBC patients were diagnosed of SSc prior to entry in the study, mainly in the limited cutaneous form. The most frequent extra-hepatic symptom was sicca syndrome in 60%, followed by arthritis in 18.8%. Raynaud's phenomenon was present in 27.6%, and it was related to CTD in 71.4% of them. Antinuclear antibodies (ANA) were positive in 74.2% of PBC patients (speckled pattern in 52%). Anticentromere antibodies (ACA) were positive in 17 patients (18%) in whom they were determined (n = 94), and they were significantly associated with the presence of SSc (58.8% vs 1.3%, $p < 0.0001$). 52.7% of patients with PBC and some associated extra-hepatic symptom showed an non significant nailfold capillaroscopy alteration.

Discussion: SSc was common in PBC population, mainly in the limited cutaneous subset. ACA positivity was more frequent in PBC-SSc patients than in each disease in isolation. This association of PBC and SSc seemed to be more significant than coincidental and suggests that both diseases might have a common autoimmune basis. Moreover, ACA positivity was associated with an increase risk of developing any CTD. This study is addressed to evaluate specific immune profile of SSc and the presence of microvascular abnormalities in patients with PBC referring extra-hepatic signs of connective tissue disease. The observed results in sex, average age and duration of PBC suggested that there was not a selection bias in our study. In our PBC database, extra-hepatic manifestations were common, mainly sicca syndrome, Raynaud's phenomenon, and arthritis.. We found a trend to higher prevalence of nailfold capillary abnormalities in PBC patients with extrahepatic signs suggestive of CTD. The most frequent findings were diffuse capillary loop dilatation and megacapillaries, similar to those described in SSc patients, although they were not significant.

Conclusions: 1) Assessment of PBC patients should always include screening for SSc related symptoms, such as Raynaud's phenomenon. 2) Screening PBC patients for ACA is not mandatory but can be considered, especially in the presence of disease related symptomathology. 3) Nailfold capillaroscopy may be a useful indicator of CTD in patients suspected of having one of them.

IF-99
DIAGNOSIS OF AUTOIMMUNE DISEASES IN A QUICK DIAGNOSIS UNIT: PREVALENCE, CLINICAL CHARACTERISTICS AND FINAL DIAGNOSIS

P. Brito-Zerón, A. Jordán, A. López Soto, X. Bosch

Quick Diagnosis Unit. Hospital Clinic. Barcelona, Spain.

Objectives: Autoimmune diseases may affect multiple organs, and due to their complexity and difficulty in diagnosing, it is not uncommon for patients with symptoms and signs suggestive of these diseases to require hospital admission. However, since 4 years ago, the Quick Diagnosis Unit of our hospital has become a crucial Unit for diagnosing these complex diseases. Objectives: to analyze the prevalence of autoimmune diseases diagnosed in a Quick Diagnosis Unit. To analyze the main reasons for referral to our Unit and to describe the final diagnoses in these patients.

Material and method: A total of 2847 patients were visited in our Unit from November 2008 to May 2012. We retrospectively analyzed the epidemiological and clinical features of patients with autoimmune diseases, which were classified as systemic or organ-specific autoimmune diseases.

Results: A final diagnosis was reached in 2681 patients (166 patients were lost to follow-up). Autoimmune Diseases were diagnosed in 199 (7.4%) patients. Of the 199 patients with autoimmune diseases, 126 (63%) were women and 73 (37%) were men, with a mean age at diagnosis of 55.66 years (15-94). Patients were mainly referred by the emergency department (49%) and primary care centers (40%). The main clinical reasons for referral were constitutional syndrome in 31 patients (16%), skin lesions in 28 patients (14%), fever in 21 (11%), cytopenias in 17 (8%), other laboratory abnormalities in 11 (5%), arthralgias/arthritis in 16 (8%), headache in 12 (6%), polymyalgia in 9 (4.5%), myalgias in 8 (4%), diarrhea in 7 (3.5%), peripheral adenopathies in 5 (2.5%) and abdominal pain in 4 (2%). Autoimmune diseases were classified as systemic in 140 (70%) patients and organ-specific in the remaining 59 (30%) patients. The main systemic autoimmune diseases diagnosed were polymyalgia rheumatica in 37 (26%) patients, vasculitis in 30 (21%) patients, systemic lupus erythematosus in 19 (14%), rheumatoid arthritis in 15 (11%), sarcoidosis in 7 (5%), inflammatory myopathies in 4 (3%) and idiopathic thrombocytopenic purpura in 3 (2%) patients. Systemic vasculitis included Horton's disease in 13 patients, small vessel vasculitis in 9, panarteritis nodosa in 3, cryoglobulinemia and Takayasu disease in 2 patients, respectively and Wegener granulomatosis in 1 patient. The main organ-specific autoimmune diseases diagnosed were celiac disease in 15 (25%) patients, erythema nodosum in 14 (24%) patients, mesenteric paniculitis and pulmonary fibrosis in 4 (7%). The mean time to achieve diagnosis of the autoimmune disease was 38 days (0-525). After the diagnosis, patients were referred to specialized Departments (67%), mostly to the Systemic Autoimmune Diseases Department (44%).

Conclusions: Seven percent of patients referred to the Quick Diagnosis Unit of Hospital Clinic were diagnosed with autoimmune diseases. Most patients were referred by the emergency department and primary care centers. The main signs and symptoms were constitutional syndrome, skin lesions, fever and cytopenias. Most patients (70%) were diagnosed with a systemic autoimmune disease, with polymyalgia rheumatic being the most frequent, while the remaining 30% were classified as having an organ-specific autoimmune disease, with celiac disease being the most frequent.

IF-100
ANTICENTROMERE ANTIBODIES (ACA): ARE THEY SO SPECIFIC OF SYSTEMIC SCLEROSIS (SSC)?

P. Rosich[1], C. Araguas[1], L. Morera[1], C. Tolosa[1], B. Marí[1], M. Amengual[2], M. Monteagudo[1], J. Oristrell[1]

[1]Department of Internal Medicine. Corporació Sanitària Universitaria Parc Taulí. Sabadell (Barcelona), Spain. [2]Immunology Laboratory. Corporació Sanitaria Universitaria Parc Taulí. Sabadell (Barcelona), Spain.

Objectives: To evaluate if ACA are so specific of the presence of SSc as suggested by an Evidence-Based Guidelines by ACR members or have a significant clinical heterogeneity as suggested in some recent studies.

Material and method: One hundred and twelve ACA positive patients were identified from January 1992 to December 2007 and were retrospectively analysed. We recorded demographical, clinical and laboratory data. Complete clinical information was available from 85 (76.78%) of them. ACA were detected using IIF with commercially prepared Hep-2 cells.

Results: 85 patients with ACA+ve were analyzed, 83 females and 2 males with a mean age of 38.2 y. The most common diagnosis was SSc, identified in 64 patients (75.29%). 48 of them had limited cutaneous (75%), 1 diffuse cutaneous (1.56%), 1 sine scleroderma (1.56%), and 14 pre-scleroderma (21.8%). In 46 of SSc patients (71.9%) SSc was the unique disease. Five SSc patients (7.8%) were associated to some other connective tissues diseases (CTD), Sjögren syndrome in 4, and rheumatoid arthritis in 1. 13 SSc patients (20.3%) were associated to other non-systemic autoimmune disease such as primary biliary cirrhosis in 10, autoimmune cholangitis in 2, and ulcerative colitis in 1. 5 ACA+ve patients (7.0%) do not have SSc diagnosis but they were diagnosed of some other CTD, Sjögren syndrome in 1, SLE in 1,temporal arteritis in 1, cutaneous lupus in 1 and rheumatoid arthritis in 1. In 7 patients (8.23%) with non-systemic autoimmune diseases we diagnosed 3 primary biliary cirrhosis, 1 idiopathic leukocytoclastic vasculitis, 1 autoimmune cholangitis and 2 autoimmune hepatitis. Finally, 9 patients (10.58%) did not suffer any autoimmune disease. Therefore, 21 out of 85 ACA+ve patients (24.70%) in our series were diagnosed of diseases other than SSc.

Discussion: In an "Evidence-Based Guidelines for the Use of Immunologic Tests" published in 2003 by ACR members, the authors concluded that ACA (determined by IIF) are rarely found in patients with CTDs other than SSc, or healthy controls, and thus they are very useful in the diagnosis of SSc. The result of our study showed that SSc was the most common disease associated with the presence of ACA but there were 24.70% of patients with diseases other than SSc, in agreement with more recent studies. Moreover, 10.85% of ACA+ve patients do not have any particular autoimmune disease.

Conclusions: 1) SSc was the most common disease associated with the presence of ACA, diagnosed in 75.29% of cases; 2) The limited cutaneous form was the most common of subset of ACA+ve SSc patients; 3) 24.70% of ACA+ve patients did not have SSc diagnoses; 4) A significant number of patients (10.85%) were not diagnosed of any particular autoimmune disease.

SPANISH REGISTRY OF PATIENTS WITH BEHÇET'S DISEASE (REGEB): DESCRIPTIVE STUDY OF CLINICAL MANIFESTATIONS AND TREATMENT IN A COHORT OF 400 PATIENTS

M. Rodríguez Carballeira[1], G. Espinosa[2], R. Solans[3], J. Larrañaga[4], R. Ríos Fernández[5], M. Castillo[6], A. Martínez Berriotxoa[7] and the REGEB Investigators

[1]Department of Internal Medicine. Hospital Universitario Mutua Terrassa. Terrassa (Barcelona), Spain. [2]Deparment of Autoimmune Diseases. Hospital Clínic. Barcelona, Spain. [3]Department of Internal Medicine. Hospital Universitario Vall d'Hebron. Barcelona, Spain. [4]Department of Internal Medicine. Complejo Hospitalario Universitario Vigo. Vigo (Pontevedra), Spain. [5]Department of Internal Medicine. Hospital San Cecilio. Granada, Spain. [6]Department of Internal Medicine. Hospital Virgen del Rocío. Sevilla, Spain. [7]Department of Internal Medicine. Hospital Universitario de Cruces. Bilbao (Vizcaya), Spain.

Objectives: To analyze the demographic and clinical manifestations of Behçet's disease (BD) in a large cohort of patients.

Material and method: The demographic and clinical features of BD in 400 patients who met the proposed criteria for the classification of BD (ISBD) from 14 Spanish centres were analyzed. This project was performed under the auspices of the Working Area of BD, on behalf of Systemic Autoimmune Diseases Group (GEAS) of Spanish Society of Internal Medicine (SEMI). This registry started in 2009, with a multicenter, consecutive, retrospective design.

Results: The cohort consisted of 219 female patients (54.8%) and 181 male patients (45.2%) with a mean ± SD age of 28.9 ± 12.3 years. The median delay in diagnosis was 24 months (range 0-420). There were 371 Caucasian (92.8%), 19 Arabic (4.8%), and 10 of other races (2.4%). The median follow-up was 139 months (range 0-439). The most common presenting manifestations were ulcers (total 75%; oral 35.6%, genital 2.5%, both 37%), followed by fever (6.5%), anterior uveitis (4.8%), arthritis (3.3%), retinal vasculitis (1.8%), erythema

nodosum (2%), aseptic meningitis (1.8%), posterior uveitis (1.5%), and pseudofolliculitis (0.5%). Other manifestations such as optic neuritis, arterial aneurysm, and inflammatory pseudotumor were less frequent. Regarding cumulative manifestations oral ulcers presented in all patients followed by genital ulcers (72.5%), pseudofolliculitis (47.3%), arthritis (39.5%), erythema nodosum (38.5%), ocular involvement (35.3%; anterior uveitis [27.3%], retinal vasculitis [12.5%], and posterior uveitis [8.3%]), venous thrombosis (18.5%; 4 cases of cerebral venous thrombosis, 2 retinal venous thrombosis, 3 inferior vena cava thrombosis, one patient with Budd-Chiari syndrome, and the remaining in form of deep venous thromboses), fever (17.8%), vasculitis (9%), aseptic meningitis (7.5%), pseudotumor cerebri (2.8%), stroke (2.8%), arterial aneurysm (1.6%), and other disorders of central nervous system in 11% of patients. Considering visual involvement, 18.3% of all patients have visual acuity deficit which represents 40.3% of all patients with ocular involvement. Regarding treatments received, the most frequently used were oral corticosteroids (79%) followed by colchicine (76.8%). Interestingly, 53% of patients required any immunosuppressive treatment during the follow-up. Oral anticoagulation was used in 16.3% of patients, anti-TNF therapies in 10.5% of patients and only 4.3% received thalidomide. In order of frequency, the main adverse effects of treatment were hypertension (6.8%), infections (6.3%), cataract (3.8%), osteopenia (3.5%), renal failure (2.3%), diabetes mellitus (1.8%), aseptic necrosis of femoral head (1%), and bone marrow toxicity (1%). Two patients died from the beginning of the registry.

Conclusions: The main clinical features of BD patients of our Registry are similar to those of other series with the same ethnic origin.

IF-102
CORRELATION OF MARKERS IMMUNE NON-INVASIVE OF LUPUS ACTIVITY

J. Barbado Ajo[1], L. Vega Valderrama[1], S. Calzada Simón[1], S. Miranda Riaño[1], A. Jimeno Carrúez[1], J. Bermejo Martín[2]

[1]Department of Internal Medicine, [2]Department of Microbiology and Immunology. Hospital Clínico Universitario de Valladolid. Valladolid, Spain.

Objectives: Cytokines and chemokines are key immune mediators that have been put in relation with the pathogenesis of systemic lupus erythematosus (SLE). The objectives is the study of the profiles of secretion of the same present in plasma and urine in patients with SLE, and compare the immune response in patients with them with different degrees of activity of the disease.

Material and method: This is a prospective observational study of 1 year duration (December 2007-December 2008) in patients with SLE in our hospital. Inclusion criteria were as follows: patients referred to consultation with our hospital diagnosed with SLE. The different degrees of disease activity were determined by the SLEDAI score. To determine the presence of lupus nephritis (LN) underwent renal biopsy. Parallel samples were collected from blood and urine of 46 patients (8 with LN), mean age 43.5 years, (82.61% women, 17.39% men), divided into groups: Group 1: mild-moderate without renal involvement (13), Group 2: no severe renal impairment (25), Group 3: severe with renal involvement (8). A group of healthy volunteers of similar age and comparable sex distribution was recruited as control (n = 10). The measurement of 17 immune mediators (cytokines, chemokines and growth factors) in plasma and urine was performed using a Biorad® 17-plex kit on a Luminex® platform. Mediators data were analyzed together with clinical information.

Results: The active SLE disease is characterized by a pattern of expression of Chemokines MCP-1, GM-CSF, IL-8, MIP-1b in plasma and MCP-1and MIP-1b in urine. IL-8 and GM-CSF in plasma amounted more significantly when the disease is moderate without LN. (1) MCP-1 increases significantly, both plasma and urine, when there are serious LN [The Mann Whitney test also showed that these differences were significant ($p < 0.05$)], and correlates significantly with SLEDAI [C C Spearman Karber, p] = [0.383; 0.19]. (2.3) MCP-1 in plasma and urine [CC Spearman Karber, p] = [283; 0.56] correlate conversely with C3 and leukocytes in plasma levels.

Conclusions: We were able to identify a trace of expression of immune mediators in active SLE, characterized by elevated plasma and urine chemokines (MCP-1, GM-CSF, IL-8, MIP-1b). Correlation of MCP-1 and MIP1b in plasma and urine with SLEDAI. Levels of MCP-1 in plasma and urine are inversely proportional to C3 and leukocytes in plasma levels. Possibility of using these chemokines as markers predictive non-invasive of activity LN. Pharmacological modulation of these mediators could lead to clinical improvement in patients.

IF-103
FULFILMENT OF THE NEW CLASSIFICATION CRITERIA FOR CRYOGLOBULINEMIC VASCULITIS IN 311 PATIENTS WITH PRIMARY SJÖGREN SYNDROME

S. Retamozo[1], C. Díaz Lagares[1], P. Brito-Zerón[1], X. Bosh[2], A. Bové[1], M. Ramos-Casals[1]

[1]Laboratory Josep Font, Department of Autoimmune Diseases, [2]Department of Internal Medicine, ICMiD. Centre Sociosanitari Hospital Clínic i Provincial de Barcelona. Barcelona, Spain.

Objectives: To analyze the fulfilment of the recently-proposed classification criteria for cryoglobulinemic vasculitis in a large series of patients with primary Sjögren syndrome (pSS).

Material and method: We evaluated 311 patients diagnosed with pSS consecutively admitted to our Department between 1990 and 2011. Inclusion criteria were the fulfilment of at least 4 of the classification criteria for SSp proposed by the American-European Study Group (2002) and repeated negative HCV serology. In all patients, we retrospectively evaluated the fulfilment of the 2010 classification criteria for cryoglobulinemic vasculitis, which included as mandatory criteria at least 2 positive results in cryoglobulin determination together with the fulfilment of at least two of the following items: I) positive questionnaire symptoms; II) cryoglobulinemic organ involvement (at least 3 of the following features: constitutional, articular, vascular and neurological involvement); and III) cryoglobulinemic-related laboratory abnormalities (at least 2 of the following: low C4 levels, monoclonal band and positive rheumatoid factor).

Results: Cryoglobulins were positive in 31 (10%) patients, with a mean cryocrit level of 1.7% (range 1 to 7.2%). Only in 5 patients, sufficient cryoprecipitate was available for analysis by immunofixation (usually around 5% of cryocrit). All cryoglobulins were classified as type II mixed cryoglobulinemia (monoclonal IgM k + polyclonal IgG). Cryoglobulins were positive in at least two determinations separated by an interval of at least 12 weeks in 16 (52%) patients. With respect to the criteria, positive questionnaire (positive answer for questions 1 and 2) was reported by 11 (35%) patients, cryoglobulinemic organ involvement was present in 27 (87%) and cryoglobulinemic-related laboratory abnormalities in 25 (81%) patients. Clinically, articular involvement was found in 17 (55%) patients, vascular involvement in 15 (48%), neurological involvement in 12 (39%) and constitutional involvement in 10 (32%); the main clinical features were arthralgias in 16 (52%) patients, purpura in 11 (35%), peripheral neuropathy in 11 (35%), arthritis in 9 (29%) and fever in 8 (20%). The most frequent immunological features were positive rheumatoid factor in 23 (74%) patients, low C4 levels in 14 (45%) and monoclonal band in 9 (29%). Eleven (35%)

patients fulfilled the item I, 8 (26%) the item II and 16 (52%) the item III. Fulfilment of cryoglobulinemic classification criteria was confirmed in only 10 (32%) patients (cryoglobulins positive at least in 2 determinations together with fulfilment of at least 2 of the 3 items). Disease activity index measured with the ESSDAI showed a mean score of 9.13 for patients with negative cryoglobulins, 17.48 for those with positive cryoglobulins without cryoglobulinemic vasculitis and 30.40 for patients who fulfilled the criteria for cryoglobulinemic vasculitis ($p < 0.0001$).

Conclusions: Although the prevalence of cryoglobulinemia in a large series of patients with pSS was around 10%, fulfilment of the recently-proposed classification criteria for cryoglobulinemic vasculitis was confirmed in only 3% of pSS patients. The main reason was that more than 50% of pSS patients with cryoglobulins had only one positive determination during the follow-up, suggesting that the presence of cryoglobulins in pSS is a dynamic immunological phenomenon. Only one of each three patients with pSS and cryoglobulins fulfilled the criteria for cryoglobulinemic vasculitis; these patients had a higher disease activity measured with the ESSDAI, with a cumulative score three times greater than that found in patients without cryoglobulins.

IF-104
INFLUENCE OF SEX ON THE PREVALENCE AND SEVERITY OF MANIFESTATIONS OF BEHÇET'S DISEASE: DATA FROM SPANISH REGISTRY OF PATIENTS WITH BEHÇET'S DISEASES (REGEB)

G. Espinosa[1], M. Rodríguez Carballeira[2], F. Martínez[3], J. Larrañaga[4], J. Callejas[5], R. González[6], A. Martínez Berriotxoa[7] and the REGEB Investigators

[1]Deparment of Autoimmune Diseases. Hospital Clínic. Barcelona, Spain. [2]Department of Internal Medicine. Hospital Universitario Mutua Terrassa. Terrassa (Barcelona), Spain. [3]Department of Internal Medicine. Hospital Universitario Vall d'Hebron. Barcelona, Spain. [4]Department of Internal Medicine. Complejo Hospitalario Universitario de Vigo. Vigo (Pontevedra), Spain. [5]Department of Internal Medicine. Hospital San Cecilio. Granada, Spain. [6]Department of Internal Medicine. Hospital Virgen del Rocío. Sevilla, Spain. [7]Department of Internal Medicine. Hospital Universitario de Cruces. Bilbao (Vizcaya), Spain.

Objectives: To determine the influence of the patient's sex on the clinical manifestations of the Behçet's disease (BD).

Material and method: The demographic and clinical features of BD in 400 patients who met the proposed criteria for the classification of BD (ISBD) from 14 Spanish centres were analyzed using a computerized database. Spanish Registry of patients with Behçet's disease (REGEB) was performed under the auspices of the Working Area of BD, on behalf of Systemic Autoimmune Diseases Group (GEAS) of Spanish Society of Internal Medicine (SEMI). This registry started in 2009, with a multicenter, consecutive, retrospective design. Presenting and cumulative demographic and clinical manifestations were compared according to the sex of the patients. Categorical variables were analyzed using the chi-square test or the Fisher exact probability test, as appropriate. Continuous variables were analyzed using the Student t-test or U-Mann-Whitney. A value of $p < 0.05$ was regarded as statistically significant.

Results: The cohort consisted of 219 female patients (54.8%) and 181 male patients (45.2%) with a mean ± SD age of 28.9 ± 12.3 years. We did not find significant statistically differences in age at diagnosis (F/M 29.8 ± 12.3 years versus 28.5 ± 12.4 years; $p = 0.17$), delay in diagnosis (59.6 ± 83.3 months versus 53.0 ± 79.6 months; $p = 0.11$), and follow-up (147.7 ± 104.1 months versus 165.6 ± 112.4 months: $p = 0.48$). Regarding presenting manifestations, there was no difference between sex distributions. When cumulative manifestations were compared, mucocutaneous manifestations were more frequent in female patients (34% versus 22.6%; $p = 0.04$). Conversely, ocular involvement was more frequent in males (43.5% versus 29.3%; $p = 0.004$; OR 1.85 95%CI 1.22-2.82). In fact, male patients had increased prevalence of posterior uveitis or retinal vasculitis as presenting manifestations (24.9% versus 14.4%; $p = 0.01$; OR 1.9 (95%CI 1.17-3.23). However, visual acuity damage was similar between male and female patients. Interestingly, venous thrombosis was more frequent in males (31% versus 12%; $p < 0.001$) Regarding immunosuppressive treatments, we did not find significant difference in the use of any of them (corticosteroids, cyclophosphamide, azathioprine, cyclosporine, methotrexate or chlorambucil). Anticoagulant treatment was used more frequently in male patients ($p = 0.001$).

Conclusions: In our Registry, sex did not determine the presenting manifestations of patients with BD. During the evolution, male patients had higher prevalence of ocular involvement and venous thrombosis.

IF-105
DESCRIPTION OF CARDIAC MAGNETIC RESONANCE IMAGING IN 14 SPANISH PATIENTS WITH SYSTEMIC SCLEROSIS. PRELIMINARY RESULTS

A. Fernández Codina[1], A. Guillén del Castillo[1], C. Simeón Aznar[1], J. Pineda[2], J. Candell[3], C. Tolosa Vilella[4], V. Fonollosa Plà[1], M. Vilardell Tarrés[1]

[1]Department of Internal Medicine, Autoimmune Disease Unit, [2]Institute for Diagnostic Imaging, [3]Department of Cardiology. Hospitals Vall d'Hebron. Barcelona, Spain. [4]Department of Internal Medicine. Consorci Sanitari Parc Taulí. Sabadell (Barcelona), Spain.

Objectives: To describe the baseline characteristics of patients with Systemic Sclerosis (SSc) regarding Cardiac Involvement (CI) findings in complementary explorations and at follow up and compare them with cardiac magnetic resonance imaging (CMRI) findings.

Material and method: Fourteen patients enrolled in a 413 subject cohort were selected according to clinical suspicion or documented CI by a senior consultant dedicated to outpatients with SSc between February 2002 and November 2011. Variables collected included: Sex, kind of SSc according to Leroy and Medsger's modified criteria; immunology; capillaroscopic patron; SSc non cardiac organic involvement; CI assessed by known clinical events or complementary explorations [Ecography, Chest X-ray, electrocardiography and stress single photon emission tomography (SPECT)]. Patients underwent CMRI using a 1.5T system (Symphony, Siemens, Germany), with a 4-element phased array antenna. Functional sequences of multislice cine-MRI were obtained.

Results: Thirteen patients (92.85%) were women; 8 (57.14%) had limited SSc (lcSSc) and 6 (42.85%) had diffuse SSc (dcSSc). Immunologically, antinuclear antibodies were present in all patients, anticentromere antibodies in 4 (30.76%) patients, and antitopoisomerase-I antibodies in 5 (35.71%) patients. Capillaroscopy showed slow patron in 7 (58.33%) subjects and an active patron in 5 (41.66%) subjects. Baseline non-CI events were: Digital ulcers 10 (71.42%), osteomuscular impairment 8 (57.14%), oesophagic involvement 13 (92.85%), interstitial lung disease 10 (71.42%), pulmonary arterial hypertension 5 (35.71%) and scleroderma renal crisis 0. As cardiovascular risk factors, systemic arterial hypertension was found in 4 (28.57%) patients and 2 (14.28%) were smokers. CI found was the following: pericardial involvement 2 (14.28%), ischemic cardiopathy 3 (21.42%), conduction alterations 6 (42.85%)

and radiologic cardiomegaly 2 (15.38%). Ecocardiographic findings were: left ventricle hypertrophy (LVH) in 5 (35.71%) patients, diastolic dysfunction in 9 (64.28%) patients; mean left ventricle ejection fraction was 62.14%, with only a patient under 50% of normal LVEF value. CMRI results were the following: > 1 CMRI alteration present in 12 (85.7%) patients, LVH in 3 (21.42%) patients, left ventricle dilatation and right ventricle hypertrophy were found in one patient (7.10%), pericardial effusion was present in 8 subjects (57.14%), left ventricle dyskinesia in 2 (14.20%) and right ventricle dyskinesia in one patient (7.10%); mean LVEF was 59.85% and only one patient was under 50% of LVEF normal value; mean right ventricle ejection fraction was 56.6%, mean left and right ventricle end-diastolic volumes were 96.78 ml/m^2 and 96 ml/m^2 respectively, mean left and right ventricle end-systolic volumes were 41.84 ml/m^2 and 51.37 ml/m^2; delayed contrast enhancement was found in 5 (35.70%) patients and ischemic cardiopathy was found in 2 (14.28%). One subject was diagnosed of non-compacted myocardiopathy.

Discussion: Utility of CMRI for CI assessment in SSc has been described by some authors. The longest work at the moment is a 2010 study from Hachulla et al. describing findings in CMRI in a French cohort. We conducted the first description of CMRI in Spanish SSc patients, regarding previously known alterations in complementary explorations and clinics, related to cardiac disease. Alterations in these patients were frequent, and the test revealed to be very sensible for detecting pleural effusion. Delayed contrast enhancement was more frequent than other studies and diminished ventricle ejection fraction was milder. This study is limited by the size of the sample and might be biased by the expert-depending selection criteria instead of a randomized selection.

Conclusions: CMRI seems to correlate well with other traditional cardiologic explorations in SSc patients when combined, but it may be more sensible than these tests when comparing them separately. Pericardial effusion, delayed contrast enhancement and LVH were the most common findings. Further studies may be conducted to make clear indications of when CMRI may be indicated in SSc patients.

IF-106
INTERSTITIAL LUNG DISEASE IN SYSTEMIC SCLEROSIS: CLINICAL PRESENTATION AND EVOLUTION DIFFERENCES BETWEEN PATIENTS WITH SCL-70 ANTIBODY VERSUS PM-SCL

A. Guillén del Castillo, C. Simeón Aznar, V. Fonollosa Plà, M. Reverté Vinaixa, S. Alonso Vila, A. Fernández Codina, A. Selva O'Callaghan, M. Vilardell Tarrés

Department of Internal Medicine, Autoimmune Disease Unit. Hospital Universitari General Vall d'Hebron. Barcelona, Spain.

Objectives: To describe the characteristics of patients with Interstitial Lung Disease related to Systemic Sclerosis (ILD-SSc), with positive Scl-70 antibodies, compared to a group with positive PM-Scl antibodies.

Material and method: A prospective study was performed in 55 patients with ILD-SSc. Of them, 48 had positivity to Scl-70 (ILD-Scl-70+) and 7 were positive to PM-Scl (ILD-PM-Scl+), all diagnosed at Vall d'Hebron Hospital since April 1980 until December 2011. The following items were compared: demography, SSc subsets, fulfilling of ACR criteria for SSc, organ involvement, pulmonary function tests, nailfold capillary pattern and average follow up.

Results: There were significant differences between ILD-Scl-70+ and ILD-PM-Scl+ in the proportion of gender (women: 89.3% vs 42.8%, p < 0.001), Raynaud Phenomenon (RP) as first manifestation of disease (75.0% vs 57.1%, p < 0.001) and prevalence of articular involvement as first manifestation of disease different than RP (27.6% vs 71.4%, p < 0.001). The diffuse subset was significant greater on ILD-Scl-70 group (70.2% vs 0%, p < 0.001), as it was fulfilling of ACR criteria for SSc (97.9% vs 71.4%, p < 0.001) and mortality (38.3% vs 14.3%, p: 0.02). There were no differences in age of onset of SSc (41.6 yr vs 43.2 yr) and age at diagnosis of ILD-SSc (51.5 yr vs 52.7 yr). Neither there were differences in elapsed time between first SSc manifestation and ILD diagnosis (9.2 yr vs 9.4 yr) nor in follow up time (11.0 yr vs 16.0 yr). Organ involvement: No differences were described on cardiac involvement (87.2% vs 85.7%). However, differences were found in the presence of Digital Ulcers (DU) (68.1% vs 57.1%, p:0.01), musculoskeletal involvement (91.5% vs 85.7%, p < 0.001), inflammatory myopathy (6.4% vs 57.1%, p < 0.001), gastrointestinal (GI) involvement (97.9% vs 85.7%, p < 0.001), pulmonary arterial hypertension (PAH) (34% vs 28.6%, p: 0.01) and scleroderma renal crisis (SRC) (8.5% vs 0%, p < 0.001) in both ILD-Scl-70+ and ILD-PM-Scl+ groups, respectively. Pulmonary function test (PFT) and CT findings: There were no differences detected at starting FVC% (70.54 ± 20.65 vs 80.58 ± 11.68), starting FEV1% (76.55 ± 21.86 vs 88.94 ± 9.20), last FVC% (58.11 ± 20.72 vs 72.58 ± 15.6), last FEV1% (65.04 ± 21.39 vs 82.93 ± 18.27) nor at last DLCO/VA% (60.42 ± 18.07 vs 63.26 ± 14.52). Nevertheless differences in starting DLCO/VA% between both groups (70.89 ± 23.16 vs 89.11 ± 7.03, p: 0.04) were identified. Respecting CT findings, the ground glass opacities pattern was found to be different in both groups (61.7% vs 100%, p: 0.02). Capillaroscopy: slow pattern was the most prevalent in both groups with differences between them (66.6% vs 85.7%, p: < 0.001).

Discussion: Results in our study have shown similar outcomes to the ones previously published, which highlights that ILD-SSc has a different behavior depending on the immunologic profile. In it, we have found that PM-Scl + is related to male gender, more joint involvement, limited or sine subsets, less mortality, more inflammatory myopathy, has better starting DLCO/VA%, and more slow pattern in capillaroscopy. On the other hand, Scl 70+ predominates in female gender, presenting patients more RP as first manifestation of disease, more fulfilling of ARA criteria, DU, musculoskeletal involvement, GI involvement, PAH and more SRC.

Conclusions: We describe a cohort of 55 patients with ILD-SSc, associated to two different types of autoantibodies, either Scl-70 or PM-Scl, over a period of 30 years. As a conclusion we can say that clinical and spirometric features as well as mortality are different in both groups depending on their immunologic profile.

IF-107
POST-PARTUM EOSINOPHILIC ENTERITIS (EE): DESCRIPTION OF A NEW FORM OF PRESENTATION TRIGGERED AFTER CHILDBIRTH

J. Millastre[1], A. Cecilio[2], E. Sánchez[3], E. Bajador[1]

[1]Department of Gastroenterology. Hospital Universitario Miguel Servet. Zaragoza, Spain. [2]Department of Internal Medicine. Hospital García Orcoyen. Estella (Navarra), Spain. [3]Department of Gastroenterology. Complejo Hospitalario de Soria. Soria, Spain.

Objectives: Eosinophilic gastroenteritis (EG) is a rare condition, characterized by recurrent eosinophilic infiltration of gastrointestinal tissue, and eosinophilic ascites (EA) is the most uncommon manifestation. Etiology and pathogenesis are still unclear and its appearance during the postpartum period is a very exceptional situation, that allows hypothesize that pregnancy and childbirth can act as triggers. Objectives: describe a new clinical picture of EE triggered in the postpartum period in terms of epidemiology, diagnosis, symptoms, radiology, pathological and laboratory findings, recurrence, treatment and prognosis.

Material and method: In relation to a case of eosinophilic ascites during the postpartum period in a patient admitted in our center, we performed a scientific literature review based on a PubMed search, using the Medline subheadings and key words "Eosinophilic

Enteritis", "Eosinophilic Gastroenteritis", "Eosinophilic Ascites", "Pregnancy", "Post Partum", "Delivery", "Childbirth" and "Labor".

Results: In addition to our case, we found three reports about this topic. Epidemiology: Women were aged between 20 and 36 years old. Except one of them with history of asthma, they were healthy women. Two of them were taking PPI and oral iron, but neither of which has been previously implicated in EE. Onset of diagnosis: One of them developed symptoms after first pregnancy. One of them developed same symptoms after first and second pregnancy. Other 2 women were diagnosed after second and fourth pregnancies respectively, but both of them reported mild gastrointestinal symptoms after previous pregnancies. Symptoms appeared during the second, fourth and tenth weeks postpartum. Symptoms: All of them reported abdominal pain, nausea, vomiting and diarrhea. One woman mentioned progressive dysphagia, being diagnosed of eosinophilic esophagitis. Two of them reported abdominal distension with ascites. All of them remain asymptomatic between or after pregnancies. Radiological findings: Besides ultrasonography findings of ascites, Computed tomography scan revealed jejunal thickening in two cases. Pathological study: In two cases with ascites, diagnostic paracentesis revealed significant eosinophilia. Only in one case, esophageal and gastrointestinal biopsies were diagnostic. Laboratory studies revealed in all cases an elevated absolute eosinophil count. Treatment and prognosis: All cases were treated with corticosteroids with complete response. Any complication was described about pregnancy, labor or neonate.

Discussion: Taking into account our patient, there are a total of four scientific papers that describe cases of women diagnosed with Post-Partum EE. One case referred a history of allergic asthma, but the other women were previously healthy and not treated with medicines or drugs that could do suspect an allergic reaction. Other possible underlying causes were ruled out such as parasitic infections, malignancy or vasculitis. Most gastrointestinal symptoms repeated in each pregnancy and women remain asymptomatic between them. In all cases except one, a firm diagnosis of EE was established based on compatible clinical, analytical and pathological criteria. All women had a satisfactory response to oral steroids in tapering.

Conclusions: Despite the limited scientific evidence about this entity due to its exceptional character, detailed analysis of the reported cases make it possible to hypoyhesize the labor as a firm trigger of puerperal eosinophilic enteritis, which can manifest in any clinical variants, with recurrence after each pregnancy, but with a satisfactory response to oral steroids and apparently without any reported risk for pregnancy, childbirth and newborn.

IF-108
PPP SYNDROME (PANCREATITIS, PANNICULITIS AND POLYARTHRITIS): REVIEW OF THE ETIOLOGY, CLINICAL PICTURE AND PROGNOSIS IN A SERIES OF 34 CASES

J. Millastre[1], M. Crespo[2], A. Mir[1], A. Cecilio[3], E. Bajador[1]

[1]Department of Gastroenterology, [2]Department of Internal Medicine. Hospital Universitario Miguel Servet. Zaragoza, Spain. [3]Department of Internal Medicine. Hospital García Orcoyen. Estella (Navarra), Spain.

Objectives: PPP syndrome (pancreatitis, paniculitis and polyarthritis) is a rare disease characterized by liquefactive necrosis of the subcutaneous fat, polyarthritis and intraosseous fat necrosis, that may constitute the first evidence of a pancreatic illness. Objectives: to delineate the clinical picture of this rare process, with particular emphasis on the etiology, clinical presentation and prognosis.

Material and method: We recruited a patient with PPP Syndrome and performed a PubMed search (PubMed database, Nat. Library of Med.) for articles published until may-2012, using the Medline subheadings and key words "pancreatitis" or "pancreatic disease," "panniculitis," "arthritis," and "intraosseous fat necrosis." Only English-, French-, and Spanish-language reports were selected for review. We included only those cases that were sufficiently detailed to be analyzed.

Results: Including our patient we found 34 cases of PPP Syndrome who meet the inclusion criteria. Twenty five of them (73.5%) were men and 9 (26.5%) were women (male-female ratio of 2.8), with a mean age at diagnosis of 52 years old (range: 10-84). Fifty percent patients were younger than 50 years old and 58.8% (20/34) had a history of alcohol abuse, past o present. The underlying pancreatic disease was acute pancreatitis in 50% (17/34) of them, chronic pancreatitis in 44.1% (15/34) and pancreatic tumor in 5.9% (2/34). Fifteen of all (44%) had a pancreatic pseudocyst, and all of them showed persistently high pancreatic enzyme levels. Surprisingly, only 38.2% had severe abdominal pain at the onset, while the rest (21/34) were not afflicted or pain was mild, making initial diagnosis of pancreatic disease difficult. The most common presentation of panniculitis was tender or painless erythematous nodules usually located at distal parts of the lower extremities (around the ankles and pretibial regions) and in 26% (9/34) progressed to abcesification with a creamy purulent-appearing oily material secretion, due to liquefaction fat necrosis. The most commonly affected joints were ankles, knees, wrists, elbows and, less commonly, the small joints of the fingers. In most patients symptoms were transient, but an evolution to chronicity was observed in a 29.4% of the cases (10/34). Characteristic radiological finding were multiple osteolytic lesions, loss of joint space and sometimes periostitis. MRI showed the best sensitivity and specificity, but was only performed in 8 patients and the lytic lesions correlated pathologically with areas of extensive intramedullar fat necrosis and trabecular bone destruction. A total of 10 (29.4%) patients died because of this process.

Discussion: To date we have found 34 cases of well referenced PPP Syndrome. The pathogenesis is still unclear, although the most widely accepted hypothesis suggests that the release of pancreatic enzymes (including lipase, amylase, trypsin, and phospholipase A) from a diseased pancreas into the systemic circulation, leads to lipolysis and secondary inflammation in several tissues, including the synovium and bone marrow. The main treatment for PPP syndrome is the control of underlying pancreatic disease and drainage or preservative surgical intervention for a pseudocyst if it is present, since there is some evidence that there may be communication between the pancreatic and the vascular stream. The prognosis is poor, about one third of patients die, so early diagnosis is essential.

Conclusions: We present the clinical features of a series of 34 patients diagnosed with PPP Syndrome, reviewing their causes, symptoms, radiological findings and development as well as discussing the most likely pathophysiological hypothesis at present.

IF-109
WORK STATUS IN PATIENTS WITH CHRONIC FATIGUE SYNDROME

J. Alegre[1], M. Faro[1], E. Ruiz[1], L. Aliste[1], A. García Quintana[2], J. Castro Marrero[1], N. Sáez[1], T. Fernández de Sevilla[1]

[1]CFS Unit. Hospital Universitari Vall de Hebron. Barcelona, Spain. [2]CFS Unit. Centre Médic Delfos, S.A. Barcelona, Spain.

Objectives: To analyze the clinical differences and the score scales for assessing fatigue in CFS patients by status of employment.

Material and method: Sectional study of consecutive cases on a population-based registry. Scope: University Hospital. Subjects: Patients diagnosed with CFS. Study period: January 2008-March 2012. Inclusion criteria. Diagnosis of CFS according to Fukuda criteria. Acceptance of participation in the study through informed consent and knowledge of the labour situation at the time of diagnosis (active and inactive). Exclusion criteria: housewives, unemployed patients and patients who do not work. Variables: socio-demographic: age, sex, employment status. Clinics: fatigue characteristics (age onset, duration, level of fatigue), presence of unrefreshing sleep, recurrent headache, cognitive symptoms, neurological symptoms, autonomic dysfunction. Questionnaires: the impact of fatigue, fatigue strength, quality of life SF-36.

Results: We included in total 1,124 CFS patients of which 293 subjects (26%) were active. The rate and severity of both cognitive and neurological symptoms as well as autonomic dysfunction were higher in inactive patients ($p < 0.05$). The age of onset of fatigue and pain was back in inactive patients ($p < 0.05$). The intensity of fatigue was higher in inactive patients ($p < 0.05$). Inactive patients scored higher on the scale of impact of fatigue (globally and in the subscripts physical, cognitive and psychosocial) and the intensity scale fatigue ($p < 0.05$). In the questionnaire of quality of life scores were lower in inactive patients ($p < 0.05$).

Discussion: The symptomatology of CFS makes a major limitation in the activities of both physical and intellectual dominance, which will determine the activities of working life and also the personal and social life.

Conclusions: There is a very high percentage of disabled labour in patients with CFS. Patients who were in employment status of inactivity had increased neurological symptoms and higher scores on the impact of fatigue and reduced quality of life. Mutua Madrileña Scholarship, 2007.

IF-110
CHRONIC FATIGUE SYNDROME IN MEN

E. Ruiz, J. Alegre, L. Aliste, A. Blázquez, J. Castro Marrero, T. Fernández de Sevilla, A. Marquino, N. Sáez

CFS Unit. Hospital Universitari Vall de Hebron. Barcelona, Spain.

Objectives: To evaluate the clinical characteristics in men with CFS and make a comparative study against women.

Material and method: A total of 1309 CFS patients (119 men and 1190 women) were diagnosed upon Fukuda criteria in the CFS Unit, Hospital Valle d'Hebron (Barcelona, Spain). Both sexes are evaluated to personal characteristics, clinical blocks grouped by symptomatic co-morbidities and the scores on the questionnaires of fatigue, pain, quality of life and cognitive dysfunction. We performed a comparative study between the men versus females for all clinical variables. Differences were considered significant at p-value < 0.05.

Results: The mean age of 43 years in men CFS and the onset of symptoms of 34 years, both ages being significantly lower than in women (48 and 37, respectively). 30% of the women are single (15%) and 32% have a skilled labor (20%). 18% of men with CFS have a history of chronic pain compared to 28% in women. The most common trigger is the infectious in men (27% vs 13% in women, in which the most common is a stressful life event). Widespread pain (78% men - women 91%), muscle contractures (83% men, women 90%), and myofascial syndrome (57% men - women 76%) are less common in men ($p < 0.001$, 0.034 and < 0.001, respectively). Dizziness and sexual dysfunction are the only changes that show gender differences, being less common in men. The immune symptomatology is less common in men than in women: Raynaud's phenomenon (78% in men vs 91% in women), morning stiffness (76% in men vs 84% in women), migratory arthralgias (79% in men vs 86% in women), drug allergy (16% in men vs 25% in women), allergy to metals (7% in men vs 17% in women), facial edema (2.5% in men vs 8% in women), candidiasis (12% in men vs 72% in women). In the pathology of sleep, nightmares and insomnia are less common in men. Fibromyalgia is less common in women than men (29% vs 58%, $p < 0.001$). The physical function subscale of the scale of impact of FMG is more affected in men. Lowest score was observed in men, in somatization. Sensory and affective dimensions of pain are lower in men.

Discussion: The SFC is exceptional in man. It is characterized by a minor impact of pain and quality of life.

Conclusions: 1. In our series of patients with CFS, 9% are male (% lower than in previous studies because it speaks of an allocation of up to 25%). 2. Based on our results, the "profile" of CFS men to men is the young, single, with a specialized job and an infectious trigger. Have less muscle and immunological symptoms that CFS men and a lower association of fibromyalgia. Mutua Madrileña Scholarship, 2007.

IF-111
QUALITY OF LIFE IN PATIENTS DIAGNOSED WITH CHRONIC FATIGUE SYNDROME

J. Alegre[1], E. Ruiz[1], L. Aliste[1], A. Blázquez[1], A. García Quintana[2], J. Castro Marrero[1], M. Rodrigo[1], T. Fernández de Sevilla

[1]CFS Unit. Hospital Universitari Vall d'Hebron. Barcelona, Spain.
[2]CFS Unit. Centre Mèdic Delfos, S.A. Barcelona, Spain.

Objectives: The aim of study is to determine the alteration of the quality of life in CFS patients and the factors associated with it.

Material and method: Prospectively included patients who met diagnostic criteria for the diagnosis of Fukuda CFS. All patients were evaluated quality of life questionnaire through the Karnofsky performance status (KF) and the SF-36 with eight decatipes specific and general health both physically and mentally. Symptoms of fatigue were measured using the fatigue impact scale (EIF) in versions 40 and 8 items and the scale of intensity. Anxious and depressive symptomatology was assessed with the scale of hospital anxiety-depression (HAD) and pain through the McGill questionnaire, with its social and sensory. To study the association between quality of life with fatigue, anxiety, depression and sleep dysfunction, we used the Spearman correlation coefficient.

Results: In total were 1,309 CFS patients (119 males and 1,190 females), mean age 47 years. The age of onset of fatigue was 37 years and the duration of fatigue was 104 months. Mean scores on the dimensions of the SF-36 were: physical function 32, 4.7 physical role, bodily pain, 20, 23.1 general health, vitality, 14.6, 32.1 social function, role emotional, 41.4, health Mental 42.9, overall physical health and overall mental health 25.7 34.1. The mean scores were 63.9 KF. The mean scores of the scales of impact of fatigue: EIF overall score, 129 cognitive PIT 32, PIT 35.3 physical, social EIF EIF-8 62.3 and 25. The mean scores 10.8 HAD anxiety, HAD depression 10.8. And mean scores on the sensory and affective dimensions were respectively 18.4 and 7.1. A good correlation was found with negative character of fatigue, anxiety-depression and the dimensions of pain and quality of life.

Discussion: In the assessment of CFS, it is important to assess the deteriorating quality of life through the health questionnaire SF-36.

Conclusions: In CFS, there is a significant change in the quality life through health questionnaire SF-36 and that will come conditioned by the levels of fatigue, anxiety, depression and dimensions of pain. Mutua Madrileña Scholarship, 2007.

IF-112
IMPACT OF FIBROMYALGIA IN PATIENTS WITH CHRONIC FATIGUE SYNDROME

J. Alegre[1], M. Faro[1], E. Ruiz[1], L. Aliste[1], A. García Quintana[2], J. Castro Marrero[1], A. Collado[3], T. Fernández de Sevilla[1]

[1]CFS Unit. Hospital Universitari General Vall d'Hebron. Barcelona, Spain. [2]CFS Unit. Centre Médic Delfos, S.A. Barcelona, Spain. [3]Fibromyalgia Unit. Centre Sociosanitari Hospital Clínic i Provincial. Barcelona, Spain.

Objectives: Assess whether there are differences in the clinical assessment of fatigue in CFS patients associated to fibromyalgia (FM).

Material and method: Sectional study of consecutive cases on a population-based registry. Scope: University Hospital and Private Medicine Centre. Subjects: Patients diagnosed with CFS. Study period: January 2008-March 2012. Inclusion criteria. Patients diagnosed with CFS according to Fukuda. Variables: socio-demographic – age, sex, clinics-FM comorbility, fatigue characteristics, presence of unrefreshing sleep, recurrent headache, cognitive and neurological symptoms and autonomic dysfunction. Questionnaires: the impact of fatigue, fatigue strength, quality of life-SF-36, FM diagnosis according to the ACR criteria 1990.

Results: We included in total 1309 patients, which 1185 were women (mean age: 47.4 ± years). In 727 CFS patients (55.7%) were associated with FM. The onset of fatigue and pain was back in FM patients ($p < 0.05$). The level of fatigue is greater in patients with FM ($p < 0.05$). Patients with CFS and FM have a higher incidence of recurrent headache, restless leg syndrome, nightmares and sleep paralysis ($p < 0.05$). The percentage of patients and the severity of both cognitive and neurological symptoms, as well as autonomic dysfunction is greater in patients with FM associated ($p < 0.05$). FM patients scored higher on the scale of impact of fatigue ($p < 0.05$) and had worse results in the quality of life questionnaire ($p < 0.05$) in all except decapitates rating scale that evaluates the physical role.

Discussion: In the study with CFS patients, it is important to assessment of comorbid phenomena, such as FM, which determined a greater functional impairment and quality of life of these patients.

Conclusions: FM comorbility worden clinical parameters, fatigue and perceived quality of life in patients with CFS. Mutua Madrileña Scholarship, 2007.

IF-113
COMORBID CONDITIONS IN A LARGE POPULATION OF CHRONIC FATIGUE SYNDROME PATIENTS IN SPAIN

J. Alegre, E. Ruiz, J. Castro Marrero, L. Aliste, A. Blázquez, N. Sáez, A. Marquino, T. Fernández de Sevilla

CFS Unit. Hospital Universitari General Vall d'Hebron. Barcelona, Spain.

Objectives: The aim of the study is to evaluate the comorbid phenomena associated in a large population of CFS patients.

Material and method: Prospectively study included patients who met the Fukuda criteria for the diagnosis of CFS. We study the various comorbid phenomena associated according to diagnostic criteria such as fibromyalgia, according to the diagnostic criteria of American College of Rheumatology 1990.

Results: In total of 1309 CFS patients (119 males and 1190 females), mean age 47 years, time at onset of fatigue symptoms was 37 years and the time of duration of fatigue was 104 months. It was found restless legs syndrome in 35.5%, sleep paralysis syndrome in 16.3% and sleep apnea syndrome in 30.3% of all studied subjects. Fibromyalgia was associated in 55.7%, regional myofascial syndrome in 65.3%, 80.9% had dry syndrome, 53% had degenerative spinal disease, 50% had tendinitis, dyslipidemia was present in 40% of cases, multiple chemical sensitivity in 24.3%, anxiety disorder in 70%, hypermobility in 30%, 5% had endometriosis and thyroid disorders hypothyroidism, hyperthyroidism and thyroid cysts in 16%. All CFS patients had two comorbid phenomena in 31% of cases, 3 comorbid phenomena in 35% of cases and more than 4 comorbid phenomena in 14% of cases.

Discussion: Comorbid phenomena such as fibromyalgia, dry syndrome and multiple chemical sensitivities should be measured and quantified in the studies with CFS patients.

Conclusions: Patients diagnosed with CFS, with the great range symptomatic muscular, cognitive, autonomic and immune systems, have a large number of phenomena that are important comorbid valuation, such as fibromyalgia, dry syndrome, metabolic syndrome and multiple chemical sensitivity. Mutua Madrileña Scholarship, 2007.

IF-114
THE IMPACT OF FATIGUE AND FIBROMYALGIA ON SEXUAL DYSFUNCTION IN WOMEN WITH CHRONIC FATIGUE SYNDROME

A. Blázquez[1], J. Alegre[1], E. Ruiz[1], L. Aliste[1], A. García Quintana[2], J. Castro Marrero[1], N. Sáez[1], T. Fernández de Sevilla[1]

[1]CFS Unit. Hospital Universitari Vall d'Hebron. Barcelona, Spain. [2]CFS Unit. Centre Médic Delfos, S.A. Barcelona, Spain.

Objectives: To evaluate sexual dysfunction in women with CFS and explore correlations with fatigue, cognitive and neurological symptoms as well as neurovegetative syndromes, and concomitant fibromyalgia, Sjögren's syndrome, and myofascial pain syndrome.

Material and method: Six-hundred-and-fifteen women diagnosed with CFS were consecutively recruited in a specialized unit. We collected socio-demographic data, performed a thorough clinical history, and analyzed type and degree of sexual dysfunction using the Golombok Rust Inventory of Sexual Satisfaction (GRISS) and impact of fatigue by Fatigue Impact Scale (FIS).

Results: Patients with more intense fatigue, a higher number of cognitive, neurological, and neurovegetative symptoms, and concomitant fibromyalgia, Sjögren's syndrome, or myofascial pain syndrome reported less frequency, satisfaction, and sensuality in their sexual relations and more avoidance, vaginismus, and anorgasmia. The differences in all cases were statistically different ($p < 0.05$). Those with concomitant fibromyalgia or Sjögren's syndrome reported less sexual satisfaction and sensuality and more vaginismus and anorgasmia. Sjögren's syndrome and myofascial pain syndrome both correlated strongly with avoidance ($p < 0.001$).

Discussion: In the study with CFS patients, it is important to assessment of comorbid phenomena, such as FM, which determined a greater functional impairment and quality of life of these patients.

Conclusions: Sexual dysfunction is greater in CFS patients with a higher number of cognitive, neurological, and neurovegetative symptoms, concomitant fibromyalgia, Sjögren's syndrome, or myofascial pain syndrome, and more intense fatigue. Further studies are needed to analyze how both physical and psychosocial factors determine the impact the sex lives of CFS patients and their partners.

IF-115
ALEXITHYMIA INFLUENCE ON FATIGUE PERCEPTION IN CHRONIC FATIGUE SYNDROME

J. Alegre[1], N. Sáez Francàs[2], N. Calvo[2], S. Valero[2], E. Ruiz[1], M. López[2], B. Olivares[2], M. Casas[2]

[1]CFS Unit, [2]Department of Psychiatry. Hospital Universitari General Vall d'Hebron. Barcelona, Spain.

Objectives: To evaluate the influence of alexithymia on CFS severity in a sample of adult CFS patients.

Material and method: The sample consisted of 102 patients. All the patients (age 46.9 ± 9.2; 94.1% women) received CFS diagnoses according to Fukuda criteria. Alexithymia was assessed with the Toronto Alexithymia Scale (TAS). Additionally, the patients completed the FIS-40, the HAD and the STAI-Anxiety state and trait scales to assess the fatigue, depression and anxiety severity.

Results: 43 CFS patients (42.2%) fulfilled criteria for alexithymia and the TAS mean score was 56.8 ± 12.7. When comparing alexithymic with non-alexithymic patients, the alexithymic ones reported more fatigue (FIS-40) (138.1 ± 17.2 vs 126.1 ± 21.3; p = 0.003), anxiety (STAI-State) (38.8 ± 13.7 vs 28.5 ± 14.3; p = 0.001), and depression (HAD-Depression) (13.0 ± 3.9 vs 10.0 ± 5.1; p = 0.002). TAS was related with fatigue severity in the linear regression analysis (b = 0.62, SE = 0.15, p < 0.001).

Discussion: CFS is important to assess the psychopathological phenomena such as alexithymia which has been little studied to date.

Conclusions: Alexithymia presence may be a negative prognosis factor in CFS patients and it should be considered in its treatment.

AUTOLOGOUS STEM CELL TRANSPLANTATION FOR SEVERE REFRACTORY SYSTEMIC LUPUS ERYTHEMATOSUS WITH LUPUS NEPHRITIS: REMOTE OUTCOMES

A. Demin[1], V. Kozlov[2], I. Lisukov[2], O. Kotova[1], A. Sizikov[2], V. Sergeevicheva[2], L. Demina[3]

[1]Department of Internal Medicine and SLE Centre. Novosibirsk State Medical University. Novosibirsk, Russia. [2]Department of Autoimmune Diseases. Clinical Immunology Institute of Russian Medical Sciences Academy. Novosibirsk, Russia. [3]Department of Nephrology. Nephrology and Dialysis City Centre. Novosibirsk, Russia.

Objectives: Systemic lupus erythematosus (SLE) is a multisystem disease characterized by abnormal production of autoantibodies and tissue deposition of immune complexes leading to a diverse array of clinical manifestations, particularly renal disease. A new approach to the treatment of SLE with lupus nephritis refractory to conventional immunosuppression with high risk of early death, is re-setting of the immune system and induced self-tolerance by high-dose immunosuppressive therapy (HDIST) with autologous stem cell transplantation (ASCT). The remote outcomes assessment was the aim of this study.

Material and method: Ten patients with severe treatment-refractory SLE with nephritis observed. All patients, who underwent high-dose immunosuppression and ASCT, were registered in the European Group for Blood and Marrow Transplantation (EBMT)/ European League Against Rheumatism (EULAR) database between 2001 and 2008. Previous immunosuppression included: pulse cyclophosphamide intravenous in all patients, azathioprine in 11, methotrexate in 4, cyclosporin A in 9, oral prednisolone 1 mg/kg/day and pulse methylprednisolone intravenous in all patients. Autologous stem cells were collected from the bone marrow (n = 4) or mobilized from peripheral blood with cyclophosphamide and granulocyte colony-stimulating factor (n = 11). Pre-transplant conditioning regimens included cyclophosphamide (n = 11), BEAM (n = 2), melphalan 140 mg/m^2 with etoposide 1,600 mg/m^2 (n = 2), antithimocyte globulin. All patients followed a standardized supportive care protocol. All patients were women aged from 18 to 36 years. Five patients had lupus nephritis class IV and 5 patients – class III (ISN/RPS criteria, 2003). Stem cells were collected from bone marrow in 1 and from peripheral blood in 9 patients. The short-term outcomes were assessed after 1 month. The long-term outcomes were assessed every 6 months after ASCT. Overall 5-years survival was analyzed using the Kaplan-Meier method.

Results: The short-term outcomes: in 6 patients (60%) partial remission, in 1 patients (10%) complete remission, in 1 patient 10%) disease activity decrease was achieved. Transplant-related mortality was 20% due to infection complications. Patient's scores on the SLEDAI, anti-ds DNA antibody level, ESR, proteinuria, creatinine clearance were significantly improved. The remote outcomes: in 6 patients (60%) partial remission, in 1 patient (10%) complete remission, in 1 patient (10%) disease progression was seen, the median follow up was 39.6 ± 6.9 month. The effect remained in the long-term period. The overall 5-years survival was 78%. All patients were independent of dialysis. Adverse events in short-term period: viremia and bacteremia with sepsis caused death in 2 patients, neutropenia – in 9, thrombocytopenia – in 5, enteropathy – in 1, mucositis – in 1, local bacterial infection – in 1 patient. Causes of deaths were in one patient CMV infection, in one patient bacterial sepsis. The deaths occurred on days +11 and +63. Adverse events in long-term period: moderate cytopenia – in 1 patient, herpes simplex – in 1, hyperuricemy – in 3, interstitial nephritis – in 2, in 1 patient secondary malignancy (renal cancer) developed.

Discussion: These results are in concordance with ongoing European experience: 5-year overall survival after ASCT is now 81% (2012). The control of clinical lupus activity was reflected by the relative falls of anti-dsDNA, normalization of complement levels and the possibility to reduce or withdraw corticosteroids in some patients.

Conclusions: The remote outcomes of severe treatment-refractory SLE with lupus nephritis by HDIST and ASCT were more effective than conventional therapy to achieve disease control.

IF-117
HOW DO WE DIAGNOSE AND TREAT LUPUS RENAL DISEASE?

L. Horrillo[1], C. Tojo[1], I. Navas[1], L. Lozano[2], A. Castro[1], M. Fernández[1], A. Zapatero[1], V. García de Viedma[1]

[1]Department of Internal Medicine, [2]Department of Nephrology. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: Lupus nephritis affects more than half of patients with lupus erythematosus. Their presence has a great influence on the prognosis of these patients, increasing morbidity and mortality, largely because of the risk of chronic kidney disease requiring replacement therapy in just about 25% of cases. Objectives: to describe the clinical, analytical and therapeutic management of patients with Lupus Nephritis followed at Hospital Universitario de Fuenlabrada (HUFLR), both newly diagnosed and those diagnosed earlier, since its opening.

Material and method: Descriptive study of cases of Lupus Nephritis monitoring in Nephrology and Internal Medicine HUFLR services in the period between June 2004 and April 2012. Classic clinical and laboratory variables were statistically analysed.

Results: We followed 27 cases of Lupus Nephritis during this period, of which 81.5% are women. The age ranges from 17 to 64 years (X = 41). 55% (15 patients) were already diagnosed when they started monitoring in this hospital. The time from diagnosis varies from 1 to 37 years (X = 10). Proteinuria, edema and impaired renal

function were the most common reasons for consulting prior to diagnosis. The most common type is diffuse lupus nephritis (37%), followed by focal (14.8%), mesangial (11.1%) and membranous (11.1%). 7 patients (25%) have not been biopsied. 51.9% of patients are hypertensive, 5 had previous renal disease (2 nephrosclerosis, 2 preeclampsia and 1 renal carcinoma) and 9 (33.3%) have other autoimmune disease apart from lupus. 4 patients have antiphospholipid syndrome. 73% of patients have had sediment alterations during follow-up, 46% have leukocytes and over 50% hematuria. 77% of patients have had proteinuria, most of them (75%) in non-nephrotic range. 24% had positive antiDNA antibodies and in up to 64% hypocomplementemia has been objectified. Regarding induction therapy, most patients in which treatment is known, steroids and cyclophosphamide were the main choice. Remission after this treatment was achieved in 50% (in 30% failed remission and 20% unknown). Maintenance therapy is most often used together with mycophenolate mofetil and low dose steroids. Other treatments used were azathioprine, cyclosporine, and hydroxychloroquine. 70% of patients received osteoporosis prophylaxis. Only 5 patients (28.5%) developed new outbreaks during this period of treatment. 3 patients have required renal replacement therapy. None of the patients have died, although one patient was lost to follow-up.

Conclusions: The most common histological type is diffuse lupus nephritis. Proteinuria is the analytical alteration most frequently observed in our patients. There were a high percentage of hypertensive patients, whose control is a priority to avoid worsening prognosis. Our initial remission rate was low. However, only a few patients had relapses, and renal replacement therapy has been required in only 3 of them. Due to the short follow-up period, is not possible to us to exclude that in future the prevalence of outbreaks or osteoporotic complications will be greater than today.

IF-118
SPECIFIC FITNESS PROFILE TO EFFORT IN CHRONIC FATIGUE SYNDROME

A. Suárez[1], J. Segovia[2], J. Silvarrey[2], J. Alegre[1], J. García Quintana[1], N. Fagoaga[1], A. García Quintana[1]

[1]CFS Unit. Centre Médic Delfos, S.A. Barcelona, Spain. [2]Medical Sport Unit. School of Medicine. Complutense University. Madrid, Spain.

Objectives: This study assessed cardioventilatory adaptation, metabolic and hormonal among a group of patients with CFS and a control group using incremental exercise test repeated for 3 consecutive days (EEP).

Material and method: The sample comprised 75 patients with CFS (age 44.6 ± 7.5 years) and with (BMI 26.1 ± 4.6), and 50 sedentary control subjects (age 40.6 ± 10.7 years) and a (BMI of 25.6 ± 4.9). Both groups have performed an initial maximal exercise test and then after a week difference, we performed a specific test with supramaximal workloads for three consecutive days are adjusted parameters: cardioventilatories (oxygen consumption (VO_2), CO_2 production (VCO_2), FE final fraction of CO_2 ($FECO_2$) FeO_2 final fraction (FeO_2), equivalent respiratory O_2 (ERO_2), respiratory CO_2 equivalent ($ERCO_2$) and True O_2). Growth hormone (GH), cortisol, prolactin and ACTH were done. Biochemical analysis included glucose, uric acid, CPK and free fatty acids.

Results: The results obtained PEE with statistically significant differences in the values of VE, QR, FR, VO_2, $FECO_2$, VCO_2, O_2 True are significantly higher in the control group with no differences between days ($F = 17.48$; $p < 0.001$). Regarding FeO_2 values, the figures are significantly higher in the group of patients during the loading phase ($F = 14.3$; $p < 0.001$) with no differences between days. As for the parameters reflecting the ventilatory economy ($ERCO_2$ ERO_2) showed statistically significant differences higher values in the group of patients for the loads ($F = 7.75$; $p < 0.001$) with no differences between days. Regarding hormonal parameters observed with a statistically significant difference in the postexercise hypocortisolism in the control group with no differences between study days (($F = 6.18$ $p < 0.001$). As for the GH differences were not statistically significant although a clear trend towards lower values in the post-exercise in the group of patients with CFS.

Discussion: In CFS is very important to quantify the intolerance to physical exercise with ergometric parameters and biochemical testing.

Conclusions: Patients with CFS exhibit differences in adaptation to physical exercise from the point of view cardioventilatory and hormonal, showing a less economical ventilation and respiratory equivalents superficial FeO_2 higher and higher in the group of patients having a lower O_2 TRUE, reflecting a possible alteration of the alveolar-capillary exchange, or even a mitochondrial alteration to the cellular level. The hypocortisolism observed the group of patients after the stimulus of exercise may explain why these patients do not adapt adequately to stress.

IF-119
SARCOIDOSIS AND TUBERCULOSIS: TWO FORMS OF A SAME ENTITY?

M. Balaguer, P. Porcar, J. Rascón, E. García Almodóvar, L. Martín, E. Esteban, L. Pallarés

Department of Systemic Autoimmune Diseases. Department of Internal Medicine. Complejo Asistencial Son Dureta. Palma de Mallorca (Illes Balears), Spain.

Objectives: Sarcoidosis and tuberculosis are two granulomatous entities that sometimes appear together in the same patient. This represents a diagnostic challenge and raises questions about their pathogenesis. We present two cases of sarcoidosis with subsequent development of tuberculosis. The objective is to discuss the association between these two entities.

Material and method: We describe two patients with demonstrated tuberculosis that were extracted from a group of 17 patients with sarcoidosis, followed up in a Systemic Autoimmune Diseases Unit in a tertiary Hospital.

Results: Case 1: Female 43 years, with pulmonary sarcoidosis histologically diagnosed, treated initially with corticosteroids (CS) and azathioprine, which was stopped for a year. 2 years later she developed fever and pulmonary infiltrates with poor response to antibiotic treatment. A bronchoscopy showed the presence of mycobacteria. Case 2: Male 76 years, with hemoptysis and dyspnea, negative microbiological tests and a CT scan showing areas of increased density in ground glass pattern. Poor response to antibiotic therapy. Bronchoscopy gave no results. High titers of angiotensin converting enzyme (ACE) detected. Sarcoidosis is suspected and CS was administered with good response. Some months later he developed fever, dysarthria and left hemiparesis. CSF analysis and MRI images were compatible with neurosarcoidosis. CS and mycophenolate was started with good initial response, but later on he suffered progressive neurological deterioration. Mycobacteria in CSF were detected.

Discussion: Although both entities share the development of granulomas, the presence of caseum and mycobacteria is pathognomonic of tuberculosis. However, some studies have also identified presence of Mycobacterium tuberculosis genome by PCR in sarcoid granulomas. The diagnosis of tuberculosis in a patient with previous diagnosis of sarcoidosis generates doubt about a secondary infection due to immunosuppression or just a primary tuberculosis from the beginning. The dilemma we propose is: are these two entities coincident in time or are they the same granulomatous disease caused by mycobacteria but with different forms of expression, depending on the host immune response?

IF-120
EPIDEMIOLOGY OF CRYPTOGENIC ORGANISING PNEUMONIA IN THE REGION OF OSONA, CATALUNYA (2000-2011)

C. Azuaje Tovar[1], C. Loste Andreu[1], X. Pla Salas[1], G. Lucchetti[1], P. Roura Poch[2], J. Brugés Terradellas[1]

[1]Department of Internal Medicine, [2]Department of Epidemiology. Consorci Hospitalari de Vic. Vic (Barcelona), Spain.

Objectives: The classification of idiopathic interstitial pneumonias has gained widespread acceptance. Cryptogenic Organising Pneumonia (COP) is one of several subtypes and represents what has also been called idiopathic bronchiolitis obliterans organising pneumonia. COP is a relatively rare disease, which is characterized for steroid responsiveness. For COP diagnosis is fundamental to rule out secondary causes of Organizing Pneumonia (SOP), like drugs, infections, malignancy, radiotherapy and autoimmune disorders. No recent studies in Catalonia that value the epidemiology, diagnosis and outcome. To determine the incidence, epidemiological features of COP and to characterize their clinical, radiology, diagnosis features. To describe outcome.

Material and method: A retrospective and descriptive study of COP in Consorci Hospitalari de Vic the region of Osona between 2000-2011 was conducted. Diagnose of the COP was based on clinical, radiology and histopathological criteria. The epidemiology, comorbility, clinical, radiological, bronchoalveolar lavage (BAL) features were described. Diagnostic method, biopsy samples, treatment and survival were also studied. Incidence was calculated. SOP cases were recorded for epidemiological reasons, but clinical and demographic features were not described. Secondary causes of pulmonary damage like radiotherapy and infections were excluded of the study. Statistic analysis was performed by SPSS.

Results: In our review, 19 patients were included with the diagnostic of OP. 15 COP (79%) and 4 SOP (21%). The mean annual incidence of overall OP was 1.33/100,000 inhabitants/year. While the mean incidence of COP was 1.05/100,000 inhabitants/year. Of COP cases, 10 (66.7%) were men and 5 (33.3%) women. The mean age was 68.6 ± 13.3 years. Most of the patients had been smokers (53.3%). 73.3% were HTA and 33.3% were diabetic. Clinical findings were: dyspnea 73.3% and cough 73.3% were the most common symptoms, followed by constitutional syndrome 60%, malaise 46.7% and fever 33.3%. A crackle was (60%) the most common sign. BAL were observed macrophages 45.7 ± 32.9%, lymphocytosis 27.4 ± 23.8% and neutrophils 22.7 ± 27.4%. The sample of lung tissue was performed by transbronquial biopsy 14 and videothoracoscopy 1 case. Diagnosis was confirmed by biopsy in 10 patients (73.3%); and the remainder (26.6%) were diagnosed by clinical evolution, radiological findings and after ruling out other causes. Delay in diagnosis was about 3.6 months (+/- 2.7m). The main radiologic manifestation was alveolar infiltrates 80% (lower lobe 53.3% and upper/middle lobe 53.3%); ground-glass opacification (53%) and nodule pattern (26.6%). All cases were treated with corticosteriods and 13.3% received associated treatment (ciclofosfamide 1 case, azatioprine 1 case). Hospital readmission was in 53.3% of cases. Only one case (6.6%) died in relation to the COP, due to pulmonary infection in corticotherapy context. Causes of SOP were haematological malignancy 75% and drug side effect 25%.

Conclusions: The incidence of COP is higher than previously reported in Spain. The COP is more common in men than in women and in sixth decade of life. More than half of the patients had been smokers and were HTA. Dyspnea and cough were the most common symptoms. Crackle was the most common sign. All patients were biopsied and diagnosis was confirmed in most cases. Chest CT scan evidenced in most cases alveolar infiltrates. Mortality was low like has been published before. In our study causes of SOP was predominantly haematological malignancy.

IF-121
VOGT-KOYANAGI-HARADA: SERIES OF 6 CASES IN A SPECIFIC UNIT OF UVEITIS AND SYSTEMIC AUTOIMMUNE DISEASES OF A INTERNAL MEDICINE DEPARTMENT

J. Bernardo Cofiño[1], L. Trapiella Martínez[2], I. Cabezas Rodríguez[3], C. Suárez Cuervo[1], M. Mera Fidalgo[1], A. Fidalgo Navarro[1], M. Fonolla Gil[4], L. Caminal Montero[1]

[1]SAD and Uveitis Unit. Department of Internal Medicine, [3]Mineral and Bone Metabolism Unit. Department of Nephrology, [4]Department of Ophtalmology. Hospital General de Asturias. Oviedo (Asturias), Spain. [2]Department of Internal Medicine. Hospital de Cabueñes. Gijón (Asturias), Spain.

Objectives: Describing the epidemiological and clinical features and treatment management of 6 patients diagnosed of Vogt-Koyanagi-Harada syndrome monitored in a specific reference of uveitis and systemic autoimmune diseases (SAD) of a Internal Medicine Department in a tertiary hospital.

Material and method: Descriptive retrospective study of six patients diagnosed of Vogt-Koyanagi-Harada disease according to American Uveitis Society modified criteria (VKH International Workshop Group, 1999-2001) (Katsimpris et al .Klinische Monatsblaetter fuer augenheilkunde. 2011;4:368-71) followed in a specific query of SAD and Uveitis between January 2006 and June 2012.

Results: 6 patients with VKH syndrome were identified in the database of uveitis and SAD Unit, 2 women and 4 men. The mean age of presentation is 49.33 years and there were no patients from other countries. The most common manifestation of the disease is uveitis, present in all cases. All had bilateral involvement, with a severe degree of activity (80% of cases as panuveitis). 3patients had meningitis, and one had deafness. Genetic study was performed in five of six patients, being DR4 positive (2) in one case. One patient had a complete form of the disease, three incomplete VKH disease and two were diagnosed as probable Vogt-Koyanagi-Harada disease. The patient performing a complete VKH disease was the most severely affected, presenting deafness and significant decrease in visual acuity despite treatment. Corticosteroids were used in all cases between 9 and 48 months, with a median of 19 months of treatment. In all the cases an immunosuppressive agent was precised, in 3 of them as coadjuvant because of lack of response to corticosteroids. The overall response was good, with only one case showing aftermath mentioned above despite treatment. Three patients had at least two recurrences, successfully managed with corticosteroids. The most common side effects of treatment was derived from the use of steroids, appearing diabetes, Cushing, acne and cataracts as a result of prolonged use of them. In one case cyclosporine had to be suspended for high blood pressure, continuing treatment with parenteral immunoglobulines.

Conclusions: Vogt-Koyanagi-Harada syndrome is a rare entity in our environment, with an age of presentation in our series (49.33 years) higher than previously reported in other series (Yamiki et al. Int Ophthalmol Clin. 2002;1;13-23). Men may be more affected. Extraocular manifestations of the disease are less frequent. There may a selection bias since 4 over 6 patients were derived from the Ophthalmology Department. VKH is a corticosensitive entity, with a median of 19 months of treatment. Three patients required immunosupresant drugs (especially cyclosporine) due to persistence of clinic (García et al. Rev Clin Esp. 2006;8;388-91). Only 1 patient had severe sequelae in the form of blindness (secondary to papillary atrophy) and deafness. Side effects derived from treatment are not infrequent, specially derived from corticosteroid prolonged therapy. Immunosupresant drugs such as azathioprine and methotrexate were employed as corticoid-sparing agents (Bordaberry. Curr Opinion Ophthalmol. 2010;21:430-5).

IF-122
THYROID DISEASE AND SJÖGREN

O. López Berástegui, B. Pinilla Llorente, T. Blanco Moya, J. Santos, N. Aldezábal Polo, M. Gómez Antúnez, A. Muiño Míguez

Monographic Consults of Systemic Diseases. Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: Study the prevalence of Thyroid disease in patients with a previous diagnosis of Primary Sjögren in order to prove the requirement of several tests and their management outpatient.

Material and method: We studied the patients of our monographic outpatient consult clinic of systemic diseases, with a previous diagnosis of Sjögren disease. It is a retrospective and observational study. We evaluated general clinical data (symptoms, diagnosis and therapy) in patients with Sjögren and then assessed the presence of Thyroid disease by performing image and laboratory tests to all of them.

Results: We included a total of 20 patients, 85% of them were women with a mean age of 66,05 years (36-90) They all had a positive parotid scintigraphy,25% positive AntiLa and 55% positive AntiRo. Main clinical manifest were arthralgias (55%), renal dysfunction disease (10%), cryoglobulins (10%) and hematological affection (25%), as previously described in other series. We studied the presence of thyroid lesions by performing ultrasonography or Computed Tomographic (CT) scan. We performed image studies to nine of our 20 patients. 77.7% had thyroid lesions and 30% of them were multinodular goiter. Then we studied if our patients had hormonal dysfunction or had presence of thyroid antibodies. All patients had thyroid hormones measurement and 25% showed to have low levels. 17% had presence of antibodies.

Discussion: Thyroid disease and specially hypothyroidism is related with Primary Sjögren disease probably because they share a common pathogenesis mechanism. Other studies have shown the association between both disease so it must be investigated thru clinical and laboratory assessment. Our results are similar to those in other studies, with an average of 30% of thyroid affection among patients with Sjögren disease.

Conclusions: 1. Thyroid disease must be assessed in patients with Sjögren disease. 2. We recommend performing ultrasonography, thyroid hormones and antibodies to all Sjögren patients.

IF-123
VOGT-KOYANAGI-HARADA SYNDROME

M. Martín-Toledano Lucas[1], M. García Butenegro[1], A. Piqueras Martínez[1], R. Rubio Díaz[1], P. Lobato[2], S. Murcia[2], J. Bayona León[1], M. Flores Chacartegui[1]

[1]Department of Internal Medicine, [2]Department of Neurology. Complejo Hospitalario de Toledo. Toledo, Spain.

Objectives: To describe two cases of syndrome Vogt-Koyanagi-Harada diagnosed in our department in the past year.

Material and method: Review of the clinical features, diagnosis, treatment and evolution of two cases of Vogt-Koyanagi-Harada syndrome diagnosed at our center last year.

Results: Case 1: 52 year old woman with no history of clinical interest that presents loss of vision, conjunctival injection and pain with ocular movements during the last five days. It is associated with severe headaches and tinnitus. Ocular fundus findings shows edematous and hyperemic papillae, posterior uveitis with serous retinal detachment in the posterior pole. Analysis of the cerebrospinal fluid showed 138 leukocytes/mm^3 (100% lymphocytes), proteins 35 mg/dl, and a glucose level of 45 mg/dl. No micro-organisms were identified. Magnetic resonance imaging of the head without contrast showed no abnormalities. The patient was treated with methylprednisolone 1 g/day for 5 days with disappearance of the headaches and tinnitus and improvement of her visual acuity. Case 2: man of 44 years with no history of interest that consults for a 6 days history of decrease in visual acuity, retroorbital pain, fever of 38 ºC and headache. Examination revealed Tyndall R +/L + +. Ocular fundus findings shows multiple yellowish choroidal lesions with serous retinal detachment mainly in the posterior pole. Hyperemic papillae. Analysis of the cerebrospinal fluid showed 147 leucocytes/mm^3 (100% lymphocytes) erythrocytes 3/mm^3, glucose 43 mg/dl, total proteins 95 mg/dL. No micro-organisms were identified. Magnetic resonance imaging of the head without contrast showed no abnormalities. Patient was treated with 1 g/day methylprednisolone for 3 days, with remission of neurological clinic and partial remission of ocular affectation but 20 days after, he consults again for aseptic meningitis despite treatment with prednisone 80 mg/day. Subsequently he was treated with cyclosporine with disappearance of clinical symptoms. Both patients are being followed by ophthalmology.

Discussion: Vogt–Koyanagi–Harada syndrome is an idiopathic, multi-system autoimmune disorder involves T-cell-mediated autoimmunity against melanocyte-associated antigens, characterized by bilateral granulomatous uveitis with neurologic, auditory and dermatologic manifestations. It is a very rare disease, in Europe accounts for 1.5-2% of endogenous uveitis. Diagnosis criterial included: 1. Absence of previous history of ocular trauma o surgery; 2. No evidence of other ocular diseases; 3. Early bilateral ocular involvement (With focal areas of subretinal fluid or serious retinal detachment) or late bilateral ocular involvement (depigmentation, sunset glow fundus, Dalen-Fuchs nodules and migration or accumulation of the pigmented epithelium of the retina); 4-Auditory and/or neurological symptoms; 5-cutaneous symptoms that appear during or after the neurological and ocular manifestations. May be classified as complete when all criteria are met; as incomplete when criterial 1, 2 and 3 plus 4 or 5 are met, or probable when only criteria 1, 2 y 3 are met. Our patients had both criteria of incomplete syndrome probably because de earlier of the diagnosis. Infectious diseases such as syphilis, tuberculosis, toxoplasmosis, fungal infections and AIDS should be ruled out during the early phases of the disease. Early and aggressive treatment with corticosteroids and/or immunosupressive drugs is essential to avoid the morbidity and complications that this disease has the potential to cause.

Conclusions: The difficulty of diagnosing this disease is probably due to its rareness and the fact that it is relatively unknown among the medical profession. Vogt-Koyanagi-Harada syndrome should always be considered whenever a patient has symptoms involving neurological, ocular, otorhinolaryngological and cutaneous manifestations. Early and aggressive treatment is essential to avoid the morbidity and complications.

IF-124
COMMON VARIABLE IMMUNODEFICIENCY SYNDROME: ANALYSIS OF A SERIES OF 48 ADULTS PATIENTS IN AN INTERNAL MEDICINE SERVICE

P. Romero Gallego-Acho, E. Rodríguez Castellanos, J. Guilloth Alfaro, V. Hontañón Antoñana, R. Mayayo Alvira, A. Robles Marhuenda, A. Gil Aguado

Department of Internal Medicine. Hospital Universitario La Paz. Madrid, Spain.

Objectives: To analyze a series of 48 cases of common variable immunodeficiency syndrome in frequency and type of infection and its association with autoimmune diseases, neoplastic, among others.

Material and method: We analyzed 48 patients over 18 years, diagnosed with common variable immunodeficiency, by the WHO

classification, followed by the service of Internal Medicine and Immunology from 1984 to 2011.

Results: We included 48 patients, 24 males and 24 females. 30 of the 48 patients were diagnosed before the third decade of life. 100% of patients had some type of significant infection, respiratory focus being the most common, present in 46 of the 48 patients, followed by abdominal infection, present in 39 of our patients. 5 had some type of CNS infection and 17 patients infection of skin and soft tissue. Showed only 17% of infections with sepsis. In addition, we observed that 20 patients had associated autoimmune disease (8 autoimmune hemolytic anemia, 3 SLE, 4 and 6 vitiligo patients other autoimmune diseases). 6 of the 48 individuals developed various types of neoplasms. There was residual respiratory disease (bronchiectasis, pulmonary fibrosis, respiratory failure) in 40 patients, GI (malabsorption, maldigestion, lymphoid nodular hyperplasia) in 12 and liver 20. 94% of the patients received iv gammaglobulin, having side effects 17 of the 48 patients. 10 patients died, with a mean age at death of 41 years The cause of death was infectious in 5 (sepsis, pneumonia), tumor in 2, chronic liver disease in 1, another due to uncertain causes and 1 patient of unknown cause.

Discussion: Common variable immunodeficiency is a primary immunodeficiency that constitutes a major deficiency syndromes antibodies. The most important feature is the presence of hypogammaglobulinemia, especially at the expense of IgG. These patients have a high susceptibility to infections and is sometimes associated with autoimmune diseases and neoplastic diseases. The treatment of choice is the use of iv immunoglobulin and, although despite this treatment is not curative, their application along with an early diagnosis have improved survival and quality of life for these patients.

Conclusions: All of our patients had infections, particularly due to respiratory infections, followed by abdominal and cutaneous focus. In addition, we observed the association with autoimmune diseases, including SLE and autoimmune hemolytic anemia and neoplastic, as described in the literature. Treatment with gammaglobulin was chosen over 90% of patients. The cause of death in 50% due to infectious diseases.

IF-125
ECHOCARDIOGRAPHIC FINDINGS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

A. Aljibe Aguilar[1], R. González Mazario[1], P. Flors Villaverde[1], L. Mico Giner[1], A. Osa Sáez[2], J. Calabuig Alborch[1]

[1]Medical Area. Department of Internal Medicine, [2]Department of Cardiology. Universitary and Politechnic Hospital La Fe. Valencia, Spain.

Objectives: Cardiovascular disease in systemic lupus erythematosus (SLE) patients is highly prevalent, a fact often not etiologically correlated with the presence of traditional cardiovascular risk factors. Our goal was to describe the type and prevalence of echocardiographic findings in a cohort of SLE patients, cardiologically asymptomatic. We also compare the classical factors of cardiovascular risk and lupus activity data with echocardiographic findings in SLE patients without clinical cardiology.

Material and method: Observational and descriptive study of 72 patients with SLE, registered in the database installed on Internet (URL: www.registroles.es). The echocardiographic variables evaluated were the growth of cavities, pericardial effusion, pulmonary hypertension, valvular abnormalities and Libman-Sacks endocarditis. The traditional cardiovascular risk factors were family history of early cardiovascular disease, hypertension, diabetes mellitus, dyslipidemia, sedentary lifestyle and tobacco smoking, and lupus activity data were consumption of complement, C reactive protein (CRP), ESR and SLEDAI.

Results: Among the 72 patients 18 had a pathological echocardiography (25%), appearing almost valvular abnormalities (88.8%), 33.3% with growth of cavities and 20% with Libman Sacks endocarditis. The mean age was 39.8 years (SD 13.8) and 93% were female. Related to CVRF: 9.7% of patients had a history of early cardiovascular disease, 22.2% had hypertension, 4.3% diabetes mellitus and 41.7% dyslipidemia. 33.3% smoking and 68% had a sedentary lifestyle. In regard to the disease activity the mean was 6.5 for the RPC, 29.7 for ESR and 5.45 for SLEDAI, and 79% were hypocomplementemia C4 dependent and C3 dependent 33.3%. The relationship between echocardiographic abnormalities and age ($p = 0.01$) and family history of premature cardiovascular disease ($p = 0.03$) were statistically significant.

Discussion: Our patients had a prevalence of echocardiographic abnormalities, similar to that observed in previous studies, being the most frequent valvular abnormalities including Libman Sacks endocarditis. The high percentage of classic cardiovascular risk factors, particularly physical inactivity, dyslipidemia, and smoking attracs the attention given the low age of our patients. The degree of SLE activity was considerable, above all the complement consumption. However, we observed statistically significant only with the appearance of echocardiographic abnormalities with age and the presence of family history of premature cardiovascular disease, a fact that could explain by the low average age of our patients.

Conclusions: Cardiac structural alterations, even in the absence of clinical symptoms are common in lupus patients, mainly in those older and with family history of premature cardiovascular disease. The performance of an echocardiogram can be useful to detect subclinical disease in order to prevent clinical events.

IF-126
UVEITIS: ETIOLOGIC ANALYSIS OF 329 PATIENTS

A. Martínez Berriotxoa[1], J. Artaraz[2], A. Fonollosa[2], S. Eguiluz[1]

[1]Department of Internal Medicine, [2]Department of Oftalmology. Hospital Universitario Cruces. Barakaldo (Vizcaya), Spain.

Objectives: To describe the etiology of 329 cases of uveitis.

Material and method: Retrospective etiologic analysis of 329 uveitis patients followed up between 2002-2012 by the Services of Ophthalmology and Internal Medicine of Cruces University Hospital (Barakaldo, Spain), a tertiary hospital with a catchment area of over 370,000 people.

Results: 329 uveitis patients (162 men and 167 women, mean age 44.6 ± 18,0 years) were studied and classified according to the uveitis pattern. Anterior uveitis (AU): 160 (48,8%) patients: 1) Acute recurrent and nonrecurrent unilateral AU (123, 37.5%): Herpes simplex (30), idiopathic no-HLA B27 (25), idiopathic HLA B27 (15), spondyloartropathies (15), Behçet's disease (10), Posner-Schlossman syndrome (8), varicella-zoster (4), cytomegalovirus (4), post-surgery (3), sarcoidosis (2), psoriasis (1), ulcerative colitis (1), Crohn's disease (1), SLE (1), temporal arteritis (1), rheumatoid arthritis (1), post-traumatic (1). 2) Acute bilateral AU (10, 3.0%): Idiopathic no-HLA B27 (7), psoriasis (1), TINU syndrome (1), SLE (1). 3) Chronic AU (27, 8,2%): Fuch's heterochromic cyclitis (11), idiopathic no-HLA B27 (9), ankylosing spondylitis (1), juvenile idiopathic arthritis (1), ulcerative colitis (1), phacogenic (1), Crohn's disease (1), psoriasis (1), breast carcinoma (1). Intermediate uveitis (IU): 28 patients (8,5%): Idiopathic intermediate uveitis/ pars planitis (23), sarcoidosis (3), probable tuberculosis (1), probable lymphoma-masquerade syndrome (1). Posterior uveitis (PU): 92 patients (28,0%): 1) Unilateral chorioretinitis (38, 11.6%): Toxoplasmosis (17), idiopathic unclassified chorioretinitis (5), cytomegalovirus (4), Bartonella henselae (3), syphilis (2), toxocariasis (1), varicella-zoster (1), tuberculous serpiginous-like choroiditis (1), progressive subretinal fibrosis syndrome (1),

ampiginous choroiditis (1), punctate inner choroidopathy (1), vasoproliferative retinal tumor (1). 2) Bilateral chorioretinitis (35, 10.4%): Punctate inner choroidopathy (9), multifocal idiopathic choroiditis (5), serpiginous choroiditis (6), unclassified idiopathic choroiditis (4), birdshot choroidopathy (3), multiple evanescent white dot syndrome (3), placoid choroidopathy (1), tuberculous serpiginous-like choroiditis (1), leptospirosis (1), sarcoidosis (1), breast carcinoma metastases - masquerade syndrome (1). 3) Retinal vasculitis (21, 6,4%): Idiopathic retinal vasculitis (9), Eales disease (5), Behçet's disease (4), primary frosted branch angiitis (2), probable tuberculosis (1). Panuveitis: 48 patients (14.6%): 1) Chorioretinitis panuveitis (13, 4.0%): Toxoplasmosis (4), chronic Vogt-Koyanagi-Harada (VKH) disease (4), idiopathic (2), Blau's disease (1), Lyme disease (1), sympathetic ophthalmia (1). 2) Vitritis panuveitis (9, 2.7%): Idiopathic (5), sarcoidosis (3), syphilis (1). 3) Retinal vasculitis panuveitis (4, 1.2%): Behçet's disease (2), sarcoidosis (1), idiopathic (1). 4) Exudative retinal detachment panuveitis (6, 1.8%): VKH disease (5), syphilis (1). 5) Unclassified panuveitis (16, 4.9%): Idiopathic no-HLA B27 (8), tuberculosis (2), sarcoidosis (2), ankylosing spondylitis (1), idiopathic HLA B27 (1), Behçet's disease (1), varicella-zoster (1).

Discussion: Uveitis is a major manifestation of a wide spectrum of diseases (infections, inflammatory eye-limited and systemic diseases, neoplastic) and diagnostic approach is often complex. Most patients can be classified into one of the twelve recognized clinical patterns of uveitis. Each pattern is frequently associated with certain etiologies, so identification of the pattern of uveitis is a helpful guide to decide the initial diagnostic plan.

Conclusions: Identification of the pattern of uveitis is a very helpful tool to guide uveitis initial diagnostic approach.

IF-127
SUSAC'S SYNDROME: A DIAGNOSTIC CHALLENGE

J. Andrés Cordón, S. Buján Rivas, A. Guillén del Castillo, F. Martínez Valle, J. Ordi Ros, M. Vilardell Tarrés

Department of Internal Medicine. Autoimmune-Systemic Diseases. Hospital Universitari General Vall d'Hebron. Barcelona, Spain.

Objectives: To present two new cases of Susac Syndrome and to review the existing literature regarding the clinical presentation, diagnostic tools and treatment strategies of this rare autoimmune endotheliopathy.

Material and method: Review of the clinical files of two patients with SS diagnosed in our center with special attention to the clinical, laboratory and image findings. These data were compared to the previously published SS series.

Results: Patient 1: 41 year-old female with recurrent vertigo episodes and sensorineural hearing loss that started at the age of 24. She presented 1 year later an episode of bilateral amaurosis with multiple branch retinal artery occlusions (BRAO) and retinal ischemia in the funduscopic examination (FE). Brain MRI showed multiple subcortical T2-hyperintense lesions that affected the white matter and corpus callosum. ANA, anti-dsDNA, anti-ENA and ANCA were negative. A S protein deficit, activated protein C resistance and V Leiden factor heterozygous mutation were detected. Under clinical suspicion of SS, oral anticoagulant therapy (OACT), oral glucocorticosteroids (GC) and oral cyclophosphamide (CYC) were initiated. CYC was later changed to azathioprine (AZA) due to lack of response and transient amenorhea. AZA only accomplished partial control of the disease and was changed to mycophenolate mophetil (MMF). These treatment accomplished clinical resolution with good tolerability. The patient remains well after 11 years of follow-up. Patient 2: 27 year-old male with recurrent episodes of transient bilateral amaurosis started at the age of 16. FE and fluorescein angiography (FA) showed multiple BRAO with retinal ischemia and periarteriolar staining. Borderline positive levels of anti-beta-2-glicoprotein IgG antibodies with negative anti-cardiolipin antibodies and positive lupic anticoagulant (isolated determination) were detected. ANA, anti-ENA, anti-dsDNA and ANCA antibodies were negative. Under a primary antiphospholipid syndrome diagnosis, OACT and aspirin, with lack of response. Eight years later he developed episodic vertigo and fluctuating encephalopathy. Brain MRI showed multiple demyelinating lesions affecting the subcortical white matter of both hemispheres and the corpus callosum. Auditive evoked potentials (AEP) were normal. After evaluation in our centre, OACT was suspended and MMF was initiated. After 12 months of follow-up, the patient remains asymptomatic.

Discussion: SS consists of the clinical trial of encephalopathy, BRAO, and sensorineural hearing loss. It is a rare disease (around 200 cases reported) usually seen in young women (3:1). Histopathological studies have shown endothelial lesion and thickening of arterial wall that cause vascular obstruction in absence of thrombi. These findings and the isolation of specific anti-endothelial cell antibodies, support the hypothesis of an autoimmune endotheliopathy. Diagnosis is made under clinical suspicion (although the full clinical trial may not be present at the beginning of the disease). MRI imaging, retinal and cochleo-vestibular evaluation provide useful support. Typical MRI findings are corpus callosum and subcortical white matter microinfarctions (central callosal involvement that is almost pathognomonic of SS). Typical findings in FE and AF are BRAO and periarteriolar staining. Audiometry and AEP can show a cochlear hypoacusia affecting lower frequencies. Treatment strategy remains controversial due to the lack of evidence-based therapeutic recommendations. In our experience MMF is a well-tolerated option that showed optimal control of the disease in our patients.

Conclusions: SS is a rare disease that consists in the clinical trial of encephalopathy, BRAO and sensorineural hypoacusia. The diagnosis is based on clinical findings and high index of suspicion should be kept in order to make an early diagnosis. MRI imaging can provide pathognomonic findings and FE, FA, audiometry and AEP findings support the clinical suspicion. Therapy is based on immunosupressive drugs, although there are not controlled trials to evaluate the best approach.

IF-128
LOW PLASMA APOPROTEIN-M LEVELS IN SEPSIS AND SEPTIC SHOCK PATIENTS. A PILOT STUDY

C. Maldifassi[1], F. Arnalich[2], G. Atienza[1], R. Montejano[2], M. Jiménez Lendínez[3], M. Quesada[2], E. López Collazo[4], C. Montiel[1]

[1]Department of Pharmacology and Therapeutics. Facultad de Medicina, UAM, IdiPAZ. Madrid, Spain. [2]Department of Internal Medicine, [3]Department of Intensive Care, [4]Department of Medical Research. Hospital Universitario La Paz, IdiPAZ. Madrid, Spain.

Objectives: Apo-M is a carrier of sphingosine-1-phosphate (S1P), which is important for vascular barrier protection. It is a negative acute phase protein that decreases during infection and inflammation. The aim of our study was to determine the plasma concentrations of apoM during septic shock or sepsis, and correlate them to prognosis.

Material and method: We performed a pilot study from a subset of the cohort of patients and controls analyzed in previous studies by our group (Crit Care. 2010;14:435). This sample was comprised of 28 patients with septic shock, 28 patients with sepsis associated with community-acquired pneumonia (CAP) and 30 healthy controls. Plasma concentrations of ApoM was estimated by a sandwich ELISA based on two monoclonal rabbit human anti-ApoM antibodies (ABNOVA), and serum cytokine levels (IL-6, TNFa) were measured by ELISA kits (R&D Systems) in blood samples obtained at 24 h of admission to the ICU or hospital ward. Nonparametric tests were

Table 1 (IF-128). Summary of laboratory data in patients groups

	Septic shock (n = 28)	CAP-Sepsis (n = 28)	Controls (n = 30)	p value (SS versus CAP-sepsis)
Age, years	69 ± 10	67 ± 11	66 ± 9	NS
C-reactive protein (mg/L)	144 (20-390)	93 (28-167)	2 (0-4)	< 0.01
Apoprotein M (microM/l)	1.20 (1.05-1.40)	1.35 (1.18-1.46)	1.48 (1.26- 1.57)	< 0.05
Plasma IL-6 (pg/ml)	62 (15-130)	41 (0-92)	11 (0-38)	< 0.05
Plasma TNF-a (pg/ml)	38 (5-52)	19 (0-60)	2 (0-8)	< 0.05

used throughout the study. The Mann-Whitney U test was used for evaluating the difference between different groups, and Spearman's rank correlation coefficient for evaluating correlations. Laboratory data are expressed as mean and IQR. Statistical analysis was performed using SPSS 14.0.

Results: Apo-M levels were lower in patients with severe sepsis and shock than in sepsis patients with pneumonia, and both groups were highly significantly different from the control group ($p < 0.001$). Significant negative correlations to the acute phase marker CRP ($r = 0.34$, $p < 0.01$) and IL-6 ($r = 0.28$, $p < 0.01$) were observed.

Discussion: The negative acute phase protein ApoM have been used as a biomarker in coronary patients (Su et al. Clin Biochem. 2009;42:365-70). The observed significant decrease in apoM levels in patients with septic shock, and also in those with sepsis and pneumonia, suggests that apoM may be a useful marker for severity of disease and prognosis in severely sick patients.

Conclusions: The plasma concentrations of Apo-M were significantly reduced in response to septic shock and sepsis related to CAP. This decrease in Apo-M could be a new marker of the ongoing inflammatory response.

IF-129
VOGT-KOYANAGI-HARADA DISEASE: REVIEW OF NINE CASES

S. Eguiluz[1], A. Fonollosa[2], J. Artaraz[2], A. Martínez Berriotxoa[1]

[1]Department of Internal Medicine, [2]Department of Oftalmology. Hospital Universitario Cruces. Barakaldo (Vizcaya), Spain.

Objectives: To describe the clinical manifestations of nine patients with Vogt-Koyanagi-Harada disease (VKHD).

Material and method: Retrospective cohort study of nine patients with VKHD diagnosed and followed up between 2002 and 2012 by the Services of Ophthalmology and Internal Medicine of Cruces University Hospital (Barakaldo, Spain).

Results: Patients are classified into three groups according to clinical course: 1) Four patients (three women and one man, aged 20-50) were referred with acute VKHD. Disease duration was less than one month. Three patients presented prodromal symptoms (headache, tinnitus, fever). Ophthalmological exploration revealed bilateral panuveitis with exudative retinal detachments confirmed by optical coherence tomography or angiography. All four cases showed impairment of visual acuity in both eyes. In two cases remission was achieved (with corticosteroids and corticosteroids plus cyclosporine, respectively) and treatment was stopped after one year. Two patients required long-term maintenance treatment with low-dose prednisone and immunosuppressive therapy (cyclosporine plus methotrexate and infliximab plus methotrexate, respectively). In all four patients visual acuity improved after treatment. 2) Four patients (women, aged 18-50) were referred with recurrent or chronic granulomatous bilateral anterior uveitis. Disease duration was 2, 9, 10 and 12 years respectively. In all cases, ophthalmological examination revealed bilateral granulomatous panuveitis with prominent chronic anterior uveitis with posterior synechiae and chorioretinal atrophy/depigmentation; in two cases typical "sunset glow" fundus was found. Patients didn't report any symptom suggestive of the acute stage of VKHD (which was probably oligosymptomatic or misdiagnosed). There were no chronic skin depigmentation signs (such as vitiligo or poliosis). One patient refused treatment and discontinued follow-up; three patients received low-dose oral prednisone plus azathioprine or methotrexate, with good control of ocular inflammation. 3) One patient (woman, aged 35) presented unilateral chorioretinitis (left eye) that was treated with high-dose oral prednisone with good response. She was referred two years later with unilateral (right eye) panuveitis with exudative retinal detachments; left eye showed chorioretinal depigmentation suggestive of chronic VKHD. She was treated with oral prednisone and azathioprine, with good control of ocular inflammation.

Discussion: VKHD is a bilateral panuveitis that is associated with systemic manifestations that include meningismus, headache, tinnitus, vitiligo, poliosis, and alopecia. The natural history of VKHD is quite varied, but ideally can be divided into four stages: prodromal (meningismus, headache, tinnitus), acute (panuveitis with exudative retinal detachments), chronic or quiescent (tissue depigmentation: vitiligo, poliosis, chorioretinal atrophy/depigmentation) and recurrent (not in all patients, with recurrent or chronic anterior uveitis). Although VKHD is typically bilateral, in a small number of cases delayed second eye involvement has been reported, as in the last patient. Most patients require corticosteroids and immunosuppressive agents for disease control.

Conclusions: VKHD is a bilateral panuveitis with systemic symptoms that presents characteristic ocular findings in the acute stage (panuveítis with exudative retinal detachments) and in the chronic/recurrent stage (chorioretinal atrophy and depigmentation, and chronic or recurrent anterior uveitis).

IF-130
SYSTEMIC MEDICATIONS FOR THE TREATMENT OF PRIMARY SJÖGREN'S SYNDROME IN SPAIN. MAIN THERAPEUTIC OPTIONS USED IN A SERIES OF 921 PATIENTS (GEAS-SEMI-SS REGISTRY)

P. Brito-Zerón[1], R. Solans[2], M. Camps[8], L. Morera Morales[3], A. Mera Fidalgo[4], G. de Luna[5], A. García Sánchez[6], O. López Berástegui[7]

[1]Department of Autoimmune Diseases. Hospital Clínic. Barcelona, Spain. [2]Department of Internal Medicine. Hospital Vall d'Hebron. Barcelona, Spain. [8]Department of Internal Medicine. Hospital Carlos Haya. Málaga, Spain. [3]Department of Internal Medicine. Hospital Parc Taulí. Sabadell (Barcelona), Spain. [4]Department of Internal Medicine. Hospital Universitario Central de Asturias. Oviedo (Asturias), Spain. [5]Department of Internal Medicine. Hospital Ramón y Cajal. Madrid, Spain. [6]Department of Internal Medicine. Hospital Infanta Leonor. Madrid, Spain. [7]Department of Internal Medicine. Hospital Gregorio Marañón. Madrid, Spain.

Objectives: To describe the main therapeutic options in a large cohort of Spanish patients diagnosed with primary Sjögren syndrome (SS), and investigate how many patients required treatment with corticosteroids and/or immunosuppressive agents.

Material and method: The GEAS-SS multicenter registry was formed in 2005 with the aim of collecting a large series of Spanish

patients with primary SS, and included 21 Spanish reference centers with substantial experience in the management of SS patients. By March 2012, the database included 921 consecutive patients, recruited since 1994, fulfilling the 2002 classification criteria for primary SS. We retrospectively investigate the use of the following drugs: pilocarpine, antimalarials (chloroquine or hydroxychloroquine), corticosteroids (> o < 20 mg/d), immunosuppressive agents (cyclophosphamide, mycophenolate, methotrexate, azathioprine or cyclosporine A), intravenous immunoglobulins or biological therapies.

Results: The cohort included 867 (94%) women and 54 (6%) men (female:male ratio, 16:1), with a mean age at diagnosis of primary SS of 54 years and a mean disease evolution of 75 months. Two hundred and twenty two (24%) patients had received pilocarpine, 225 (24%) antimalarials, 353 (38%) corticosteroids (189 at doses > 20 mg/d), 103 (11%) immunosuppressive agents, 20 (2%) intravenous immunoglobulins and 19 (2%) rituximab. Three hundred and sixty four (40%) patients were treated with corticosteroids and/or immunosuppressive drugs (including intravenous immunoglobulins and rituximab). With respect to the main features at baseline, these patients had a higher frequency of positive salivary gland biopsy (93% vs 85%, p = 0.014), rheumatoid factor (64% vs 52%, p < 0.001), anti-La/SS-B (50% vs 43%, p = 0.035), extraglandular involvement (78% vs 49%, p < 0.001), anemia (22% vs 13%, p < 0.001), leukopenia (23% vs 18%, p = 0.035), ESR > 50 mm/h (41% vs 22%, p < 0.001), monoclonal band (12% vs 7%, p = 0.045), low C3 levels (12% vs 7%, p = 0.03), low C4 levels (16% vs 9%, p = 0.007) and cryoglobulins (18% vs 9%, p = 0.001) in comparison with patients who did not require corticosteroid/immunosuppressive drugs. The use of these drugs was also associated with a higher ESSDAI score in the constitutional (p = 0.008), lymphadenopathy (p = 0.007), glandular (p = 0.019), articular (p < 0.001), pulmonary (p < 0.001), renal (p = 0.03), hematological (p = 0.015) and biological (p = 0.003) domains, and with the mean ESSDAI score at baseline (7.65 vs 5.94, p = 0.015) and cumulated at the end of the follow-up (11.93 vs 7.53, p < 0.001).

Conclusions: Nearly half the patients with primary SS received corticosteroids and/or immunosuppressive drugs (including intravenous immunoglobulins and rituximab), even though the majority of drugs are not licensed for the disease and that the available studies, which are overwhelmingly uncontrolled, are mainly designed to evaluate sicca rather than systemic outcomes. In primary SS, therapeutic decisions are still based on a combination of personal experience and reported scientific evidence, principally from uncontrolled studies.

IF-131
GIANT CELL ARTERITIS. 5 YEAR RETROSPECTIVE STUDY IN A HOSPITAL IN THE NORTHWEST OF SPAIN

I. Fernández Regal, J. Marnotes González, L. Núñez Calvo, C. Mouronte Sánchez, L. Rey González, E. Seco Hernández, E. González Vázquez, A. Chamorro Fernández

Department of Internal Medicine. Complejo Hospitalario Universitario Ourense. Ourense, Spain.

Objectives: The aim of the study is to evaluate epidemiological, clinical, laboratory, radiological and treatment features of patients admitted to our hospital, with a discharge diagnosis of GCA.

Material and method: Retrospective study of episodes of ACG in the area corresponding to our hospital (900 beds), data were obtained through the collection of stories between 2006 and 2010. We selected all cases in which the diagnosis was as principal diagnosis and between 2 and 3 instead of the side.

Results: 76 cases were collected over the 5 years with a mean age of 77 years, being 53.9% female. 42% belong to the Department of Internal Medicine and 27.6% to Rheumatology. 59.2% had hypertension, 10.5% DM. The most common symptom at diagnosis was recent headache (65.8%), and later, we found jaw claudication (26.3%) and systemic symptoms: weight loss (21.1%), anorexia (18.4%) and fever (9.2%). 11.8% had anterior ischemic neuritis and 2.6% occlusion of the central retinal artery. Rheumatic polymyalgia is associated with GCA in 40.8% of patients. Palpation of the temporal artery was abnormal 59.2%: no pulse (15.7%), thickening (10.5%). The mean Hb was 11.5 g/dl. Biopsy was performed in 40 patients (52.6%), being positive in 19 (25%). Only one patient underwent temporal artery doppler. 9.1% of our patients had ESR < 50. 90.8% were treated with corticosteroids: 81.6% prednisone, methylprednisolone 2 patients, being most orally (80.3%). 15.8% relapsed and relapse 10.5%. 7.9% required methotrexate. 64.5% received calcium + VitD and 31.6% bisphosphonates. Only 9 patients received ASA. At follow-up only one patient underwent chest X-ray. The most frequent complications were infections (14.5%), followed by DM corticosteroid. Only one patient had osteoporotic fracture. 17.1% were exitus, representing infections 9.1%.

Conclusions: We detected a little follow-up clinical, laboratory and imaging test, with only 11.8% of antiplatelet prophylaxis, despite the recommendations of major international guidelines. The most frequent were infections exitus.

IF-132
DERMATOMYOSITIS AS A PARANEOPLASTIC PHENOMENON

S. Aguilar Huergo[1], J. Sabio Sánchez[1], N. Navarrete Navarrete[2], A. González Alejos[3], S. Pérez Morayo[4], M. Zamora Pasadas[2], J. Vargas Hitos[2], J. Jiménez Alonso[2]

[1]Department of Internal Medicine. Complejo Asistencial de León. León, Spain. [2]Department of Internal Medicine. Complejo Hospitalario Virgen de las Nieves. Granada, Spain. [3]Department of Internal Medicine. Hospital Clínico Universitario. Valencia, Spain. [4]Department of Internal Medicine. Hospital Virgen de la Salud. Elda (Alicante), Spain.

Objectives: To find out the rate of inpatients admitted in IM Department diagnosed of dermatomyositis as a paraneoplastic phenomenon of an unknown cancer in Virgen de Las Nieves Universitary Hospital (Granada) for the last 5 years. To determinate their clinical characteristics and theirs test result findings. Finally, to clarify if our results are consistent with the previously published literature.

Material and method: It is a retrospective descriptive study of inpatients admitted in Internal Medicine Department of Virgen de las Nieves Hospital (Granada) with the final diagnosis of dermatomyositis from January 2007 to March 2012. We have used a previously established data collection protocol of the sample (14 patients) and we have revised medical stories. At last, we have analyzed data with SPSS statistical program.

Results: The sample includes 14 inpatients with a mean age of 63 years old (min 20-max 90, SD 21, median 69). Most of them are female (71.4%). The most common symptoms are symmetric proximal muscle weakness (64.3%) and malaise & asthenia (50%). The skin lesions are present in all our patients, but they are only typical in 50% of them (28.6% Heliotrope rash and 21.4% Gottron's signs). The rate of respiratory symptoms is 35.7% (21.4% of them with dispnea on moderate exertion with no radiologic data of fibrosis and one case of TEP secondary to an unknown active neoplasia). To highlight between laboratory results, we find elevated CK and LD levels in 28.6% of cases. Autoantibodies detected are positive for ANA (21.4%) and Ro (7.1%). EMG is suggestive of DM in 21.4% of cases and the anatomopathologic study was definitive in 7.1% of them. The treatment is essentially sustained on glucocorticoids (90% of patients (maintenance dose

0.5 mg prednisone/kg/day (57.1%) vs 1 mg prednisone/kg/day (30.8%)). The osteoporosis treatment is included in 42.9% of patients and the immunosuppressive treatment is also added in 57.1% (from them, azathioprine 62.5%, methotrexate 25% and cyclophosphamide 12.5%). The clinical manifestation as a paraneoplastic phenomenon is present in 35.7% of the cases, in which the main neoplastic lineage are kidney and digestive. There is an overlad syndrome in one case (Sharp syndrome: LES, DM, seronegative RA & SS) and one antisynthetase syndrome. There are 2 deaths of inpatients (14.3% of them) during their hospital stay because of a neoplastic cause.

Discussion: We have found out a moderate prevalence of neoplastic cause in patients with dermatomyositis. Moreover, we stand out the need of glucocorticoids with a lower maintenance doses as possible and if it is necessary we can support in immunosupressive therapy. Furthermore, our results are quite consistent with the previously described in literature.

Conclusions: The paraneoplastic phenomenon is a way of presentation of our patients with dermatomyositis in more than 30% of the cases, so we ought to perform a complete screening of tumor. The diagnosis of DM is based on a combination of clinical features, laboratory findings, EMG and AP study. The mainstay of treatment are glucocorticoids and the occasional complementary help of immunosuppressive drugs.

IF-133
SARCOIDOSIS: REVIEW OF 56 PATIENTS WITH HISTOPATHOLOGICAL DIAGNOSIS

F. Saiz García, A. Ibáñez Botella, E. Calvo

Department of Internal Medicine. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: Study of the management of patients with sarcoidosis, from diagnosis to treatment, monitoring and clinical course, and later compare it to other reviews and updates of the subject.

Material and method: Retrospective study of 56 patients with histopathological diagnosis of sarcoidosis in the H. Clínico San Carlos in a period of 5 years from 2006 to 2011. We reviewed the medical records of patients diagnosed with sarcoidosis in 5 years at the Clínico San Carlos Hospital, creating a database with epidemiological, clinical, biological, radiological, diagnostic and therapeutic variable data.

Results: In our study (30 women, 26 men), the middle age is 49 years old. Mostly patients were studied for presenting symptoms (72%), being the most common respiratory symptoms (34.2%) like coughing and dyspnea. 7.8% had fever or other nonspecific symptoms, 13.5% palpable extrathoracic nodules and 18,4% erythema nodosum. Diagnosis is made primarily with evidence of consistent histopathology and clinical support. For improving histopathology the most sensitive is mediastinoscopy. The sensitivity of the transbronchial biopsy is 69%. If there is parenchymal involvement, the sensitivity is 75%, while if it is not, it's 38%. Other specific diagnostic tests have less importance each time, but support the diagnosis (angiotensin-converting enzyme or the CD4/CD8 ratio). The most common lung disease is the intrathoracic lymph node involvement, (33%- 35% in stage I-II). Few patients in stage I or II started steroid systemic therapy cause most of them had no functional involvement and were expected having spontaneous remission. Even if they needed steroid treatment they generally had good performance. Patients who required steroids for more than one year, were usually patients in stage IV. They had tendency to disease progression, requiring in many cases maintaining steroid treatment or immunosuppressive therapy such as methotrexate. Two cases with anatomopathological diagnosis of sarcoidosis became in lung adenocarcinoma and gastric adenocarcinoma after one year of follow-up.

Discussion: Only 56 patients had histopathology of sarcoidosis in 5 years. Only 35% of our patients were from 10 to 40 years old, while it is estimated between 70 and 90% in other studies. Only 28% of the patients were asymptomatic, in front of the 50% in other studies. The most frequent symptoms are coughing and dyspnea. Only 7.8 had fever and asthenia while it is expected a 30% in other reviews. Transbronchial biopsy has 69% of sensibility, which is improved if there is parenchymal involvement. The most frequent presentation is the stage I or II which have usually good prognosis. Cases in stage IV need treatment and usually they must keep steroids or immunosuppressive maintaining treatment.

Conclusions: Despite the good prognosis of this disease, we must always reject a cancer with similar presentation, usually with aggressive test like mediastinoscopy in 39% of patients.

IF-134
POLYMYOSITIS IN A THIRD LEVEL HOSPITAL

S. Aguilar Huergo[1], J. Sabio Sánchez[2], A. González Alejos[3], S. Pérez Morayo[4], E. Magaz García[1], N. Navarrete Navarrete[2], J. Vargas Hitos[2], J. Jiménez Alonso[2]

[1]Department of Internal Medicine. Complejo Asistencial de León. León, Spain. [2]Department of Internal Medicine. Complejo Hospitalario Regional Virgen de las Nieves. Granada, Spain. [3]Department of Internal Medicine. Hospital Clínico Universitario. Valencia, Spain. [4]Department of Internal Medicine. Hospital Virgen de la Salud. Elda (Alicante), Spain.

Objectives: To find out the clinical features of polymyositis of inpatients admitted in IM Department in Virgen de Las Nieves Universitary Hospital (Granada) for the last 5 years. To discover their complementary findings and their laboratory results. Finally, to clear up if our results are consistent with the previously published literature.

Material and method: It is a retrospective descriptive study of inpatients admitted in Internal Medicine Department of HVN Universitary Hospital with the final diagnosis of polymyositis from January 2007 to March 2012. We have used a previously established data collection protocol of the sample (9 patients) and we have revised medial stories. At last, we have analyzed data with SPSS statistical program.

Results: The sample includes 9 inpatients with a mean age of 49.1 years old (min 18-max 84, SD 20.5, median 55). Most of them are female (66.7%). The most common symptoms are symmetric proximal muscle weakness (77.8%) and malaise, asthenia and weight loss (66.7%). The articular symptoms are commonly present in 66.6% of the cases (joint pain (33.3%) and joint stiffness (22.2%)). The rate of respiratory symptoms is 66% (33.3% of them with dispnea on moderate exertion with fibrosis without home oxygen and 22.2% of them with fibrosis and need of home oxygen). To highlight between laboratory results, we find elevated CK and LD levels in 76% of cases. Autoantibodies detected are positive for ANA (44.4%), Jo-1 (22.2%) and Anti-Knu+PL12 (11.1%). EMG is suggestive of PM in 21.4% of cases and the anatomopathologic study was definitive in 11.1% of them. The treatment is essentially sustained on glucocorticoids (77.8% of patients (maintenance dose 0.5 mg prednisone/kg/day in almost all the patients). The osteoporosis treatment is included in 66.7% of patients and the immunosupressive treatment is also added in 61.9% (from them, azathioprine 66% and cyclophosphamide 12.5%). There is an overlad syndrome in one case (Sharp syndrome: LES, DM, seronegative RA & SS) and a not uncommon combination with antisynthetase syndrome (PM + interstitial pneumonitis + "mechanics hands" + Raynaud phenomena + inflammatory polyarthritis+ anti-synthetase antibodies).

Discussion: We have found out the existence of a occasional combination of polymyositis and antisynthetase syndrome. Also, in many cases of PM they have secondary fibrosis as a long-term complication. Moreover, we stand out the need of glucocorticoids with a lower maintenance doses as possible and if it is necessary we can support in immunosupresor therapy. In cases of interstitial pneumonitis and resistance to corticoid therapy, cyclophosphamide can be an effective alternative to use. Furthermore, our results are quite consistent with the previously described in literature.

Conclusions: Polymyositis is an idiopathic inflammatory myopathy that sometimes overlap with other diseases such as antisynthetase syndrome. So we ought to perform a complete study to exclude it. The diagnosis of PM is based on a combination of clinical features, laboratory findings, EMG and AP study. The mainstay of treatment are glucocorticoids and the occasional complementary help of immunosuppressive drugs (specially cyclophosphamide in cases of corticoid resistance and a bad control of the illness).

IF-135
PARAPROTEINEMIA IN SCLERODERMA

C. Silva[1], A. Seixas[1], S. Nihtyanova[2], V. Ong[2], C. Denton[2]

[1]Department of Internal Medicine. Centro Hospitalar de Vila Nova de Gaia/Espinho, EPE. Vila Nova de Gaia, Portugal.
[2]Rheumatology. Royal Free Hospital. London, United Kingdom.

Objectives: To determine frequency and significance of paraproteinemia in a well characterized large single centre Systemic Sclerosis (SSc) cohort.

Material and method: Systematic search of clinical charts, research database.

Results: The SSc cohort presents itself with 2900 patients; our review was based on a sub-cohort of 2145 patients. From these, 12 patients were found with paraproteinemia: 9 patients had monoclonal gammapathy of undetermined significance (MGUS) and 3 multiple myeloma. The average age was 63 years old. In terms of auto-antibodies, anti-nuclear antibodies (ANA) was positive in 9 patients (75%), with an equal distribution between the homogeneous and the centromere pattern; the extra-nuclear antibodies (ENA) was positive in 5 patients, being mainly anti-SCL 70 (2 patients) and anti RNP (2 patients); 2 patients had anti-CCP positive and 1 had anti neutrophil cytoplasmatic antibody.

Discussion: Several questions arise when evaluating these patients. It is known that paraproteinemia is common in other autoimmune diseases and in the overall demographics mainly above 70 years old. The prevalence of MGUS increases with age, from < 2% in people aged < 40 years to 5% in those aged > 70 years and 9% in those aged > 85 years in general demographics. Studies show that up to 20% of patients with primary Sjögren and up to 5.4% in patients with systemic lupus erythematosus (SLE) may have associated MGUS. When evaluated our cohort the frequency was extremely low (0.56%), against what was expected, being SSc an autoimmune condition. When trying to find special features of SSc that might suggest predisposition to paraproteinemia, we verified that there were none, but the number of patients with both conditions in our case series was very low. It can be suggested that the treatment commonly applied may alter not only the disease course, but also other secondary associated diseases.

Conclusions: Paraproteinemia is uncommon in SSc in comparison with other autoimmune diseases such as Sjögren. We would expect, by analogy with the general population, at least about 5% of paraproteinemia in our cohort, which doesn´t happen.

IF-136
ANTISYNTHETASE SYNDROME IN A THIRD LEVEL HOSPITAL

S. Aguilar Huergo[1], J. Sabio Sánchez[2], E. Magaz García[1], E. Castelar Delgado[1], M. Zamora Pasadas[2], N. Navarrete Navarrete[2], L. Jaimez Gamiz[3], J. Jiménez Alonso[2]

[1]Department of Internal Medicine. Complejo Asistencial de León. León, Spain. [2]Department of Internal Medicine, [3]Autoimmunity Laboratory. Complejo Hospitalario Regional Virgen de las Nieves. Granada, Spain.

Objectives: To find out the clinical features of antisynthetase syndrome of inpatients admitted in IM Department of Virgen de las Nieves Universitary Hospital (Granada) for the last 5 years. To discover their complementary findings and their laboratory results. Finally, to clear up if our results are consistent with the previously published literature.

Material and method: It is a retrospective descriptive study of inpatients admitted in Internal Medicine Department of HVN Hospital (Granada) with the final diagnosis of antisynthetase syndrome from January 2007 to March 2012. We have used a previously established data collection protocol of the sample (8 patients) and we have revised medical stories. At last, we have worked out an statistical analysis with SPSS program.

Results: The sample includes 8 inpatients with a mean age of 60.13 years old (min 45-max 73, SD 8.4, median 60). Most of them are female (62.5%). All the patients have interstitial pneumonitis (based on functional lung tests and imaging). The degree of the dyspnea is on moderate exertation in 25% of cases and with minimal effort in 50% of them, requiring in this last case home oxygen in this proportion. The pulmonary hypertension was present in 12.5% and also dilated cardiomiopathy and CHF with the same rate. The characteristic skin lesions of "mechanic hands" are present in 87.5%. The non-erosive polyarthritis appears in 75% of them. The carpal tunnel syndrome happens in 25% of them and the Raynaud phenomena in 37.5% respectively. The association with dermatomyositis or polimyositis occurs in 50% of the sample. To highlight between laboratory results, we find positive antisynthetase autoantibodies for Jo-1 (50%) and Anti-Knu+PL12 (12.5%). There are concomitant autoimmune diseases: Sjögren's syndrome (37.5%), systemic sclerosis (12.5%) and autoimmune hypothyroidism (12.5%). The treatment is essentially sustained on glucocorticoids (75% of patients (maintenance dose 0.5 mg prednisone/kg/day in almost all the patients)). The osteoporosis treatment is included in 25% of patients and the immunosupressive treatment is also added in 50% (from them, essentially cyclophosphamide 37.5% and azathioprine 12.5%). There is an overlad syndrome in one case with Sjögren's syndrome and systemic sclerosis.

Discussion: We have found out the occasional combination of antisynthetase syndrome with other autoimmune diseases. Also, in most of the cases, they have secondary interstitial fibrosis as a long-term complication. Moreover, we stand out the need of glucocorticoids with a lower maintenance doses as possible and if it is necessary we can support in immunosuppressive therapy. In cases of interstitial pneumonitis and resistance to corticoid therapy, cyclophosphamide can be an effective alternative to use. Furthermore, our results are quite more or less consistent with the previously described in literature.

Conclusions: Antisynthetase syndrome is an idiopathic autoimmune illness that sometimes overlap with other diseases and commonly with lung fibrosis, so we ought to perform a precocious and meticulous study to exclude it and a close ambulatory following up. The pulmonary fibrosis happens frequently and it is an indication of intensifying immunosuppressive treatment. Cyclophosphamide is a valuable alternative therapy in cases of corticoid resistance and bad control of the illness.

IF-137
RETROSPECTIVE ANALYSIS OF PERIPHERAL NERVOUS SYSTEM VASCULITIS DIAGNOSED BY BIOPSY IN THE HEALTH AREA OF VIGO

M. Alonso[1], M. Freire[1], E. Álvarez[3], A. González[2], I. Villaverde[1], R. Lorenzo[1], A. Rivera[1], B. Sopeña[1]

[1]Thrombosis and Vasculitis Unit, Department of Internal Medicine, [3]Department of Neurology, [2]Department of Pathology. Complejo Universitario de Vigo. Vigo (Pontevedra), Spain.

Objectives: The term vasculitis refers to the destruction or vessel injury secondary to an inflammatory condition of the vessel wall. Vasculitic neuropathies traditionally have been classified in non-systemic (isolated vasculitis of the PNS-peripheral nervous system-, for some authors in the spectrum of polyangiitis microscopica-PAM- but without systemic involvement) and systemic, which can be further subdivided into primary (PAN, Wegener, Churg Strauss, PAM) and secondary to other processes (infections, collagen diseases, toxics...). We analyze the clinicopathologic features and the most common entities associated with vasculitis of peripheral nerve in our Hospital.

Material and method: We conducted a retrospective study of medical records from patients with peripheral nerve biopsy diagnosis of vasculitis, selected through the coding system pathology department of the Hospital of Vigo (SNOMED). We detected 13 cases since January 1, 1995 to January 1, 2012.

Results: 7 patients were men and 6 women. Mean age at diagnosis was 55 years (range 33-76). 5 patients were diagnosed with isolated PNS vasculitis (38.5%), 3 PAM (23%), 2 PAN (15.4%), 1 Churg-Strauss, 1 Cryoglobulinemia associated with Sjögren's and other diagnosis was uncertain. The most frequent reason for consultation was parestesia, present in 61.5% of patients, usually asymmetrical. 15.4% mixed clinical related sensory-motor, 7.7% had weakness of foot dorsiflexion (foot drop) and 7.7% myalgia. Laboratory findings were unremarkable, highlighting a rising phase reactants, with mean ESR 45.5 mm/h (range 10-110) and CRP 22 mg/L (range 5-54) and two cases with impaired function renal (1 PAM, 1 Sjögren/cryoglobulinemia). Neurophysiological findings (only available in 8 patients) showed axonal sensorymotor polyneuropathy data in 4 (50%), mononeuritis multiplex in 3 (37.5%) and demyelinating polyneuropathy in one. Biopsy showed lymphocytic vasculitis data in 8 cases (61.5%), fibrinoid necrosis in 4 (30.8%) and perivascular eosinophilic infiltration in a patient with Churg-Strauss. Treatment was performed in 53.8% only with steroids and the remaining 46.2% with corticosteroids and other immunosuppressive (3 CPM, 2 MTX, 1 IG and 1 AZA).

Conclusions: 1. Peripheral nerve vasculitis is a rare diagnosis in our demographic area. 2. Isolated PNS vasculitis was the most frequent diagnosis, followed by microscopic polyangiitis and polyarteritis nodosa. 3. The most common clinical manifestation was asymmetric sensory alteration with electrophysiological data of mixed axonal PNP or MNM. 4. Histology findings of lymphocytic vasculitis were associated ($p = 0.004$) with the clinical diagnosis of vasculitis isolated PNS. ESR: erythrocyte sedimentation rate CRP: reactive c protein CPM: cyclophosphamide MTX: methotrexate IG: immunoglobulins AZA: azathioprine MNM: mononeuritis multiplex.

IF-139
KIKUCHI-FUJIMOTO DISEASE - CASUISTRY OF AN INTERNAL MEDICINE DEPARTMENT

R. Velho Sousa, E. Bustabad, P. Cunha, J. Cotter

Department of Internal Medicine. Centro Hospitalar do Alto Ave - Guimarães. Guimarães, Portugal.

The Kikuchi-Fujimoto Disease (or histiocytic necrotizing lymphadenitis) is a relatively rare entity, with unknown aetiology. It manifests as linfadenopathy of cervical predominance, associated with typical clinical manifestations often observed in upper respiratory tract infections, including fever. It is usually a self-limited phenomenon. The authors present 5 cases of Kikuchi-Fujimoto Disease. All of these pertain to 5 women, with ages between 22 and 37 years old. As main clinical complaints they presented asthenia, anorexia and slimming, having searched for medical care at the detection of cervical adenopathies of elastic consistency, mobile and peri-centimetric. The hystologic diagnosis was obtained through excisional biopsy. In one of these cases there was a concurrent tonsillar infectious process, in other of these cases it was identified a lower urinary tract infection by Escherichia coli, and in a third case it was observed a posterior development of ganglionar tuberculosis. A weight loss superior to 10% was only observed in one case. In none of these cases were proven auto-immune or lymphoproliferative diseases. The disease always took a self-limited course, without the actual need of therapeutic intervention, namely corticotherapy.

IF-140
ASSOCIATION OF ANTI- ENA WITH CYTOPENIA IN PRIMARY SJÖGREN`S SYNDROME

A. Mera[1], C. Suárez Cuervo[1], L. Mozo[2], J. Bernardo[1], A. Fidalgo[1], M. Fernández Almira[1], L. Caminal[1], B. Díaz López[1]

[1]Department of Internal Medicine, [2]Department of Immunology. Hospital General de Asturias. Oviedo (Asturias), Spain.

Objectives: The presence of Anti-Ro/SS-A and anti- La/SS-B is an established hallmark of Sjögren's syndrome. We selected 48 patients who fulfilled the International consensus criteria in order to evaluate the association of anti-SS-A/Ro, anti-SS-B/La and anti-RNP, with haematological involvement in primary Sjögren's syndrome.

Material and method: We performed a detailed analysis of autoantibodies, determined by immunoblotting and haematologic parameters in these patients.

Results: Anti-SS-A/Ro 60 and/or 52 were detected in 39 patients (81.2%). Among these patients, 43 (89.6%) were women, 36 (75%) showed anti-SS-A/Ro 52 alone, anti-SS-A/Ro 60 reactivity was found in 30 patients (62.5%), whereas 27 (56.2%) were positive for anti-SS-A/Ro 60 and 52. In addition, anti SS- B/La was found in 19 (39.6%), linked to anti-SS-A/Ro 52 or Ro 60 in all cases. Finally, only 2 cases (4.2%) were positive for anti-RNP, in both cases were associated with other autoantibodies. Anti-SS-A/Ro 52 and anti-SS-B/La antibodies were found to be significantly associated with anemia and anti-RNP with neutropenia ($p < 0.05$). When we analyzed patients with anemia, all cases (10 patients) were anti-SS-A/Ro 52 positive. As well as all the anti-RNP positive cases had leukopenia and neutropenia. Significantly diminished cell numbers were found especially in lymphocytes with reference to anti-SSA/Ro 52 and a significant decrease in the hemoglobin levels was associated with anti-SSB/La ($p < 0.05$). Moreover, a significant association was found between a drop in leucocytes and neutrophils and the presence of anti-RNP antibodies.

Discussion: The prevalence of anti-SS-A, anti SS- B and anti-RNP was much higher in patients with cytopenia. No significant correlation was found concerning platelets in any of the autoantibody groups.

Conclusions: The presence of specific autoantibodies as anti-SS-A/Ro 52 and anti SS-B/La seem to play an important role in the genesis of hemocytopenia in primary Sjögren's syndrome.

IF-141
CLINICAL ASSOCIATIONS OF ANTI-SS-A/RO 60 AND 52 ANTIBODIES IN SYSTEMIC LUPUS ERYTHEMATOSUS

A. Menéndez[1], A. Mera[2], L. Mozo[1], J. Arbesú[1], C. Suárez Cuervo[2], M. Fernández Almira[2], L. Caminal[2], B. Díaz López[2]

[1]Department of Immunology, [2]Department of Internal Medicine. Hospital General de Asturias. Oviedo (Asturias), Spain.

Objectives: In order to analyse the clinical associations of anti-SS-A/Ro and 52 antibodies in systemic lupus erythematosus (SLE), we selected 153 patients who fulfilled the ACR criteria and whose clinical features were recorded in a data base of SLE patients established in Asturias since 2003.

Material and method: In these patients, disease activity was periodically measured by SLEDAI and anti-SS-A/Ro 60 and 52 were determined by enzyme fluoroimmunoassay.

Results: The presence of anti-SS-A/Ro 60 and/or 52 was detected in 58 (37.9%) of patients. Among these patients, 32 (55.2%) were positive for anti-SS-A/Ro 60 and 52, 24 (41.4%) showed anti-SS-A/Ro 60 alone whereas isolated anti-SS-A/Ro 52 reactivity was only found in 2 (3.4%). By logistic regression adjusted for sex, age at diagnosis and age at time of analysis, both antibodies were found to be independently associated with photosensitivity ($p < 0.05$), Raynaud's phenomenon ($p < 0.05$), keratoconjunctivitis sicca ($p < 0.05$) and secondary Sjögren syndrome (sSS) ($p < 0.05$). When analyzing together patients with keratoconjunctivitis sicca and/or sSS (40), anti-SS-A/Ro 60 and/or 52 were detected in 22 (55.0%) whereas these antibodies were present in only 18 of the remainder 113 patients (15.9%) ($p < 0.001$). Anti-SS-A/Ro 52 antibodies were also found to be significantly associated to cytopenia ($p < 0.05$). Anti-SS-A/Ro 60 and 52 levels were very stable over time and did not correlate with SLEDAI.

Discussion: Anti- SS-A/Ro 52 and Ro 60 are associated with photosensitivity and Raynaud's phenomenon whereas association with cytopenia is exclusive of anti-SS-A/Ro 52.

Conclusions: In SLE, the presence of anti-SS-A/Ro 60 and 52 defines a subgroup of patients with higher probability to develop sSS, as well as other clinical features.

IF-143
IS NEUROSARCOIDOSIS A DIAGNOSIS OF EXCLUSION?

L. Martín Fajardo[1], E. Esteban Marcos[1], M. Picado[2], E. García Almodóvar[1], P. Porcar[1], M. Balaguer[1], J. Rascón[1], L. Pallares[1]

[1]Department of Internal Medicine, [2]Department of Radiology. Son Espases University Hospital. Palma de Mallorca (Illes Balears), Spain.

Objectives: Sarcoidosis is a systemic granulomatous disease that affects various organs and tissues. The nervous system is involved in 5% of cases. The clinical presentation may adopt different forms, from headache, aseptic meningitis, visual disturbances or cranial nerve palsies, to symptoms due to spinal cord, brainstem, cerebellar or pituitary gland dysfunction. In about 50% of patients no other organ is affected, complicating the diagnosis process. Objectives: to analyse the clinical presentation patterns and the criteria that led us to the final diagnosis of neurosarcoidosis in a series of patients.

Material and method: Retrospective analysis of 5 patients with a diagnosis of neurosarcoidosis followed up in a Systemic Autoimmune Diseases Unit in a tertiary hospital over a period of 10 years (2002-2012). We analysed the clinical manifestations, diagnostic tests, treatments and outcomes.

Results: Case No. 1: women 43 years old. Right retroocular headache without other symptoms. Angiotensin converting enzyme (ACE): 85 U/l (< 50 U/l). Orbital MRI: right orbital pseudotumor. Case No. 2: women (45). Generalized seizures and later aseptic meningitis. Brain MRI: diffuse lesions in both spinal and cerebral hemispheres. Case No. 3: women (43). Right retroocular headache, proptosis, loss of visual acuity, proptosis, upper lid ptosis and alteration of the extrinsic ocular motility (paralysis of cranial nerve II) of the right eye. MRI: right orbital pseudotumor that included the optic nerve Case No. 4: women (43). Pulmonary and skin sarcoidosis (biopsy positive). After 6 years developed aseptic meningitis and optic nerve failure. MRI: involvement of leptomeninges infra and supra-tentorial ependymal with nodular images. Case No. 5: Male, 77. Pulmonary sarcoidosis and decreased strength in left limbs, aseptic meningitis and compatible brain MRI lesions.

Discussion: Diagnosis of neurosarcoidosis remains a challenge, especially in the absence of extraneural involvement, adding the technical difficulties for definite histological confirmation. The symptoms are varied (any portion of the central or peripheral nervous system could be affected) and tests (other than histological) lack specificity. A broad differential diagnosis, including lymphoma and tuberculosis, is always necessary. In many cases the diagnosis of exclusion is based on clinical symptoms, brain MRI images, CSF examination and the response to treatment. In our patients the most useful tests for diagnosis were the CSF study (lymphocyte pleiocitosis, elevated protein levels and glucose consumption) and the MRI images (brain and spinal cord with compatible lesions). ACE was elevated in 4 patients and it helped in the diagnosis. The clinical evolution and response to treatment confirmed the diagnosis in all cases.

IF-144
RETROPERITONEAL FIBROSIS: A RETROSPECTIVE REVIEW IN A THIRD LEVEL HOSPITAL

T. Blanco Moya, A. Torres Dorrego, O. López Berástegui, J. Santos Martínez, M. Gómez Antúnez, J. Cabrera Aguilar, A. Muiño Míguez, B. Pinilla Llorente

Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: To describe the clinical manifestations, laboratory results, imaging findings, and treatments in patients with retroperitoneal fibrosis seen at Gregorio Marañón Hospital in the last ten years.

Material and method: In this retrospective study we enrolled all patients evaluated for retroperitoneal fibrosis at Gregorio Marañón Hospital in the last ten years. Medical data were reviewed and clinical information was abstracted.

Results: Of the 14 patients identified as having retroperitoneal fibrosis six were men and eight were women. Mean age at diagnosis was 55 years. Nine patients were identified as idiopathic fibrosis and six as secondary. Ten patients were identified as class III retroperitoneal fibrosis (lateral extension of fibrosis with compression of one or both ureters) two as class I fibrosis and two as class IV. Biopsy specimens were obtained in eight patients. The most common presenting symptoms were abdominal pain or discomfort (50%) and ureteral obstruction (71%). Baseline erythrocyte sedimentation or/and C reactive protein levels were elevated in eight patients. Ten patients were treated with corticoids and five with ureteral procedures. Four patients died.

Discussion: Retroperitoneal fibrosis is characterized by fibroinflammatory tissue surrounding the abdominal aorta and the iliac arteries. This process may extend into the retroperitoneum and envelop surrounding structures like ureters. In our study most patients were women with idiopathic fibrosis. Radiotherapy was the main cause of secondary fibrosis. Most patients were identified as class III retroperitoneal fibrosis and treated with corticoids. The

most common presenting symptom was ureteral obstruction. Although nowadays the idiopathic retroperitoneal fibrosis is considered a IgG4 related disease, serum IgG4 concentrations were not measured. The reason could be that it is a novel determination in our clinical laboratory.

Conclusions: Retroperitoneal fibrosis is an uncommon condition with an estimated incidence of 1.38 cases per 100,000 people. To know clinical features of presentation is important for diagnosis. We should measure serum IgG4 concentrations in those patients with retroperitoneal fibrosis. Although corticoids were the most frequent treatment, we should consider immunosuppressive drugs as an option of treatment for corticoid resistant patients.

IF-145
RETROSPECTIVE CASE SERIES FROM A SINGLE CENTER OF ANTI-TNF FOR PATIENTS WITH REFRACTORY NONINFECTIOUS POSTERIOR, INTERMEDIATE AND PANUVEITIS

F. Martínez Valle[1], A. Sellas[2], M. Ramentol[1], B. Rodríguez[2], E. Munté[1], S. Farietta[2], C. Macià Badia[3], R. Solans-Laqué[2]

[1]Department of Internal Medicine, [2]Department of Rheumatology, [3]Department of Ophtalmology. Hospital Universitari General Vall d'Hebron. Barcelona, Spain.

Objectives: To evaluate the efficacy of infliximab and adalimumab in refractory non-infectious intermediate, posterior, and panuveitis in a retrospective study concerning all patients treated in a single center in the last seven years.

Material and method: We analyzed the effect of infliximab and adalimumab in patients diagnosed of non-infectious intermediate, posterior, or panuveitis refractory to immunosuppressive drugs (IMSD) and oral glucocorticoids (oGC). Efficacy was analyzed by measurement of visual acuity, inflammatory activity, the incidence of new episodes of uveitis, and reduction or withdrawal of oGC and IMSD.

Results: From 2004 to January 2011, 16 patients were included (10 women, 6 men), mean age: 37.94 (range 23-61 years), mean follow-up 23.29 months (range 3.47-80). Six patients had Behçet disease, 4 idiopathic vasculitis, 2 birdshot choroidoretinopathy, 1 Harada disease, 1 psoriatic arthritis, 1 serpenginous choroidopathy, 1 idiopathic pars planitis. All of these patients have been previously treated with IMSD and oGC. At the beginning of anti-TNF therapy, all these patients were treated with immunosuppressive drugs and oral glucocorticoids. Eleven patients (68.8%) have been treated with infliximab 5 mg/Kg/IV on 0,2,6 and every 8 weeks, 3 patients (18,8%) have been treated with adalimumab 40 mg each other week, and 2 patient have been treated firstly with infliximab and after with adalimumab. Eleven patients (68.8%) improved visual acuity, 13 patients improved inflammation (81.25%), 10 patients (62.5%) improved these two parameters, 3 patients (18.8%) improved inflammation without improve visual acuity, 1 patient (6.25%) improved visual acuity without improved inflammation, and 2 patients (12.5%) did not show any improvement. 4 patients discontinued treatment, 1 due to inefficacy, 1 due to remission, 1 due to adverse event (infusional reaction), and 1 was lost in follow-up. Patients discontinued to inefficacy and adverse event have been treated with infliximab and after have been switched to adalimumab. OGC dose was tapered in all patients, and IMSD was tapered in 3 patients. 9 patients (56.25%) had not new episodes of uveitis, 5 patients (31.25%) suffered only one new episode of uveitis (close related at beginning of treatment), and 2 (12.5%) patients suffered new severe episodes. Patient in remission relapsed four month after stopped treatment.

Discussion: Even of small size of the sample and that it is a retrospective analysis, it seems that infliximab and adalimumab are save and useful for treatment of refractory posterior uveitis, improving visual acuity, inflammation or diminishes relapses or flares. On the other hand, infliximab and adalimumab could contribute to taper and/or withdrawal glucocorticoids and other immunosuppressive drugs, however prior state of patients could limit this action. No observed life-threatening adverse effects in our series.

Conclusions: Anti-TNF therapy is useful in refractory uveitis. Moreover, prospective randomized trials are necessary to assess the efficacy of these treatments.

IF-146
EARLY INDICATIONS OF BIOLOGICAL THERAPY IN SARCOIDOSIS

E. García Almodóvar[1], L. Martín Fajardo[1], J. Rascón[1], E. Esteban[1], A. Palomero[2], L. Pallarés[1]

[1]Department of Internal Medicine, [2]Department of Pharmacy. Complejo Asistencial Son Dureta. Palma de Mallorca (Illes Balears), Spain.

Objectives: Sarcoidosis is a granulomatous systemic disease of unknown etiology, involving macrophages and lymphocytes with production of proinflammatory cytokines. Steroids and immunosuppressive drugs are indicated for the majority of cases. Identification of refractory cases may benefit from early intervention with biological therapies. Objectives: to analyze the profile of patients with sarcoidosis requiring anti-TNF therapy.

Material and method: Retrospective study of 17 patients with sarcoidosis followed at the Systemic Autoimmune Diseases Unit of a tertiary Hospital during the period 2002-2012. We selected the cases when conventional treatment failed, and in which biological therapy with infliximab or adalimumab was started. Linking symptomatic improvement with resolution of the granulomas. The follow-up was 3 years.

Results: Biologic therapy was indicated in 7 patients. Adalimumab was the first choice in 5/7 (71.4%) cases: 2 patients with systemic disease, and 3 with neurosarcoidosis. Symptomatic and functional improvement was achieved. Infliximab was the first choice in 2/7 (28.6%) patients: 1 with neurosarcoidosis and 1 with systemic and a facial resistant plaque. In this last patient treatment failed and it was switched to adalimumab. None of the patients presented serious adverse effects.

Conclusions: The failure to standard therapy in our patients was mostly related with the presence of neurological sarcoidosis activity. Most of them had good response and evolution with anti-TNF agents. Adalimumab was the most effective drug with sustained clinical remission. However, more experience about the optimal dose and the duration of treatment is necessary. We believe that early intervention with anti-TNF agents may be beneficial in cases of neurosarcoidosis or in sarcoidosis with high activity and extension.

IF-147
SYSTEMIC LUPUS ERYTHEMATOSUS IN THE NORTHWEST OF SPAIN: COMPARISON WITH THE REST OF SPAIN FROM 2006 TO 2010

E. Seco Hernández[1], A. Pérez Iglesias[1], P. Rodríguez Álvarez[1], V. Pérez Carral[1], I. Fernández Regal[1], P. López Mato[1], J. Jiménez Martínez[1], A. Chamorro Fernández[2]

[1]Department of Internal Medicine, [2]Department of Internal Medicine, Section of Autoimmune and Systemic Disease. Complejo Hospitalario Universitario Ourense. Ourense, Spain.

Objectives: We present a comparison between a region in the northwest of Spain (Galicia) and the rest of Spain including the

main epidemiological variables of patients admitted with systemic lupus erythematosus (SLE) as the primary diagnosis (PD).

Material and method: Retrospective study from 2006 to 2010 using data from the SERGAS (Health Service of Galicia), and the rest of Spain through the website of the Ministry of Health http://www.msps.es. We used ICD-9 code 710.0 for SLE and the 710 "diffuse connective tissue diseases" (excluding vasculitis), in both search. Variables such as sex, age, hospital and department of discharge were studied.

Results: There were 779 patients with a DP of SLE in Galicia and 8,086 in Spain. Regarding sex, 77.5% of cases occurred in Galician women while in the rest of the Spain was about 84%. The mean age was 37.89 (SD ± 15.47) in Galicia. Referring mortality (SLE as PD), there were 7 in Galicia (0.9%) and 96 in Spain (1%). Classifying by hospitals, the largest number of admissions was registered in A Coruña with 228 (29.3%), followed by Lugo 178 (22.8%) and Vigo 125 (16%). In Galicia the highest percentage of admissions belongs to: Rheumatology (41.5%), Nephrology (38%) and Internal Medicine (11.3%). According to the total of patients in Rheumatology, the largest number belongs to Lugo 142 (44%), in Nephrology in A Coruña 172 (58.1%) and 42 (47.7%) in Internal Medicine from Vigo. While Internal Medicine was the first in number of admissions (30.4%), Nephrology (26.9%) and Rheumatology (26.2%), in the whole of Spain,. On the other hand, admissions due to autoimmune diseases in the whole country were 14,963. Third of them, 4,880 belong to Internal Medicine, in the majority from Emergency room (57.6%), contrary to Nephrology 2,264 (32.6%) and Rheumatology 4,610 (34%) where scheduled admission was the primary way.

Discussion: The data analyzed in Galicia were very similar to the rest of Spain except for the percentage of admission in Internal Medicine with SLE as PD, if we compare it with other departments that also manage this disease (up to 75% less admissions than in others departments). SLE is a multisystemic disease that could benefit from a global and multidisciplinary manage. Relationship and cooperation with other specialities must be strength. As selection bias, we did not include the secondary diagnosis of SLE neither the cases followed by an ambulatory form.

Conclusions: Our results showed that there were differences in admissions of SLE as a primary diagnosis between the Galician Internal Medicine departments and also compared to the rest of Spain.

IF-148
GASTROINTESTINAL MANIFESTATIONS OF SYSTEMIC SCLEROSIS - ABOUT 10 CASES

N. Ghannouchi, A. Bouker, A. Atig, E. Ben Jazia, A. Alaoua, M. Khalifa, F. Bahri, A. Braham

Department of Internal Medicine. Farhat Hached Hospital. Sousse, Tunisia.

Objectives: Systemic sclerosis (SSc), is a multisystem disease of unknown etiology. Gastrointestinal involvement (GII) is frequent, occurring in 75 to 90% of patients with diffuse or limited cutaneous SSc. All levels may be affected. The aim of this study is to determine the prevalence of GII in Tunisian population.

Material and method: This is a retrospective and descriptive study about 10 patients with SSc monitored during the period from 1995 to 2011 in the department of internal medicine of Farhat Hached hospital (Sousse, Tunisia). All patients fulfilled ACR criteria.

Results: All patients are females. The mean age was 42 years (extremes: 23-70 years). All patients had a diffuse form. All patients developed one or more digestive manifestations. GII was inaugural in 4 cases and late in 6 cases, appeared at a mean of 3.5 years after the onset of disease. Oesophageal abnormalities was the most frequent GII observed in 8 patients. Clinical manifestations were dysphagia (n = 5) and pyrosis (n = 3). The digestive fibroscopy made among 7 patients were normal in 4 cases and has shown a gastritis erosive, an abnormal gastric motility and a peptic oesophagitis in one case each. The manometrie has been practiced among 7 patients and showed a hypotonic lower sphincter of the esophagus in all cases. Intestinal involvement was noted in 4 cases attested clinically by transit disorder and or meteorism. Microrectie was noted in one case. There is nether case of pseudoobstruction syndrome nor gastrointestinal bleeding. All intestinal involvement occurred in the course of the disease. One patient had a malabsorption syndrome related to a celiac disease associated.

Discussion: The result of our study confirms that GII in SSc is common. Esophageal involvement is the most frequent manifestation and appear early in the course of the disease.

IF-149
A COHORT OF PATIENTS WITH DIAGNOSIS OF UVEITIS IN MURCIA, SPAIN

J. Gómez Verdú[1], F. Sarabia Marco[1], M. Giménez Belló[1], J. Muñoz Sánchez[1], F. López Andreu[1], M. García Puche[1], M. Millán Rodríguez[1], P. Moreno Albaladejo[2]

[1]Department of Internal Medicine. Hospital General Universitario Reina Sofía. Murcia, Spain. [2]Department of Stadistic. University of Murcia. Murcia, Spain.

Objectives: Our hospital is a second level center which attends a population of 202.000 people in Murcia. Our objective is to describe the uveitis pattern in our health area (VII Health Area, Murcia, Spain).

Material and method: A cross-sectional study between 1st January 2008 and 1st May 2012 was done. We reviewed the medical records of all patients referred to Internal Medicine Outpatient Department from Ophthalmology Department. Anatomical patterns (IUSG and SUN), age, sex, laterality, histological type, presence of vasculitis and clinical course were analyzed.

Results: The continuous variables were expressed as mean and standard deviation and qualitative variables as percentages. 63 patients were finally included from a total of 69. 50.8 percent were men. The mean age was 44.24 years (SD ± 17.22). On the other hand, 37 (58.7%) were anterior uveitis, 7 (11.1%) intermediate uveitis, 6 (9.5%) posterior and 13 (20.6%) panuveitis. 32 (50.8%) was unilateral. In addition, 4 (6.3%) were granulomatous and in 5 (7.9%) cases vasculitis was described. At last, 26 (41.3%) were acute, 6 (9.5%) were chronic and 31 (49.2%) were recurrent.

Discussion: Global trends of uveitis are changed in the last decades. Uveitis results from several etiological entities. Causes are known to vary in different populations depending upon the ecological, genetic and socioeconomic variations. Uveitis has an equal distribution between male and females, and the most common pattern is anterior uveitis. Mean age of incidence of uveitis, according to several studies, varies from 32 to 45 years. Moreover, infectious diseases were found as the cause of uveitis in 5.2% of patients in developed countries. Therefore, non-infectious diseases were recommended as the major cause of uveitis. Also, we know that there are also some specific HLA dependent inflammatory diseases which can lead to uveitis like Behçet's disease (HLA-B51) or acute anterior uveitis (HLA-B27).

Conclusions: In our hospital, 91.3% of patient with the diagnosis of uveitis can be correctly classified. In our sample, the most common localization was the anterior uveitis and the most frequent clinical course was recurrent.

IF-150
CLINICAL SIGNIFICANCE OF RAISED SERUM BETA-2 MICROGLOBULIN LEVELS IN 177 PATIENTS WITH PRIMARY SJÖGREN SYNDROME: CLOSE ASSOCIATION WITH CLINICAL ACTIVITY AND IMMUNOLOGICAL EXPRESSION

P. Brito-Zerón, S. Retamozo, C. Díaz Lagares, M. Soto Cárdenas, M. Pérez de Lis, M. Akasbi, M. Gandía, M. Ramos-Casals

Department of Systemic Autoimmune Diseases. Hospital Clínic. Barcelona, Spain.

Objectives: To analyze the clinical significance of beta-2 microglobulin, a serum marker closely related to B-cell hyperactivity, in a large cohort of primary Sjögren syndrome (SS) patients, and to analyse the main clinical and immunological characteristics that SS patients with raised levels of serum beta-2 microglobulin may have.

Material and method: We included 177 consecutive patients diagnosed with primary SS in the Department of Autoimmune Diseases in whom serum beta-2 microglobulin levels were retrospectively tested at least twice. Patients fulfilled the 2002 classification criteria for primary SS. The new 2010 EULAR-SS disease activity index (ESSDAI) was also retrospectively calculated. Raised serum levels of beta-2 microglobulin were defined according to the laboratory hospital reference (> 2.3 mg/L).

Results: Of the 177 patients with primary SS, 167 (94%) patients were women and 10 (6%) were men, with a mean age at SS diagnosis of 53.76 ± 1.15 years (range: 18-87). Ninety-seven (55%) patients had raised beta-2 microglobulin levels (> 2.3 mg/L). These patients had a higher mean age at diagnosis of SS (57.39 ± 1.53 vs 49.36 ± 1.63, p < 0.001) and a higher prevalence of lymphopenia (17% vs 7%, p = 0.071), anti-Ro/SSA antibodies(88% vs 62%, p < 0.001) and anti-La/SSB antibodies (69% vs 40%, p < 0.001) in comparison to SS patients with beta-2 microglobulin < 2.3 mg/L. Primary SS patients with raised serum beta-2 microglobulin levels had a higher degree of disease activity measured with the ESSDAI score. In comparison with patients with normal levels of beta-2 microglobulin, those with raised levels had a higher mean cumulated ESSDAI score, a higher mean ESSDAI score at baseline (p = 0.024) and a higher mean score during follow-up (new degree of activity) (p = 0.001). When the mean scores of each domain of the ESSDAI index were compared according to normal or raised values of beta-2 microglobulin evaluated, patients with raised levels had a higher mean score in main systemic domains, including the pulmonary (p = 0.015), kidney (p = 0.032), muscle (p = 0.015) and peripheral nervous system (p = 0.03) domains in comparison with patients with normal beta-2 microglobulin levels.

Conclusions: 55% of patients with primary SS had high levels of serum beta-2 microglobulin. Patients with raised levels were diagnosed with primary SS at an older age and had a higher prevalence of the main SS-related autoantibodies (anti-Ro/SSA and anti-La/SSB). Patients with high beta-2 microglobulin levels also had a high global ESSDAI score and higher scores in the main organ domains. We confirm a close correlation between raised beta-2 microglobulin levels and clinical/immunological activity in patients with primary SS.

IF-151
TREATMENT REGIMENS FOR LUPUS NEPHROPATHY

M. Miranda[1], M. Neves[2], N. Figueiredo[2], L. Rodrigues[2], F. Macário[2], M. Campos[2]

[1]Department of Internal Medicine. Centro Hospitalar Entre o Douro e Vouga. Santa Maria da Feira, Portugal. [2]Department of Nephrology. Centro Hospitalar e Universitário de Coimbra. Coimbra, Portugal.

Objectives: Lupus nephropathy (LN) is a major cause of morbidity and mortality in patients with systemic lupus erythematosus (SLE). The aim of this study is to compare therapeutic regimens in LN.

Material and method: Retrospective study based on clinical records of patients with biopsy-proven lupus glomerulonephritis. We collected demographic and clinical data, histological classification on biopsy, treatment regimens and disease progression.

Results: Ninety-five patients were included in this study, 90% of which were women and the mean age at diagnosis for systemic disease was 27.4 ± 10.9 years. On average, 6.5 ± 1.1 diagnostic criteria for SLE were present, being the most common arthritis (91.2%) and immunological criteria (antinuclear and anti-double stranded DNA antibodies positive in 90.5%). Renal biopsy was performed in all cases, mostly due to hematuria and proteinuria or nephrotic syndrome. Fifty-two patients underwent therapy with pulses of cyclophosphamide (CYC): 7 in a low-dose and 45 in high-dose regimen. There was no statistical difference between the schemes applied concerning presentation of renal disease, number of complete remission (p = 0.09) and flares (p = 1.00), progression to chronic kidney disease (p = 0.66) or need for renal replacement therapy (p = 1.00). Seventeen patients underwent maintenance therapy with mycophenolate mofetil (MMF) and 50 patients with azathioprine (AZA). Comparing both groups, there was no differences concerning presentation of renal disease, histological classification at diagnosis, number of complete remissions (p = 0.27) and flares (p = 0.30), progression to chronic kidney disease (p = 0.13) or need for renal replacement therapy (p = 0.43).

Discussion: As expected, both induction regimens with CYC were similar. Contrary to what is described in the literature there was no differences between maintenance therapy with MMF and AZA, which can be explained by the reduced sample.

Conclusions: The ideal therapy in LN should seek to reduce progression to end-stage renal disease, prevent clinical flares and induce a rapid remission with few adverse effects.

IF-152
GIANT CELL ARTERITIS: WHEN THE TIME IS IMPORTANT

M. Fernández, A. Castro, I. Navas, O. Mateo, M. Guerrero, P. Cuenca, V. García, A. Zapatero

Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: Giant cell arteritis or temporal arteritis is the most frequent of the systemic vasculitis. It affects medium and large vessels with preference for the extracranial carotid territory affecting almost exclusively, people around de fiftieth decade. The most common clinical manifestations are headache, jaw claudication, fever and a constitutional syndrome. The objective is to describe the clinical and analytical characteristics as well as the therapeutic management of the giant cell arteritis diagnosed during the period of 9 years, since the opening of the Universitary Hospital of Fuenlabrada (HUFLR) in June 2004 to April 2012.

Material and method: Retrospective descriptive study of all the cases of giant-cell arteritis diagnosed in the HUFLR from June 2004 to April 2012. They were statistically analysed the following clinical and analytical variables: age, sex, clinical features (headache, fever, disorders of the temporal artery in exploration, constitutional syndrome, visual disturbances, jaw claudication, association with polymyalgia rheumatica) We also analized the treatments administered, including the doses of prednisone, if the descending pattern of corticoids was correct, the improvement after treatment, relapses, realization of biopsy and its result. Analytical features analised: hemoglobin, VCM, leukocytes, VSG, PCR and autoimmunity study.

Results: 9 cases of arteritis giant were diagnosed. They were predominantly elder patients (age: 75 years) and women (66.7%). Constitutional syndrome was the most common symptom and the

reason why the consulted (77.8%) followed by headache (55.6%), fever (55.6%) and jaw claudication (55.6%). Only one patient debuted with amaourosis fugax. Two patients (22.2%) showed alterations in the temporal artery in exploration. Up to 6 patients had rheumatic polymyalgia clinic (66.7%). A high level og VSG was found in 87% of the patients along with normocytic (VCM: 88.7 fl) anaemia (Hb: 11.1 g/dl) and elevated CRP (15 mg/dl). There was no leukocytes elevation (10,500). Autoimmunity study was performed in four patients; with positive ANA's in one patient. The average time until de diagnosis was performed, was approximately 12.8 days. 100% of patients initially received prednisone at the beginning (61.1 mg/d); and in three patients (33.3%) methotrexate was added later. The time since the diagnosis is suspected until the treatment with corticosteroids was begun is short (1-2 days), and there is a subjective improvement in symptoms in the fourth-fifth day of treatment in most patients (8) finding no improvement in the patient with amaurosis fugax. Biopsy was performed in 7 patients (two of them before starting treatment with steroids). It was positive in three cases (33.3%). 4 patients made a correct corticoids decrease, with only one relapse after trying to suspend the steroids. Of the remaining four that didn't make a correct downward pattern, three relapse and one fails to improve (amaurosis fugax). A patient was lost during the follow-up.

Conclusions: We observed that this entity is more common in older women who consult with constitutional syndrome along with headache, fever, and jaw claudication, normocytic anemia and high VSG, Initial treatment with steroids resulted in a rapid initial improvement of symptoms, but if the downward pattern is not done correctly there is a high probability of relapse.

IF-153
PATTERNS OF BIOLOGIC AGENT USE IN ELDERLY PATIENTS IN AN AUTOIMMUNE DISEASES UNIT

H. Gruner, A. Antunes, F. Moraes-Fontes, N. Riso, V. Riscado

Department of Internal Medicine 2. Hospital Curry Cabral. Lisboa, Portugal.

Objectives: Even though there is a high prevalence of rheumatological diseases in elderly patients for which biological agents can be the only effective form of therapy, there are few reports regarding their use in this age group. Safety concerns in the elderly are exacerbated by frequent co-morbidities, polypharmacy, underlying immunosenescence and increased risk of infection, cancer and accelerated atherosclerosis, which may inadequately exclude elderly patients from such therapies. The aim of this study was to characterize elderly patients (> 65 years old), treated with biological agents.

Material and method: Retrospective study with review of the files of all elderly patients treated with biological agents in an Autoimmune Diseases Unit. Patients were characterized according to sex, age, autoimmune disease, biological agent, switch rate, efficacy and adverse side effects.

Results: Of the 124 patients using biological agents, 19 patients (15.3%) were older than 65 years (y): mean age 69 y. Only 1 patient was older than 75 y (80 y); 12 (63%) were female. Rheumatoid arthritis (RA) was present in 13 patients; anquilosing spondylitis (AS) in 2 patients and psoriatic arthropathy (PA) in 1. The use of biological agents was Off label in 3 patients with Systemic lupus erythematosus in 1; Wegener syndrome in 1; and thrombotic thrombocytopenic purpura in 1. As first line therapy, etanercept was used in 11 patients (9 with RA, 2 with AS and 1 with PA); rituximab was used in 5 patients (2 with RA and 3 off label); adalimumab in 1 and tocilizumab in 1 patient, both with RA.

Discussion: After a mean duration of 3.7 years of therapy, 4 (21%) AR patients required a switch in therapy with etanercept (n = 3) due to primary failure (n = 1) and due to infectious adverse events (n = 2) namely pulmonary tuberculosis and palmoplantar pustulosis, both treated with success; switch in therapy with tocizilumab (n = 1) patient was due to primary failure. The switch was made from etanercept to tocizilumab (n = 2) of wich one still awaits the begining of the therapy, and rituximab (n = 1); and from tocizilumab to infliximab (n = 1). Suspension ocurred in 2 (10.5%) AR patients due to angioedema (rituximab) and prostate adenocarcinoma (etanercept). Concerning efficacy in AR patients the DAS 28 pre biological therapy was 5.35 and at present 2.85.

Conclusions: The overall rate of adverse events reported with biological therapies in the elderly is not well known. In our group of patients for a mean of 3.4 years of treatment with biological agents, the rate of adverse events was 10.5%. The stop/switch rate was 32%, the same as other published articles. Etanercept and rituximab were an effective form of therapy, well tolerated in this group of elderly patients with AR.

IF-154
TREATMENT OF SEVERE AND/0R REFRACTORY BEHÇET DISEASE WITH ANTI-TNF: ANALYSIS OF 32 PATIENTS

C. Díaz Lagares[1], F. García Hernández[2], A. Martínez Berriotxoa[3], R. Gómez de la Torre[4], L. Caminal[5], L. Pallarés[6], J. Callejas[7], J. Cánora Lebrato[8]

[1]Laboratory of Autoimmnune Diseases "Josep Font". Centre Sociosanitari Hospital Clínic i Provincial de Barcelona. Barcelona, Spain. [2]Department of Internal Medicine. Hospital Virgen del Rocío. Sevilla, Spain. [3]Department of Internal Medicine. Hospital de Cruces. Barakaldo (Vizcaya), Spain. [4]Department of Internal Medicine. Hospital San Agustín. Avilés (Asturias), Spain. [5]Department of Internal Medicine. Hospital General de Asturias. Oviedo (Asturias), Spain. [6]Department of Internal Medicine. Hospital Son Espases. Palma de Mallorca (Illes Balears), Spain. [7]Department of Internal Medicine. Hospital de Especialidades San Cecilio. Granada, Spain. [8]Department of Internal Medicine. Hospital de Fuenlabrada. Fuenlabrada (Madrid), Spain.

Objectives: To evaluate the efficacy and safety of rituximab in patients with Behçet disease and severe involvement refractory to conventional treatment.

Material and method: In 2006, the Autoimmune Diseases Study Group (GEAS) of the Spanish Society of Internal Medicine created the BIOGEAS registry, a multicenter study designed to collect data on the use of biological therapies in patients with systemic autoimmune diseases refractory to conventional treatment (failure at least of two immunosuppressants). The information is collected from cases reported by members of GEAS (last updated: 30 May 2012).

Results: 32 patients with Behçet disease treated with anti-TNF agents (infliximab 21, adalimumab 6, and etanercept 5 patients) have been included in the registry (19 women and 13 men, with a mean age of 37 years. The clinical manifestations presented by these patients that motivated the indication were as follows: uveitis (19 cases, 63%), skin and mucous involvement (8 cases, 27%), arthritis (5 cases, 17%), central nervous system involvement (5 cases, 17%), gastrointestinal involvement (5 cases, 3%) and lung involvement (1 case, 3%). They were heavily treated patients, who had previously received corticosteroids and cyclosporine A (20, 63%), methotrexate (14, 44%), azathioprine (11, 34%), colchicine (9, 28%), pentoxifiline (5, 16%), cyclophosphamide (5, 16%), mycophenolate (4, 13%), tacrolimus 3 (9%) interferon (3, 9%), thalidomide (2, 6%) and immunoglobulins (1, 3%). In 27 (84%) concomitant immunosuppressive therapy was added to biological therapy. 27 (84%) patients had a favorable response to treatment (72% complete response, partial response 12%, 16% no response). The response to treatment by organ was as follows (analyzed those organs with a minimum of 5 cases): eye (78% complete response,

11% partial response and 11% no response), mucocutaneus (63% complete response, 12% partial response and 25% no response), arthritis (60% complete response, 40% partial response) and central nervous system (80% complete response, 20% no response). The time of follow-up was 23 months. 4 patients (13%) suffer a relapse during follow up. 6 (19%) patients suffered an adverse event, including 3 (9%) an infection, two cases of demyelinating disease and one case of psoriasis. No patient died during the follow-up period.

Conclusions: Anti-TNF treatment may be an effective and safe option for patients with severe Behçet disease refractory to conventional treatment. Uveitis was the clinical problem that was treated more frequently with anti-TNF, achieving in more than 80% of cases a favorable response. Two patients developed probable demyelinating disease after the treatment.

IF-155
SCLERODERMIC SYNDROMES: THREE CASES REPORT

M. Fernández, A. Castro, C. Tojo, I. Navas, J. Marrero, B. Frutos, A. Romero, J. Canora

Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: Sclerodermic syndromes are defined by the presence of an increase in the dermis and the hypodermis of the collagen deposits. These depostis of collagen cause skin fibrosis and induration, which reduces the skin elasticity. The incidence is between 3.7 and 19 new cases per million inhabitants/year and the prevalence between 30.8 and 286 cases per million inhabitants/year. Affecting woman more often. The objective is to describe the clinical features of three cases of sclerodermiform syndromes which have been diagnosed and treated in the department of Internal Medicine at the Universitary Hospital of Fuenlabrada. This hospital covers a population of 230,000 inhabitants.

Results: We describe three different cases. The first is a 52 year-old, former smoker with hypercholesterolemia, induration and darkening of the skin of the abdomen and legs along with dysphagia and fever. The fingers presented taut skin and vasomotor phenomena. Hystological findings show a remarked fibrosing process of the reticular dermis and subcutaneous tissue he was finally diagnosed of systemic sclerosis. The next case consists of a 57 year-old man, former smoker, with hypercholesterolemia, DM type 2 and mitral insufficiency, that complained of increased diameter of the lower limbs, forearms and hands, with taut skin that hindered joint mobility. He had a thickened skin with erythema and peau d'orange with pitting edema, no signs of skin atrophy. Analytically it highlighted an important eosinophilia and histological findings were consistent with eosinophilic fasciitis. Tha last case was a male born in Equatorial Guinea that was admitted to the hospital in an acute confusional state. He admitted alcohol intake and begun to present a stuporous state. In the physical examination it draws attention a micropapular lichenoid rash predominantly in the thorax and upper extremities. The electroencephalogram showed diffuse encephalopathy and skin biopsy findings disseminated papillary mucinosis, consistent with scleromyxedema (associated with neurological disorders). Analytically, the three patients presented slightly elevated acute phase reactants (C-reactive protein < 4 mg/dl) with normal CBC (except case 2 who had eosinophilia). Case 3 had acute renal failure secondary to rhabdomyolysis (creatinine: 1.43 mg/dl and CK: 1907 U/L). In all cases the autoimmunity was negative. Thyroid hormones were normal and the protein profile was normal (except for case 3 with a monoclonal IgG lambda). The first two cases received corticosteroids (case 1 associated with methotrexate, and case two with hydroxychloroquine) and the third with intravenous immunoglobulins.

Conclusions: Although the clinical and laboratory findings present some differences, histological samples that include the subcutaneous tissue and muscle fascia, are essential for the differential diagnosis.

IF-156
HOW FREQUENT ARE RENO-PULMONARY SYNDROMES?

A. Castro, M. Fernández, I. Navas, L. Lozano, B. Matía, R. Calderón, D. Rejas, L. Horrillo

Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: Reno-pulmonary syndromes encompass a wide range of entities, relatively infrequent and of autoimmune etiology, which should be included in the differential diagnosis of patients with acute renal impairment and/or anemia of uncertain etiology. Its diagnosis however is not easy and requires more targeted testing that facilitates a narrowing of a broad range of options. Still today, it's a challenging diagnosis with a clinical and prognostic impact. The objective of this study is to evaluated epidemiological, clinical and laboratory data of the patient with this disease in Fuenlabrada's Hospital.

Material and method: Retrospective study including patients diagnosed of reno-pulmonary syndrome (encompassing in this group, granulomatosis with polyangiitis-in clinical practice split in microscopic polyangiitis and Wegener's granulomatosis-) at the Universitary Hospital of Fuenlabrada from date of opening (2004) until February 2012. The inclusion criteria include de evidence of autoimmunity and histological study in a compatible clinical setting. In the study, we evaluated epidemiological, clinical and laboratory outcomes.

Results: Of the 20 patients included, 5 of them were excluded because it was not possible to establish a specific diagnosis (there were no histological samples, laboratory tests...). The remaining diagnoses were distributed as follows: microscopic polyangiitis (9), Wegener (4) and Goodpasture (2). There was a slight predominance of males (57% vs 43%) and the clinical presentation was predominantly with renal failure (64%) together with an anemia, of varying severity (that affected 100% of the patients). The treatment consisted in a combination regime of corticosteroids and cyclophosphamide for at least a year, with good response either with partial remission or total in most cases.

IF-157
ABDOMINAL MANIFESTATIONS IN ANTIPHOSHOLIPID SYNDROME: OUR EXPERIENCE

A. Camacho, C. Díaz, S. Bermejo, S. Cuatrino, I. Martín

Department of Internal Medicine. Área Hospitalaria Juan Ramón Jiménez. Huelva, Spain.

Objectives: Antiphospholipid syndrome (APS) is characterized by recurrent thrombosis, pregnancy losses and the presence of antiphospholipid antibodies. Venous or arterial thrombosis could involve any vascular territory resulting in a big variety of clinical manifestations. Abdominal involvement is not frequent and its main symptom is abdominal pain. To describe clinical features and prognosis of patients with APS and abdominal manifestations.

Material and method: Observational retrospective study from our cohort of patients with APS and abdominal involvement.

Results: Twelve patients were included (66% male, age in years 44.2) and we reviewed their clinical records. Main clinical manifestations were: abdominal pain (90%), arterial thrombosis (58%), venous thrombosis (33%) and bleeding (8%). Other clinical features were: livedo reticularis (16%), ulcers in lower extremities

(8%), thrombocytopenia (16%). Only one case presented with haemolytic anemia. About 83% of patients presented with abdominal involvement as first manifestation of APS. A CT angiogram was performed in more than 80% of patients, followed by arteriography (8%). Histologic findings showed vasculitis and thrombosis of small vessels. IgG Anticardiolipin antibodies were positive in 50% of cases and lupic anticoagulant in 41%. Anticoagulant treatment was started in more than 70% of patients and was combined with AAS and hydroxychloroquine in approximately 8% of cases. We used rituximab in 8% of cases who presented with recurrent thrombosis. About 8% of patients died before starting an adequate treatment.

Discussion: According to the medical literature, abdominal involvement was more frequent in young male. In our cohort, differing from other studies, we observed arterial thrombosis as the most frequent abdominal presentation. Indefinite anticoagulant is a safe and effective treatment to prevent recurrent thrombosis in APS.

Conclusions: Although abdominal manifestations are rare in APS, a proper diagnosis it's required in order to start a specific treatment to prevent major complications. We recommend including APS in differential diagnosis when we witness an abdominal complication and any thrombotic event. In our cohort, APS presented with abdominal involvement as first manifestation of the disease.

IF-158
SYSTEMIC SCLEROSIS: A DESCRIPTIVE STUDY

N. Ramos Vicente[1], L. Pantoja Zarza[2], C. Díez Morrondo[2], C. Buelta González[1]

[1]Department of Internal Medicine, [2]Department of Rheumatology. Hospital El Bierzo. Ponferrada (León), Spain.

Objectives: With this study we describe clinical manifestations presented throughout the disease and focused on skin ulcers and effectiveness of treatment for the same.

Material and method: We selected the Medical Records of 22 patients in outpatient follow-up to describe sex, clinical immunological, clinical manifestations and treatment.

Results: Of the 22 patients diagnosed with Systemic Sclerosis, 20 were women and 2 men. 9 of them had digital ulcers with good results with vasodilator therapy, except in one patient who required amputation of the same. Antibody Anti Scl 70 is present in most patients.

Discussion: Systemic sclerosis is a disease whose pathophysiology combines immune system activation, microvascular alterations and the proliferation of fibroblasts with a consequent increase in collagen deposition in tissues. Clinical manifestations include the characteristic skin thickening or scleroderma, Raynaud's phenomenon, altered gastrointestinal apparatus, mainly the esophagus, interstitial lung disease, pulmonary hypertension, renal disease and musculoskeletal system. The clinical expression of systemic sclerosis and prognosis can be very variable. There is no specific treatment and therefore healing thereof. But in recent years numerous therapies have proved effective in some of the manifestations of the disease.

Conclusions: 1. It is more common in females than males in a 9:1 ratio. 2. The prevalence of digital ulcers is estimated between 30 and 60%. In our series of patients, were presented in 41%. 3. Pulmonary involvement: fibrosis, and esophageal: hypomotility and reflux are frequently present in these patients. 4. They are very important general measures such as avoiding snuff, stress and cold for the good management of skin involvement. 5. The use of vasodilators such as non-selective antagonist of endothelin receptors (bosentan) has good results in pulmonary hypertension and digital ulcers.

IF-159
ANTIPHOSPHOLIPID SYNDROME (APS) IN A INTERNAL MEDICINE DEPARTMENT

A. Melgarejo González, E. García Villalba, M. Egea Campoy, F. Sarabia Marco, M. Giménez Belló, A. Uceda Galiano, T. Carbajo Mateo, F. López Andreu

Department of Autoimmune Diseases. Hospital General Universitario Reina Sofía. Murcia, Spain.

Objectives: To describe the clinical manifestations, analytical data and management of patients with diagnosis of APS in a General Internal Medicine Department.

Material and method: We performed a descriptive analysis of clinical, epidemiological, analytical and treatment profile of 48 patients with diagnosis of APS in an Internal Medicine Department from 1st January 2000 to 31st May 2012.

Results: From a total of 48 patients included, 29 were women with a mean age of 44.13 years (SD ± 18.86) and 19 men with a mean age of 46.87 years (SD ± 17.62). 36 patients (75%) has a primary APS and 12 (25%) had APS associated to autoimmune disease (AD). From those associated with AD, 10 were due to lupus erythematosus (SLE) and 2 due to ulcerative colitis. Of all patients, 50% debuted with venous thromboembolism (11 patients had a pulmonary embolism and deep vein thrombosis 13), 43.75% debuted with arterial thrombosis (13 stroke, 1 thrombosis of the subclavian artery, 5 thrombosis of the central artery of retina, 1 acute myocardial infarction and 1 repeat abortion), 4.16% with antibody-positive (with a history of neurological symptoms) and 2.08% with skin lesions. The most common lupus anticoagulant was the antiphospholipid antibody (85.41%). The treatments were: 60.41% in anticoagulation with acenocoumarol, a 2.08% anticoagulated with warfarin, an anticoagulant and antiplatelet 20.83% (half with cardiovascular risk factors), an antiplatelet 14.58% and 2.08% by antiplatelet therapy plus heparin sodium (patient with catastrophic APS). In an average of 7 years of follow-up, complications were: a stroke after removing warfarin, cerebral venous thrombosis, a stroke and renal infarction (infradosificate acenocoumarol), three TIA, gastrointestinal bleeding (acenocoumarol overdose), a psoas hematoma and three died (1 EP complicated, 1 SLE and 1 catastrophic APS).

Discussion: Several studies published about primary antiphospholipid syndrome have estimated a prevalence up to 0.3 to 1% of population, affecting more often women than men (5:1), especially in patients with other associated pathologies. Most cases, about 53%, are primary, 36% associated to SLE and the rest of them to another autoimmune disease. The main age of onset is around 30 years and even though patients with no other diseases usually have a decade later onset, APS has been described at any age. The main form of presentation is deep vein thrombosis followed by thrombocytopenia, although patients over 50 years, especially male, often present with angina and stroke. Epidemiological results in our series do not match those described in literature, showing our study a larger proportion of male patients slightly older than usual. Those epidemiological data correlate our clinical findings, according to what's been published, about the presence of more severe events (pulmonary thromboembolism and stroke). We recalled a high number of patients under treatment with antiplatelet or anticoagulant drugs either because of their higher incidence of additional cardiovascular risk factors or the presence of more than one clinical event.

Conclusions: The proportion of patients presenting with associated- antiphospholipid syndrome is low in comparison with medical literature, possibly due to a sooner antiaggregation in those cases with antibodies positive. A large number of main thrombotic events have been seen in our study, what we correlate with an increase in the average age of our population so with the

presence of another cardiovascular risk factors lupic anticoagulant was the immunologic parameter most frequently involved.

IF-160
ADULT STILL'S DISEASE IN A THIRD LEVEL HOSPITAL

S. Aguilar Huergo[1], J. Sabio Sánchez[2], M. López Veloso[1], N. Carracedo Falagán[1], S. Raposo García[1], N. Navarrete Navarrete[2], M. Zamora Pasadas[2], J. Jiménez Alonso[2]

[1]Department of Internal Medicine. Complejo Asistencial de León. León, Spain. [2]Department of Internal Medicine. Complejo Hospitalario Regional Virgen de las Nieves. Granada, Spain.

Objectives: To look up the clinical features of adult Still's disease of inpatients admitted in Internal Medicine Department of Virgen de Las Nieves Universitary Hospital (Granada) for the last 14 years. To study their symptomatology, complementary findings and their laboratory results. Finally, to clarify if our results are consistent with the previously published literature.

Material and method: It is a retrospective descriptive study of inpatients with the final diagnosis of adult Still's disease admitted in Internal Medicine Department of VN Hospital in Granada from January 1998 to March 2012. Although the low prevalence of this illness (it is described in many sources around 0.16 cases/100,000 people), our sample is formed by 10 cases. We have used a previously established data collection protocol of the sample and we have revised medical stories and finally, an statistical analysis with SPSS program.

Results: The sample included 10 inpatients with a mean age of 29 years old (min 17-max 52, SD 10.2, median 26.5). Most of them were female (80%, 8/10). The age range between 17 and 30 involves 80% of them. We have analyzed if our patients meet Yamaguchi criteria and 80% of them were positive (presence of 5 features (2 being major diagnostic criteria)). The other 20% were negative with 4 points. Fever (more than 39 ºC lasting more than 1 week) was present in 100% of cases. Asthenia was concomitant in 80% and non-measured weight loss only in 20% of them. The arthralgias (80% (8/10)) and arthritis (60%) lasted at least 2 weeks. Skins lesions were present in 80% of them (from them 70% with the typical salmon-colored nonpruritic maculopapular rash). Other common symptoms were odynophagia (50%) and dyspnea on moderate effort (30%) in the context of a respiratory cold. To stand out of the physical examination, we found adenopathies (40%, also in imaging) and no megalies, being the rest normal. To highlight between laboratory results, we find leukocytosis (10,000/mL) in a rate of 70% and left deviation in 80%, elevated APR [ESR > 50 (100%), CRP > 5 (90%)], ferritin > 500 (20%). ANA, autoimmunity test and RF were negative in 100% of cases. All microbiological test, serologies, echocardiography (made in 20% of them) were negative. Biopsy was performed in 20% in adenopathies (20%, with normal AP study) and bone marrow (10%, also within the normal). The treatment was sustained on antipyretics, glucocorticoids (70% of patients, with a maintenance dose of 0.5 mg prednisone/kg/day in most of them), NSAIDs (50% of cases, especially indomethacin) and ASA (10%). In most of the cases and with the joint assistance, we achieved a good control of the disease. Only in 30% of the cases we needed immunosuppressive drugs (methotrexate) to improve the treatment response.

Discussion: We have found out that adult Still's disease is a cause of fever of unknown origin in young adults with a very suggestive clinical picture and negative results of plenty of studies such as microbiological, autoimmune tests and imaging. Moreover, sometimes the empiric use of glucocorticoid and immunosuppressive therapy have an early response and that point can prompt us to think about this clinical entity. Furthermore, our results are quite consistent with the previously described in literature.

Conclusions: Adult Still's disease is an inflammatory disorder with quotidian fevers, arthritis and a evanescent rash and negative results for microbiological and autoimmune tests. The mainstay of treatment are glucocorticoids, NSAIDs, ASA and the occasional aid of immunosuppressive agents.

IF-161
SUBCLINICAL ATHEROSCLEROSIS IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS EVALUATED BY CAROTID DOPPLER ULTRASOUND

R. González Mazarío[1], A. Aljibe Aguilar[1], P. Flors Villaverde[1], L. Micó Giner[1], C. Ballester Vallés[2], J. Calabuig Alborch[1]

[1]Medical Area. Department of Internal Medicine, [2]Department of Radiodiagnostic. University Hospital La Fe. Valencia, Spain.

Objectives: Cardiovascular disease is a major cause of late mortality in systemic lupus erythematosus (SLE). The classic cardiovascular risk factors do not explain for if alone this increase in the morbidity and mortality. The carotid doppler ultrasound is a simple diagnostic technique that allows to evaluate the presence of subclinical atherosclerosis across the measure of carotid intima-media thickness (cIMT) and the presence of carotid plaques. The aims of our study have been: 1. To determine the prevalence of increased cIMT and carotid plaques in a women's cohort with SLE. 2. To investigate his possible relation with the traditional cardiovascular risk factors, SLE activity and treatment used.

Material and method: We conducted a transversal, retrospective and observational study in 90 women with SLE, registered in a database online (www.registroles.es) for the study of cardiovascular risk, and controlled in our hospital. The increase of cIMT and the presence of carotid plaques were evaluated by Doppler ultrasound (B-mode). We assessed classical cardiovascular risk factors, and markers of lupus activity. Data were analyzed using SPSS (version 19).

Results: The patients' mean ± SD age was 38.8 ± 12.3 years. The most important cardiovascular risk factors in descending order were: sedentary (68.9%), dyslipidemia (41.1%) and smoking (35.6%). 15.6% patients had a history of early cardiovascular disease. Only 11.1% received lipid-lowering therapy, and 31.1% antipaludic drugs. With regard to disease activity: C reactive protein mean was 10.08 mg/L, erythrocyte sedimentation rate 31.59, and SLEDAI of 5.14. The 64.4% had hypocomplementemia C4 and 20% C3 hypocomplementemia. The average number of outbreaks was 3.87. Carotid doppler ultrasound was pathological in 24/90 patient (26.7%). There were carotid plaques in 21/90 patient (23.3%, of that 10% were calcified plaques, and 13.3% fibrolipidic plaques), and an increase of the GIM in 13/90 (14.4%). The presence of plaques was associated with age (p = 0.01), smoking (p = 0.04) and the number of outbreaks (p = 0.00), differences statistically significant.

Discussion: The prevalence of pathological findings in carotid Doppler ultrasound was similar to that observed in previous studies. A high percentage of patients had classic cardiovascular risk factors are potentially reversible, especially hypertension, dyslipidemia, sedentary lifestyle and smoking. The degree of activity of SLE was high, with a considerable percentage of outbreaks, complement consumption and increased CRP. Further studies are required (with healthy controls) to confirm these findings.

Conclusions: Noninvasive diagnostic techniques such as carotid ultrasound allow us to investigate the importance of subclinical cardiovascular disease in patients with SLE. Our study shows a high prevalence of pathological findings in the carotid Doppler ultrasound (26.7%), in a cohort with low mean age (38.8 years). Furthermore,

the prevalence of traditional cardiovascular risk factors, potentially treatable was very considerable.

IF-162
PREGNANCY OUTCOMES IN PATIENTS WITH SYSTEMIC AUTOIMMUNE DISEASES AND/OR ANTIPHOSPHOLIPID ANTIBODIES

J. Moreno Díaz[1], L. Sáez Comet[2], C. López Lapuerta[1], L. Bolea Laderas[1], E. Martínez Pagán[1], J. Velilla Marco[2], M. Pérez Conesa[2], L. Rello Varas[3]

[1]Department of Internal Medicine, [2]UEAS, Internal Medicine, [3]Department of Biochemistry. HU Miguel Servet. Zaragoza, Spain.

Objectives: To describe pregnancy outcomes in connective tissue diseases (CTD) and/or antiphospholipid antibodies (APA). To compare pregnancy outcomes in 3 groups: CTD, CTD with APA and patients with APA alone. To evaluate clinical and immunological factors involved in those pregnancy outcomes.

Material and method: Retrospective study of all pregnancies followed-up since june 2007 in our Systemic Autoimmune Diseases Unit. Patients included had previous results of APA positive or a previous diagnosis of CTD: systemic lupus erythematosus (SLE), systemic sclerosis (SSc), Sjögren's syndrome (SjS) or undifferentiated connective tissue disease (UCTD). A follow-up protocol was designed, including clinical data like obstetric and thrombotic history, autoantibodies (ANA, ENAs, DNA, ACA IgG and IgM, AB2-GPI IgG and IgM and LA). Therapies used during pregnancy were also included. Pregnancy outcomes were collected in a clinical review 3 to 6 months after birthdate: gestational age, weight at birth, eclampsia or preeclampsia, miscarriages and CTD flares during pregnancy or 3 months postpartum. Univariate analysis with chi square tests was used.

Results: 143 pregnancies in 129 patients were included: 31 (21.7%) with UCTD, 22 (15.4%) SLE, 43 (30.1%) APA+, 23 (16.1%) UCTD + APA, 24 (16.8%) SLE + APA. 114 (79.7%) pregnancies ended in a newborn alive, with a mean pregnancy length of 38 weeks and a mean weight at birth of 3,041 g. The overall results are shown in table 1. Factors related with worse pregnancy outcomes (miscarriages) were: Diagnostic group (worse outcomes in APA, then in CTD-APA and then in CTD, p 0.029). Lupus anticoagulant (p 0.025). IgM anticardiolipin (p 0.047). Any APA (p 0.010). Previous miscarriages ($p < 0.001$). ANA positive (p 0.044). Use of aspirin prior to pregnancy (p 0.001).

Discussion: Worse outcomes are seen in patients with previous miscarriages and APA, especially with LA and IgM ACL. Aspirin prior to pregnancy and ANA negative patients have worse results, probably due to a bias because of the presence of APA.

Conclusions: We report worse pregnancy outcomes in patients with APA, with a higher rate of miscarriages than in CTD.

Table 1 (IF-162). Pregnancy outcomes in patients with CTD and/or APA

Results	Number of pregnancies (out of 143)	% of pregnancies
Miscarriages	28	19.6%
Prematurity	19	13.3%
Low weight at birth	17	11.9%
Eclampsia or preeclampsia	4	2.8%
CTD flares	29	20.3%
1st trimester miscarriage	23	16,1%
Fetal deaths	5	3.5%

IF-163
ACTIVITY LOG OF A SYSTEMIC AUTOIMMUNE DISEASE SPECIALIZED OUTPATIENT CONSULTATION

J. Santos Martínez[1], F. de la Calle Prieto[1], T. Blanco Moya[1], M. Ferrer Civeira[2], D. Salor Moral[2], M. Gómez Antúnez[1], A. Muíño Míguez[1], B. Pinilla Llorente[2]

[1]Department of Internal Medicine 2A, [2]Internal Medicine Unit D. Hospital G.U. Gregorio Marañón. Madrid, Spain.

Objectives: To analyze the causes and reasons for outpatient consultation, diagnostics, therapeutic approach and comorbidities of patients attending a Systemic Autoimmune (AI) Disease Specialized Consultation, in order to evaluate the suitability of the existence of such consultations realized by an Internal Medicine physician; extract epidemiological data on the prevalence of systemic autoimmune diseases in our environment.

Material and method: We analyzed epidemiological data, diagnostics, therapeutic approach and treatments of 127 consecutive patients who attended this outpatient consultation (belonging to a university hospital complex in Madrid, Spain) between 1/9/10 and 31/5/11.

Results: 127 patients were included in this study (74% women, 26% men); mean age was 59.66 + 18.12 years old. 66.1% of all the patients came to this consultation referred from other Internal Medicine physicians, 22.9% came from other medical specialties physicians, and 11% were derived from primary care. Reasons for consultation: previous diagnostic of AI disease in 43.3% (which were referred for treatment and follow-up), plus suggestive symptoms and/or suggestive blood test of AI disease in 56.7%. Concerning comorbidities in this group of patients, 14.2% of them had digestive, 13.4% cardiovascular, 11.8% nephro-urological, 11.8% haematological and 8.7% neoplastic disease previously diagnosed, to mention some examples. Diagnosis for erythematosus systemic lupus supposed 14.2% of all patients, scleroderma 5.5%, Sjögren syndrome 10.2%, sarcoidosis 3.1%, temporal arteritis 4.7%, another type of vasculitis 4.7% (PAN, cryoglobulinemia...), primary biliary cirrhosis 3.1%, and undefined AI disease with positive auto-antibodies 14.2%, among others. On the other hand, 21.3% of all patients were not diagnosed with an AI disease. 4.7% were diagnosed of infectious non AI disease, 1.6% of haematological non AI disease, and 15% of other type of non AI disease. The mean time of monitoring was 32 + 30 months. 39.4% of total were already receiving specific treatment for an AI disease. 75.6% continued follow-up and 21.3% were discharged from this consultation. In a deeper analysis, statistically significant association was found between diagnosis for erythematosus systemic lupus and neoplastic comorbidity, and also between diagnosis for an undefined AI disease and haematological comorbidity. Considering age and diagnosis of AI disease, we found association between diagnosis for Sjögren's syndrome and the group of individuals above 65 years old, and between the diagnosis for undefined AI disease with positive antibodies and the group of patients below 65 years old.

Discussion: Most of our patients were women, mainly submitted by Internal Medicine or primary care physicians, which justifies the elevated mean age and the high prevalence of comorbidity. The broad spectrum of autoimmune diseases diagnosed and the high prevalence of comorbidity, requiring long follow-ups, highlights the benefit of an integrate specialty such as Internal Medicine to attend these patients.

Conclusions: The patients with an AI disease referred to this outpatient Internal Medicine consultation have a high percentage of comorbidity. The broad spectrum of autoimmune diseases diagnosed, the high prevalence of comorbidities, as well as the need for monitoring and specific treatment, highlight the benefit of an integrate specialty such as Internal Medicine to attend these patients.

IF-164
ANTIPHOSPHOLIPID SYNDROME (APS) WITH ISCHEMIC NEUROLOGIC MANIFESTATIONS: DESCRIPTION OF SEVEN CASES

D. Colunga[1], S. Colunga[2], A. Martínez[1], A. Fidalgo[1], J. Bernardo[1], V. Cárcaba[1]

[1]Department of Internal Medicine, [2]Department of Cardiology. HUCA. Oviedo (Asturias), Spain.

Objectives: To describe the epidemiological, clinical characteristics and the antiphospholipid antibodies (aPL) present in the cases of APS with neurological manifestations of cerebral ischemia as diagnostic criterion, registered at the database of the Unit of Autoimmune Systemic Diseases of the HUCA, in Asturias from May 2006 up to December-2010.

Material and method: Retrospective review of computerized reports of 7 patients recorded in the database of the Unit with APS and neurologic manifestations as diagnostic criterion. We recorded: Age, sex, kind of APS (primary or secondary), clinical neurological manifestations, arterial territory involved, thrombocytopenia or hypertension if associated, laboratory diagnostic criteria (positive aPL test), transthoracic echocardiography results and treatment given (anticoagulants, aspirin, hydroxychloroquine).

Results: 32 patients with APS fulfilling Sydney's diagnostic criteria were registered between May in 2006 and December 201, 7/32 (21.87%) with neurological manifestations as clinical criterion. 6/7 they were women, middle ages to the diagnosis 36 years (15-60 years). The clinical manifestation was stroke or transient ischemic attack due to middle cerebral artery occlusion in 5/7 patients; one patient had chorea and white matter lesions on MRI and in another one had an ischemic stroke affecting basilar arterial circulation. Only 2 of them had migraine as associated condition. There was no livedo reticularis registered. Only in 2/7 arterial hypertension was registered, only a patient with SLE presented thrombocytopenia and in only a case cardiac murmur was registered. The positive test for aPL activity was lupus anticoagulant (LA) t in 3/7 patients and anti-beta2glycoprotein I IgG in 4/7 (3 of them with associated anticardiolipin antibody (aCL) IgG). Only one patient had both LA and ACL IgG positive activity tests. There was only one positive IgM aCL test. Though 6/7 patients had positive ANA test, only 3 were assembling SLE's diagnostic criteria. A transthoracic echocardiography was performed in all patients, and in 6/7 of them a mitral slight insufficiency was diagnosed. Tests for detection of proteinuria in urine of 24 hours were not performed in any patient. Curiously the only patient male was the only one with positive Ig M aCL test with high titers, he had associated hypertension, the stroke was affecting basilar territory and he was also the only patient without valvular affectation in the echocardiography. 6/7 patients started oral anticoagulant therapy, 5/6 with acenocumarol and in a case with rivoraxaban. The patient with chorea and white matter lesions on MRI was the only one who received treatment with aspirin, associated to hydroxychloroquine.

Discussion: The APS is strongly linked to ischemic stroke in patients under the age of 50, and it is associated with feminine sex, presence of hypertension, valvular heart disease, positive IgG aCL and anti-beta-2-glycoprotein I tests and stroke or TIA of de middle cerebral artery. Nevertheless, there are few trials that apply strict diagnostic criteria. In patients with definitive APS, high-intensity warfarine is used, but little evidence exists regarding optimal treatment regimens.

Conclusions: 1) APS must be ruled out in patients under the age of 50 and stroke, especially if women and without another vascular risk factors. 2) Our patients had similar epidemiologic and clinical features and aPL activity test as registered in literature, including valvular heart disease diagnosed by transthoracic ecochardiography. 4) As recommended, secondary thromboprophylaxis with oral anticoagulants was initiated for the chronic management of the patients 6) Other conditions associated with the APS as livedo, migraine, nephropathy can be ignored if not specifically searched.

IF-165
ISCHEMIC MANIFESTATIONS IN ELDERLY AND VERY ELDERLY PATIENTS WITH GIANT CELL ARTERITIS

M. Ramentol Sintas, E. Munté, I. Conejo, F. Martínez Valle, S. Buján Rivas, J. Bosch, R. Solans Laqué

Department of Internal Medicine-Autoimmune Diseases. Hospitals Vall d'Hebron. Barcelona, Spain.

Objectives: To determine the prevalence of irreversible ischemic damage in a cohort of elderly and very elderly patients with giant cell arteritis (GCA), and to compare it with younger patients. To identify clinical and serological risk factors related to ischemic events according to the age of onset of the disease.

Material and method: We included all the patients diagnosed of CGA in our hospital from 1991 to 2011, according to the American College of Rheumatology (ACR) classification criteria. Patients were classified according to the age at GCA diagnosis as: elderly (more than 75 years old at GCA diagnosis) and very elderly (more than 80 years old at GCA diagnosis). Statistical analysis was performed using the SSPS vs 15.0.

Results: Among the 174 patients included in the study, 95 (54.6%) patients were considered elderly and 55 (31.6%) patients very elderly. Neither headache (86.3%), nor jaw claudication (53.7%), nor local hyperesthesia (24.3%) and polymyalgia (40%), were more common in the elderly and very elderly patients than in the global cohort. However, both permanent amaurosis and especially permanent bilateral amaurosis were significantly more prevalent among patients older than 75 years old at GCA diagnosis ($p = 0.034$ and $p = 0.010$, respectively). Anemia was more frequent in elderly and very elderly patients ($p = 0.028$), and low VSG (< 50 mm/h) was more frequent in young patients ($p = 0.017$). Thrombocytosis (> 500,000 platelets) was more frequent among elderly patients with permanent amaurosis ($p = 0.027$). No statistical differences were found related to the presence of intimae hyperplasia and inflammatory infiltrate in artery biopsy from elderly patients compared to young patients. However, inflammatory infiltrate and giant cells were significantly more prevalent in temporal artery biopsy from elderly patients with permanent bilateral amaurosis ($p = 0.034$ and $p = 0.028$, respectively). Multivariate analysis showed: was related to the presence of jaw claudication ($p = 0.021$), inflammatory infiltrate in temporal artery biopsy ($p = 0.043$), VSG > 80 mm/h ($p = 0.022$) and age > 75 years old at GCA diagnosis ($p = 0.020$). We did not found any significant correlation between permanent amaurosis and vascular risk factors.

Discussion: GCA is a vasculitis of large and medium-sized vessels, affecting the Aorta and its main branches with a predisposition to the extracranial circulation. GCA is the most prevalent vasculitides among the elderly people in the European countries and its main source of comorbility and residual damage arises from the irreversible ischemic events due to the inflammation of the vessel walls. Currently, according to the majority of reported series, around 15% of patients with GCA will suffer and irreversible ischemic damage. It is well known that the very elderly often present a distinct clinical pattern of some autoimmune diseases. Indeed, this work demonstrates that patients with GCA and age > 75 are at increased risk of suffering and irreversible ischemic event and a greater impairment of their quality of life. Notably, classical vascular risk factors were not significantly correlated with ischemic events in the GCA. Therefore a more intensive management and a close follow-up, at least in the earliest stages of the disease, should be considered in this subgroup of patients with GCA.

Conclusions: Permanent amaurosis, the most frequent ischemic sequel in GCA patients, is significantly more prevalent among

patients older than 75 years at CGA diagnosis. In fact, being older than 75 years old at the onset of the disease is a major risk factor for irreversible amaurosis. Therefore, these patients should be managed cautiously and quickly treated when the suspicion of GCA arises.

IF-167
CLINICAL AND THERAPEUTIC CHARACTERISTICS OF PATIENTS WITH BEHÇET IN THE SERVICE OF INTERNAL MEDICINE AT A GENERAL HOSPITAL

C. Maldonado Úbeda, S. Domingo Roa, A. Barnosi Marín, M. Esteban Moreno, P. Sánchez López, A. García Peña, B. Hernández Sierra, B. Cervantes Bonet

Department of Internal Medicine. Complejo Hospitalario Torrecárdenas. Almería, Spain.

Objectives: To evaluate the epidemiology and the clinical manifestations, both at the beginning as during the course of the disease. We evaluated the therapy received in patients diagnosed with Behçet's disease at the Internal Medicine department of a general hospital.

Material and method: We identified all patients diagnosed with Behçet's disease in the outpatient clinic of Systemic Diseases (Internal Medicine) during the last six months (December 2011 to May 2012). They conducted a retrospective study regarding 14 patients. Information was collected about sociodemographic, clinical characteristics at the beginning and during the evolution of the disease. Also we evaluated the therapy received and iatrogenic derived from it. Statistical analysis was performed using the 20.0 version SPPSS.

Results: We studied 14 patients diagnosed with Behçet's disease in the last six months. The mean age was 34.5 ± 8.9 years. Most patients belonged to Caucasian race in 91.7%. 50% of patients were male and the rest women. The delay in diagnosis was 7 ± 12 months. In 85.7% of patients HLA B51 was negative. Clinical manifestations in the debut of the disease were: oral thrush (41.7%), genital ulcers (8.3%), oral and genital aphthosis (33.3%), fever (8.3%), rethrombosis with the same percentage as the latter. Up to a total of 42.9% had one of the following manifestations: lymphadenopathy, skin lesions, arthritis, headache or papilledema. The signs and symptoms presented from disease onset to the present were: fever (50%), oral thrush (85.7%), genital ulcers (57.1%), pseudofolliculitis (35.7%), erythema nodosum (14.3%), arthritis (42.9%), aseptic meningitis (7.1%), polyneuropathy (7.15), thrombosis (35.7%), anterior uveitis (14.3%) and retinal vasculitis (21.4%).In terms of treatments received, medications most frequently used was oral corticosteroids (93.3%) at a mean dose of 30 mg/day, followed by immunosuppressants (azathioprine 60%, 40% methotrexate, cyclophosphamide or cyclosporine A 20%), colchicine or NSAIDs (53.3%), antiplatelet (26.7%) pentoxifylline (20%), anticoagulants (13.3%) and biological (adalimumab infliximbab 6.7% and 6.7%). Other therapies used were sucralfate (20%) and hydroxychloroquine (13.3%). Adverse reactions to therapy used stressed skin lesions (22%), infections of any type (14.3%) and laryngeal edema (14.3%). Other less common (7.1%) were steroid diabetes, hypertension, renal failure, osteopenia, cataracts, myopathy, and asthenia.

Discussion: Behçet's disease, despite being an uncommon disease in our environment, debuts and/or presents with a variety of clinical manifestations and a variety of complications, so early diagnosis is essential to achieve an adequate control.

Conclusions: The total number of patients diagnosed with Behçet's disease in the consultation of a Systemic Diseases Internal Medicine over the last six months was 14. Most of them were young adults (mean age 34.5 ± 8.9 years), sex as often (50% male, 50% women). Oral aphthosis was the most frequently encountered clinical manifestation in both the debut (41.7%) of the disease or during its course (85.7%), followed by genital ulcers (57.1%) and fever (50%). Oral corticosteroids (93.3%) were the most commonly used therapy in these patients at some point in their illness. The most frequently observed iatrogenic skin lesions corresponded to (22%).

IF-168
AUTOIMMUNE DISEASE, URTICARIAL REACTION OR ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA?

L. Sanz Trepiana[1], C. da Silva Rodríguez[3], C. Párraga Prieto[2], D. Díaz Díaz[4], C. Magro Checa[2], A. Borda Molina[3], L. Yankova Komsalova[2], A. Plasencia Ezaine[2]

[1]Department of Internal Medicine, [3]Department of Hematology, [2]Department of Rheumatology, [4]Department of Pathology. Hospital 12 de Octubre. Madrid, Spain.

Objectives: Angioimmunoblastic T-cell lymphoma (AITL) is a rare type of non-Hodgkin lymphoma. Patients typically present systemic manifestations, including fever, lymphadenopathy, rash, and less often with arthritis and autoimmune symptoms. For these reasons, these patients are mostly admitted in the Rheumatology and Internal Medicine Departments, instead of Hematology services. Our aim was to describe epidemiological, clinical and analytical characteristics of a series of patients diagnosed of AITL in our tertiary referral hospital from 2000 to 2012.

Material and method: We retrospectively analyzed all cases of AITL pathologically diagnosed from 2000 to 2012. Epidemiological, clinical and laboratory data, all of which was enclosed in the patients' clinical history, were analyzed. We used SPSS program to calculate our results.

Results: In the analyzed sample there were 7 patients, 3 men and 4 women; the median age was 60.14 years (range, 25-80 yr), everyone Caucasian, 6 were born in Spain and 1 in Romania. At diagnosis, localized nodes were present in 14.3% of patients, and were generalized in 85.7% of cases. Asthenia was reported in 42.9% of cases, spleen enlargement in 57.1% and hepatomegaly in 42.9%. A cutaneous eruption, morbilliform, urticarial, or more polymorphic, was present in 42.9% of patients; in 28.6% of them, the eruption was reported after drug administration. Musculoesqueletal manifestations, such as myalgias, were described in 57.1% of cases. Other clinical manifestations included arthralgia (28.6%) or arthritis (14.3%); night sweats (28.6%); weight loss (28.6%); pruritus (42.9%); gastrointestinal manifestations (42.9%); disnea (14.3%); pulmonary involvement (14.3%). Among laboratory abnormalities there were elevated lactate dehydrogenase levels (42.9%), hypergammaglobulinemia (42.9%), beta 2-microglobulin elevation (71.4%), hemolytic anemia (14.3%), no hemolytic anemia (28.6%) and thrombocytopenia (28.6%).

Discussion: AITL must be included into the differential diagnosis when a patient presents systemic symptoms such as rash, musculoesqueletal manifestations, constitutional symptoms related to anemia and weight loss in the 6th or 7th decade of life. Anemia, thrombocytopenia, elevated serum lactate dehydrogenase (LDH), polyclonal hypergammaglobulinemia, hemolytic anemia and elevated beta-2 microglobulin may be present in the blood analysis. Biopsy of the lymph nodes and assessment of the morphology and immunophenotyping are mandatory to make the diagnosis.

Conclusions: Our current study underlines the diversity of presenting manifestations of angioimmunoblastic T-cell lymphoma which sometimes mimics autoimmune diseases and urticarial reactions.

IF-169
OUTCOMES OF RETRIEVABLE VENA CAVA FILTERS

C. Vázquez Triñanes[1], I. Villaverde Álvarez[2], L. González González[2], R. Longueira[2], M. Casal[3], M. Freire Dapena[1], A. Rivera Gallego[1], B. Sopeña Pérez-Argüelles[1]

[1]Thrombosis and Vasculitis Unit, [2]Department of Internal Medicine, [3]Department of Radiology. Complejo Universitario de Vigo. Vigo (Pontevedra), Spain.

Objectives: To assess adequacy of indications, efficacy and safety of retrievable vena cava filters (RVCF).

Material and method: All patients who underwent placement of a RVCF from January 1 until December 31, 2011 were selected from the prospective database of the Interventional Radiology Service of the Complexo Hospitalario Universitario de Vigo, a tertiary care hospital. Clinical records of all of them were reviewed and clinical and analytical data were recorded. The follow-up period was defined as the time between the implantation of the RVCF to the last evaluation by a doctor or to the date of death. Complications of RVCF were defined as death resulting from its implementation or withdrawal; bleeding, thrombosis or infection of the skin at the access point; pseudoaneurysm; filter migration; perforation or thrombosis of the inferior vena cava and post-thrombotic syndrome. Data were analysed using the SPSS statistical program, version 18.0. Descriptive statistics including the percentage, mean ± SD and interquartile range were used.

Results: 15 patients underwent placement of a RVCF. Any other type of vena cava filter was implanted in the period of the study. The mean age was 66.8 ± 16.34 years (range 21-95) and 53% were women. The most frequent indications were: bridge to anticoagulation, in elective surgery or other situations of risk of bleeding, (53%) and major bleeding (33%). Other indications were: 1 recurrence of pulmonary embolism (PE) despite optimal anticoagulant dose of LMWH and 1 floating thrombus in iliac vein during an outbreak of Crohn's disease. Any RVCF was placed to prophylaxis. Only 1 patient (7%) had a recurrence of PE despite RVCF, 64 days after filter placement; the indication had been recurrent PE despite an optimal anticoagulation. This patient had a peripheral progressive polyneuropathy of unknown origin, and died at 2 days of this recurrence of PE because of a respiratory failure due to hypoventilation. The filter was implanted in the first 3 months after the venous thromboembolism in 12 (92%) out of the 13 patients in whom the indication of RVCF had been bridge to anticoagulation or bleeding. Only 1 of these 13 patients (8%) had a venous thrombosis of the lower limb while anticoagulation was withdrawn. There were no complications resulting from the implantation of the RVCF. The RVCF was withdrawn in 8 patients (53%), without any complications, on average at the 24.8 days of implantation (range 14-46).

Discussion: There are 3 types of vena cava filters: permanent, temporary and retrievable. Currently, the use of RVCF is becoming more frequent. RVCF offer the option of withdrawing or permanently maintained. Despite the positive results in recent studies, there are several issues that remain unresolved: the adequacy of indications, the appropriate maximum time to maintain the filter in place and the possibility of effective and safe retrieval.

Conclusions: The most frequent indications of RVCF were bridge to anticoagulation and bleeding, according to the current recommendations. RVCF in these situations is effective in preventing pulmonary embolism and is safe.

Osteoporosis

O-7
EPIDEMIOLOGY OF OSTEOPOROTIC HIP FRACTURES IN A REGIONAL HOSPITAL IN BURGOS, SPAIN

C. de la Higuera Arranz, V. Pardo Gutiérrez, P. Álvarez Álvarez, V. Centeno Peláez, J. Delgado Morales, S. de Lózar Ortega, C. Sáinz de la Torre, P. Cancelo Suárez

Department of Internal Medicine. Hospital Santos Reyes. Aranda de Duero. Burgos, Spain.

Objectives: To describe the epidemiological characteristics of hip fractures in patients admitted in a regional hospital in Southern Burgos, Spain.

Material and method: Retrospective, observational study including all patients aged 45 years or more with acute hip fracture admitted to our hospital between January and December 2010. We excluded patients with pathological fractures (neoplasm, Paget´s disease, bone cyst etc) and also fractures due to a severe trauma (falls on the hip from more than standing height). Data collected included age, sex, place of residence (rural or urban area/home or elderly rehabilitation centers), type and side of fracture, previous hip fracture, earlier treatment with calcium/vitamin D supplements or anti-osteoporotic drugs, postsurgical complications and mortality. The source of information employed was that of the database of "Clinical Documentation and Admission Service", identified by codes 820.0 through 820.9 of the International Classification of Diseases ninth edition (ICI-9-CM).

Results: There were 63 cases reported of hip fractures (12 men -19.05%- and 51 women -80.95%-). Mean age was 84.70 (range 45-90). Most of them, 92.60% (n = 58), were residents of the rural areas. A total of 45 hip fractures (71.43%) lived at home, and 18 (28.57%), in a nursing home. Place of fall was also at home in 45 cases (71.43%). A previous fracture was reported in 9 subjects (14.29%). Only 6 patients were taking calcium and/or vitamin D supplements (50% both calcium and vitamin D), and 2 received bisphosphonates (risendronate) before fracture. There were no significant differences with respect on the type of hip fracture (50.79% trochanteric fractures and 49.21% cervical ones). Fractures was on the left side in 52.38% of the cases (n = 33). Surgical repair or replacement was required in most cases (46.03% osteosynthesis and 44.44% prosthesis). Postoperative complications were observed in 28 patients (44.44%), most frequent were: urinary infection, acute renal insufficiency, delirium, adynamic ileus and cardiac failure. Overall and perioperative mortality (within the first month after discharge) was 25.40% and 12.50%, respectively.

Discussion: The present review showed a higher incidence of hip fracture in elderly patients (mean age 84), most of them living in rural areas (home or nursing home), who felt at home. The female-male ratio was 4.2. Only a few subjects received calcium/vitamin D supplements or an anti-osteoporotic drug before the event. No significant differences were observed related to the type of fracture (trochanteric or cervical). Most of patients required a surgical treatment (mainly osteosynthesis or prosthesis) and a high number of them suffered post-surgical complications such as infections, delirium, acute renal insufficiency and cardiac failure. Perioperative mortality was about 12%, increasing to 25% in terms of overall mortality.

Conclusions: The incidence of osteoporotic hip fractures increases exponentially with aging, being the most important of osteoporosis-related fractures in terms of death, functional dependence, and social cost. Estimation of risk of hip fracture, lifestyle interventions and properly drug therapies for the treatment and prevention of the osteoporosis, especially in elderly patients, may reduce these adverse outcomes.

O-10
RISK FACTORS FOR OSTEOPOROSIS AMONG PATIENTS WITH TYPE 1 AND TYPE 2 DIABETES

R. Nan[1], E. Rusu[2], A. Cursaru[3], R. Dragut[1], M. Jinga[2], H. Popescu[1], F. Rusu[4], G. Radulian[2]

[1]Department of Diabetes 2. National Institute of Diabetes, Nutrition and Metabolic Diseases. Bucharest, Romania. [2]Department of General Medicine. University of Medicine "Carol Davila". Bucharest, Romania. [3]Department of Orthopedic 2. Bucharest Emergency University Hospital. Bucharest, Romania. [4]Department of Urology 1. "Dr. Carol Davila" Central Military Emergency Hospital. Bucharest, Romania.

Objectives: The prevalence of diabetes and osteoporosis are increasing in worldwide. The relationship between diabetes and osteoporosis is complex and, although it has been investigated extensively, the subject remains controversial The purpose of this study was to evaluate risk factors for osteoporosis among patients with type 1 and type 2 diabetes admitted to the National Institute of Diabetes, Nutrition and Metabolic Diseases, during January-December 2011.

Material and method: A retrospective study that evaluated 5,600 patients with diabetes. 171 of these patients have been diagnosed with osteoporosis. The diagnosis of diabetes was based on using ADA criteria/recommendations 2011 and diagnosis of osteoporosis was based on assessment of bone mineral density at the proximal femur by dual energy X-ray absorptiometry (DXA). The variables analyzed were sex, age, smoking, environment, alcohol consumption, history of fracture, menopause, BMI, HbA1c, treatment with oral antidiabetic medication or insulin, use of proton pump inhibitors (PPIs). The characteristics of cases with osteoporosis and controls were compared using the χ^2 test and the logistic regression method (Odds Ratio, OR) was used to determine osteoporosis risk.

Results: The average age for patients with diabetes and osteoporosis was 72.3 ± 7.8 years. Predictive factors of osteoporosis in multivariate analysis included female sex [odds ratio (OR) 7.1, 95% confidence interval (3.5-14.4), p = 0.0001], BMI less than 18.5 [OR 5.2 (1.02-1.1), p = 0.0017], age over 65 [OR 4.6 (2.3-8.1), p = 0.001], menopause [OR 4.4 (2.13-8.1), p = 0.0001], alcohol [OR 4.2 (1.8-9.5), p = 0.0001], smoking [OR 1.9 (1.01-3.8), p = 0.04], treatment with PPIs [OR 1.1 (1.01-1.8), p = 0.03].

Conclusions: In patients with diabetes who have positive risk factors for osteoporosis (female sex, BMI less than 18,5, age over 65, menopause, alcohol, smoking, treatment with PPIs), or in those who present with fractures, evaluation of bone density should be done and respective preventive or therapeutic interventions should be applied.

O-11
VITAMIN D LEVELS IN NEWLY DIAGNOSED BREAST CANCER WOMEN

M. Sánchez Pérez[1], L. Rodríguez Rodríguez[2], E. Rodríguez Rodríguez[1], R. Hernández Sangil[2], J. Cruz Jurado[2], F. Armas González[1], M. Rodríguez Gaspar[1], A. Martínez Riera[1]

[1]Department of Internal Medicine, [2]Department of Medical Oncology. Hospital Universitario de Canarias. San Cristóbal de La Laguna (Tenerife), Spain.

Objectives: Low levels of vitamin D have been related with carcinogenesis in cohorts like NHS (Nurses' Health Study) and WHS (Women's Health Study). Though several studies have found low 25OH vitamin D levels in newly diagnosed breast cancer women, a recent meta-analysis did not confirmed this inverse association between breast cancer and low 25(OH)D levels years before diagnosis. On the other hand, it has been described high incidence of vitamin D insufficiency at the end of neoadjuvant chemotherapy with anthracyclines-taxanes. We studied vitamin D levels from a group of patients newly diagnosed of breast cancer, before they received any cancer treatment and after chemotherapy.

Material and method: We determined vitamin D levels (1.25OH D3 and 25OH D3, ng/mL) from a group of 168 women diagnosed of non advanced breast cancer, before they received any treatment excepting surgery. We compare them with a control group of 55 women without cancer (matched by age). Then, we compared vitamin D levels in women before treatment, immediately after chemotherapy and 12 months after diagnosis.

Results: Women were 55 ± 12 years old. Patients and controls had not differences on postmenopausal status (62% vs 58%; p = NS), previous osteoporosis diagnosis (4.3% vs 1.8%; p = NS) or fractures history (14.6% vs 12.7%; p = NS). Patients had greater BMI (28.3 ± 5 vs 26.3 ± 3; p = 0.001) and were more sedentary (71.7% vs 52.7%). 71.4% of the women had normal vitamin D levels (at least 30 ng/mL), 20.5% had sufficient levels, 7.1% had insufficient levels and 0.9% deficient levels. There were not significant differences between patients and control for basal levels of 1.25OH D3 (38.4 ± 18.8 vs 48.9 ± 23.3; p = NS) or 25OHD3 (39.1 ± 14.8 vs 44.4 ± 15.5; p = NS). There were not significant differences between basal levels and those determined after chemotherapy for 1.25OH D3 (53 ± 2.8 vs 31.5 ± 27.5; p = NS) or 25OH D3 (28.4 ± 13.5 vs 36.6 ± 15.1; p = NS), neither between basal levels and those determined one year after diagnosis for 1.25OHD3 (46.5 ± 6.4 vs 21 ± 2.8; p = NS) or 25OHD3 (36.5 ± 11 vs 39.9 ± 14.9; p = NS).

Discussion: More than 70% of the breast cancer patients had normal vitamin D levels before treatment, without differences with controls. These results contrast with previous studies but are in the line of the meta-analysis. Perhaps these patients had higher levels than other who live in different latitudes because of more sun exposition hours. Besides, vitamin D levels did not significantly changed over time (diagnosis, after chemotherapy and one year after treatment), in contraposition with the previous study commented. So, further studies are needed to clarify the relationship between vitamin D levels and breast cancer, and the influence of chemotherapy.

Conclusions: The majority of the newly diagnosed breast cancer women had normal vitamin D levels before treatment, and these levels did not changed after chemotherapy or 12 months later.

O-12
VITAMIN D LEVELS IN WOMEN WITH BREAST CANCER AND AROMATASE INHIBITORS (AI)

M. Sánchez Pérez[1], R. Hernández Sangil[2], E. Rodríguez Rodríguez[1], L. Rodríguez Rodríguez[2], R. Ros Vilamajo[1], M. Durán Castellón[1], E. Martín Ponce[1], R. Pelazas González[1]

[1]Department of Internal Medicine, [2]Department of Medical Oncology. Hospital Universitario de Canarias. San Cristóbal de La Laguna (Tenerife), Spain.

Objectives: Frequently, breast cancer patients have low bone mass before they begin aromatase inhibitors treatment. Recent studies have found that these women also have low levels of vitamin D before starting AI therapy, and these low levels continue after initiating them. Treatment with calcium and 25OHD protected against bone loss in those women. We studied vitamin D levels before and after IA treatment in a group of breast cancer women.

Material and method: We determined vitamin D levels (1.25OH D3 and 25OH D3, ng/mL) from a group of 122 breast cancer patients before initiating AI treatment (AI were prescribed with standard clinical criteria). After initiating AI all women were treated with calcium and at least 800 UI/day of vitamin D. Analysis were repeated after 12 and 24 months of treatment.

Results: Patients were 62.6 ± 9 years old and their BMI was 30 ± 5. Only 44.6% of the women consumed at least 3 dairy products and 86.1% were sedentary. 11.5% referred some fracture history. All women had been operated. 84.3% of them were treated with radiotherapy, 48.4% with chemotherapy and 33.6% had received previous tamoxifen. At the moment of initiating AI, 37.7% had normal bone mass, 45.1% had osteopenia and 17.2% osteoporosis. Basal 1.25OHD levels were 45.9 ± 13 and 25OHD levels 46.5 ± 18. 1.25OHD was under 30 ng/mL only in 9.8% of the cases and 25OHD in 14%. There were not significant differences between basal 1.25OHD levels from osteoporotic women and those of normal BMD patients (47.9 ± 14 vs 51.1 ± 13; p = NS), though basal 25OHD levels tended to be lower in osteoporotic women (48.2 ± 17 vs 40 ± 14; p = 0.06).

Basal 1.25OHD levels tended to be lower in osteopenic women than in normal BMD ones (42.5 ± 12 vs 47.9 ± 14; p = 0.058), but there were not significant differences for basal 25OHD levels (47.3 ± 20 vs 48.2 ± 17; p = NS). Curiously, basal 1.25OHD levels were lower in osteopenic women than in osteoporotic ones (42.5 ± 12 vs 51.1 ± 13; p = 0.023), without differences for 25OHD levels (47.3 ± 20 vs 40 ± 14; p = NS). After a year of treatment with AI, basal 1.25OHD levels did not changed (46.5 ± 15 vs 47.1 ± 13; p = NS), though basal 25OHD levels tended to increased (47 ± 18 vs 51.3 ± 17; p = 0.059). At this time, 1.25 OHD was under 30 mg/mL in 2.7% and 25OHD in 12.8% of the women. After two years of treatment, basal 1.25OHD (44.7 ± 20 vs 44.4 ± 5; p = NS) and 25OHD levels (52.2 ± 20 vs 52.6 ± 26; p = NS) did not changed. Then, all women had normal 1.25OHD levels and 15.4% had 1.25OHD levels under 30 mg/mL.

Discussion: Despite more than 60% of the patients in this study had osteopenia or osteoporosis before initiating AI therapy, and less than 50% consumed enough dairy products, vitamin D levels were above 30 ng/mL in 85-90% of the women, without relevant differences between osteoporotic, osteopenic and normal BMD patients. After 12 and 24 months of treatment levels did not significantly changed. Perhaps the latitude (sun exposition) could explain the difference with other studies.

Conclusions: Most of the women with breast cancer who initiate AI therapy had normal vitamin D levels, perhaps because of the sun exposition.

O-13
VITAMIN D LEVELS IN HIP FRACTURE PATIENS AND RELATION WITH MORTALITY

J. Viña Rodríguez[2], M. Herrera Pérez[1], E. Rodríguez Rodríguez[2], P. Sánchez Pérez[1], J. Alvisa Negrín[2], A. Pérez Ramírez[2], A. Ayala Rodrigo[1], C. Andarcia Bañuelos[1]

[2]Department of Internal Medicine, [1]Department of Traumatology and Orthopaedics. Hospital Universitario de Canarias. San Cristóbal de La Laguna (Tenerife), Spain.

Objectives: Patients with hip fracture have high mortality rates (near 30% one year after the fracture). Hypovitaminosis D is frequent in these patients: a study found that 55% of hip fracture patients had 25OHD levels < 30 ng/ml at Spain. On the other hand, low levels of vitamin D have been related with mortality in general population, and calcium/vitamin D supplements have shown to reduce mortality in the elderly. We determine vitamin D levels in a group of women with hip fracture and studied their relation with mortality.

Material and method: We determine basal vitamin D levels (25OHD, ng/ml) from 100 women (at least 60 years old) that were admitted to our hospital after an osteoporotic hip fracture (low intensity traumatism) in order to perform surgery. We registered age, BMI, origin (home or institution), consume of dairy products or calcium/vitamin D supplements, and measured the contralateral hip BMD (g/cm2). All patients were prescribed calcium, vitamin D and a bisphosphonate, when possible. We registered mortality at hospital and after 6 months of monitoring, and looked for related variables.

Results: Patients were 80.1 ± 7 years old and 95% lived at their home. Only 25% of the women used at least 3 dairy products. BMI was 24.9 ± 4 (11% of the patients had BMI under 20). 61.9% were osteoporotic and 38.1% osteopenic. 25OHD levels were 34.6 ± 15 (55% of the patients had normal vitamin D levels: > 30 ng/ml). 18% of the women had died after 6 months. Women who died were older (85.3 ± 8 vs 78.9 ± 8, p = 0.006) and they consumed less dairy products (less than 3 dairy products 17% vs at least 3 dairy products 1%; p = 0.038), but these variables were not independently associated with mortality. BMI and calcium/vitamin D supplements were not related with mortality. There were not significant differences in basal levels of 25OHD between patients that died and those who survived (32.2 ± 8 vs 35.1 ± 16; p = NS), neither for mortality between women with normal vitamin D levels and those with low levels (11% of the women with vitamin D > 30 ng/ml versus 7% of the women with lower levels; p = NS).

Discussion: Hip fracture patients in this study consumed few dairy products and 11% of them had BMI under 20. All of them were osteoporotic or osteopenic. 45% of the women had low vitamin D levels (a similar percentage was described for general Spanish population). After 6 months 18 patients had died. These women consumed less dairy products, but there were not differences for BMI, calcium/vitamin D supplements or levels of 25OHD.

Conclusions: In our study, 45% of the fractured women had low vitamin D levels, but we did not found a relation with mortality.

O-17
IS OSTEOPOROSIS A INVISIBLE DISEASE IN INTERNAL MEDICINE DEPARTMENTS?

S. Neila Calvo, S. García Rubio, M. García Hoyos, P. Garmilla Ezquerra, M. Aller Fernández, C. García Ibarbia, D. Nan, J. González Macías

Department of Internal Medicine. Hospital Valdecilla. Santander (Cantabria), Spain.

Objectives: To study the incidence of osteoporosis in patients admitted to Internal Medicine, determinate the proportion of patients diagnosed and well treated, measure the risk of fracture in Internal Medicine by applying the FRAX calculation tool and study levels of Vitamin D.

Material and method: We performed a prospective and descriptive study, making the review of 195 patients admitted to internal medicine during the month of April 2012 through the use of electronic medical records. Data collection consisted in filiation, clinical risk factors for osteoporosis, comorbidities, radiology, laboratory data and treatment.

Results: The mean age was 80.33 years old (SD 12.47). 51.8% (101) were male. El IMC medio fue 27.6 Kg/m^2 (SD 6,18). Comorbidities were distributed in: alcohol 21 (10.8%), smoking 17 (8,7%), chronic obstructive pulmonary disease 49 (25.1%), ischemic heart disease 41 (21%), heart failure 69 (35.4), cerebrovascular disease 40 (20.5%), dementia 61 (31.3%), dyslipemia 63 (31, 3%), Parkinson 9 (4.6%), neoplasia 41 (21%), venous tromboembolism 17 (8.7%), diabetes mellitus 255 (28.2%), hypertension 121 (62.1%), renal dysfunction 69 (35.4%). Risk factors analyzed were: menopause < 45 years 4 (2.1%), rheumatoid arthritis, 8 (4.1%), hyperthyroidism, 9 (4.6%), hypothyroidism 14 (7.2%), hyperparathyroidism 4 (2.1%), hypogonadism, 6 (3.1%), malnutrition, 24 (12.3%), malabsorption 18 (9.2%), hepatopathy 18 (9.2%), diabetes mellitus type 1 0 (0%), urolithiasis 15 (7.7%), cataract 45 (23.1%). The most important drugs for our work were: steroids 12 (6.2%), beta-blockers 24 (12.3%), anticonvulsants, 6 (3.1%), anticoagulants 39 (20%), thyroid hormones 11 (5.6%), hypnotics/

benzodiazepines 71 (36.4%), opiates 25 (14.7%), statins 58 (29.7%), proton pump inhibitors 88 (45.1%), antidepressants 29 (14.9%). 2 patients (1.9%) had family history of hip fracture, previous diagnosis of osteoporosis 25 (12.8%) and prior treatment 11 patients. The average Spanish FRAX for major fracture and hip fracture was 10.54% (SD 8.7) and 5.39% (SD 5.5) respectively. The average UK FRAX for major fracture and hip fracture was 14.84% (SD 10.8) and 7.63% (SD7, 1) respectively. Vitamin D was determined in 52 patients with a mean value 16 (SD 12.4).

Discussion: The prevalence of osteoporosis is similar to other common diseases in Internal Medicine, however it is less diagnosed. Patients admitted in Internal Medicine departments have many comorbilities and risk factors of osteoporosis. Moreover, usually these patients take many medicines in relation with this disease. Vitamin D 25OH levels are low in over 80% of patients.

Conclusions: Osteoporosis is a prevalent disease in patients of Internal Medicine, underdiagnosed and undertreated. Risk factors for fracture aren't frequently valued.

O-18
VITAMIN D AND BONE MASS LOSS IN PATIENTS WITH CHRONIC CORTICOESTEROID TREATMENT

M. Ruiz Campuzano[1], M. Esteban Moreno[2], M. Ortego Jurado[3], M. García Morales[3], R. González Ferrer[3], N. Ortego Centeno[3], J. Callejas Rubio[3], R. Ríos Fernández[3]

[1]Department of Internal Medicine. Hospital General Universitario Rafael Méndez. Lorca (Murcia), Spain. [2]Department of Internal Medicine. Complejo Hospitalario de Especialidades Torrecárdenas. Almería, Spain. [3]Department of Internal Medicine. Hospital de Especialidades San Cecilio. Granada, Spain.

Objectives: Osteoporosis is the most common complication of chronic treatment with glucocorticoids (GC), appearing fractures in nearly half of the patients. The vitD is essential in bone homeostasis. Although it is recommended to maintain levels above 30 ng/mL, there is no evidence that this is accompanied by less loss of bone mass (BM). Our objective was to analyze whether maintaining adequate levels of VitD is correlated with a lower percentage of loss of BM.

Material and method: We established the initial MO (HOLOGIC QDR4000) and after one year of treatment, and VitD levels were measured in summer and winter, using the mean as reference value. It was considered suboptimal if VitD level < 30 ng/mL and severe deficiency if < 15 ng/mL.

Results: We analyzed a total of 141 patients (76.6% female), mean age 56 ± 15 years; half prednisone dosage 5.19 ± 3.5 mg/day. The table lists the concomitant treatments received s.

Conclusions: Half of our patients had vit D levels below 30 ng/mL and found no significant association with higher percentage of bone loss. We only observed a higher percentage of bone loss in CF in patients with vitamin D levels below 15 ng/mL next to statistical significance but, generally, no differences were found between lower levels of VitD and the percentage of bone mass loss.

O-20
OSTEOPOROSIS AND ITS TREATMENT. OUR EXPERIENCE

M. Torrea, M. Artacho, C. Fanciulli, P. Díez, M. Olmedo, J. Filgueira, C. Díez, I. Cabezón

Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: Osteoporosis is a very prevalent disease in developed countries. It is caused by the cumulative effect of bone resorption in excess of bone formation. It affects mainly to postmenopausal women. Drug therapy should be considered in high risk postmenopausal women with T-scores between -1.0 and -2.5, with particular attention in women with a recent fracture, including hip fracture, because they are at high risk for a second fracture. There are several drugs, but to present day there are not studies comparing the efficacy and security between the different therapies. The aim of our study is to make a first approach in comparing the different therapy strategies in osteoporosis treatment in postmenopausal women.

Material and method: We have selected 24 postmenopausal women from an Osteoporosis practice in our hospital (H.G.U. Gregorio Marañón). We classified them in 3 groups: 9 receive therapy with PTH 1-84, 9 with oral bisphosphonates (BF vo) and 5 with intravenous bisphosphonates (BF iv). We followed them during one year. We compared basal characteristics: serum calcium, phosphate, PTH and vitamin D and femoral and vertebral densitometry (DMOF and DMOL, respectively) with the same parameters after one year of each treatment. We also compared previous fractures and its localization with fractures after treatment. We use the PSW 18 statistic program.

Results: The mean age was 71.3 years old. There were no statistical differences between basal characteristics. The mean DMOF was -2.8, and DMOL -2.9. The mean number of fractures was 1.23, and 66.6% were vertebral fractures. We found statistical differences in increasing the DMOL between PTH and BF iv ($p = 0.12$), and between BF o and BF iv ($p = 0.03$). In both cases BF iv was least effective than the comparative treatment. There were no differences between PTH and BF o. Only one patient had a new vertebral fracture during the study. We did not register any adverse effect.

Discussion: Even although our study has a small sample we found differences in favour of BF o and PTH in contrast with BF iv, so probably bigger studies will be able to detect more differences between treatments. In addition, we register no new fractures which are a very important part of the treatment. This is concordant with previous studies.

Conclusions: More studies are needed between therapies in order to find the most cost-effectiveness treatment for our patients, due to the fact that the Osteoporosis is a high prevalent disease nowadays, which causes important morbidity, and that previous studies are only made in comparison with placebo.

O-21
VITAMIN D AND OSTEOPOROSIS IN SYSTEMIC LUPUS ERITEMATOUS (SLE) PATIENTS

C. López Robles[1], R. Ríos Fernández[2], E. Moreno Escobar[3], J. Callejas Rubio[2], N. Ortego Centeno[2]

[1]Department of Internal Medicine. Hospital General Antequera. Antequera (Málaga), Spain. [2]Department of Systemic and Autoimmune Diseases, [3]Department of Cardiology. Hospital de Especialidades San Cecilio. Granada, Spain.

Objectives: SLE patients have experienced an increase in life expectancy. It´s necessary to control long term conditions such as osteoporosis in order to improve quality of life in these patients. Lupus patients have higher prevalence of osteoporosis than general population. Obviously because LES patients have more risk factors, but that it's not only the cause. Vitamin D levels are diminished in this population. The aim of the study is to determine the frequency of osteoporosis and levels of vitamin D in lupus population.

Material and method: We undertake a cross-sectional descriptive study in a group of SLE patients. We collected demographic and clinical data from medical records. Vitamin D serum levels were determined. Bone Mineral Density (BMD) was determined by densitometry DXA (Dual X-ray absorptiometry). Statistical analysis was performed using SPSS 15.0.

Results: We studied 63 patients (55 women, 87.3%) with an average age of 44 years. Demographic and clinical characteristic are shown in Table 1. In our study 88.9% of the patients showed sub-optimal levels of vitamin D (< 30 ng/ml). Moreover, deficient 25-OH-vitamin D (< 15 ng/mL) were found in 47.6% of the patients in our group. Despite the fact, 65.1% of the patients were treated with calcium and vitamin D and 27% with antiresorptive drugs. Vitamin D levels did not correlate significantly with the use of steroids or SLEDAI. Moreover, 14.3% had osteoporosis and 27% osteopenia. There was no significant relationship between osteoporosis/osteopenia and consumption of drugs such as corticosteroids, immunosuppressants or cyclophosphamide.

Discussion: Several cross-sectional studies have evaluated BMD and prevalence of osteoporosis in SLE patients. The majority of them showed that these patients have lower BMD than general population, and a wide range of prevalence of osteoporosis: between 3% and 43%. In our study, 14.3% of patients had osteoporosis. Osteoporosis related to steroid consumption has been widely studied; In this regard, authors find discrepancies in SLE patients. Not always an association between corticosteroid consumption and osteoporosis prevalence has been described. On the other hand, there is growing evidence of hypovitaminosis D in lupus patients. This may be caused by a lower sun exposure, due to photosensitivity or secondary to lupus nephritis. However, it is possible that other factors related to disease may affect vitamin D serum levels and prevalence of osteoporosis in SLE patients.

Conclusions: SLE patients showed a higher prevalence of vitamin D deficiency and osteoporosis than general population. This may be related to the presence of classic risk factors, but also by other factors related to the characteristics of the disease. However, it is necessary to undertake prospective studies with a greater number of patients to clarify this situation.

Table 1 (O-21). Demographic and clinical characteristics

Variable	Median ± SD/n (%)
Sex (Female/Male)	55/8 (87.3/12.7)
Smoking(Yes/No)	18/45 (28.6/71.4)
BMI (Kg/m^2)	25.97 ± 6.63

Vascular risk

RV-1
FATAL INTRACRANIAL HEMORRHAGE (BARC 5) AS A SERIOUS ADVERSE REACTION TO VITAMIN K ANTAGONISTS/VKA IN THREE ELDERLY PATIENTS

R. Qanneta[1], J. Pi I Sanchez[2], E. Moltó Llarena[1]

[1]Department of Internal Medicine, [2]Department of Geriatrics and Gerontology. Hospital Sociosanitari Francolí. Tarragona, Spain.

Objectives: Atrial fibrillation with or without valvular disease is the 1st cause of embolism, with an incidence of 6 to 8 per 100 patients per year. In recent years has increased the use of VKA for primary or secondary prevention of thromboembolic events. However the VKA therapy carries a substantial risk of bleeding. We present three cases of fatal intracranial bleeding duo to VKA.

Material and method: Descriptive analysis of three cases of fatal intracranial bleeding duo to VKA reviewing medical record data.

Results: 1st patient: 64 year old male patient, who was treated with VKA since January 2011 for right ischemic stroke with left hemiplegia duo to debut of atrial fibrillation. In April 2011, immediately to an accidental fall he has decreased level of consciousness, aphasia and right hemiplegia. Blood tests showed INR > 8. Cranial scan: hematoma of the left hemisphere with mass effect. Prothrombin complex concentrate was initiated. The patient was died within 12 hours. 2nd patient: 68 year old male patient, who was treated with VKA since April 2010 for left ischemic stroke with aphasia and right hemiplegia duo to debut of atrial fibrillation. In June 2011, he was presented left hemiplegia and gaze aversion to the right side of hours of development as well as tonic epileptic seizure that was self-limiting with intravenous diazepam. Blood test showed INR 6.5 and creatinine 2 mg/dL. Cranial scan: intraparenchymal hematoma of right parietal. Prothrombin complex concentrate was initiated. The patient was died within 48 hours. 3rd patient: 71 year old male patient, with high blood pressure and chronic atrial fibrillation who was treated with VKA of long evolution. He was found unconscious by his wife, that requires orotracheal intubation by emergency medical service. Blood test showed INR 3.4. Cranial scan: intraparenchymal hematoma of basal ganglia and white matter with extensive perilesional edema as well as intraventricular bleeding. Intravenous K Vitamin was initiated. The patient was died within 24 hours.

Discussion: The increased risk of fatal intracranial bleeding (BARC 5/Bleeding Academic Research Consortium) due to VKA (the most often fatal or disabling bleeding) is usually in large studies of less than 0.3% per year. In observational studies and the clinical practice, they accumulate experience and events for many years and have shown that the risk of bleeding is higher in those who have had a prior ischemic stroke, INR labile and the older patients as seen in our three patients. The Guidelines of European Society of Cardiology for the management of Atrial Fibrillation 2010 recommend HAS/BLED score for risk prediction of bleeding. The risk is highest with a SCORE of 3 or more such as in our three cases.

Conclusions: The HAS-BLED is a user-friendly score to assess risk of major bleeding duo to VKA and can help us (together CHA2DS2-VASc score) to reach the sweet spot.

RV-2
FAMILIAL HYPOALPHALIPOPROTEINEMIA AND CARDIOVASCULAR DISEASE

M. Pavón Moreno[1], R. Alonso Karlezi[1], J. Defesche[2], I. Robles Barrena[1], G. Rodríguez de Lema Tapetado[1]

[1]Department of Lipid Clinic, Department of Internal Medicine. Fundación Jiménez Díaz. Madrid, Spain. [2]Department of Molecular Biology. Academic Medical Center. Amsterdam, Netherlands.

Objectives: To analyse 2 cases of severe familial hypoalphalipoproteinemia with particular emphasis on genetic test and their relationship with cardiovascular diseases.

Material and method: Two female patients studied in our centre with extraordinary low HDL-cholesterol levels. Family (pedigree) and medical history were recorded. Lipid profile was measured using enzymatic methods. Genes coding for LCAT, ABCA1, GALNT2 and APOA1 were analysed using automated sequencing. Carotid ultrasound and coronary CT-scan were performed in both patients.

Results: Clinical characteristics of FHA patients are shown in table 1.Genetic testing confirmed LCAT deficiency (V70E: GTG to GAG on position 209 in exon 2) in case 1 and Tangier disease in case 2 (2 mutations were detected: W424X, TGG to TGA at position1272 in exon 11(heterozygous), and 160+5G to A in intron 5 (heterozygous) in ABC1 Vascular studies showed no atherosclerotic disease in both cases.

Discussion: Low HDL-c is a classic risk factor for coronary artery disease (CAD). However, these cases with very low HDL-c levels since birth, were asymptomatic and also, no evidence of atherosclerosis disease was observed with imaging techniques.

Table (RV-2)

	Case 1. LCAT Defiency	Case 2. Tangier disease
History of cardiovascular disease	No	No
Case 1st degree relatives	No	No
Smoking	No	Yes
HDL-C (mg/dl)	13 mg/dl	2 mg/dl
LDL-C (mg/dl)	28	58
Triglycerides (mg/dl)	113	64
Coronary CT scan	No atherosclerosis	No atherosclerosis
Carotid Ultrasound	No plaques, IMT 0.7	No plaques, IMT 0.6

Besides, they do not have family history of CAD. Genetic testing confirmed the diagnosis of 2 rare disorders. Analysis of relatives is important to prevent development of CAD.

Conclusions: 1. LCAT deficiency and Tangier disease are rare disorders. 2. Although low HDL-c levels is a risk factor for CAD, some genetic disorders do not show this increased risk.3. Treatment of these cases remain controversial.

RV-3
HEMATOCRIT AND BLOOD BIOMARKER LEVELS OF CARDIOVASCULAR MORTALITY

N. Jaén Sánchez[1], P. Braillard[1], S. Suria[1], N. Esparza[1], A. Ramírez[1], R. Guerra[1], A. Calderín[2], M. Checa[1]

[1]Department of Nephrology, [2]Department of Angiology and Vascular Surgery. Complejo Hospitalario Universitario Insular-Materno Infantil. Las Palmas de Gran Canaria, Spain.

Objectives: To study the hematocrit of patients with arterial peripheral disease (APD) and its association to blood biomarker levels of cardiovascular disease or mortality, easily measurable in the daily clinic.

Material and method: 40 patients with APD were studied to their revenue in the Service of Vascular Surgery. After signing the informed assent, there were requested for analytical including hemogram, biochemistry in blood and urine and PCR's levels, beta2-microglobulin and NT-proBNP.). NT-ProBNP was measured by a radial partition immunoassay (RPIA) in solid phase (Acute Care™ for Stratus® CS de Siemens). Beta-2-microglobulin was measured by immunonephelometry (BNII of Siemens). The statistical studies were realized by the SPSS 15.0.

Results: There were studied 40 patients (33 men and 7 women) (68.03 + 11.10 years) whose hematocrit was 37.94 + 5.90%, their red distribution width (RDW) (15.08 + 2.18%) and with PCR's levels: 7.56 + 9.17 mg/dl, beta2-microglobulin: 4.73 + 4.90 pg/ml and NT-proBNP of 1,564.71 + 2,008.60 mg/dl. Urine creatinine clearance was 64.55 + 26.45 ml/min and the levels of serum albumin 3.58 + 0.44 g/dl. The hematocrit was inversely related to PCR ($r = -0.59$; $p = 0.001$), beta2-microglobulin ($r = -0.66$; $p = 0.001$) and NT-proBNP's levels ($r = -0.54$; $p = 0.001$) and positively correlated with serum albumin ($r = 0.55$; $r = 0.001$).

Discussion: Anemia is an important cause of morbidity, principally through increased cardiovascular disease. The development of moderate to severe anemia at any time during the hospital stay was independently associated with increased mortality. The results of this study show that the hematocrit of patients with APD diminishes as their blood biomarker levels of cardiovascular disease or mortality (PCR, beta-2 microblobulin and NT-proBNP) increase and it might explain, at least partly, that the increased mortality related to decreased hematocrit levels of chronic patients should be associated with increase for the above mentioned biomarkers.

Conclusions: The hematocrit of patients with chronic disease as APD was inversely related to PCR, beta2-microglobulin and NT-proBNP's levels and positively correlated with serum albumin. This could explain the association between anemia and increased mortality through an increased rate of cardiovascular disease.

RV-4
COLITIS, DIFFERENCES BETWEEN CLINICAL AND PATHOLOGICAL DIAGNOSES IN A SAMPLE OF 172 PATIENTS ADMITTED TO A LOCAL SPANISH HOSPITAL

R. Hurtado-García[1], J. Murcia Zaragoza[1], A. Guillén[1], J. Ruiz Maciá[3], A. Seva Llor[1], E. Muñoz[2], J. López Lozano[4], J. Custardoy[1]

[1]Department of Internal Medicine, [3]Department of Pathology, [2]Department of Digestive, [4]Department of Preventive Medicine. Hospital Vega Baja de Orihuela. Orihuela (Alicante), Spain.

Objectives: Primary: to describe the causes and prevalence of ischemic colitis (IC) and clinical characteristics of these patients. Inclusion criteria: Patients with acute bloody diarrhea without etiological cause (non-infectious disease, negative bacteriologic studies and colonoscopy with biopsy to complete the study. Exclusion criteria minors without colonoscopy. To describe the 3 major groups in the sample obtained: IC, inflammatory bowel disease (IBD) including Crohn's disease and ulcerative colitis and the rest (including nonspecific colitis and idiopathic in nature and neoplasic disease).

Material and method: Retrospective longitudinal observational study of all pathological anatomy in patients with colitis between 01/06/2010 and 01/03/2012 by measuring the variables associated with cardiovascular risk factors (hypertension, hypercholesterolemia, diabetes mellitus, triglycerides, total cholesterol, HDL, LDLc, smoking, etc.) and demographic variables such as sex and age. Statistical analysis using SPSS v.20.

Results: N = 172. The average age of the sample was 57.68 years. IC patients were older than other groups (73.64), statistically significant differences ($p < 0.001$) between the ages of the 3 groups evaluated (IC, IBD and others). IBD patients were younger (46.94). 25 patients (14.5%) of the sample had IC, 62 (36%) IBD, 2 (1.2%) neoplasms, 83 (48.3%) other types of colitis. When comparing the mean cholesterol levels, triglycerides, HDL and LDL cholesterol among patients with IC compared to other colitis, there were no statistically significant differences. There were no differences in doing so with IBD. Hypertension (HT) ($p < 0.001$), diabetes (DM) ($p = 0.004$) and dyslipidemia (DLP) were associated most to have IC. Taking antiplatelet agents has been correlated ($p < 0.001$), statins ($p < 0.001$), diabetes ($p = 0.001$) and pressure ($p < 0.001$) with IC. Also taking anticoagulants ($p = 0.013$) and ischemic stroke ($p = 0.044$).

Discussion: Ischemic colitis (IC) is the most frequent bowel ischemia (70%) and arises when the colon is private transiently vascular flow. Its true prevalence is clearly underestimated, because the milder forms may go unnoticed. The estimated incidence of IC in the general population ranges between 4.5 and 44 cases per million inhabitants per year and is higher among people over 65 years. It has been linked with a number of factors predisposing or precipitating as arteriosclerosis, myocardial infarction, hypotension, chronic heart failure, cardiac arrhythmias. In our sample has been correlated in most cases. IC patients were taking more drugs against vascular risk than the rest of the groups. 50% of patients in the sample had IBD or IC while 48% had some type of colitis of unknown etiology, this begs the possibility of a prospective study to objectify what type pathology developed these patients with a diagnosis pathology uncertain.

Conclusions: IC patients are older and more associated cardiovascular-comorbidities than other groups (as in the existing literature), they also take more drugs than other groups. Patients with IBD are younger and do not associate greater risk for having associated cardiovascular risk factors. In our sample there is a lot of patients with a pathologic diagnosis uncertain. Is needed to track prospective latter to objectify the correlation between clinical and pathological diagnoses. We emphasize that many cases of ischemic colitis may go unnoticed if the doctor is not initially suspected this possibility, and can erroneously be classified as infectious colitis or diverticulitis.

RV-6
LOW FREQUENCY OF A DECREASED ANKLE BRACHIAL INDEX AND ASSOCIATED CONDITIONS IN THE PRACTICE OF INTERNAL MEDICINE IN A TURKISH POPULATION SAMPLE

M. Gezer[1], I. Tasci[2], O. Demir[1], C. Acikel[3], R. Akar[1], K. Saglam[1], H. Kabul[4], B. Koc[1]

[1]Department of Internal Medicine, [2]Department of Geriatrics, [3]Department of Epidemiology, [4]Department of Cardiology. Gulhane School of Medicine, Ankara, Turkey.

Objectives: Peripheral arterial disease (PAD) is a less known condition in the practice of internal medicine, due mostly to lack of specific symptoms and low rates of physician awareness. However, cardiovascular disease (CVD) incidence is not significantly different between patients with symptomatic or asymptomatic disease. Ankle brachial index (ABI) measurement is an easy and cost-effective tool for the diagnosis of PAD. In the present study, frequency of low ABI and associated factors were investigated in the setting of internal medicine practice.

Material and method: Patients above 70 years old and patients between 50 and 69 years with CVD or at least one atherothrombosis risk factor were included in the study. ABI was determined with handheld Doppler. Measurements were determined for both lower extremities. Lower of the right or left ABIs was taken as the final value. Low ABI was defined as ≤ 0.9.

Results: A total of 303 subjects between 50 and 83 years of age were enrolled (female/male: 186/117). Mean ABI was 1.14 ± 0.15. A low ABI was detected in 15 cases (4.95%). Prevalence was 7% in females and 1.7% in males (p = 0.039). Low ABI value was not associated with any of the demographic parameters, presence of major risk factors or basic laboratory values. A high ABI was found by 5.6%.

Discussion: In the present study, frequency of PAD as determined by ABI was found lower than those reported previously in most European countries. Nonetheless, our results showed that PAD affects at least 1 in 20 outpatients in the practice of internal medicine.

Conclusions: In the present study, frequency of PAD as determined by ABI was found lower than those reported previously in most European countries. Nonetheless, our results showed that PAD affects at least 1 in 20 outpatients in the practice of internal medicine.

RV-8
INTIMA-MEDIA THICKNESS AS A MARKER OF SUBCLINICAL ATHEROSCLEROSIS IN WOMEN WITH HISTORY OF VASCULAR COMPLICATIONS OF PREGNANCY

I. Domínguez Fernández[2], E. Sánchez García[1], C. Arenas Muñoz[1], B. García Olid[1], Á. Blanco Molina[1]

[1]Department of Internal Medicine. Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), Universidad de Córdoba. Córdoba, Spain. [2]Department of Internal Medicine. Reina Sofía University Hospital. Córdoba, Spain.

Objectives: Vascular complications of pregnancy, including preeclampsia, eclampsia and hemolysis, elevated liver enzymes and low platelet count (HELLP) syndrome, determine a prothrombotic and proinflammatory state. In addition, the presence of endothelial dysfunction, which constitutes the initial event for the development of atherosclerosis, has been described. These findings contribute to an increased risk in the development of cardiovascular diseases at the time of the event and later in life. The aim of this study was to determinate whether the presence of vascular complications during pregnancy (pre-eclampsia, eclampsia and HELLP syndrome) can be considered as an independent risk factor for the development of subclinical atherosclerosis through the measurement of the intima-media thickness (IMT).

Material and method: We carried out a cross-sectional case-control study, comparing a group of 15 primiparous women with previous history of vascular complications of pregnancy with a control group of 15 nulliparous women, matched by age, body mass index and smoking habit. A carotid IMT measurement by Doppler ultrasound was performed in order to evaluate the presence of subclinical atherosclerosis as well as other cardiovascular biochemical markers.

Results: Patients with previous history of vascular complication of pregnancy had significantly higher levels of erythrocyte sedimentation rate (ESR) and triglycerides (p = 0.01 and 0.04 respectively), and lower levels of high-density lipoprotein (HDL) (p = 0.002) compared with the control group. IMT was significantly increased in patients with vascular complications of pregnancy (p = 0.001). In the univariate regression analysis, the presence of previous vascular complications of pregnancy (R: 0.578; R^2: 0.335; p = 0.001), high ESR (R: 0.376; R2: 0.141; p = 0.04) and low plasmatic HDL concentration (R: 0.518; R^2: 0.269; p = 0.003) proved to be independent risk factors for the presence of a larger carotid IMT. After multivariate analysis, the antecedent of vascular complication of pregnancy remained significant (R: 0.629; R^2: 0.395; p = 0.02).

Discussion: Our study shows an increased IMT in the group of women with vascular complications of pregnancy, which might indicate an accelerated atherosclerosis in these patients. Therefore, the presence of a vascular complication of pregnancy could be considered as independent risk factor for the development of atherosclerosis and cardiovascular diseases.

Conclusions: Our findings suggest that women with vascular complication of pregnancy may benefit from preventive measures of early cardiovascular diseases. These might include certain changes in lifestyle, such as low-lipid diet and exercise, as well as more exhaustive control of arterial blood pressure, plasmatic

lipids and glucose, in order to avoid future cardiovascular events.

RV-9
RISK FACTORS OF LACTIC ACIDOSIS IN PATIENTS WITH TYPE 2 DIABETES TREATED WITH METFORMIN

R. Daroca, J. Mosquera, S. García Guerreros, E. Ruiz de la Cuesta, J. Peña, E. Mozos, M. Casañas, J. Gómez Cerquera

Department of Internal Medicine. Hospital San Pedro. Logroño (La Rioja), Spain.

Objectives: To study the prevalence of factors favouring lactic acidosis (LA) in a series of patients with type 2 diabetes (DM2) in treatment with metformin admitted to an Internal Medicine (IM) service.

Material and method: Descriptive transversal study. Patients previously diagnosed with DM2 following treatment with metformin which were admitted in our IM service between February 15th and June 15th 2011 were included. Risk factors of LA were: recent administration of iodinated contrasts, chronic renal failure, (creatinine > 1.4 in women and > 1.5 mg/dL in men), hepatopathy, alcoholism, heart failure, hemodynamic instability; age groups were analyzed. Cases presenting metabolic acidosis, anion gap > 12 mmol/L and lactate > 22 mg/dL in absence of other causes of lactate increase were considered as LA.

Results: 71 patients were included, mean age of 79.5 ± 9, 59.2% were women, median duration of DM2 10 years, mean lasting treatment with metformin 5.8 ± 5.8 years (median of 4). 18 patients were on associated treatment with insulin, with other oral antidiabetics in 50. Mean HbA1c: 7.6 ± 1.5%. Prevalence of LA risk factors is exposed in Table 1. It is also indicated the percentage of elderly patients, as advanced age is a metformin use limitation criterion for some authors. During the period of study, 5 cases of LA were reported, all of them in the context of prerenal acute renal failure. None of them had LA risk factors, although their ages were 81, 83, 86, 90 and 92. Evolution was favorable in all cases.

Discussion: Metformin-induced LA is associated with risk factors that, if present, must make avoid or use with caution this drug. In the present study these risk factors are less frequent than in previous ones, which may indicate a good selection of patients for treatment with metformin. However, cases of metformin-induced LA only happened in elderly patients without other risk factors. Estimated incidence of metformin-induced LA is 0-9 cases/100,000 patients/year. In our study, this incidence is much higher (associated with advanced age and acute renal failure).

Conclusions: Lactic acidosis risk factors are moderately frequent in our patients with DM2 following metformin treatment. LA incidence in our study seems to be much higher than that described in literature, and it is associated to advanced age. It is suggested to maximize precaution in patients > 80 years old treated with metformin.

Table 1 (RV-9). Prevalence of risk factors of lactic acidosis

Heart failure	21%
Renal Failure	9.9%
Recent use of iodinated contrast	4.2%
Liver disease	2.8%
None	49.3%
Aged 80 or over	53.1%
Aged 85 or over	33.8%

RV-11
PRIMARY ALDOSTERONISM LIKE CAUSE OF HYPERTENSION: DESCRIPTIVE STUDY

Y. Hernández Aguiar, S. Suárez Ortega, J. Artiles Vizcaíno, M. Serrano Fuentes, A. Gil Díaz, B. Alonso Ortiz, S. Santana Baez, P. Betancor León

Department of Internal Medicine. Hospital Universitario de Gran Canaria Doctor Negrín. Las Palmas de Gran Canaria, Spain.

Objectives: The primary aldosteronism (PA) is the most common cause of hypertension (HTN) of known etiology. We report a descriptive study of PA conducted in an office of Hypertension.

Material and method: Two thousand hypertensive patients have been studied by control difficulties or suspected secondary hypertension with a general analytical protocol, electrocardiogram and abdominal echo. It was considered inappropriate the kaliuria > 30 mEq/day, with kaliemia < 4 mEq/l. The unclarified hypokalemia with inappropriate kaliuria or increased adrenal (incidentaloma) determined the performance of aldosteronemia (A) and plasma renin activity (PRA). When the A was high and the ratio A/PRA > 30 is held a suppression test (captopril or saline) to confirm the diagnosis of PA and after it was tested to determine etiology and treatment. The A and PRA were measured in supine position with a diet of 200 mEq of NaCl. Data collected and processed in SPSS 16.

Results: It demonstrated PA in 62 (3.1%) hypertensive patients. The mean age was 55.7 ± 11.6 years (range 29-85). Thirty two (51.5%) patients were women; 16 (25.8%) patients were in geriatric age. Mean baseline BP was 187.3 ± 19.9/105.2 ± 11.2 mmHg. The blood pressure after treatment was 136.5 ± 8/82.5 passing ± 4.6. In all cases the kaliemia was below 4 mEq/l (mean 3.36 mEq/l, range from 4 to 2; aldosteronemia high (mean: 38.8 ± 30.2 µg/dl, range from 198 to 20), ratio A/RPA (mean: 137 ± 113, range from 585 to 32; RPA less than 0.2 ng/ml/h in 48, and the rest less than 1 ng/ml/h, with positive captopril test. Kaliuria inappropriate (mean: 89 ± 23.3 mEq/d, range from 158 to 46). All cases underwent abdominal CT scan revealed an adrenal nodule ofmore than one cm in diameter in 33 (53%), 3 with bilateral. Of these, in 13 cases was detected by echo the nodule (sensitivity 39%). Among the kaliemia and SBP there was a correlation of α = -0.34 (p = 0.01). In 3 cases, adrenal vein catheterization performed, showing an increase of aldosterone in the adrenal nodule. The 31 PA with normal-sized adrenal were considered adrenal. Adrenalectomy (laparoscopically) was performed in 19 cases. Hypertension was controlled in 44 cases (71%) combining surgery, aldosterone antagonists and other antihypertensives.

Discussion: Although there is a tendency to attribute the PA as a major cause of hypertension doubts arise if the spectrum covered by this concept or it should be limited to well-defined cases, excluding borderline cases for inclusion in refractory essential hypertension with low renin. This latter view is that modulates this work, which is tempered by the low prevalence and the high percentage of cases with Conn's syndrome.

Conclusions: 1. The kaliemia less than 4 mEq/l, associated with inappropriate kaliuria has been the guiding in the search data PA. 2. It is constant in the PA an high aldosteronemia, low basal PRA and a ratio A/PRA > 30. 3. These tests associated with abdominal CT is usually sufficient for diagnosis of PA, except in cases of hereditary PA or DOCA producers. 4. The abdominal ultrasonic study offers low sensitivity for adenoma in the PA (39%). 5. The laparoscopic adrenalectomy is the surgery of choice in Conn's syndrome. 6. Specific treatment PA, associated with other antihypertensive achieves BP control in 71% of cases.

RV-12
PRIMARY HYPOCITRATURIA, URINARY STONES AND HYPERTENSION

M. Hernández Meneses, S. Suárez Ortega, J. Artiles Vizcaíno, A. Puentes Fernández, J. Arencibia Borrego, P. Melado Sánchez, J. Delgado Martínez, P. Betancor León

Department of Internal Medicine. Hospital Universitario de Gran Canaria Doctor Negrín. Las Palmas de Gran Canaria, Spain.

Objectives: Hypocitraturia is a common finding in acidotic processes. As a primary entity, usually associated a genetic profile is extremely rare. It manifests as bilateral urolithiasis, a circumstance which, moreover, is often associated with high blood pressure. We report the detection of primary hypocitraturia in an office hypertension.

Material and method: We review the prevalence and clinical manifestations of primary hypocitraturia in an office Hypertension. We were established as guiding data for detection of hypocitraturia: the debut of the stone within 30 years, the bilateral urolithiasis, absence of hyperparathyroidism, normal urinary sediment and/or negative urine culture and lack of response to conventional therapy. All patients were hypertensive and they received 12.5 mg hydrochlorothiazide at the time of 24 hours urine collection.

Results: We studied 1,600 hypertensive patients, of whom 198 (12.4%) had urinary stones, and 19 cases showed primary hypocitraturia. The following characteristics were observed at the time of diagnosis: Mean age was 40.47 ± 14.8 years (range 14-60). Twelve (63%) were women. Four cases were part of the same family (autosomal dominant). All patients with hypocitraturia had renal colic and bilateral urolithiasis. The citraturia average was 52.1 ± 33.2 mg/day, with a range of 5-95 mg/day (normal range 140 to 940 mg/day). There were no differences in the elimination of urate (566 ± 178.1 mg/day), calciuria (250.8 ± 97.7 mg/day) and natriuria (168.8 ± 74.7 mEq/day) in relation with the urolithiasis patients of a 900 hypertensive patients population. Eleven cases had hypercalciuria (with hydrochlorothiazide 12.5 mg), in 6 patients there were osteoporosis, 7 patients required lithotripsy and dental alterations were observed in 16 patients.

Discussion: Hypocitraturia be suspected in patients with hypercalciuric urolithiasis is not controlled with thiazides, if it has been ruled out primary hyperparathyroidism. Before considering primary disorder should be ruled out multiple secondary causes (acidotic) and urinary infections. The proper treatment improves the clinical profile of patients with primary hypocitraturia.

Conclusions: 1. The primary hypocitraturia is a rare disorder to rule in bilateral urolithiasis in young patients. 2. For the diagnosis it's necessary to exclude other causes of hypocitraturia secondary and bilateral stones. 3. The coexistence of hypertension is a common finding and is part of the binomial hypertension-urolithiasis. 4. Treatment focuses on combining citrate and thiazides, which improves urinary symptoms.

RV-13
EFFECTS OF AMLODIPIN AND VALSARTAN ON LIPID PROFILE IN PATIENTS WITH HYPERTENSION

S. Ay[1], M. Karaman[1], T. Çelik[2], S. Balta[2], E. Arslan[1], F. Bulucu[1], S. Demirbas[1], K. Saglam[1]

[1]Department of Internal Medicine, [2]Department of Cardiology. Gulhane Military Medical Faculty. Ankara, Turkey.

Objectives: The aim of the present study was to investigate the effects of valsartan as an angiotensin II receptor antagonist and amlodipine as a calcium channel blocker on the lipid profile in patients with essential hypertension.

Material and method: Patients applying to the internal medicine and cardiology outpatient clinics who had a newly diagnosed essential hypertension were recruited in the study. Patients were randomized to one of the following intervention protocols: An (A) angiotensine II receptor blocker (valsartan, 80-320 mg/day) or (B) calcium channel blocker (amlodipine, 5-10 mg/day), for 12 weeks immediately after baseline measurements. Serum lipid profile levels of the patient groups were measured before treatment and on the 12nd week.

Results: This study was performed on 50 patients with newly diagnosed essential hypertension (group A; n = 28 and group B; n = 22). In the amlodipine group, there was a significant decrease in levels of LDL-C (median LDL-C/before-after: 136.4/125; $p < 0.05$) in comparison with valsartan. No significant changes were observed in the levels of TG, T-C, HDL-C after both drug arms.

Discussion: In this study, we observed a beneficial effect of amlodipine on lipid profile with a significant reduction of LDL-C in comparison to valsartan.

Conclusions: As a result, in the treatment of hypertension, prior knowledge of the levels of plasma cholesterol could be important in antihypertensive drug choice.

RV-14
THE COMPARATIVE EFFECTS OF AMLODIPIN AND VALSARTAN ON VITAMIN D LEVELS IN PATIENTS WITH HYPERTENSION

S. Ay[1], M. Karaman[1], S. Balta[2], E. Arslan[1], F. Bulucu[1], S. Demirbas[1], M. Cakar[1], T. Celik[2]

[1]Department of Internal Medicine, [2]Department of Cardiology. Gulhane Military Medical Faculty. Ankara, Turkey.

Objectives: The previous epidemiological and clinical studies in the last decades show a connection between vitamin D levels and blood pressure (BP), but the mechanism(s) underlying this condition are uncertain. There are various studies showing positive effects of antihypertensive treatment, particularly ACE inhibitors, on bone metabolism. However, data about that issue were limited. In this study, we analyzed the effects of amlodipine and valsartan on 25-hydoxyvitamin D(25(OH)Vit D) levels in patients with essential hypertension.

Material and method: Patients applying to the internal medicine and cardiology outpatient clinics who had a newly diagnosed essential hypertension were recruited in the study. Patients with a history of secondary hypertension, atherosclerotic heart disease, diabetes, chronic kidney disease, thyroid dysfunction, chronic liver disease, osteoporosis and other chronic diseases were excluded. Patients were randomized to one of the following intervention protocols: An (A) angiotensine II receptor blocker (valsartan, 80-320 mg/day) or (B) calcium channel blocker (amlodipine, 5-10 mg/day), for 12 weeks immediately after baseline measurements. Serum 25(OH)Vit D, calcium(Ca), phosphorus(P) and parathormone (PTH) levels of the patient groups were measured before treatment and on the 12nd week.

Results: This study was performed on 50 patients with newly diagnosed essential hypertension (group A; n = 28 and group B; n = 22). No statistically significant difference among the groups in terms of age, sex and body mass index (BMI) has been determined (group A/B; mean age: 52.9/50.1, female: 22/13, male: 6/9, BMI: 30.3/30.4; $p > 0.05$). Again, except for 25(OH) Vit D levels, there was no significant difference in laboratory parameters indicating bone metabolism between the groups (median PTH1: 47.4/54.5, median PTH2: 45.1/51.5, median Ca1: 9.8/9.7, median Ca2: 9.7/9.9, median P1: 3.5/3.5, median P2: 3.7/3.1; $p > 0.05$). 25(OH) Vit D levels in the amlodipine group were significantly higher after therapy (median 25(OH) Vit D1: 14.3, median 25 (OH)Vit D2: 21.4; p:0.022). However, on the valsartan group, levels of vitamin D

increased after treatment, but this increase was not statistically significant (median 25(OH)Vit D1: 16.8,median 25(OH)Vit D2:17.3; p: 0.156).

Discussion: In the treatment of hypertension, prior knowledge of the levels of 25(OH)Vit D could be important in antihypertensive drug choice and we think that this observation should be supported by further studies.

Conclusions: In this study, compared to valsartan, amlodipine had a positive effect on vitamin D levels.

RV-15
PROGRESSIVE REMISSION OF CHRONIC RENAL FAILURE AFTER TREATMENT OF PRIMARY HYPERALDOSTERONISM

J. Almaraz Marroquin, S. Suárez Ortega, A. Gil Díaz, S. Santana Baez, Y. Hernández Aguiar, R. Castillo Rueda, L. Salas Reinosa, M. Serrano Fuentes

Department of Internal Medicine. Hospital Universitario de Gran Canaria Doctor Negrín. Las Palmas de Gran Canaria, Spain.

Objectives: The different evolution of chronic renal failure in essential hypertension against primary aldosteronism (PA) has been published in the last decade. In the course of the last 10 years we have followed two patients with PA which debuted with chronic renal failure. It was demonstrated in both bilateral adrenal hyperplasia by CT. With adequate control of blood pressure and correction of potassium the disappearance of renal failure has been observed in later years. It is the reason of this presentation.

Material and method: During 10 years 62 PA have been diagnosed in our clinic. Two of them required hospitalization for severe general deterioration and present with renal failure. In the evolution, with adequate control of blood pressure and correction of hypokalemia, we observed the normalization of the renal function.

Results: First Case: A 59 years-old man was admitted to the emergency in 2005 by general weakness. It detected elevated blood pressure and severe hypokalemia. He was admitted with the diagnosis of paralysis secondary to hypokalemia. The hypertension treatment consisted of verapamil, doxazosin and valsartan. A physical examination revealed: blood pressure: 152/86 mmHg, with flaccid tetraparesis, grade 1/5. The kaliemia was 1.44 mEq/l with metabolic alkalosis. Electrocardiogram: atrial fibrillation at 60 bpm. Echocardiography: Mildaortic regurgitation with concentric left ventricular hypertrophy. The patient was treated with electrolyte replacement and 200 mg of spironolactone per day, and was released pending hormonal studies, which showed (with valsartan): ARp < 0.2 ng ml/h (normal 1.3-4). Serum aldosterone 360 pcg/ml (normal 40-160). Captopril test was considered positive by the valsartan treatment. Computed tomography and the adrenal scintigraphy showed adrenal bilateral hyperplasia. Subsequently with the spironolactone treatment the creatinine levels gradually have been declining from 2.86 mg/dl to 1.20 mg/dl (estimated creatinine clearance of 71 ml/min/1.73 m^2). Second case: A 47 years-old man was admitted to the emergency in 2002 by constitutional symptoms. High pressure values were observed (196/124 mmHg), left ventricular hypertrophy and hypertensive retinopathy grade 4. He followed not antihypertensive treatment. The initial creatinine was 2.43 mg/dl. The patient was treated with 4 antihypertensive drugs, maintaining the blood pressure in stage 1. During the next 2 years the kaliemia ranged between 3.4 and 3.8 mEq/l. The plasma renin activity was 0.3 ng/ml/h and serum aldosterone 493 pcg/ml, considered to be the test positive for captopril (in treatment with enalapril). A CT abdomen showed no adrenal adenoma. Spironolactone, 100 mg and modifications of other antihypertensive drugs were introduced. Subsequently treatment with mineralcorticoids blocking of was maintained and the creatinine levels gradually have gone down to 1.20 mg/dl (estimated creatinine clearance of 76 ml/min/1.73 m^2).

Discussion: In few situations the remission of established chronic renal failure has been observed in the context of hypertension. It has recently been demonstrated in PA, an entity of high frequency in patients with hypertension. This observation and the high prevalence of PA justify rule out the PA in the hypertensive patients.

Conclusions: 1. The diagnosis of PA is important because the hypertension, the metabolic disorders and the kidney chronic disease are potentially curable. 2. The Hypertension in the PA can be severe and of difficult control with the traditional medication.

RV-16
C3 CONVERTASE AND THE FRAMINGHAM SCORE CALIBRATED FOR SPANISH POPULATION: A WELL-MATCHED MARRIAGE

A. Rodríguez Guerrero, M. Fabregate Fuente, R. Fabregate Fuente, C. Martínez, S. Tello Blasco, A. Guerri, J. Sabán Ruiz

Department of Endothelial Pathology. Hospital Universitario Ramón y Cajal. Madrid, Spain.

Objectives: The aim of the study was to investigate the correlation between serum C3 convertase levels and REGICOR model.

Material and method: Population: We evaluated 332 subjects from the endothelial pathology unit, who had serum C3 determinations in their first visit. Patients with coronary heart disease (CHD), type 1, LADA and MODY diabetes were excluded. C3 convertase was measured by nephelometry (mg/dl). Outliers were excluded (mean ± 3-fold SD). Biochemical parameters of glucose and cholesterol were measured by an HITACHI autoanalyzer and blood pressure by an OMRON 705 CP sphygmomanometer. Cardiovascular risk assessed according to the REGICOR model, (Framingham function calibrated for Spanish population). Statistical analysis: Continuous variables described as mean (SD: standard deviation). Pearson's correlation coefficient. Comparison between groups: student's t-test. Normality assessed by Kolmogorov–Smirnov test. Levene test for equality of variances. p = 0.05.

Results: Population: aged 55.5 (10.7) range 35 to 74 years, 59.0% males, 55.1% hypertensives, 22.9% smokers, 27.7% with Type 2 diabetes mellitus. Females were slightly older than males (57.1 (10.7) vs 54.3 (10.6)). C3 serum levels ranged from 65 to 216 mg/dl. Mean 133.1 (SD: 26.4). No significant differences were found in C3 levels between males and females. C3 levels were not correlated to age. 10-years coronary risk in overall population: 4.6% (3.6), range: 0.1 to 23.1. Males had higher risk than females (5.4(4.0) vs 3.5 (2.6); p < 0.001). C3 was positively correlated to coronary risk (r = 0.167; p = 0.003) in our whole population. We divided the population into groups by sex and age. Just in males between 35 and 44 y.o. C3 was significantly correlated to coronary risk (r = 0.316; p = 0.041). In females, C3 was linearly related to coronary risk in every age group below 65 y.o. From 35 to 44 y.o: r = 0453, borderline significance. 45-54 y.o: r = 0573, p < 0.001. 55-64 y.o.: r = 0.437, p = 0.004.

Discussion: The C3 complement factor is an acute phase reactant, produced by the liver, a cytokine secreted by activated macrophages at inflammation sites and adipocytes. It has been associated with atherosclerosis and cardiovascular risk (Muscari et al. 2000; Onat et al. 2005). The evidence indicates the crucial role of inflammatory processes in all stages of atheroma formation, including infiltration of inflammatory cells in the intima and secretion of cytokines. Therefore systemic inflammatory proteins have been evaluated as predictive biomarkers of cardiovascular disease. The C3 was the unique inflammatory marker independent of body mass index, insulin and other inflammatory markers (Engstrom et al. 2005). However, the association of C3 with the full development of

metabolic syndrome and cardiovascular risk has not been studied independently until today.

Conclusions: High levels of C3 convertase are correlated with increased risk of primary cardiovascular event in the overall population of our study. High levels of C3 come forward as good predictors of cardiovascular risk in young patients and very significantly in premenopausal/perimenopausal women. Our study is consolidating a relationship between primary cardiovascular risk in women with C3 serum levels.

RV-17
RESISTANT HYPERTENSION: HOW MANY AND WHAT HYPOTENSIVE DRUGS ARE TAKEN BY PATIENTS WITH RESISTANT HYPERTENSION IN THE VASCULAR RISK UNIT OF SALAMANCA IN A PERIOD OF 7 YEARS

L. Mateos Polo, R. Fernández Santalla, M. García García, E. Puerto Pérez, A. Sánchez Rodríguez

Department of Internal Medicine. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca Spain.

Objectives: To establish the clinical and biological characteristics, the age distribution, the kind of drugs and the most common combinations of hypotensive drugs of the patients admitted in the Hypertension and Vascular Risk (HVR) Unit of the Clinical University Hospital of Salamanca with a diagnosis of resistant hypertension during a period of 7 years, between January 2005 and December 2011.

Material and method: All patients in the HVR unit database with a diagnosis of resistant hypertension were selected. We reviewed the clinical records that met these requirements: anamnesis and physical exploration, anthropometric indexes, ABMP for 24 and/or 48 hours, treatment and hypotensive drugs, antiaggregant drugs and statins. The circadian patterns of ABMP (ambulatory blood pressure monitoring) were defined as: decrease > 20%: extreme dipper; decrease between 10 and 20%: dipper; decrease < 10%: non-dipper; arterial pressure higher than day arterial pressure: riser. The statistics were made with SPSS.18 for the analysis of the descriptive frequencies, Student's t-test for independent variables and chi-squared test for dependent variables.

Results: Out of the 194 patients selected in the first stage, 102 cases were ruled out because they did not meet the requirements. In the other 92 cases, the average age was 64.5 years, with a median of 63 and a mode of 56. The mean for men was 62 years and for women it was 65 years, with no significant differences in both groups. 51.6% of the patients were women and 48.4% were men. With regard to the hypotensive drugs, 100% of the patients took diuretics, 49.5% took thiazides (HTZ 12.5 in 25.8% of the cases and HTZ 25 in 23.7% of the cases) and 24.8% took torasemide. 82.6% of the patients received angiotensin II receptor antagonists (olmesartan 26.6%; valsartan 25.3%; irbesartan 15.2%). 65.6% of the patients received calcium channel blockers (40.3% amlodipine; 24.2% lercanidipine; 11.3% diltiazem). 45.2% of the patients received beta blockers (34.9% carvedilol; 23% bisoprolol 18.6%). ACE inhibitors were prescribed in 34% of the cases (enalapril in 40.9%, enalapril 20 in 34.4% of the cases); ramipril in 28.2% of the cases (ramipril 10 in 12.5% of the cases) and perindopril in 15.7% of the cases. Peripheral vasodilators were used in 24% of the cases with doxazosin and in 23.3% of the cases with nevibolol. Renin inhibitors were used in 18% of the patients (13% of the patients received aliskiren 150 mg/day). Statins were used in 64.8% of the patients, with atorvastatin in 51.6% of the cases, simvastatin in 13.3% of the cases and pravastatin in 10% of the cases. Antiaggregants were administered in 53.3% of the cases, with acetylsalicylic acid 100 mg in 44.4% of the cases, clopidogrel in 2.2% of the cases and double anti-aggregation in 5.6% of the cases.

Conclusions: In our series, resistant hypertension is more common in women with an average age of 66 years. The most commonly used drug types were angiotensin II receptor antagonists, followed by calcium antagonists, beta blockers, ACE inhibitors and vasodilators. With regard to the drugs themselves, olmesartan was the most commonly prescribed angiotensin II receptor antagonist, both in diabetic and non-diabetic patients, followed by the calcium antagonist amlodipine. In the third place were the beta blockers (bisoprol) and in fourth place the ACE inhibitors (enalapril). Doxazosin ranks fifth. With regard to diuretics, all the patients took them, as described in the conditions for resistant hypertension. Thiazides and indapamide were the ones most commonly used, always combined with angiotensin II receptor antagonists and/or calcium antagonists. Statins and antiaggregants were not prescribed in enough cases (less than 80%), as might be expected in this group with high comorbidity rates.

RV-18
PREVALENCE OF MTHFR GENES MUTATIONS IN RESISTANT HYPERHOMOCYSTEINEMIA

C. de la Puerta, R. Fabregate, C. Martínez, M. Murchante, R. Esteban, S. Esteban, N. de la Torre, J. Sabán Ruiz

Department of Endothelial Pathology. Department of Internal Medicine. Hospital Ramón y Cajal. Madrid, Spain.

Objectives: To evaluate the prevalence of MTHFR genes mutations in resistant hyperhomocysteinemia.

Material and method: N = 33 patients with moderate-high CV risk and clinical & biochemical criteria for resistant hyperhomocysteinemia (RH) consented to genetic screening by the use of molecular genetic testing; 24 males (72.7%): 53.8 ± 17.2 yrs; BMI: 29.1 ± 4.4 Kg/m^2; 9 females (27.3%): 62.7 ± 20.3 yrs. BMI: 28.5 ± 6.5 Kg/m^2. Smokers 18.2%; Hyperglycemia 48.5%. Hypertension 66.7%. Clinical atherosclerosis (including coronary heart disease) in 33.3%.; venous thrombosis history in 9.1%. Subjects with type 1 diabetes, LADA, folic acid and/or vitamin B12 deficiency, and chronic renal failure were excluded. RH defined by: Hcy > 16 uM/L (normal values in local laboratory: < 12) after 6 months of treatment with 5 mg of folic acid and 150 mg of vitamin B6 or a dose of 1000 gammas of injected vit B12 every 2 or 3 months. Plasma Homocysteine: IMX Abbott. Statistical analysis: Continuous variables described as mean ± SD.

Results: N = 20 (60.6%) were homozygous; n = 10 (30.3%) heterozygous for MTHFR C667T mutation. Only 3 subjects (9.1%) were non carriers. 29/33 (87.9%) showed at least one Cardiovascular Risk Factor (CVRF) associated. In our study, homozygous prevalence was higher than expected in the general population (60.6% vs 15-25%), whereas heterozygous prevalence was slightly lower than estimated in Caucasian population (30.3% vs 45%). Clinical atherosclerosis (including coronary heart disease) is more prevalent than venous thrombosis history (33.3% vs 9.1%).

Discussion: The role of the homocysteine (Hcy) as a cardiovascular risk factor has been questioned for a long time but according to recent data from MESA study and NHANES study, patients with elevated Hcy levels show an increased risk not only for blood clots in the veins, but also for heart attack and stroke. MTHFR C667T is an autosomal recessive mutation within the MTHFR gene that results in the production of a thermolabile enzyme with decreased activity for methylating homocysteine. This mutation involves a single nucleotide substitution of thymidine for cytosine at nucleotide position 667 of the MTHFR gene. Carriers of this mutation are associated with elevated levels of homocysteine in plasma, which, in turn, increases the risk of arterial disease and venous thrombosis. The prevalence of the MTHFR C667T mutation in the general population is estimated to be 15-25% of homozygosity. Heterozygosity has a reported incidence of approximately 45% in

the Caucasian population. This genotype, however, is not reported to significantly increase homocysteine levels. Is controversial whether the genetic study aids to the initial management of hyperhomocysteinemia but do we know the prevalence of mutations MTHFR genes in the treated population and resistant to the therapy?

Conclusions: Our work is the first one to study the prevalence of mutations in RH. The resistant hyperhomocysteinemia is mostly accompanied by a gen alteration. Hyperhomocysteinemia is not a trivial alteration and the present study emphasizes the relevance of genetic testing at least in patients with resistant hyperhomocysteinemia. Further studies should be designed specifically to meet the proper handling of drugs and doses for this situation, especially in subjects at high cardiovascular risk. When no genetic testing is available, the evaluation of a short-term response to treatment could be a good alternative.

RV-19
UTILITY OF GENETIC TESTING FOR DIAGNOSIS OF LDLR AND APOB RELATED HETEROZYGOUS FAMILIAL HYPERCHOLESTEROLEMIA (FH)

J. Sabán Ruiz[1], R. Fabregate Fuente[1], C. Pérez Soriano[2], A. García García[2], N. de la Torre Alonso[1], A. Alonso Pacho[1], M. Fabregate Fuente[1], V. Lozano Colomer[4]

[1]Department of Endothelial Pathology. Department of Internal Medicine, [4]Department of Radiology. Hospital Ramón y Cajal. Madrid, Spain. [2]Department of Genotyping and Genetic Diagnosis. Valencia Clinical Hospital Research Foundation-INCLIVA. Valencia, Spain.

Objectives: 1. To evaluate of utility of genetic testing for diagnosis. 2. To study specificity and sensibility of the Achilles tendon ultrasonography.

Material and method: N = 57 patients with clinical criteria of heterozygous FH (Williams et al: Am J Cardiol, 1993) consented to genetic screening by the use of molecular genetic testing; Age: 46.9 ± 15.3 years old (mean ± SD). Gender: 33 males (57.9%): 44.3 ± 14.48 years old, BMI: 27.47 ± 14.48 kg/cm^2, weight: 80.37 ± 12.05 kg; 24 females (42.1%), 50.63 ± 15.91 years old, BMI: 26.09 ± 3.81 kg/cm^2, weight: 66.51 ± 12.66 kg. Smokers: N = 13 (23.2%) (9m/4f); Hyperglycemia: N = 15 (26.3%) (8m/7f). Hypertension: 21 (36.8%) (11m/10f). Clinical atherosclerosis (including coronary heart disease): N = 8 (14%). (4m/4f). Two APOB fragments involving parts from exons 26 and 29, and the 18 LDLR exons were analyzed by capillary sequencing. In 23 patients an Achilles tendon ultrasound was carried out. Statistical analysis: Continuous variables described as mean ± SD. Alpha = 0.05. Chi-square test for the comparison of two proportions. Specificity and sensibility.

Results: 1. N = 20 (39.2%) were mutation carriers. 2. N = 8 of these subjects (8/20) (40%) had mutations not previously described and with uncertain diagnostic significance. 3. N = 37 (72.5%) diagnosed patients by non-genetic standards clinical and biochemistry criteria, were noncarriers and considered as false positives. 4- In the 23 patients studied with ultrasound the test showed signs of tendinosis in 10 (43.4%) (4 carriers (m) and 6 non-carriers (f)) whereas 13 (56.5%) (9 carriers -5m/4f- and 4 non-carriers -2m/2f) had a normal study. Sensitivity = 30.8%. Specificity = 40%.

Discussion: Both LDLR-related Familial Hypercholesterolemia (FH) and APOB-related familial defective apolipoprotein B-100 (FDB) are dominantly inherited conditions associated with premature CHD and myocardial infarction. The mutation that causes this genetic abnormality occurs on chromosome 19. The diagnosis of homozygous form is easy whereas the diagnosis of the heterozygote is not so. The use of clinical criteria to diagnose heterozygous FH in general practice had a sensitivity of 46.2% and a specificity of 88.0%. (Leren et al. Community Genet. 2008;11:26-35). The Achilles tendon ultrasonography has been proved useful as a complementary diagnostic tool in the homozygous form but is unclear its contribution in the diagnosis of the heterozygous form. The genetic confirmation is a low-cost test, equivalent to 2 months of statin therapy, however there are still many barriers for it use in large scale.

Conclusions: The utility of non-genetic diagnostic criteria for heterozygous FH in general practice is very low. The Achilles ultrasound test gives false positive results in women and false negative in both gender. Molecular genetic testing should be implemented in clinical medicine due to a main reason: to avoid an unnecessary medical mistake that has a cost equivalent to two-months of statin therapy. The economical, clinical and familiar implications related to this disease warrants a better diagnosis. The present study emphasizes the relevance of genetic testing in screening and treatment of heterozygous FH patients and the needing of further research in this lethal disease.

RV-20
CORRELATION OF FLOW-MEDIATED DILATION WITH C-REACTIVE PROTEIN AND CAROTID INTIMA-MEDIA THICKNESS IN A POPULATION WITH MODERATE-HIGH CARDIOVASCULAR RISK UNDER TREATMENT

A. Reyes Valdivia[1], E. Marín Manzano[1], M. Fabregate Fuente[2], R. Fabregate Fuente[2], A. Alonso Pacho[2], C. Martínez[2], C. Cuesta Gimeno[1], J. Sabán Ruiz[2]

[1]Department of Vascular Surgery, [2]Department of Endothelial Pathology. Department of Internal Medicine. Hospital Ramón y Cajal. Madrid, Spain.

Objectives: 1. To correlate endothelium-dependent vasodilation as measured by flow-mediated dilation (FMD) with high-sensitive C-reactive protein (hs-CRP), carotid intima-media thickness (CIMT) and coronary risk. 2- To correlate FMD with salbutamol-mediated dilation (SMD).

Material and method: 74 patients (51.3% males), age: 61.1 (13.2) years were studied: 78% hypertensives, 34.2% with type 2 diabetes mellitus and 14.5% smokers. Patients with type 1 diabetes, latent-autoimmune-diabetes-adult, established cardiovascular disease or hs-CRP above 15 mg/dl were excluded. CIMT was assessed on the posterior wall of the common carotid artery using a 5-12 MHz multi-frequency linear array ultrasonic transducer (General Electric Vivid-5s). Endothelium-dependent vasodilation was assessed according to the Celermajer's test (15 seconds after cuff deflation) and FMD expressed as percentage change from basal diameter of the brachial artery (%). Then, two pharmacological tests were carried out: inhaled salbutamol (5, 10 and 15minutes after 100mcg) and sublingual nitroglycerin (3, 5 and 10 minutes after 400mcg). SMD at each point expressed as percentage change from basal diameter (%). Nitroglycerin was used to exclude patients with impaired endothelium-independent vasodilation (none was excluded). hs-CRP (mg/dl) by Siemens Nephelometer. 10-year coronary risk (%) according to Framingham model calibrated for Spanish population (REGICOR). Statistical Analysis: continuous variables as mean (standard deviation). Pearson's correlation coefficient (r).

Results: 1. In our population the mean FMD was 5.67 (7.17)%. Mean values of CIMT and 10-year coronary risk were 0.74 (0.23) mm and 3.66 (2.74)% respectively. 2. FMD was inversely correlated with hs-CRP ($r = -0.257$, $p = 0.039$) and with CIMT ($r = -0.229$, $p = 0.05$), but did not show significant correlation with coronary risk. 3. The results of SMD at every point were strongly correlated to FMD (5 min: $r = 0.435$, 10 min: $r = 0.397$, 15 min: $r = 0.464$; $p < 0.001$). Particularly, in non-diabetics, the association between CIMT and SMD seems to be stronger than with FMD at several points (5 min: $r = -0.352$, $p = 0.016$; 15 min: $r = -0.309$, $p = 0.037$).

Discussion: SMD has been recently introduced as a complementary test of FMD evaluated according to Celermajer. Traditional cardiovascular risk estimation losses predictive ability in treated patients. Therefore, it may be advisable to resort to non-traditional risk factors as FMD, CIMT and hs-CRP.

Conclusions: 1. Our results supports the hypothesis that beta-adrenergic vasodilator response –SMD- and FMD are both dependent on Nitric-Oxide synthesis. 2. Besides, elevated hs-CRP serum levels are associated with a blunted systemic endothelial vasodilator function. 3. Finally, we found that in patients with cardiovascular risk under treatment, hs-CRP and CIMT correlate better with brachial FMD than coronary risk models based on traditional risk factors.

RV-21
IDENTIFICATION OF A NOVEL MUTATION (CYS352SER) IN THE LDLR GENE IN THE SPANISH POPULATION

J. Sabán Ruiz[1], D. González Nieto[2], R. Fabregate Fuente[1], C. Pérez Soriano[3], A. García García[3], S. Tello Blasco[1], C. de la Puerta[1], D. Gómez Coronado[4]

[1]Department of Endothelial Pathology, Department of Internal Medicine.[4]Research Service. Department of Biochemistry Research. Ramón y Cajal Hospital. Madrid, Spain. [2]Center for Biomedical Technology. Research Service. Universidad Politécnica. Ramón y Cajal Hospital. Madrid, Spain. [3]Department of Genotyping and Genetic Diagnosis. Valencia Clinical Hospital Research Foundation-INCLIVA. Valencia, Spain.

Objectives: In this study we have identified several members of a family with clinical diagnosis of hypercholesterolemia (HC) carrying a novel mutation in the LDLR gene (p.Cys352Ser).

Material and method: Subjects: we have included in this study four siblings who had given informed consent and were examined for HDL-C, LDL-C and Total-C levels using a Hitachi autoanalyzer. Two APOB fragments involving parts from exons 26 and 29, the 18 LDLR exons, including intron-exon boundaries, and part of the promoter region were analyzed by capillary sequencing.

Results: At the age of diagnosis, three siblings (probands 1-3) showed high levels of Total-C and LDL-C levels in plasma (> 300-500 mg/dl), suggestive of FH, while the other proband (4) had normal levels. Proband 1: Male, 39 years old. Age at onset of HC: 25. Currently in treatment with pitavastatin (4mg/day) and ezetimibe (10 mg/day); Lipid profile: Total-C: 191 mg/dl (4.9 mmol/l); HDL-C: 32 mg/dl (0.8 mmol/l); LDL-C: 139 mg/dl (3.6 mmol/l). Proband 2: Male, 41 years old. Age at onset of HC: 26. In treatment with atorvastatin (10 mg/day) and ezetimibe (10 mg/day); Lipid profile: Total-C: 209 mg/dl (5.4 mmol/l); HDL-C: 32 mg/dl (0.8 mmol/l); LDL-C: 151 mg/dl (3.9 mmol/l). Proband 3: Woman, 30 years old. Age at onset of HC: 15. In treatment with atorvastatin (20mg/day); Lipid profile: Total-C: 252 mg/dl (:6.5 mmol/l); HDL-C: 75 mg/dl (1.9 mmol/l); LDL-C: 157 mg/dl (4 mmol/l). Proband 4: Male, 37 years old. Without medical treatment; Lipid profile: Total-C: 176 mg/dl (4.5 mmol/l); HDL-C: 36 mg/dl (0.9 mmol/l); LDL-C: 119 mg/dl (3.1 mmol/l).

Discussion: Low-density lipoprotein receptor (LDLR) gene mutations cause familial hypercholesterolemia (FH), a genetic disorder with a prevalence of 1 in 500 that is associated with high levels of cholesterol (C) and LDL-C levels in the plasma and early cardiovascular disease.

Conclusions: Our genetic analysis revealed that the affected probands carried a heterozygous mutation in the exon 7 (c.1054T > A) that modifies the amino-acid at position 352 from cysteine to serine. This mutation was not found in the proband non-affected of HF. To our knowledge this mutation has not been previously described in the Spanish or European population, although the exact mutation was found recently in a Taiwanese family with FH (Chiou et al. Atherosclerosis. 2011;216:383-9). The amino-acid Cys352 is highly conserved in the LDLR among other species and is part of the calcium-binding EFG-like domain. Interestingly other amino-acid changes, stop codons or frame-shift mutations have been described in the same position in other families with FH (http://www.ucl.ac.uk/ldlr), highlighting the importance of this residue in LDLR function. On the basis of these findings the mutation Cys352Ser is probably responsible for the hypercholesterolemic phenotype observed in the affected patients. At mechanistic level, experimental assays are required to elucidate with precision the specific functional alterations associated with this LDLR mutation.

RV-22
PROVIDING A CLEAR AND COMPREHENSIVE OVERVIEW OF THE BASELINE METABOLIC STATUS IN LIPID-NAIVE TYPE 2 DIABETIC PATIENTS

J. Rodríguez Encinar, M. Fabregate Fuente, R. Fabregate Fuente, S. Tello Blasco, A. Guerri, A. Rodríguez, C. de la Puerta, J. Sabán Ruiz

Department of Endothelial Pathology. Department of Internal Medicine. Ramón y Cajal Hospital. Madrid, Spain.

Objectives: To evaluate the relative prevalence of hypercholesterolemia, hypertrigliceridemia, low-HDL, combined or isolated, in T2DM patients without lipid lowering drugs.

Material and method: N: 126 T2DM patients, under no lipid-lowering drugs (lipid-naive), were selected. Males: n = 86; age: 59.5 ± 10.8 years (range: 36-88); time from T2DM diagnosis: 6.1 ± 7.4 yrs (1-35); BMI (body mass index): 28.3 ± 4.2 Kg/m^2 (20-43.6). Females: n = 40; age: 66.7 ± 11.2 years (45-95); time from diagnosis: 10.2 ± 8.4 years (1-30); BMI: 31.4 ± 5.8 Kg/m^2 (22-57.9). A lipid profile was carried out including total-cholesterol (t-C), HDL-cholesterol (HDL-C) and triglycerides (TG), measured by Hitachi autoanalyzer. LDL-cholesterol (LDL-C) was calculated in subjects with TG < 400 mg/dl (< 10.3 mmol/L) using the Friedewald equation. Atherogenic or diabetic dyslipidemia was defined as: hypertriglyceridemia (TG > o = 150 mg/dl (1.7 mmol/L)) & low HDL-C (≤ 40 mg/dl (1 mmol/L) in males or ≤ 50 mg/dl (1.3 mmol/L) in females). A1c (DCCT) in %. Statistical analysis: continuous variables are described as mean ± SD. Significance 0.05 for mean comparations. Student-t test for independent samples. Levene's test for variance homogeneity.

Results: 1. In males, 10.5% presented isolated hypercholesterolemia; 26.7% had hypertriglyceridemia and just 5.8% showed mixed dyslipidemia. Isolated low HDL-C was observed in 22.1%, low HDL-C & hypercholesterolemia in 3.5%; low HDL-C & hypertriglyceridemia (diabetic or atherogenic dyslipidemia) in 18.6%. 2. In females, 17.5% presented isolated hypercholesterolemia; 27.5% had hypertriglyceridemia and just 2.5% showed mixed dyslipidemia. Isolated low HDL-C was observed in 17.5%, low HDL-C & hypercholesterolemia in 5.0%; low HDL-C & hypertriglyceridemia (diabetic or atherogenic dyslipidemia) in 25.0%. 3. Isolated or combined low-HDL was observed on 53.5% of males and 50% of females. 4. Low HDL-C and hypertriglyceridemia, but not hypercholesterolemia, were related to a worse glycemic control evaluated by A1c (DDCT). Subjects with hypertriglyceridemia presented higher A1c than those with normal TG (7.95 ± 1.7 vs 7.4 ± 1.7). Similar differences were observed in regard to low HDL-C (7.8 ± 1.8 vs 7.4 ± 1.6). These differences did not achieve statistical significance.

Discussion: Although only 17% of the ACCORD participants had atherogenic or diabetic dyslipidemia, it is usually thought that this is the most frequent dyslipemic alteration in type 2 diabetes patients (T2DM) without lipid lowering drugs. On the other hand, prevalence of hypercholesterolemia is considered to be relatively

low, although it is higher in women than men (UKPS, Lancet, 1997). The prevalence of mixed dyslipidemia (hypercholesterolemia & hypertriglyceridemia) is not well-known.

Conclusions: 1. The term "diabetic dyslipidemia" does not implies that it is the most frequent lipemic alteration in T2DM. According to our results and the ACCORD study the prevalence of diabetic dyslipidemia is really low. 2. Low HDL-C is the most prevalent alteration. Half of lipid-naïve T2DM patients showed isolated or combined low HDL-C. 3. Hypertriglyceridemia is also more frequent than diabetic dyslipidemia. 4. TG and HDL-C, but not LDL-C, seem to be related to glycemic control. 5- This kind of study provides a clear and comprehensive overview of the baseline metabolic status in lipid-naïve T2DM patients.

RV-23
EFFECTIVENESS OF EDUCATIONAL PROGRAMS FOR PATIENTS WITH TYPE 1 DIABETES MELLITUS: A META-ANALYSIS

U. Errasti Amiano, M. Vaquero Valencia, X. Kortajarena Urkola, A. Berroeta Iribarren, A. Fuertes Rodríguez, M. Elola Zeberio, N. Pérez Fernández, M. del Hierro Balenziaga

Department of Internal Medicine. Hospital Universitario Donostia. Donostia (Guipúzcoa), Spain.

Objectives: To assess the effectiveness of educational programs in terms of metabolic control measured by HbA1c, and show the influence on acute complications (hypoglycemia and diabetic ketoacidosis). Also consider changes in the quality of life.

Material and method: Search strategy: We searched The Cochrane Library, MEDLINE, EMBASE, TRYP database, Clinical Evidence and PASCAL. Additionally, we searched reference lists of relevant studies identified. No language restriction was made. Selection criteria: Studies were included if they were randomized controlled trials comparing diabetes education programs with standard care in people between 12 and 65 years old with type 1 diabetes mellitus. Studies were included if the outcomes were changes on glycosylated hemoglobin, proportion of hypoglycemic episodes or diabetic ketoacidosis and/or changes on life quality. Data collection and analysis: Two authors independently assessed risk of bias and extracted characteristics of included studies. Meta-analyses using a random-effects model were performed.

Results: Seven studies randomized 946 participants with type 1 diabetes to either intervention. Overall, studies quality was poor and the heterogeneity elevated. There was not a statistically significant difference in glycemic control (mean difference -0.07, 95% confidence interval -0.29 to 0.16). Patients on educational group presented less hypoglycemic episodes, although that it was not statistically significant (RR 0.75, 95% confidence interval 0.46 to 1.22). Only two studies show information about diabetic ketoacidosis, but presented a high heterogeneity (I2 87%). There were no obvious differences after data combination (RR 0.97, with p 0.99). Life quality was evaluated with ADDQoL scale, obtaining better punctuation in the educational group, but without significance (weighted mean difference 0.20, 95% confidence interval -0.19 to 0.58, p 0.31).

Discussion: There were only seven studies that met the inclusion criteria. Many studies were excluded from the review because they were not randomized controlled trials or because they included both patients with diabetes mellitus type 1 and type 2, or in cases involving only type 1 diabetics, they were pediatric patients. The included studies were generally of poor quality, mainly due to inadequate allocation concealment and having a small sample size. None of those included studies was blind. As the intervention is an educational program that requires the involvement of patients assigned in that group, it is very difficult to blind it. As the studies have a high heterogeneity, we consider that the best option would have been to have made a qualitative analysis instead of having performed a meta-analysis of pooled data.

Conclusions: It seems that educational programs can improve metabolic control in diabetic patients, without increasing at the same time hypoglycemic episodes and in that way improving life quality, but we did not obtain statistically significant results. On the future, more randomized controlled trials with better methodological quality must be made.

RV-24
COMPLEXITY ANALYSIS: A BETTER PREDICTOR THAN VARIABILITY FOR GLUCOSE REGULATORY SYSTEM DYSFUNCTION

B. Vargas, R. Ruiz, C. Rodríguez, L. Vigil, A. Muñana, P. González, M. Varela

Department of Internal Medicine. Hospital Universitario de Móstoles. Madrid, Spain.

Objectives: Glucose variability seems to be a risk factor for diabetic complications per se, independently of the glucose levels. However, the metrics usually employed to assess glucose variability are fraught with problems. Recently, new methods derived from nonlinear dynamics seem to offer more sensitive and reliable tools to detect subtle dysfunctions of the glucorregulatory system with prognostic relevance, and to provide a new point of view on glycemic fluctuations. We compare complexity analysis of glucose time series (obtained by continuous glucose monitoring system) with the most commonly employed metrics to assess glycemic variability (namely Mean Amplitude of Glucose Excursions (MAGE) and Continuous Overlapping Net Glycemic Action (CONGA) in two datasets:.- an ambulatory group (n = 41) composed of healthy volunteers and ambulatory patients with increased vascular risk (defined as complying with at least one of the following conditions: BMI > 30, essential hypertension or a first degree relative with diabetes mellitus type 2, while not being diabetics themselves). This group included 16 patients complying with the NCEP-ATPIII criteria (3 or more) for the Metabolic Syndrome.- a group (n = 36) of critically ill patients admitted in the ICU Furthermore, we provide a free software to analyse both variability and complexity of glycemic profiles. The software is available at http://fractal-lab.org/Downloads/gluc_complex.html.

Results: In each dataset there was an inverse correlation between complexity and variability (direct correlation between DFA and variability metrics)... Complexity (but not variability) was significantly higher in healthy volunteers than in patients with the metabolic syndrome (DFA 1.30 (SD 0.13) vs 1.40 (SD 0.08), p = 0.009, no significant differences for MAGE or CONGA). There was a significant inverse correlation between complexity and the number of criteria for the metabolic syndrome met by each patient (rho = 0.433, p = 0.008). The correlation between variability metrics and the number of criteria did not achieve statistical significance. In critically ill patients, complexity (but not variability) was significantly different in surviving vs non-surviving critically ill patients (DFA: 1.48 (SD 0.10) vs 1.62 (SD 0.15) (p = 0.004); no significance differences for MAGE or CONGA), with a higher complexity (lower DFA) conferring a better prognosis. An increase in 0.1 in DFA implied an OR for survival of 0.35.

Discussion: While at first glance similar, complexity and variability are in a certain sense the opposite: high variability is a consequence of a "sluggish" glucoregulatory system, which needs fairly large departures from normality to unleash correcting processes. On the other hand, high complexity (low DFA) reveals a "sharp" glucoregulatory system, able to detect and quickly correct minor deviations. Variability metrics have considerable methodological problems, most notably an arbitrarily defined span of time to measure CONGA, and an arbitrarily definition of glycemic excursion

to obtain MAGE. Complexity analysis avoids these "red marks", and studies glycemic fluctuations without having to define arbitrary limits, therefore arguably providing a swifter and more physiological point of view. We suggest that the first signs of glucose control impairment would be a loss of complexity in the glycemic profile. Indeed, in both of our databases glycemic complexity was able to identify relevant clinical data not detected by conventional variability metrics.

Conclusions: Complexity analysis provides a more sensitive and specific tool to analyse glycemic fluctuations and may offer a more precise picture of the early steps of glycemic dysregulation.

RV-25
THE ROLE OF DPP-4 INHIBITORS ON THE LIPID PROFILE AND CARDIO-VASCULAR RISK OF PATIENTS WITH TYPE 2 DIABETES

M. Popoviciu

Department of Internal Medicine. University of Oradea, Faculty of Medicine. Oradea, Romania.

Objectives: Type 2 diabetes has been officially as a major cardiovascular risk factor and is equivalent to coronary diseases. This paper aims to show the benefit of DPP-4 inhibitors treatment on the lipid profile and to quantify the cardiovascular risk assessment by Framingham score and SCORE chart in patients with type 2 diabetes.

Material and method: In this study participated 37 type 2 diabetes patients treated with DPP-4 inhibitors, in the Clinical Center of Diabetes in Oradea, and they were followed over a period of 6 months. Lipid profile in the context of the study: cholesterol and triglycerides as well HDL-cholesterol and LDL-cholesterol. Framingham Score: uses 6 risk factors: sex, age, smoking status, total cholesterol, HDL cholesterol, systolic blood pressure. SCORE charts provides 10-year prediction of cardiovascular mortality, uses 5 risk factors: sex, age, smoking status, total cholesterol, systolic blood pressure.

Results: The gender distribution of cases results in a ratio 1:1 between women and men: 70.2% had ages between 51-70 years; 54.1% had cardio-metabolic family history; associated diseases were not recorded only in 3 patients (8.1%), majority having arterial hypertension (64.9%) and dyslipidemia (62.2%). The most frequent associating was between hypertension + dyslipidemia (32.4%).73.0% had a duration of the diabetes mellitus evolution under 5 years. Over 70% of patients say that they do moderate physical exercise and 70.3% have pro-aterogen diet. Triglycerides had above normal values at the times of the 3 measurements, however still decreased from 216.8 mg/dl to 188.0 mg/dl ($p < 0.001$). The evolution of total cholesterol ($p = 0.021$), of HDL-cholesterol ($p < 0.001$) and of LDL-cholesterol ($p = 0.027$) was favorable. The Framingham score indicated an increased cardiovascular risk, mean values being over 20 (23.59), at 3 months it was still at the level between moderate risk and increased risk, and at 6 months it indicated a moderate risk (17.95). In correlation with the evolution of cholesterol, HDL-cholesterol, arterial hypertension, the treatments results in a decrease in the cardiovascular risk (ES = -2.14). Mean value of the Framingham score is significantly higher in men than in women (26.4 versus 20.9) ($p < 0.001$) and is observed along with increase in age, resulting in a direct correlation between increased age and cardiovascular risk($r = 0.96$). During all 3 evaluations the SCORE index indicated an increased risk, the values being over 5 (12.32, 10.80, respective 9.89). However there was a decreasing trend of the SCORE index, which indicated a good effect of the treatment upon reducing the cardiovascular risk (ES = -1.76).

Discussion: Between fasting glucose, HbA1c and Framingham score exists a direct reverse correlation ($r = 0.61$), in fact the less metabolic control the greater the cardiovascular risk.

Conclusions: 1. Improved lipid profile, decrease in total cholesterol, LDL-cholesterol and triglycerides was observed ($p = 0.021$, $p = 0.027$, $p < 0.001$) and HDL-cholesterol increased ($p < 0.001$). 2. The effect of treatment on blood pressure was good, SBP values decreased from 150.6 to 138.2 mmHg ($p = 0.021$) and DBP from 90.4 to 84.8 mmHg ($p = 0.047$). 3. Framingham score averages were significantly higher in men than in women (26.4 versus 20.9) ($p < 0.001$) and the Framingham score increased with age, resulting in a direct correlation between age and cardiovascular risk ($r = 0.96$) 4. Regarding the evolution of metabolic profile, fasting glucose, and the 2-hour postprandial glycemia decreased significantly at 6 months compared to the baseline ($p < 0.001$). HbA1c had a downward trend during the 6 months (initial 7.17 to 6.23 in the first 3 months, and then to 5.72 in 6 months.

RV-26
USE OF ANTIHYPERTENSIVE DRUGS, COMMON ASSOCIATIONS AND DURATION OF ESSENTIAL HYPERTENSION IN THE VASCULAR RISK UNIT OF THE UNIVERSITY HOSPITAL COMPLEX OF SALAMANCA IN A PERIOD OF 2 YEARS

L. Mateos Polo, S. Argenta Fernández, M. García García, A. Crisolino Pozas, T. García Guerrero

Department of Internal Medicine. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca, Spain.

Objectives: Retrospective study of the use of antihypertensive drugs, duration of the hypertension, target organ impact and common associations in the patients with essential hypertension who were admitted in the Vascular Risk Unit of the University Hospital Complex of Salamanca in a period of 2 years, from January 2010 to December 2011.

Material and method: The Vascular Risk Unit services the whole province of Salamanca. We collected all the clinical records of patients with a diagnosis of essential hypertension which included complete anamnesis, 3 automated blood pressure measurements, electrocardiogram, echocardiogram, fundus of the eye, ankle-arm index, renal function, lipid profile, microalbuminuria in urine after 24 hours, number of antihypertensive drugs, doses and associations, and we assessed the therapeutic adherence with the Morisky-Green-Levine test and its 4 classic questions. The statistics were made with SPSS.18 for the analysis of the descriptive frequencies, Student's t-test for independent variables and chi-squared test for dependent variables.

Results: 143 patients were analyzed, and 40 of them were ruled out because they did not meet the requirements. Out of the 103 remaining patients, 53% were women with an average age of 71 years and 46% were men with an average age of 68 years. Essential hypertension of less than 5 years of evolution was present in 44% of the women and in 55% of the men, and the same condition of more than 5 years of evolution was present in 73% of the women and in 26% of the men. The differences between sexes were statistically significant ($p < 0.046$). 52% of the patients showed some kind of organ impact: nephropathy in 64.7%, cardiopathy in 30.3%, vascular involvement of the CNS in 18.4%, ophthalmopathy in 6.7% and triple involvement in 6% (cardiopathy, vascular involvement of the CNS and the PNS), and no statistically significant differences were found regarding sex ($p = 0.92$). 73.8% of the patients received diuretics (1.33 times more in the case of women), 57% of the patients received calcium antagonists (1.45 times more in the case of women), 32% received beta blockers (3.1 times more in the case of men), 69% received ARA-2 (1.36 times more in the case of women), 29% received ACE inhibitors (with the same levels for both sexes), 25% received alpha blockers (2 times more in the case of men) and 23% received renin inhibitors (1.81 times more in the case of men). 84% of the patients received more than 2 drugs, and 15% received

more than 3. The most commonly used diuretics were hydrochlorothiazide (64.5%) and furosemide (22%). In the case of calcium antagonists it was amlodipine (67%), followed by lercanidipine (15.3%). In the case of ARA-2 it was valsartan (38.9%), followed by olmesartan (25%) and irbesartan (9.7%). In the case of beta blockers, it was bisoprolol (36%) followed by atenolol (18%) and metoprolol (15%). 91% of the patients reported adherence to the antihypertensive treatment, according to the Morisky-Green-Levine test.

Conclusions: Patients with essential hypertension admitted in the Vascular Risk Unit of the Hospital Complex in a period of 2 years are mainly women of middle-advanced age, with hypertension of more than 5 years of evolution, who present kidney and heart involvement as target organ impact and who take more than 2 antihypertensive drugs. The most common triple association is one diuretic (hydrochlorothiazide) with one angiotensin II receptor antagonist (valsartan) and one calcium antagonist (amlodipine), followed by a combination of diuretics and one angiotensin II receptor antagonist. Notably, ACE inhibitors have been replaced by angiotensin II receptor antagonists in the treatment. Also, beta blockers and alpha blockers are seldom used, and they are mainly prescribed for men, probably because they present cardiopathies with an associated prostatic hypertrophy. There is a high adherence to the antihypertensive treatment due to the use a combined treatment with double and triple association of medication.

RV-27
USE OF ANTIDIABETIC MEDICATION AND GLYCATED HEMOGLOBIN LEVELS IN TYPE 2 DIABETIC PATIENTS IN THE VASCULAR RISK UNIT OF THE SALAMANCA HOSPITAL COMPLEX IN A PERIOD OF 7 YEARS

L. Mateos Polo, R. Fernández Santalla, A. Crisolino Pozas, M. García García, N. Cubino Bóveda

Department of Internal Medicine. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca, Spain.

Objectives: Retrospective study of associated diseases, duration of diabetes, target organ damage, glycated hemoglobin levels and use of oral and non-oral medication in type 2 diabetic patients who were admitted in the Vascular Risk Unit of the Salamanca Hospital Complex in a period of 7 years, from March 2006 to March 2012.

Material and method: The Vascular Risk Unit services the whole province of Salamanca, and it is located in the Virgen Vega Hospital of the Hospital Complex. We collected all the clinical records of patients with a diagnosis of diabetes mellitus which included complete anamnesis, 3 automated blood pressure measurements, lipid profile, glycated hemoglobin (HbA1C), microalbuminuria in urine after 24 hours and the treatment. We was applied. Metabolic syndrome was defined according to the criteria of the National Cholesterol Panel Expert III (NCPE III). The statistics were made with SPSS.18 for the analysis of the descriptive frequencies, Student's t-test for independent variables and chi-squared test for dependent variables.

Results: 121 patients were analyzed, and 50 of them were ruled out because they did not meet the requirements in the "Material and Methods" section. Out of the 71 remaining patients, 52% were women with an average age of 75 years and 48% were men with an average age of 67 years. With regard to their clinical records, hypertension appeared in 54% of the women and 45.8% of the men. Metabolic syndrome was found in 75% of the men and in 25% of the women ($p < 0.16$), 42% of the patients presented some kind of organ damage: 28% showed nephropathy, 26% presented cardiopathy and 4.7% showed vascular involvement of the CNS. The average level of glycated hemoglobin was 7.16 mg/dl in women and 7.13 mg/dl in men, and the difference between them was not statistically significant. 52% of the women and 47% of the men were diabetic for more than 5 years. No statistically significant association was found between the duration of diabetes for more than 5 years and HbA1C levels. 70% of the patients received metformin (66% of women), 23% received DPP-4 inhibitors (inhibitors of dipeptidyl peptidase 4), 17% received glinides and 12% received sulfonylureas (SU). 35% of the patients were insulinized and 8% received liraglutide. 42% of the patients received more than 2 drugs (metformin and DPP-4 inhibitors in 75% of the cases) and 12% of the patients received more than 3 drugs (in 57% of the cases SU was added to the previous two.

Conclusions: Diabetic patients admitted in the Vascular Risk Unit of the Hospital Complex in a period of 7 years were mainly middle-aged women, mostly hypertense, with renal involvement (the stage of the condition was not measured), with the glycated hemoglobin levels under control and more than 5 years of evolution of their metabolic condition. They take at least two oral antidiabetic drugs (metformin and DPP-4 inhibitors) and they are barely insulinized. We can highlight the decrease in the SU consumption and the growing use of subcutaneous GLP-1, as well as a higher prevalence of metabolic syndrome in diabetic men, compared with the women.

RV-28
EPIDEMIOLOGICAL STUDY OF VASCULAR RISK FACTORS AND TARGET ORGAN LESIONS IN DIABETIC PATIENTS IN THE VASCULAR RISK UNIT OF THE CLINICAL HOSPITAL OF SALAMANCA IN A PERIOD OF 2 YEARS

L. Mateos Polo, R. Fernández Santalla, C. Martín Hernández, P. Miramontes González, E. Puerto Pérez, A. Sánchez Rodríguez

Department of Internal Medicine. Hospital Universitario Virgen de la Vega. Salamanca, Spain.

Objectives: Retrospective study of patients with type 2 diabetes who were treated in the Vascular Risk Unit of the Clinical Hospital of Salamanca for 2 years, from January 2010 to December 2011, in order to establish their clinical and biological characteristics, age, sex, body mass index, LDL levels, classic vascular risk factors (VRF), target organ lesion (TOL), statin consumption and type of statins.

Material and method: We gathered the clinical records of all diabetic patients who were treated in the Vascular Risk Unit for 2 years and recorded data regarding complete anamnesis, anthropometric indexes, arterial pressure and AP monitoring after 24 hours if required, AP staging according to the guidelines of the European Society of Hypertension (grade 1: PAS 140-159 and/or PAD 90-95; grade 2: PAS 160-179 and/or PAD 100-109; grade 3: PAS ≥ 180 and/or PAD ≥ 110), electrochardiography, echocardiogram, ophthalmoscopy, ankle-arm index, renal function, lipid profile, microalbuminuria in urine after 24 hours and treatment applied. The statistics were made with SPSS.18 for the analysis of the descriptive frequencies, Student's t-test for independent variables and chi-squared test for dependent variables.

Results: 121 diabetic patients were studied, and 20 were ruled out because they did not meet the requirements. Out of the 101 remaining patients, 58.8% were women with an average age of 73 years and 41.2% were men with an average age of 69 years. The average body mass index was 30.88 in women and 29.09 in men, and the difference between sexes was statistically significant. 42% of the patients presented hypertension (68.4% of the women). In this group, an optimal BP was obtained in 63.1% of the patients, it was normal-high in 20.2% of the patients, grade 1 in 33% of the patients and grade 2 in 27.1% of the patients. The average LDL levels were 104.3 in women and 102 in men with no significant differences regarding sex. With regard to VRF in women, obesity-dyslipidemia was present in 51.2% of the cases, obesity and postmenopause in 39% of the cases and ischemic cardiopathy in

9.8% of the cases. In men, obesity-dyslipidemia was found in 37.5% of the cases (differences between sexes were statistically significant), active tobacco consumption in 16.7% of the cases and ischemic cardiopathy in 9.8% of the cases. The target organ lesion was not found in 49% of the cases. There was some degree of nephropathy in 34.7% of the cases (in women this rate was 34.1%), cardiopathy in 32.8% of the cases, CVA in 27.3% of the cases, nephropathy and ophthalmopathy in 18.9% of the cases and alteration of the ankle-arm index in 5.5% of the cases. 65% of women and 58% of men received statins: atorvastatin in 33.3% of the cases, simvastatin in 8.9% of the cases and fluvastatin in 4.9% of the cases. There were no statistically significant differences between LDL levels and statins consumption.

Conclusions: Diabetic patients in the Vascular Risk Unit of the Clinical Hospital of Salamanca are mainly women of an advanced age, obese and dyslipidemic, with controlled hypertension (optimal). In most of the cases they present nephropathy as organ target impact, with unacceptable LDL cholesterol levels for diabetic patients, according to the Guidelines of the NCEP 2010 (National Cholesterol Education Program). Renal involvement, followed by cardiopathy, is the most commonly found lesions in our series. Atorvastatin is the most commonly used statin in both sexes.

RV-29
NEW VASCULAR AGE CHARTS FROM FRAMINGHAM GENERAL CARDIOVASCULAR RISK PROFILE

J. Cuende, R. Marcos, Y. Morán, F. del Campo, P. Benito, I. Pérez de Diego

Department of Internal Medicine. Complejo Asistencial de Palencia. Palencia, Spain.

Objectives: Vascular age is a new epidemiological concept in patient management. Vascular age calculation is a new approach to evaluate non-high risk cardiovascular patients, especially young ones, as stated in the European cardiovascular guidelines recently published. There are two methods to calculate cardiovascular age from cardiovascular risk tables. The first method is derived from Framingham Heart Study (FHS) with several point-based tables. The second method is derived from SCORE project with coloured tables. The objective of this study is to create vascular age charts derived from FHS but with SCORE project stylus which is more useful in daily practice.

Material and method: Coefficients from the Cox model used in FHS general cardiovascular risk profiles were used to calculate vascular age. The variables used in the calculation were age, sex, total cholesterol, HDL-cholesterol, systolic blood pressure, hypertension treatment, smoking and diabetes. Several box charts were created according the values of the variables. The values in the boxes are the vascular ages calculated with the values of the variables. The result is presented in a SCORE chart stylus.

Results: Several box charts are presented to calculate vascular age. There are 2 charts depending on sex, splitted by smoking and diabetes status. The value of vascular age depends on systolic blood pressure, total cholesterol and age. There are two additional modifying factors: HDL-cholesterol and treatment for hypertension.

Discussion: The new vascular age charts are presented as box-charts like SCORE risk charts. This chart format is more serviceable than point chart format as vascular age can be calculated easier and can be presented to patient in a friendly way. Vascular age is recommended for helping to communicate about risk, especially to younger people. The last European guidelines on cardiovascular disease prevention recommend "Speak to the individual in his/her own language" as one of the principles of effective communication to facilitate behavioural change.

Conclusions: Vascular age derived from Framingham Heart Study can be presented as charts in the same way as SCORE vascular age charts. These new charts are more useful than usual point charts.

RV-30
CARDIOVASCULAR COMORBIDITY IN PATIENTS HOSPITALIZED FOR ACUTE COPD

C. Josa Laorden, S. Luna García, L. Royo Trallero, M. Aibar Arregui, M. Sánchez Marteles, F. Ruiz Laiglesia, J. Pérez Calvo

Department of Internal Medicine. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: Chronic obstructive pulmonary disease (COPD) is associated with several comorbidities that confer a multiorgan character. The aim of this study is to quantify the prevalence of major cardiovascular disease in these patients: hypertension, heart failure, ischemic heart disease and vascular disease (including: pulmonary thromboembolism, valvular, aortic aneurysm and peripheral arterial disease) and the main risk factor for these diseases: smoking.

Material and method: Observational, retrospective, transversal descriptive study, in which we have reviewed the reports of patients discharged consecutively at the Hospital Clínico Universitario Lozano Blesa in the period from January to December 2011, being the first or second diagnosis COPD (ICD 491), emphysema (ICD 492) and chronic airflow obstruction (ICD 496). We reviewed a total of 516 reports, extracting demographic data and comorbidities described.

Results: 20% of admitted patients were women (N = 77), and 80% male (N = 299), with a mean age of 74.4 years (range 39-100). The average patient stay was 12 days, with a median of 10 days. Of the 516 reports, 140 were readmissions, so the number of patients amounted to 376. 25% of patients were readmitted within 3 months or had entered the previous month. Hypertension is the most prevalent comorbidity in these patients, 62.7% (59.5% men, 72.7% of women), with a readmission rate of 24.3%. The prevalence of heart failure was 29.8% (29% men, 34% of women), with a readmission rate of 20%. Ischemic heart disease is present in 16% (17% men, 13% of women), with a readmission rate of 30%. As vascular disease was included the following diseases: pulmonary thromboembolism, valvular, aortic aneurysm and peripheral arterial disease. The prevalence of these diseases as a whole was 19% (16% of women and 20% of men), with a re-entry of 27%. A 20.6% of patients remain as active smokers (20.8% women, 20.4% of men).

Discussion: It should be noted that over 60% of patients have hypertension. Readmitted patients more than the average are those with ischemic heart disease, with a rate of 30% (vs 20%), however the number of readmissions per patient is lower than the average (1.35 vs 1.5). It is known that mortality in these patients is often due to comorbidities. Exacerbated COPD revenues have been four times more common in men, probably due to earlier incorporation of smoking. All cardiovascular diseases that were analyzed in this study were more frequent in women with the exception of ischemic heart disease, which affects treatment and closer monitoring in these patients. The coexistence of COPD with heart failure (29.8%), determines a detriment to the quality of life and greater dependency. Importantly, 20.6% of patients remain active smokers, so it would be necessary to implement a program of active struggle against smoking.

Conclusions: This study determines the high rate of comorbidity in patients with COPD, with the impact in the prognosis that it implies. Proper diagnosis and treatment of these comorbidities will allow a better development of the disease itself and the overall prognosis. It is necessary to implement active control programs against smoking.

RV-31
PHEOCHROMOCYTOMA: DIAGNOSIS AND CARDIOVASCULAR COMPLICATIONS

E. Nadal, E. Rovira, M. Abdilla, R. Julve, I. Ezquerra, S. Ferrandis, J. Esteve

Department of Internal Medicine. Hospital Universitario La Ribera. Alzira. Valencia, Spain.

Objectives: Cardiovascular signs and symptoms associated with pheochromocytoma are an important cause of morbidity and mortality. The aim of this study was to analyze the clinical presentation, test abnormalities (biochemical test and imaging studies), differential diagnosis and treatment of patients with pheochromocytoma focusing on associated cardiovascular manifestations previous to the surgical treatment.

Material and method: Patients diagnosed with pheochromocytoma from 1999 to 2011 in Hospital La Ribera were retrospectively reviewed. Demographic and clinical data were collected as well as diagnostic test results, treatment and cardiovascular complications.

Results: 16 patients (6 men and 10 women), 52.12 year-old on average were diagnosed with pheochromocytoma. At diagnosis clinical presentation was adrenal mass in 7 cases, symptomatic triad in 3, uncontrolled arterial hypertension in 2, tachyarrhythmia in 2, pheochromocytoma associated syndromes in 3 and myocardial infarction in 1 case. Arterial hypertension was the most frequent sign in 89% (labile 37.5%, uncontrolled 37.5% and 25% paroxysmal hypertension). Hormonal determinations were elevated in 88.9% of patients. Urinary tests detected increased hormonal values in all cases but in different proportion: noradrenaline in 14 cases, normetanephrine in 5, vanillymandelic acid in 8, adrenaline in 7, dopamine in 7, metanephrine in 5 and homovanillic acid in 4 cases. Plasma tests detected increased hormonal values in noradrenaline in 6 cases, dopamine in 3 cases and adrenaline in 2 cases. A direct correlation between severity of clinical findings and hormone levels or number of altered hormonal types not always were observed although most affected patients had at least four times higher values than normal levels in hormonal determinations. Imaging studies were performed in most patients: MRI (72%; compatible 55%), metaiodobenzylguanidine study (MIBG) (72%; compatible 50%), CT (66%, compatible 61%) and echography (28%, compatible 11%). Adequate tensional control was obtained before the surgery in 71.4% cases. Tensional control required treatment with alpha blockers in 69% of patients. The average number of drugs needed prior to surgery was 2.66 ± 1.43. After the surgical treatment, the number of drugs decreased to 1 ± 1.2 with an adequate tensional control in all cases. Surgical removal was carried out in 87.5% of patients. Two patients died before the surgery, due to myocardial infarction with cardiogenic shock (autopsy diagnosis) and pheochromocytoma multi-systemic crisis.

Discussion: Pheochromocytoma-associated cardiovascular features can be cause of severe morbidity and mortality. Early diagnosis and good tensional control previous to the surgical treatment are of essential importance. There is not always a linear correlation between the clinical severity and analytical values. Nevertheless the most affected patients had at least four times higher values than normal levels in hormonal determinations. Although typical, the presence of classic triad with hypertension, not always occurs. A correct diagnosis is confirmed with the combination of compatible clinical manifestations, evidence of catecholamine hypersecretion and/or their derivatives, and radiological images. Genetic tests are important diagnostic tools in a hereditary context as the clinical manifestations occur in earlier ages.

Conclusions: Pheochromocytoma is usually suspected after an incidental finding of an adrenal mass in radiological studies. Presence of pheochromocytoma is suspected in younger patients with hypertension, arrhythmia and/or coronary artery disease. Most patients have uncontrolled arterial hypertension at diagnosis. Isolated arterial hypertension is not sufficient to make a diagnosis. It is based on clinical suspicion, hormonal determinations and radiological exams. MIBG is a confirmation test. In pheochromocytoma-associated syndromes genetic studies are crucial. Cardiovascular events are an important cause of morbidity and mortality previous to the surgical treatment.

RV-32
TAKO-TSUBO DESCRIBED IN PATIENTS IN INTERNAL MEDICINE SERVICE OF REGIONAL HOSPITAL

J. Ruiz Izquierdo[1], B. Batalla Insenser[1], T. Poblet Farrés[2], E. Niño Aragón[1], M. Sánchez Torres[1], G. de la Red Bellvís[1], C. Molinos Carrasco[1], C. Navas Navas[2]

[1]Department of Internal Medicine, [2]Department of Cardiology. Fundació Hospital de L'Esperit Sant. Barcelona, Spain.

Objectives: The Tako-Tsubo or transient apical dyskinesia, a syndrome that may mimic an acute coronary event, accompanied by anginal chest pain, electrocardiographic changes in precordial and moderate increase in cardiac enzymes, is characteristic anteroapical dyskinesia of the left ventricle (LV) reversible within normal coronary angiography. Also intend to show the keys in the differential diagnosis with respect to myocardial infarction.

Material and method: Retrospective study of clinical features, treatment and outcome of a series of patients diagnosed with Tako-Tsubo from January 2009 to May 2012.

Results: During the study period were diagnosed 6 cases of Tako-Tsubo all women. The mean age was 69.7 years (range: 52-86). 80% had the classic cardiovascular risk factors in treatment (most commonly hypertension and dyslipidemia) without evidence of ischemic heart disease or history of pheochromocytoma. The triggering factor in 4 cases was the emotional stress and physical 2. The clinical presentation in all cases was pain with anginal chest pain remission between 3 and 6 h with classical anti-anginal therapy, in both cases, the debut was acute pulmonary edema. Of the constants in emergency medium voltage figures were PAS 152/93 mmHg, with HR in the range of 60-107 ppm with other held constant. Observed in the ECG pattern identifies a superior ST elevation in V4-V6 precordial and lateral in I and aVL with normalization in the range of 1-2 weeks. Regarding laboratory tests, the elevation of troponin I in the 1st h was 0.49 ng/ml (range 0.06-1.08) and CK (range 24-330) with normalization in a week on average. The echocardiogram performed between 24-48h of admission will be observed in all cases the characteristic image of hypo/antero-apical and medial LV with depressed EF mean 44.8% (range 32-72) with EF normalized between 3 week-1 month in the control study. In all patients underwent coronary angiography showing healthy being in 3 cases of tortuous and irregular. All cases had favorable clinical course without complications. Four of the patients received during their admission and discharge beta-blocker treatment with bisoprolol.

Discussion: According to the analyzed results can define the characteristic profile for diagnosis is suspected, middle-aged woman under emotional stress with coronary angina pain, ST elevation in antero-lateral, moderate increase in CK and troponin I with echocardiogram evidence moderately depressed EF and anterior-medial hypokinesis of the LV with normal angiographic study. The clinical course and prognosis is most favorable, being BBblocker treatment of choice. The recovery order is usually improved to 2-3th day clinic, resolution of ECG changes until days or weeks and ultrasonographic changes are normalized within 3 to 31 days.

Conclusions: 1. The Tako-Tsubo is indistinguishable from an acute coronary syndrome by two characteristic features: one, ST elevation in V4-V6 > in V1-V3, with absence of abnormal Q, and two, no change specular underside. 2. The echocardiogram is the key test

for displaying the image of antero-apical dyskinesia of VI characteristic, assisting in the management of these coronary patients and opt instead for fibrinolytic therapy. 3. The physiology of this syndrome is currently unknown, the most obvious hypothesis is maintained catecholaminergic cascade causing vasoconstriction of the microcirculation heart, so the medical treatment of choice are beta-blockers.

RV-33
FREQUENCY ANALYSIS OF POLYMORPHISMS ASSOCIATED WITH TYPE 2 DIABETES IN SPANISH POPULATION AND ITS RELATION CLINICAL MEANING

L. Andreu Urioste[1], Á. Jiménez Arranz[3], B. Domingo Escudero[3], M. Pedromingo Kus[1], F. Gómez Peralta[2], H. Mendoza Ruiz de Zuazu[1], D. Sánchez Fuentes[1], G. Cobas Pupo[3]

[1]Department of Internal Medicine. Hospital Nuestra Señora de Sonsoles. Ávila, Spain. [3]MyGEN Laboratories. Madrid Science Park. Autonoma University. Madrid, Spain. [2]Department of Endocrinology. Hospital General de Segovia. Segovia, Spain.

Objectives: To analyze the prevalence of different genetic polymorphisms (SNPs) related to the development of type 2 diabetes mellitus in a Spanish population (Avila & Segovia), and to search a possible relationship between them and clinical characteristics.

Material and method: Retrospective longitudinal study of 450 patients from Avila & Segovia; we are presenting here the first sample of N = 70. Patients were recruited after obtaining informed consent, by a working group (Diabila). Analyzed 64 SNPs of genes related to T2DM, obesity, dyslipidemia, other factors of cardiovascular disease and pharmacokinetics (CDKAL1, CKDN2B, MC4R, KCNJ11, FTO, TMEM18, MC4R, APOE...), in an open array for real-time PCR (by Mygen laboratories), of which this paper will present 14 of 64. Getting following clinical and epidemiological data: sex, age and BMI (current and diagnosis), dyslipidemia, HBP, retinopathy, nephropathy, ischemic heart disease. All data above were consolidated and analyzed with SPSS 18. *Results:* (Tables).

Discussion: In T2DM interacting behavioral, environmental and genetic factors. There's variation in response between patients for the same drug and no clinical data to predict the response to a drug. Association studies of genetic variants with T2DM (GWAS) have confirmed the existence of at least 40 loci associated with T2DM.In the study population we observed a lower prevalence of risk factors which lead us to believe that genetic factors strongly influence them. The current results aren't yet reliable to represent a small sample, but serves as a guide.

Conclusions: Despite the observed high prevalence of dyslipidemia and hypertension, its coexistence with T2DM is lower than that found in studies of other population samples. In general, there is increased expression of SNP risk in our population at baseline (study CEU) and even lower expression of protective SNP.

RV-34
RELATIONSHIP BETWEEN GENE VAV2 (VAL 584 MET POLYMORPHISM) AND DIASTOLIC BP

J. Miramontes González[1], I. González Fernández[1], D. Pescador Hernández[1], L. Mateos Polo[1], C. Cieza Borrella[2]

[1]Department of Internal Medicine. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca, Spain. [2]Department of Medicine. Department of Molecular Medicine. Salamanca, Spain.

Objectives: Essential hypertension is a multifactorial entity. It has demonstrated the influence of many genes in development and the influence that it have on the damage to organs such as cardiomyopathy or hypertensive nephropathy. We studied the influence of this gene, through the analysis of one polymorphism in the development of diastolic blood pressure to levels considered pathological.

Material and method: We studied 298 patients from a hypertension unit integrated into M. Internal. We studied 155 men and 143 women. Were taken BP obtained from the ABPM diagnosis, have been used for 24-hour mean values to make the classification and analysis.

Results: we obtained a sample of 118 individuals without hypertension. Individuals with hypertension have been classified into three categories with the following results grade 1 hypertension: 108 individuals, hypertension grade 2: 46 individuals and hypertension grade 3: 26 individuals. The diastolic BP distributed by sex showed the following results: Men: 155 with mean of diastolic BP: 80.33 mmHg and DS: 14.307 Women: 143 with mean of diastolic BP: 80.62 mmHg and DS: 12.251 The genotyping results are as follows: No HTA: TC: 67, TT: 29, CC: 22 HT: TC: 67, TT 48, CC: 42. The study of statistical association between diastolic BP in hypertensive patients and hypertensive patients with the genotype results, has shown no statistical association. Chi squared test: 0.479.

Conclusions: No statistical association was found between diastolic blood pressure and VAV-2 polymorphism Val584Met. Need further studies with larger samples and with data from pathology secondary to hypertension.

L-CARNITINE REDUCES SUNITINIB-INDUCED CARDIAC FIBROSIS

O. Aramburu Bodas[1], M. Ruiz Armenta[2], S. Zambrano Sevilla[2], A. Blanca Lobato[2], J. Arias Jiménez[1], M. Arévalo Gómez[3], A. Mate Barrero[2], C. Vázquez Cueto[2]

[1]Department of Internal Medicine. Complejo Hospitalario Regional Virgen Macarena. Sevilla, Spain. [2]Department of Phisiology. Universidad de Sevilla. Sevilla, Spain. [3]Department of Human Anatomy and Histology. Universidad de Salamanca. Salamanca, Spain.

Objectives: Sunitinib is a tyrosine kinase inhibitor used to treat both advanced renal cell carcinoma and gastrointestinal stromal tumors. One of its major side effects is hypertension, which leads to the development of cardiac fibrosis. Our research group has previously demonstrated an antifibrotic effect of L-carnitine (LC) in the heart of hypertensive rats. The aim of this study was to analyze the effects of LC on sunitinib-induced cardiac fibrosis in rats, and to explore possible mechanisms of LC action.

Material and method: Studies were performed in Wistar rats weighing 280-350 g. Animals were randomly divided into four groups: (1) normotensive control; (2) rats treated with sunitinib (25 mg/kg body weight/day); (3) rats treated with LC (400 mg/kg bodyweight/day); and (4) rats treated with sunitinib plus LC. Treatment with LC started 2 weeks before treatment with sunitinib; thus, the former was maintained for 10 weeks and the latter for 8 weeks. Heart rate and diastolic and systolic blood pressures were recorded weekly. At the end of the experimental period, the animals were anesthetized; the heart was removed intact and weighed, and cardiac index was calculated by dividing each heart weight value by the corresponding animal weight. The left ventricle was then dissected and cut perpendicular to the apex-to-base axis into two pieces. One of these pieces was frozen in liquid nitrogen, stored at -80ºC and used for mRNA expression of type I collagen, TGF-α, CTGF, Nox2 (subunit of NADPH oxidase) and PPARγ. The remaining cardiac tissue was stained with Masson´s trichrome and also with Sirius Red for fibrosis quantification.

Results: Heart rate, systolic and diastolic blood pressure values, and cardiac index were significantly increased in rats treated with sunitinib, while the simultaneous administration of LC restored blood pressure values and cardiac index, and reduced the heart rate values significantly. A significant increase in gene expression of type I collagen, profibrotic factors (TGF-β and CTGF), and the NADPH oxidase subunit Nox2 was found in rats treated with sunitinib. Interestingly, rats treated with both sunitinib and LC presented a decrease in the expression of all these elements, leading to normal values. In addition, Masson's trichrome revealed interstitial cardiac fibrosis, irregularly distributed. When the extent of fibrosis was evaluated by Sirius Red collagen staining, the interstitial spaces occupied by extracellular matrix were increased in the heart of sunitinib-treated rats. However, simultaneous treatment with LC diminished the interstitial fibrotic areas. All these results were accompanied by a downregulation of PPARγ gene expression in heart of rats treated with sunitinib, an effect that was also reverted by simultaneous treatment with LC.

Discussion: The mechanisms underlying sunitinib-induced arterial hypertension are not well known. In this work, we show that a combination therapy, sunitinib plus LC, reduces hypertensive cardiopathy induced by the tyrosine kinase inhibitor. Furthermore, we demonstrate that LC is able to reduce sunitinib-induced cardiac fibrosis; this antifibrotic effect of LC is related with an upregulation of PPARγ system.

Conclusions: 1. The combined therapy, sunitinib plus LC, reduces sunitinib-induced arterial hypertension.2. LC attenuates sunitinib-induced cardiac fibrosis through a modulation of PPARγ pathway.A.

RV-36
EPIDEMIOLOGIC CHARACTERIZATION OF THE ISCHEMIC STROKE IN INDIVIDUALS AGE OR LESS 65 YEARS – LEARNING IN ORDER TO PREVENT

D. Franco[1], C. Leitão[2], E. Pirtac[1], D. Alves[1], C. Carretero[1], J. Gama[4], A. Vaz Patto[3]

[1]Department of Internal Medicine, [2]Department of Gastroenteorology. ULS- Castelo Branco. Castelo Branco, Portugal. [4]Department of Mathematics. Universidade da Beira Interior. Covilhã, Portugal. [3]Faculdade Ciências da Saúde. Universidade Beira Interior. Covilhã, Portugal.

Objectives: 1. Study the incidence of the ischemic stroke in individuals age or less 65 years between 2007 and 2011; 2. Analyze the risk factors, usual medication and alterations found in the complementary diagnose exams; 3. Identify which are the predictor factors of the post stroke sequelae (exit value of the NIHSS) and the duration of hospitalisations.

Material and method: In order to perform the present retrospective study, the authors undertook an identification of hospitalisation episodes between January-2007 and the December-2011, indexed to the main diagnose of ischemic stroke hospital discharge. A selection of the corresponding clinical files was performed along with posterior identification of: date of birth, gender, atherosclerotic risk factors and cardioembolics, usual domicile therapeutic, stroke type and anatomic location, results of the complementary diagnose exams carried out, value of the NIHSS at hospital discharge and duration of the hospitalisation. The data was statistically processed using Microsoft Excel® 2010 and SPSS® applications. The statistic tests used were: chi-square test, t test for two independent samples, and linear regression models were created.

Results: The 137 individuals who integrated our study were aged between 25-65, corresponding to an average age of 56.1. 63% were male. The risk factors more frequently found were arterial hypertension (70%), dyslipidemia (60%), mellitus diabetes (24%) and auricular fibrillation (10.9%). Around 60% of the individuals revealed alterations in the echocardiogram and 30.3% in the carotid computed angiotomography (CT). In one of the linear models created, the exit NIHSS scale value predictor variables, were the admittance NIHSS value and the factor: existence or not of hypertension. It was observed that 53.9% of the variability was explained by that model. In the other linear model, the predictor variables of the hospitalisation duration were the admittance NHSSI, the total cholesterol value and LDL, and it was verified that 32.2% of the variability is explained by this model.

Discussion: The incidence of ischemic stroke increases with age and, as we expected, most individuals were in higher age groups, being the average age around 56. However the incidence in the younger population is not one to neglect as, depending on the series, it varies between 5-20%. The classical risks factors for arteriosclerosis were the most frequently identified in the etiopathogeny of ischemic stroke in our population, being hypertension and dyslipidemia the main intervenient. An already evident fact in other series. It must be highlighted that, according to our study, the mentioned risk factors were not only important in the stroke aetiology but also some of them seemed to have an important relation with sequels occurred and with the duration of the hospitalization.

Conclusions: The considerable morbidity and mortality caused by stroke in an active population represent a high socio economic

impact. Therefore, population studies on this subject are of utmost importance. Regardless of the need to analyze some thrombophilias and other rarer or more differenced stroke causes, when other obvious causes are not identified, the high prevalence of arteriosclerosis classic risk factors reinforces, even in the younger population, its importance in prevention and control.

RV-37
USE OF PORTABLE ECHOCARDIOGRAPHY IN INTERNAL MEDICINE SERVICE, HOSPITAL GENERAL UNIVERSITARIO DE LORCA RAFAEL MÉNDEZ

J. Simón, A. Wilches, E. Mené

Department of Internal Medicine. Hospital General Universitario Rafael Méndez. Lorca. Murcia, Spain.

Objectives: 1. Know the most common echocardiographic diagnostic studies in the last 4 months in internal medicine at the Hospital General Universitario de Lorca Rafael Mendez with portable ultrasound. 2. Estimate the value of portable echocardiography as an adjunct in the initial screening of patients admitted to internal medicine General Hospital Rafael Méndez de Lorca in the last 4 months. 3. Estimate the average time spent on echocardiographic examination with a portable ultrasound.

Material and method: Resource Professional: 5th year Resident in Internal Medicine with a level 2 training in echocardiography. (Levels according to the guidelines of the Spanish Society of Cardiology). Technical Resource: Portable Ultrasound GE VSCAN. Patients: admitted to the Internal Medicine ward in the last 4 months in the Hospital General Universitario Rafael Mendez De Lorca. He was assigned to a resident of 5 th year of Internal Medicine with a level 2 training in echocardiography, a portable ultrasound (General Electric VSCAN) for echocardiographic studies of patients admitted to a dependent, for the guards (5 per month) and in Cardiovascular Risk consultation during the months of January through April of this year, pertaining to Internal Medicine, University Hospital Rafael Méndez de Lorca. During this period he was assigned cases with pathologies of the cardiovascular system preferably. Then we analyzed the echocardiographic studies and classified by the predominant findings.

Results: A total of 124 studies. Of which: 27.4% (34 patients) were normal. 27.4% (34 patients) had left ventricular hypertrophy. 18.5% (23 patients) had systolic dysfunction and altered segmental contractility. 17.7% (22 patients) had valvular disease. 7.2% (9 patients) had other findings (pericardial effusion, pleural effusion, aortic root dilatation, atrial dilatation, right ventricular dilatation). And 3.2% (4 patients) had left ventricular hypertrophy entering into hypertrophic cardiomyopathy. The average in the study was 5.45 minutes.

RV-38
APPROACHING THE MAP OF PRIMARY HYPERALDOSTERONISM THROUGH A PROTOCOLIZED ASSESSMENT OF ALDOSTERONE RENIN RATIO

A. Fernández, S. Tello Blasco, A. Alonso, N. de la Torre, A. Guerri, R. Fabregate, J. Sabán Ruiz

Department of Endothelial Pathology. Department of Internal Medicine. Ramón y Cajal Hospital. Madrid, Spain.

Objectives: 1. To evaluate the prevalence of suprarenal pathology (hiperplasia as well as adrenal nodules) in a hypertensive population with moderate-high cardiovascular risk. 2. To evaluate the characteristics of the population with hyperplasia or adrenal nodules and the severity index of hypertension at the time of diagnosis.

Material and method: We studied a population of 174 hypertensive patients with moderate-high cardiovascular risk, all Caucasian. Ratio between the aldosterone/renin measured in blood: radioimnunoanalysis (RIA). Cortisol in urine of 24 hours: chemiluminescence. Metanephrines in urine of 24 hours: Cromatography system. Image studies of adrenal glands with magnetic abdominal Resonance or axial computerized Tomography.

Results: 1. The prevalence of suprarenal pathology was12.6% (21 patients). 2. There were 11 cases with adrenal nodule and 10 with adrenal hyperplasia. We approached the statistical analysis of the two groups with the following features: Adrenal nodules: Average 61.73 ± 10.38, 72.7% adult males (8), 27.3% adult females (3), average age at the time of the diagnosis was 48.91 ± 10.55. Most of the patients (81.8%, 9) had stage 1 hypertension, 18.2% (2) had stage 2. A high renin aldosteron ratio was seen in 63.6%, cortisol and metanephrines had normal values in all the patients. In 36.4% the nodule was removed by laparoscopic surgery. Adrenal hyperplasia: average age was 69.70 ± 7.78, same percent males and females (50%, 5 patients), average age at the diagnosis 47.00 ± 12.71. Most of the patients (70%, 7) had stage 1 hypertension, 20.00% (2) had stage 2 and only one patient had stage 3 hypertension (10%). A high renin aldosteron ratio was seen in 80%, cortisol and metanephrines had normal values in all the patients. 100% of the patients had bilateral adrenal hiperplasia.

Discussion: Hypertension is one of the most common worldwide diseases, with an important morbidity, mortality and economic cost. Essential hypertension is really a diagnosis of exclusion (has not an identifiable secondary cause). The percentage of patients suffering from secondary hypertension depends on the screening done, that explains differences between 5-20% of hypertensive subjects. The prevalence of Primary aldosteronism (PA) in the general hypertensive population remains an unresolved issue. Historically, PA has been considered a rare disease, affecting about 1% of hypertensive patients. However, several studies performed in the last decade report a much higher prevalence of PA (> 10%), suggesting an "epidemic" of this condition. Primary hyperaldosteronism account for 20% of resistant hypertension (hypertension that requires maximally tolerated doses of 3 or antihypertensive medications and one of the medications is a diuretic, full dose).

Conclusions: 1. The prevalence of adrenal pathology related to hypertension in our study reaches 12.6%, which is a significant enough number to insist upon the search for this etiology in our daily routine. 2. A high renin aldosteron ratio has a 84% sensitivity and a 95% specifity in our population. It is a good first step in the screening of primary aldosteronism.

RV-39
STUDY OF THE HFE GENE MUTATIONS IN THE HYPERFERRITINEMIA ASSOCIATED WITH HYPERTENSION, TYPE 2 DIABETES MELLITUS AND INSULIN RESISTANCE SYNDROME

S. Tello Blasco[1], A. Fernández[1], D. Rey[2], M. Fabregate[1], E. Marín[3], R. Fabregate[1], D. Herrera[1], J. Sabán Ruiz[1]

[1]Department of Endothelial Pathology. Department of Internal Medicine, [2]Department of Medical Genetic, [3]Department of Vascular Surgery. Ramón y Cajal Hospital. Madrid, Spain.

Objectives: 1. To evaluate the prevalence of hyperferritinemia (HF) in a population with mild-high cardiovascular risk. 2. To assess the presence of mutations in patients with HF and its relationship with the hypertensive state, hyperglycemia and metabolic syndrome.

Material and method: We studied a population of 884 patients with moderate-high cardiovascular risk (used for that purpose the Framingham scale adapted for the Spanish population -REGICOR-),

499 men (56.4%) and 385 women (43.6). 128 had HF (14.5%), 115 male (89.8%) 13 female (10.2%), media aged and standard error was 52.7 ± 12.1 (range 20 to 77 years old) and 65.1 ± 11.8 (range 40 to 80 years old) respectively, and was statistically significant p = 0.001. HF criteria: serum ferritin ≥ 180 mg/dl according to our laboratory normal range, twice in a minimum period of two months; measured by natural chimioluminiscence. The DNA was from blood samples and was tested for C282Y y H63D DNA mutations and the gene HFE using real-timed CPR. 3 of the patients were excluded from the genetic study due to technical difficulties.

Results: 1. The prevalence of HF was 14.5%. 2. In the male group: 37.4% (43) had diabetes, 33.9% (39) was type 2 diabetes, 57.4% (66) had hypertension, 54.8% was the primary form (63), 13.9% (16) had liver fatty, 50.4% (58) had metabolic syndrome. 3. In the female group: 38.5% (5) had diabetes, all of them type 2 diabetes, 84.6% (11) had hypertension, allow them primary, 15.4% (2) had liver fatty, 38.5% (5) had metabolic syndrome. 4. There were gene mutations in 48.8% (61) of the patients: Carriers (heterozygous): 41 patients (34.4%), heterozygous for C282Y: 8.0% (10), heterozygous H63D: 26.4% (33), Homozygous for C282Y: 0, Homozygous for H63D: 11.2% (14), Double heterozygous: 3.2% (4).

Discussion: The Insulin Resistance Syndrome (IRS) is a cluster of abnormalities associated with insulin resistance, including hyperinsulinemia, dyslipidemia, hypertension, hyperglycemia and, lately, hyperferritinemia, either alone or related to a non-alcoholic steatohepatitis (NASH) due to ectopic fat storage. On the other hand, hyperferritinemia is a biomarker of hereditary hemochromatosis (HH) (primary hyperferritinemia), alcoholism and an acute-phase reactant (APR). IRS, alcoholism and APRs have secondary forms of hyperferritinemia. HH was first described in 1865 by Armand Trousseau in an article of diabetes. The HFE gene of HH has two common mutations, C282Y and H63D. Most people with two copies of C282Y or one copy each of C282Y/H63D do not manifest clinical hemochromatosis, a phenomenon known as low incomplete penetrance. It is not ruled out that many of the HF associated with metabolic pathology/hypertension have genetic bases, and that is the main contribution of our study.

Conclusions: 1. The proportion of patients with HF in a population of mild-high cardiovascular risk is low, but this diagnosis is critical for an appropriate patient management. 2. Many of these patients with HF had metabolic syndrome, type 2 diabetes and/or were hypertensive, all of these in relation to insulin resistance. 3. The most important gene mutation in our study was the heterozygous H63D. 4. The genetic study is important not only for the patient but also for the family members.

RV-40
MORBIMORTALITY ANALYSIS IN SECONDARY CARDIOVASCULAR PREVENTION AT 9-YEARS FOLLOW UP: MIRVAS STUDY

D. Trujillo, R. Puchades, P. Ibañez, C. Suárez

Department of Internal Medicine. Hospital Universitario La Princesa. Madrid, Spain.

Objectives: To determine whether secondary cardiovascular prevention, involving the comprehensive and intensive treatment of cardiovascular risk factors at 3 years follow up, reduces total morbimortality and total mortality at 9-years follow up.

Material and method: The study design of MIRVAS (Medicina Interna Riesgo VAScular) study comprised a randomized, controlled, open trial in a routine clinical practice setting. In total, 247 patients who presented with acute coronary syndrome (ACS) or stroke were selected. They were randomized to comprehensive and intensive treatment of cardiovascular risk factors (n = 121) or to follow-up based on usual care (n = 126). At 3-years follow up the percentage of patients in whom each risk factor was successfully controlled was determined. We present a cross-sectional analysis study of total morbimortality and total mortality at 9-years follow-up.

Results: Basals characteristics were (intensive vs control group): age 64.89 ± 11.53 vs 65.6 ± 14.3, p = 0.6; woman 20.7% vs 30.2%, p = 0.1; event inclusion: ACS 64.5% vs 66.7%, p = 0.7; stroke 35.5% vs 33.3%, p = 0.4; tobacco smoking 41.3% vs 35.7%, p = 0.4; hypertension 52.9% vs 61.1%, p = 0.2; LDL > 100 mg/dl 62.8% vs 54.8%, p = 0.2 and diabetes mellitus 31.4% vs 26.2%, p = 0.4. Control risk factors at 3-years follow-up were (intensive vs control group): tobacco smoking 90.6% vs 86.3, p = 0.4; global blood pressure target 82.1% vs 71.4%, p = 0.1; LDLc < 100 mg/dl 88.8% vs 56.4%, p < 0.001 and HBA1c < 7% 75.7% vs 28.6%, p = 0.004. Total morbimortality at 9-years follow up was (intensive vs control group): 46.8% vs 64.1%, p = 0.01 and total mortality was 14.% vs 27.8%, p < 0.001. Loss to follow-up at 9-years was 33 (13.4%): 23 (18.3%) in control group and 10 (8.3%) in intensive group, p = 0.003.

Discussion: Basal characteristics are similar to other series. In STENO 2 study the mean treatment period was 7.8 years and patients were subsequently followed observationally for a mean of 5.5 years. The primary end point in STENO 2 study at 13.3 years of follow-up was death from any cause (30% in intensive group vs 50% in control group). Our study shows that sustained benefit with respect to total morbimortality and total mortality outcomes (seen long after the conclusion of the trial) could appear in a shorter intensive treatment period (3- years follow up). If these results are due to a legacy effect or due to a better cardiovascular risk factors control is being analyzed. MIRVAS study has certain limitations. One of them is the heterogeneity of patient follow-up, since patients had no limitation on consultations with different specialists. However, we believe that any additional follow-up is not more frequent in one group than in another, i.e., is equal for both groups, and does not affect the results. The number of patients included in our study is not very large, but has been sufficient to show decreased mortality and morbidity. The number of patients who dropped out of intensive follow up is relatively high. The reason for this dropout rate was mainly duplication of consultations. In spite of the fact that a single follow-up in internal medicine consulting offices would have improved adherence, for ethical reasons we did not consider the possibility of limiting visits to other specialists. Although results at 9-years follow up are better than other studies, loss to follow up were significantly different. An intention to treat analysis and is being performed.

Conclusions: Secondary cardiovascular prevention involving comprehensive and intensive treatment of cardiovascular risk factors at 3 year follow up, reduced both total morbimortality and total mortality at 9-year follow up independently of control risk factors.

RV-41
FACTORS ASSOCIATED WITH HYPERHOMOCYSTEINEMIA IN THE HIV-INFECTED POPULATION

B. Roca, M. Penades, E. Resino, J. Ferrero, P. Albiol, B. Orobitg

Department of Medicine. Hospital General Universitat Jaume I. Castellón, Spain.

Objectives: To assess the possible association of increased homocysteine serum level with multiple blood analyses parameters in HIV-infected patients.

Material and method: This is a cross-sectional study, carried out as a supplementary task to the usual control required by HIV-infected patients, in the outpatients' clinic of the Hospital General of Castellon, Spain, along two consecutive visits. The possible

association of homocysteine serum level with multiple blood analyses parameters and with sociodemographic variables was assessed with a multiple linear regression analysis.

Results: A total of 145 patients were included. Creatinine was higher than normal in 7 patients (5%), prothrombin time was higher than normal in 36 patients (25%), and a monoclonal gammopathy was detected in 2 patients (1%). An association was found between high homocysteine serum level and the following variables: high creatinine (P > 0.001), low folic acid (p > 0.001), HIV risk behavior sexual (vs parenteral) (p = 0.033), hepatitis C virus co-infection (p = 0.014), and high height (p = 0.009). An association was found between low homocysteine serum level and the following variables: high prothrombin time (p = 0.027), and presence of monoclonal gammapathy (p = 0.019).

Conclusions: An association was found between high homocysteine serum level and high creatinine, and between low homocysteine serum level and high prothrombin time and presence of monoclonal gammopathy.

RV-42
ATHEROGENIC DYSLIPIDEMIA IN PATIENTS WITH TYPE 2 DIABETES

M. Popoviciu

Department of Internal Medicine. University of Oradea, Faculty of Medicine. Oradea, Romania.

Objectives: Dyslipidemia (DLP) have become a public health issue in all developed countries, due to the high prevalence over 40% in the adult population. More and more research is suggesting that a major factor which determines the residual macrovascular risk is atherogenic dyslipidemia, characterized by a high level of triglycerides (TG) and a low level of HDL-cholesterol. Our study's aim was to determine the prevalence of atherogenic dyslipidemia in patients with type 2 diabetes.

Material and method: We had a study group of 300 patients with type 2 diabetes who were hospitalized at the Clinical and Emergency County Hospital of Oradea, during Jan 2010-Mar 2011. For every patient was made a study sheet in which was noted: sex, age, area of origin, duration diagnosed with diabetes, type of diabetic treatment, family history (metabolic and/or cardiovascular),complications of diabetes mellitus, type of diet and physical activity weight and abdominal circumference, metabolic control, lipid profile (total cholesterol, HDL-cholesterol, LDL-cholesterol, triglycerides), inflammatory status (fibrinogen, C-reactive protein).

Results: In our study group, atherogenic dyslipidemia resulting in a prevalence of 37.3%. The prevalence of atherogenic dyslipidemia was over 1.4 times higher in women than in men (44.6% versus 31.1%) (p < 0.05) and was highest between the ages of 41-60 years (41.7%). The higher the duration of development of diabetes the higher prevalence of atherogenic dyslipidemia (30.4% for those with a duration of development of diabetes < 5 years and 51.8% for those over 10 years). The lowest prevalence of atherogenic dyslipidemia was in patients with ADO + insulin (23.6%) and highest in patients treated with Biguanide + Sulphonylurea (62.2%). The prevalence of atherogenic dyslipidemia increases with the degree of obesity (from 28.1% in normal weight, to 64.3% in obesity grade III). Atherogenic dyslipidemia risk is over 1.5 times higher in obese than in normal weight individuals (RR = 1.54) and nearly 1.4 times higher than in overweight individuals (RR = 1.37). Atherogenic dyslipidemia risk is over 2.5 times greater in diabetics with abdominal obesity than in those without (RR = 2.54).In terms of lipid profile, there are significant difference between patients with and those without atherogenic dyslipidemia (p < 0.001). Inflammatory status; was significantly better in patients without atherogenic dyslipidemia (p < 0.001).Complications of diabetes were present in 106 patients with atherogenic dyslipidemia (94.6%) and 150 patients without atherogenic dyslipidemia (79.8%) (p < 0.05).

Discussion: In Romania DLP are one of the more important factors responsible for the increased frequency of co-morbidities and cardiovascular deaths. The reduced levels of HDL-cholesterol and increased levels of TG are individually associated with increased cardiovascular risk.

Conclusions: 1. Atherogenic dyslipidemia risk is almost two times higher in patients with cardiovascular family history (RR = 1.88). 2. The highest prevalence of atherogenic dyslipidemia is in patients with hyperlipidic and hyper-caloric diet (62.5%) or only hyperlipidic (59.5%). 3. The more intense the physical exercise it, the lower the prevalence of atherogenic dyslipidemia (29.0% forthose with daily exercise versus 68.2% in those without physical activity). 4. Atherogenic dyslipidemia risk is over 1.5 times higher in obese than in normal weight individuals (RR = 1.54) and nearly 1.4 times higher than in overweight individuals (RR = 1.37). 5. Atherogenic dyslipidemia risk is over 2.5 times greater in diabetics abdominal obesity individuals (RR = 2.54). 6. Metabolic control, lipid profile and inflammatory status were better in patients without atherogenic dyslipidemia (p = 0.251, p < 0.001, respectively p < 0.001).

RV-43
OBESITY PREVALENCE WITHIN A LIPIDS UNIT POPULATION SUFFERING FROM HYPERTRIGLYCERIDEMIA

D. Salor Moral[1], A. González Munera[1], A. García-Espona[1], M. Ferrer Civeira[1], C. Recarte[1], B. Pinilla[1], C. Pérez de Oteyza[1], J. Millán Cortés[2]

[1]Department of Internal Medicine D, [2]Department of Vascular Risk and Lipids. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: Establishing the undergone prevalence of the obesity in the Spanish population suffering of hypertriglyceridemia is the goal of this study. A sub-analysis was made to study possible differences in the obesity prevalence comparative according to the age.

Material and method: An epidemiologic, prospective, observational, non-controlled study was performed in the Lipids Unit of U.G.H. Gregorio Marañón. Patients were included in the Arteriosclerosis Spanish Society National Hypertriglyceridemia registry during one year. The study set is composed by general Hypertriglyceridemia-diagnosed Spanish population. The Body Mass Index (BMI) was the diagnostic tool used. According to the World Health Organization classification, three ranges are defined given the BMI value: Normal weight (BMI < 25 Kg/m^2), overweight (25-29.9 Kg/m^2) and obesity (BMI > 30 Kg/m^2).

Results: 82 patients were included; the expressed results are rates of the BMI (Kg/m^2): < 25: 13.4% (11 patients), 25-29: 28% (23), and > 30: 58.5% (48). In this sub-analysis, the rates for the BMI ranges per weight status per age are: < 40 years (10, 40, 50), 40-60 years (16, 28, 56) and > 60 years (8.3, 8.3, 83.3).

Discussion: In the general population the estimated obesity prevalence is 13.9%. This high percentage of obesity in our society and the low rate of normal-weight population define an important associated cardiovascular risk and show a significant lineal dependency between age and BMI. It demands the creation of specialized units able to monitor the treatment and evolution of their patients because of a possible causal relationship with the hypertriglyceridemia. Broader studies may be needed.

Conclusions: The estimated obesity prevalence defines an important associated cardiovascular risk and the creation of specialized units.

RV-44
LOW 25-HYDROXI-VITAMIN D LEVELS ARE ASSOCIATED WITH HIGHER MEAN SYSTOLIC BLOOD PRESSURE AND INCREASED BLOOD PRESSURE VARIABILITY IN PATIENTS WITH HYPERTENSION AS MEASURED BY 24-HOUR AMBULATORY BLOOD PRESSURE MONITORING

L. Abejón López[1], J. García de Tena[2], D. Bernal Bello[1], C. Hernández Gutiérrez[1], M. Torralba González de Suso[1], P. Horcajo Aranda[2], J. Mateos Hernández[2], M. Rodríguez Zapata[2]

[1]Department of Internal Medicine. Hospital Universitario. Guadalajara, Spain. [2]Department of Medicine. Universidad de Alcalá. Alcalá de Henares. Madrid, Spain.

Objectives: To assess the relationship between vitamin D (25-OH D) serum levels and blood pressure parameters as determined by 24-hour ambulatory blood-pressure monitoring (ABPM) in patients with hypertension evaluated in a Hypertension-Vascular Risk Unit.

Material and method: We enrolled consecutive patients seen in the Hypertension-Vascular Risk Unit who underwent 24-h ABPM. Plasma vitamin D levels were measured by radioimmunoassay considering vitamin D deficiency if vitamin D concentration was < 15 ng/ml. Serum PTHi concentration was quantified using an electrochemiluminescent procedure. We determined clinic systolic and diastolic blood pressure (SBP and DBP), mean SBP and DBP, pulse pressure, mean BP daytime, nightime and 24h period as determined by ABPM. High SBP variability was considered if standard deviation of mean SBP was > 18%. Association between vitamin D levels, PTHi and blood pressure (BP) parameters were calculated using correlation coefficient with Spearman or Pearson tests as appropriate. U-Mann-Whitney was used to compare different quantitative values according to the presence of vitamin D deficiency.

Results: Forty-eight patients were enrolled in this study (age [mean ± SD] 57.3 yrs ± 15.8; 37.5% female). The prevalence of vitamin D deficiency was 27.1%. No statistically significant association was observed between vitamin D and weight, height, age, body mass index or renal function. However, a statistically significant inverse association was found between vitamin D levels and PTHi (r = -0.325; p = 0.029) clinical SBP (r = -0.368; p = 0.011), mean SBP daytime (r = -0.3; p = 0.039), and SBP variability (r = -0.318; p = 0.028). We have also found statistically significant differences among main BP parameters (expressed in mmHg) in patients who have vitamin D deficiency compared with those of patients without vitamin D deficiency: 24-h mean SBP (136 vs 127, p = 0.014), mean SBP daytime (140 vs 127, p = 0.011), mean DBP daytime (85 vs78, p = 0.026), 24-h mean BP (105 vs 93, p = 0.011), mean BP daytime (108 vs 95, p = 0.007) and mean BP nighttime (92 vs 89, 0.037). There were no significant differences between dipper and non-dipper subjects.

Discussion: It has been reported a potential link between vitamin D and cardiovascular risk through its effects on BP. However, clinical data remains controversial. ABPM has shown a closer relationship with cardiovascular risk compared with that of clinical BP. In our study we have shown a significant inverse association between vitamin D status and an increase in different blood pressure values as assessed by 24-hour ABPM in a series of patients with hypertension. Furthermore, we have found an association between low vitamin D levels and higher SBP variability that in turn has been recently linked to a higher cardiovascular risk. Given the biological effects of PTHi on vascular wall, we hypothesize that an excess of PTHi levels secondary to low vitamin D levels might account for the high SBP variability observed in the subset of patients with vitamin D deficiency. Whether low vitamin D levels have an etiologic role in hypertension remains to be confirmed in ongoing clinical trials searching for the effect of vitamin supplementation on cardiovascular risk.

Conclusions: In our series, low 25-hydroxi-vitamin D levels are associated with higher mean SBP and elevated SBP variability in patients with hypertension as measured by 24-hour ABPM. Our findings might explain the increased cardiovascular risk in patients with vitamin D deficiency.

RV-45
METABOLIC AND INFLAMMATORY MARKERS OF CARDIOVASCULAR RISK IN PATIENTS WITH SLEEP APNOEA SYNDROME

J. Fernández-Lahera, F. García Río, S. Rojas, M. Lerín, M. González, J. Fernández-Bujarrabal, A. Martínez Verdasco, C. Villasante

Department of Pneumology. Hospital Universitario La Paz. Madrid, Spain.

Objectives: 1) To determine whether there is an association between certain cardiovascular risk markers and the sleep study parameters and anthropometric characteristics of patients with sleep apnoea-hypopnea syndrome (SAS). 2) To determine whether there are significant differences in the magnitude of these markers depending on the severity of the disease.

Material and method: Plasma levels of CRP, triglycerides, HbA1c and uric acid and urine levels of microalbuminuria were measured in 130 patients referred for consultation for suspected SAS. We performed a sleep study (respiratory polygraphy or polysomnography) and recorded the patient's anthropometric measurements. Characteristics: age 53 ± 12 years, 69% males, 31% females, BMI 30.6 ± 5.7 kg/m^2, neck circumference (NC) 42 ± 5 cm, sleep apnoea-hypopnea index (AHI) 33.7 ± 26 h-1, desaturation index (DI) 33.4 ± 27 h-1, mean nocturnal SpO_2 91.3 ± 3%.

Results: The mean values were as follows: CRP 4.1 ± 5.7 mg/L, triglycerides 140 ± 73 mg/dL, HbA1c (NGSP) 5.6 ± 0.5, uric acid 5.7 ± 1.3 and microalbuminuria 7.9 ± 13.5 mg/L. Using a Pearson correlation analysis, we found the following significant correlations: a) Anthropometric measures: CRP with NC (r = 0.21) and BMI r = 0.61). Triglycerides with NC (r = 0.35) and BMI (r = 0.21). HbA1c with BMI (r = 0.18). Uric acid with NC (r = 0.436) and BMI (r = 0.28). b) Sleep parameters: triglycerides with DI (r = 0.20). HbA1c with AHI (r = 0.32) and DI (r = 0.31). Uric acid with AHI (r = 0.26) and DI (r = 0.29). Microalbuminuria with AHI (r = 0.31) and DI (r = 0.30). Using ANOVA and the Bonferroni test, we looked for differences in the magnitude of the values of the markers and the severity of SAS. To accomplish this, we defined three groups: A (AHI < 10), B (AHI 10-30) and C (AHI > 30). We found significant differences between the groups in terms of triglycerides (p < 0.02), HbA1c (p < 0.0001) and uric acid (p < 0.001). There were no differences for CRP and microalbuminuria.

Conclusions: 1) We found that some cardiovascular risk markers were significantly correlated to sleep parameters and anthropometric measures. 2) The values for triglycerides, HbA1c and uric acid increased as the AHI increased.

RV-46
CHARACTERIZATION OF PROTEIN PROFILES RELATED TO DIET AND EXERCISE AS MOLECULAR SIGNATURES OF VASCULAR WELLNESS

M. Durán-Ruiz[1], R. Toro[3], J.Á. Alonso[2], D. Corrales[3], E. Segura[3], F. García-Cózar[1], A. Mangas[3]

[1]Department of Research, [3]Department of Medicine. Hospital Universitario Puerta del Mar. Cádiz, Spain. [2]Department of Biomedicine, Biotechnology and Public Health. Universidad de Cádiz. Cádiz, Spain.

Objectives: 1. Evaluate the combined effect of diet and exercise on the protein profile of healthy individuals. 2. Determine protein

profiles related to diet and exercise as potential signatures of physical wellness. 3. Identify protein variations that promote the beneficial effects of diet and exercise in order to better characterize the molecular mechanisms involved. 4. Compare, in the future, the protein profiles obtained here with those related to cardiovascular disorders.

Material and method: 53 rugby players were enrolled in this study and included in two groups, one following a hyperproteic diet with low glucemic index, and another following a standard Mediterranean diet. Blood and urine samples were collected on day 0 and 6 months later. Plasma was obtained by centrifugation and both, plasma and urine were aliquoted and stored at -80 ºC. Exercise intensity during the 6 month period was also recorded. Protein profiles in both plasma and urine, were analysed using a Surface-Enhanced Laser Desorption and Ionization Time of Flight (SELDI-TOF) mass spectrometer. Strong anion exchange (Q10) affinity array was selected for the study, allowing the detection of a high number of protein peaks. For protein identification, a chromatographic approach using a strong anion exchange column (Uno Q) with the same binding conditions employed in SELDI was carried out, obtaining several fractions that were further separated by SDS-PAGE. Identification by mass spectrometry of differentially expressed proteins is currently in progress.

Results: Interestingly, most of the subjects following the hyperproteic diet (63%) gained weight after the six month period, while the majority of those following the Mediterranean diet didn't show any significant weight changes (57%). SELDI analysis reported differential protein profile between subjects following Mediterranean and hyperproteic diets. In addition, different profiles were observed between same diet individuals that gained or lost weight. Proteins with significant intensity variations (p-value < 0.05) between groups (Mediterranean/hyperproteic, weight changes, moderate/extreme exercise) have been selected for further identification by mass spectrometry.

RV-47
WAIST-TO-HEIGHT RATIO AS AN ANTHROPOMETRIC PREDICTOR OF MICROINFLAMMATION IN HEMODIALYSIS PATIENTS

S. Bevc[1], T. Zorman[1], R. Ekart[2], R. Hojs[1]

[1]Department of Nephrology, Department of Internal Medicine
[2]Department of Dialysis. University Medical Center Maribor. Maribor, Portugal.

Objectives: The aim of our study was to determine possible relationship between waist-to-height ratio (WHtR) and some inflammatory mediators in hemodialysis (HD) patients.

Material and method: 72 HD patients were enrolled in our study (32 women and 40 men, mean age 60 years, ranged from 22 to 81 years). WHtR was calculated by dividing patient's waist circumference by their body height in centimeters. According to the National Health and Nutrition Examination Survey (NHANES) data abdominal obesity was defined as WHtR > 0.5. Inflammatory mediators (interleukin 2 receptor (IL-2R), interleukins 6, 8, 10 (IL-6, IL-8, IL-10), vascular cellular adhesion molecule-1 (VCAM-1), intercellular adhesion molecule-1 (ICAM-1), tumor necrosis factor-alpha (TNF-alpha)) were measured by standard laboratory methods.

Results: Mean overall WHtR value was 0.58 (range 0.42-0.84), for men 0.57 (range 0.42-0.78) and for women 0.59 (range 0.45-0.84). Abdominal obesity was found in 75% of enrolled patients (78% of women; 72.5% of men). WHtR values correlated with IL-6 ($p < 0.046$) and IL-10 ($p < 0.006$). With multiple regression analysis relationship between WHtR and IL-10 ($p = 0.009$) was found, in men an additional relationship between WHtR and IL-6 ($p = 0.025$) was found.

Discussion: Various anthropometric surface measures are used to access obesity in general population, but less is known about the role of WHtR in HD patients. Abdominal adipose tissue has important inflammatory properties and is a source of various inflammatory mediators. According to the fact that concentrations of some inflammatory mediators are higher among HD patients than in the general population, abdominal obesity may play an important role in the pathogenesis of microinflammation which is known to be accelerated in HD patients.

Conclusions: The results of our study indicate that abdominal obesity defined with WHtR is associated with microinflammation in HD patients.

RV-49
VASCULAR RISK AGE FROM FRAMINGHAM HEART STUDY DOES NOT NEED TO BE CALIBRATED

J. Cuende, A. Alba, C. Ferrer, J. Pardo, F. Sánchez-Barranco, I. Pérez de Diego

Department of Internal Medicine. Complejo Asistencial de Palencia. Palencia, Spain.

Objectives: Absolute cardiovascular risk equations need to be calibrated if they are going to be used in other populations than original. SCORE project proposed two different models for high and low risk countries. Framingham derived equations have been calibrated to different countries. Vascular/heart age is a new concept on patient management and was described originally from General Cardiovascular Risk Profile obtained from Framingham Heart Study. The objective of this study is to explore the need to calibrate vascular age to different populations.

Material and method: The equation from General Cardiovascular Risk Profile was obtained from previous publication. This equation calculates the probability of a mortal or non mortal cardiovascular event in the next 10 years based on sex, age, systolic blood pressure, treatment for hypertension, total cholesterol, HDL-cholesterol, smoking and diabetes. The mathematical model of the equation is proportional risk model (Cox model). The model has different coefficients for each variable and takes into account the prevalence of each cardiovascular risk factor and survival. To calibrate the equation to a different population, prevalence and survival data must be changed according to the different population. Vascular age of a patient is the age of a hypothetical patient with the same absolute risk but with all cardiovascular risk factors in normal range. If risks of both patients (real and hypothetical) are the same we can obtain an equality of two expressions where population data are withdrawn, and vascular age depends only on risk factor data.

Results: We obtained an equation where vascular age depends on risk factors data and not on population data. We can solve the equation with patient data, which are independent of population data, and with risk factor levels considered as normal. If population data are not necessary to calculate vascular age, then vascular age is independent of population data, so vascular age does not need to be calibrated. Also we can construct a figure where age and absolute risk are related to vascular age. For example, a 40 years old man with absolute cardiovascular risk of 12.5% has a vascular age of 60 years.

Discussion: The main result of this investigation is very important and practical. There are a lot of publications about calibration of absolute risk equations, but vascular age is a new universal concept that does not need calibration. Vascular age is dependent on personal data and normal risk factor levels. Discussion is not centered on calibration but on assessment of normal levels. Vascular age is a new epidemiological concept that has been adopted in the last "European Guidelines on cardiovascular disease prevention in clinical practice (version 2012)". Now we have demonstrated that vascular age does not need calibration, making easier their use.

Conclusions: Vascular age is a universal concept that does not need to calibrate.

RV-50
SLEEP APNEA IN DIABETIC POPULATION

R. Louro[1], J. Alves[2], P. Mendes[2], C. Carneiro[1], N. Vieira[1], E. Ferrão[1], M. Grade[1], L. Arez[1]

[1]Department of Internal Medicine. Centro Hospitalar do Barlavento Algarvio. Portimão, Portugal. [2]Linde. Portimão, Portugal.

Objectives: The sleep apnea was considered by the International Diabetes Federation (IDF) one of the chronic complications of type 2 diabetes mellitus, but the prevalence and impact of this condition in diabetic population isn´t well defined. We aim to study the prevalence of sleep apnea in a diabetic population, identify the main characteristics of this patients and their impact in patient's life.

Material and method: Transversal analytic study with a prospective data collection. Were included patients with type 2 diabetes followed in our Outpatient Department, with age between 20 and 70 years. Were collected demographic data, history of disease and co-morbidity of diabetes mellitus. Were applied various tools like Epworth, Berlin and Stanford Questionnaires and all patients were submitted to spirometry and sleep apnea prove.

Results: There were included 203 patients in this study. The average age was 60 years and 10 months, 50.3% were males and this population had an average length of 23 years of diabetes. The co-morbidity studied, hypertension was present in 78.9%, dyslipidemia in 51.7% and 5.9% had previous pulmonary disease (pulmonary obstructive chronic disease or asthma). The average glycated hemoglobin was 7.8%, the body mass index was 29.4 kg/m^2 and the Abdominal Perimeter 104.2 cm. The complications of diabetes were also present and the most prevalent were diabetic neuropathy (27.6%) and diabetic retinopathy (27.1%). Of all, 21 patients had to be excluded of the study because their results were not completed clear. The final results show that 14% had a sleep apnea in high degree, 13% had sleep apnea in moderate degree and 35% had sleep apnea in low degree (total of 62%).

Discussion: The results showed a important prevalence of sleep apnea (62% in total) in this diabetic population, and only 5.9% had previous pulmonary disease diagnosed. The metabolic control was reasonable with glycated hemoglobin of 7.8% and 73.56% had total cholesterol below 200 mg/dL. The other complications related with diabetes mellitus were much better diagnosed and treated that sleep apnea.

Conclusions: The prevalence of sleep apnea in diabetic population appears to be more important that was supposed to be. Unfortunately this tends to be sub-diagnosed in the diabetic patient. The doctor should be alert for this reality and the early diagnosis can allow the adequate and attempted intervention.

RV-51
CERVICAL-ARTERY DISSECTIONS: CLINICAL CHARACTERISTICS, DIAGNOSIS AND PROGNOSIS

C. Mella Pérez[1], C. Barbagelata López[1], A. Aneiros Díaz[2], E. Fernández Bouza[1], B. Vázquez Vázquez[1], D. García Alén[1], I. Gómez Buela[1], P. Sesma Sánchez[1]

[1]Department of Internal Medicine, [2]Department of Neurology. Complejo Hospitalario Arquitecto Marcide-Prof. Novoa Santos. Ferrol (A Coruña), Spain.

Objectives: Cervical-artery dissections are a frequent reason of cerebral ischemia in young adults, that can appear with a wide spectrum of clinical manifestations, from migraine or cervical pain to fatal ictus. This association has been suggested by diverse risk factors. The incidence is probably underestimated, due to the difficulty establishing the image diagnosis and the lack of clinical suspicion. Prognosis is in general good. To describe the clinical, diagnostic and pronostic characteristics of patients admitted with the diagnosis of cervical-artery dissections (carotidea and vertebral), in the last 5 years, in our sanitary area.

Material and method: We retrospectively collected the clinical information of patients safety from cervical-artery dissections in the Architect Marcide Hospital, from January 2008 to December 2011.

Results: Nine patients were included; mean age was 41 years (range 28-59), 5 males (55.6%). One case appeared after cervical maneuver. Another case presented as Horner's syndrome with cerebral ischemia image. 88.9% of patients had cerebral ischemia signs (CT and/or MR). 62% occurred on MCA territory, and 38% like dizziness syndrome with hemihypoestesia. Subarachnoid hemorrhage cases did not appeared. Predisposing factors were migraine (one case), connective disease (one case) and oral contraception (75% of women). The most used neuroimagen technique was MR angiography (55.6%) and sonography (44%). Dissection location in order of frequency was right-ICA (44%), VA (22%) and left-ICA (22%). 88.9% of patients received anticoagulation during a minimum of 6 months, followed by antiaggregation. In one case a stent was placed. Image control was done in 6 cases, between 3 and 12 months after the event, detecting partial recanalation in 40% of cases. The functional outcomes were satisfactory (Rankin ≤ 1 in 70%), exitus was not collected and one case suffered early recurrence.

Conclusions: Cervical-artery dissections were more frequent in middle age males, as described in other series. MR-angiography was the most used technical vascular image. Medical treatment (anticoagulation) and prognosis were similar other published cases on reviewed literature.

RV-52
AGE, GENDER, CENTRAL BLOOD PRESSURE AND SMOKING AS MAIN DETERMINANT FACTORS OF AUGMENTATION INDEX EVALUATED BY PULSE WAVE ANALYSIS

S. Tello-Blasco[1], A. Guerri[1], M. Fabregate[1], A. Fernández[1], C. Martínez[1], E. Marín[2], J. Sabán-Ruiz[1]

[1]Department of Endothelial Pathology. Department of Internal Medicine, [2]Department of Vascular Surgery. Ramón y Cajal Hospital. Madrid, Spain.

Objectives: 1. To evaluate the contribution of a series of cardiovascular risk factors to the arterial stiffness measured by the Augmentation Index (AIx).

Material and method: N = 118 patients with moderate-high cardiovascular risk. Type 1 diabetes and latent autoimmune diabetes in adults were excluded. Age: 59.2 (12.9) years. 71 males (60.2%). Hypertensive: n = 87 (73.7%). Hyperglycemia: n = 81 (68.6%). Type 2 diabetes: n = 46 (39%). Smokers: n = 31 (26.3%). (Former smokers were considered as non-smokers after 1 year). Metabolic Syndrome: ATP-III-2005 criteria. Pulse wave analysis by SphygmoCor (AtCor Medical). AIx was adjusted to a standard heart rate of 75 bpm at an inverse rate of 4.8% for each 10 bpm increment. Triglycerides, total cholesterol, HDL-C, LDL-C and uric acid (mg/dl): HITACHI. LDL-C by Friedewald formula if TG < 400. High-sensitivity C-reactive protein (hs-CRP, mg/L): nephelometric. Statistical analysis: mean (standard deviation); Pearson's correlation coefficient (r). Multivariate linear regression models (B: non-standardized coefficient; Bs: standardized coefficient; R^2: model coefficient of determination), backwards method. SPSS v15.0.

Results: 1. As expected, a strong linear correlation between AIx and age in both, males and females, was found. Males: r = 0.628;

p < 0.001; females: r = 0.576; p < 0.001. 2. Female sex was associated to higher AIx for the whole age range: B = 6.74; p < 0.001; R2 = 0.443. 3. Association between AIx and smoking status remains significant after adjustment by sex and age (B = 3.93; p = 0.030; R^2 = 0.468). 4. After adjustment by sex and age, peripheral diastolic blood pressure (B = 0.227; p = 0.041. R^2 = 0.465), central systolic blood pressure (B = 0.133; p = 0.029. R^2 = 0.468), central diastolic blood pressure (B = 0.252; p = 0.022. R^2 = 0.471) contributed to a significant increment of AIx, unlike chronic hyperglycemia, Metabolic Syndrome, hypertensive status, peripheral systolic blood pressure, waist circumference or hs-CRP. 6- Age (B = 0.252; Bs = 0.619; p < 0.001), female sex (B = 6.587; Bs = 0.299; p < 0.001), central diastolic blood pressure (B = 0.271; Bs = 0.181; p = 0.012) and smoking (B = 4.265; Bs = 0.174; p = 0.016) remained as significant predictors of AIx when all the above proposed covariates were included in a multivariate regression model (R^2 = 0.500).

Discussion: Arterial stiffness seems to be a prognostic and independent biomarker of cardiovascular risk. SPHYGMOCOR is a new non-invasive tool to evaluate the arterial stiffness. The analysis of the central pulse wave morphology (carotid artery), estimated from the radial artery, provides a number of central cardiovascular parameters, one of the most important is AIx, an indirect measure of the arterial stiffness. The increase of the above mentioned stiffness is the result of a series of structural and functional changes that happen in the arterial wall in relation to the process of aging, but whose speed could be modified both for both genetic aspects and cardiovascular risk factors.

Conclusions: 1. Age was the main determinant factor of AIx. By gender, females showed higher values. 2. Aging, female sex, smoking and higher central blood pressure were independent predictors of higher AIx. 3. Our study provides a better understanding of the factors contributing to accelerate the stiffening process.

RV-53
NEEDING A LARGER BELT. SPANISH MALES CARRIERS OF THE FTO (FAT MASS AND OBESITY ASSOCIATED) RISK ALLELE HAVE HIGHER WAIST CIRCUMFERENCE, THE PRELUDE OF CARDIOMETABOLIC DISEASE

A. Alonso Pacho[2], D. Rey Zamora[1], M. Fabregate Fuente[2], R. Fabregate Fuente[2], S. Tello Blasco[2], A. Guerri[2], C. Martínez[2], J. Sabán Ruiz[2]

[1]Department of Medical Genetics, [2]Department of Endothelial Pathology. Department of Internal Medicine Ramón y Cajal Hospital. Madrid, Spain.

Objectives: To evaluate the influence of FTO rs9939609 genotypes in FTO obesity, metabolic syndrome (MS) and diabetes mellitus (DM2).

Material and method: N = 155 patients of 50 years or older with type 2 diabetes and/or at least one classic cardiovascular risk factor. BMI (body mass index): kg/m2.Waist: cm, weight: kg. MS criteria of ATP III 2005. DM2 according to Standards of Medical Care in Diabetes (ADA) 2012. Genotyping of rs9939609 was carried out using TaqMan SNP Genotyping Assays (Applied Biosystems). Statistical analyses were performed using SPSS version software 15.0. Continuous variables described by mean ± standard deviation. Two-tailed p < 0.05 was considered significant. Chi-square test to evaluate the Hardy-Weinberg equilibrium. A Descriptive study, adjusted for age and sex, was performed by contingency table where association was evaluated by chi-square tests. Comparison of means according to the number of alleles: ANOVA with post hoc Tukey contrast or Kruskal–Wallis as appropriate.

Results: 1. The 18% of patients had two risk alleles (AA), 47% had only one risk allele (AT) and 35% did not have the risk allele (TT). Allele frequencies in this population did not deviate from Hardy-Weinberg equilibrium (p = 0.147). 2. Among subjects with DM2 no statistically significant association was found. 3. Associatiion between MS and risk allele presented borderline significance (p = 0.08). 4. In male subjects (N = 115), higher values of BMI, waist and weight were significantly associated to a greater number of risk alleles. For BMI the AA: 30.4 ± 4.4, the AT 28.1 ± 4.1 and those with no risk allele (TT) 27.1 ± 3.8 kg/m^2 with p = 0.026. With regard to waist circumference, AA: 105.8 ± 13.3; AT: 98.3 ± 9.2, TT 96.3 ± 8.7 cm, p = 0.007. Significant differences were observed between TT and AA (p = 0.005) and between AT and AA (p = 0.027). Differences in weight reached borderline significance: (p = 0.06), although post hoc contrast showed significant differences between AA and TT (p = 0.027) and between AA and AT (p = 0.049). 5. In women (N = 40) similar trends were observed for BMI, waist circumference and weight, although no significant differences were found.

Discussion: In a world of contrasts, epidemics of the XXI century are starvation and cardiometabolic diseases. Both have deep sociopolitical roots of opposite sign: the first linked to abandonment or negligence; the other linked to progress. Due to the latter, the waist circumference of the subjects continues growing. The knowledge of the genetic determinants of this waist growth should become an obligation of scientists but also of governments. The control of these epidemics, demands a combined struggle of both politicians and health professionals. Since 2007, in a study of GWAS, Frayling and colleagues found a strong association between the FTO gene (read "fatso") and human obesity, the SNP rs9939609 in the first intron of this gene has been linked to BMI in various populations. It has also been associated with DM2 and MS.Our results agree with reports about the association between the FTO gene and obesity.

Conclusions: 1. BMI and waist circumference seem genetically determined and at least in men FTO gene plays a small role, but clinically relevant. 2. Our study should encourage social organizations to design genetic studies with a much larger sample to measure what is the genetic (non-modifiable) impact and what is the environmental (modifiable) one in this costly epidemic that "invades" our society with obesity, MS and DM2, including many of us.

RV-54
DO WE KNOW THE REAL PREVALENCE OF LOW-LDL-CHOLESTEROL IN DIABETIC PATIENTS WITHOUT LIPID-LOWERING THERAPY? HOW MANY OF THESE PATIENTS SHOULD TAKE STATINS ACCORDING TO STANDARDS OF MEDICAL CARE IN DIABETES?

J. Sabán Ruiz, J. Rodríguez Encinar, M. Fabregate Fuente, R. Fabregate Fuente, S. Tello Blasco, E. Tutor Pellicer, C. Martínez Ruiz, A. Alonso Pacho

Department of Endothelial Pathology. Department of Internal Medicine. Ramón y Cajal Hospital. Madrid, Spain.

Objectives: 1. To count up how many of our type-2 diabetic patients with no statins have constitutive low-LDL-C levels. 2. To count up how many of these low-LDL-C patients have at least one statin treatment criterium according to the Standards of Medical Care in Diabetes-2012.

Material and method: N: 126 DM2 patients under no lipid-lowering drugs were included. Males = 86, 59.5 years old ± 10.8 (36-88); 6.1 yr duration of disease ± 7.4 (1-35); BMI (body mass index): 28.3 ± 4.2 (20-43.6). Females = 40: 66.7 years ± 11.2 (45-95); 10.2 yrs duration of disease ± 8.4 (1-30); BMI: 31.4 +- 5.8 (22-57.9). A lipid profile was carried out including total-cholesterol, HDL-cholesterol and triglycerides, measured by Hitachi autoanalyzer. LDL-cholesterol (LDL-C) was calculated in subjects with TGs < 400 mg/dl using the Friedewald equation. HbA1c (DCCT) in %. Statin therapy criteria to type 2 DM patients: according to the ADA Standards of Medical Care in Diabetes-2012: Statin therapy should be added regardless of baseline lipid levels, for diabetic

patients: a) with overt CVD; LDL-C target: < 70 mg/dl (< 1.82 mmol/L), b) without CVD who are over age 40 years and have one or more other CV risks factors. Statistical analysis: Mean ± SD. alfa = 0.05. Chi-square test for the comparison of two proportions.

Results: 1. N = 25 (19.8%) of total population had low-LDL. 2. In males: 18.6% had LDL < 100 mg/dl (< 2.6 mmol/L); 16.6% of patients had LDL-C > 160 mg/Dl (4.1 mmol/L); 64.8% between 100-160 mg/dl (2.6-4.1 mmol/L). In 5.8% high-LDL-C was associated with high-TGs (> 150 mg/dl) (> 1.7 mmol/L) (mixed dyslipidemia) 3.5% had high-LDL with low-HDL. 2.3% had mixed dyslipidemia and low-HDL (< 40 mg/dl) (< 1 mmol/L). 3. In females: 22.5% had LDL < 100 mg/dl (< 2.6 mmol/L); 20.0% of patients had LDL-C > 160 mg/Dl (4.1 mmol/L); 57.5% between 100-160 mg/dl (2.6-4.1 mmol/L). In 2.5% high-LDL-C was associated with high-TGs (mixed dyslipidemia) 5.0% had high-LDL with low-HDL. 2.5% had mixed dyslipidemia and low-HDL (< 50 mg/dl in females) (< 1.3 mmol/L). 4. The prevalence of low-LDL-C levels was slightly higher in women than men but this difference did not achieve statistical significance. 5. Statin therapy criteria were applied according the Standards of Medical Care in Diabetes-2012 with the following results: 76% complies with the criteria for statins according to age ≥ 40 yrs + ≥ 1 CV Risk Factor; 20% had CVD (LDL-C-target < 70 mg/dl (< 1.82 mmol/L); only 4% did not meet any of these criteria.

Discussion: The LDL-C target in type 2 diabetic patients without coronary disease is 100 mg/dl (< 2.6 mmol/L) but a number of these patients have these levels before beginning the statin therapy raising doubts about the need of this therapy. In USA, a mutation of LDL-r (PCSK9) can be responsible of this "advantageous anomaly" in black people. But how many patients have constitutively these low levels in Spain? And how should we act according to the ADA Standards of Medical Care in Diabetes-2012?

Conclusions: 1. In a Spanish population, one out of five type 2 diabetic patients has constitutively low-LDL-C levels. The prevalence of low-LDL-C levels was slightly higher in women, although this difference was not statistically significant. 2. After applying the statin treatment criteria according to the Standards of Medical Care in Diabetes-2012 only one out of 25 (4%) did not meet any criteria. A take-home message in type-2 diabetic patients: "statins for everybody".

RV-55
SPORTS ACTIVITY IN THE YOUTH AND CARDIOVASCULAR HEALTH IN THE MIDDLE AGE

Y. Venevtseva, A. Melnikov, T. Gomova, O. Borisova, E. Kazidaeva

Department of Internal Disease. Tula State University. Tula, Russia.

Objectives: Little is known about influence of long-term exercise training in the youth on cardio-respiratory system in the middle age.

Material and method: 24 moderately physically active males 32-82 yrs (mean (M ± m) 53.2 ± 2.7 yrs) and 16 females 31-73 (51.3 ± 3.5) yrs with > 10 yrs vigorous exercise training were included in the past athletes (A) group, 41 males (55.7+/-1.9 yrs) and 35 females (56.3 ± 2.0 yrs) with mild arterial hypertension were studied as controls (C). Ambulatory 24h monitoring of ECG, BP and respiration (Cardiotehnika, Incart, Russia) was conducted in all patients.

Results: A reported less symptoms (palpitation, dizziness). Males-A had lower body mass index (BMI, 27.3 ± 0.7 and 28.8 ± 0.6 kg/m^2, p = 0.04), lower heart rate (HR) at day and night (72.7 and 78.3; 56.6 and 61.4), more frequent transient II degree AV- block (16.7 and 2.4%), transient long QT interval (25.0 and 7.3%), premature ventricular contractions > 50/24 h (50.0 and 31.7%), episodes of supraventricular tachycardia (41.1 and 22.2%) and couplet supraventricular beats (66.6 and 48.8%). BMI in the females did not differ (26.7 ± 1.3 and 28.6 ± 0.8 kg/m^2). Only early repolarization syndrome in the night-time in females-A was seen more often (25.0 and 2.8%, p = 0.03). No significant between-groups difference was detected in the incidence of multiple premature ventricular contractions (62.5 and 47.7%), but number of polymorphous premature ventricular contractions (25.0 and 8.7%) and repetitive premature ventricular contractions had tendency to be greater in the A. No difference was found in the incidence of the II degree AV-block (6.2 vs 5.7%), supraventricular tachycardia (18.8 vs 14.3%) and transient long QT interval (18.8 vs 14.3%).Power spectral analysis of heart rate variability revealed that power of all spectral bands (VLF, LF and HF) both in the day and night in females-A and power of VLF band in the day-time in males-A was significantly greater than in C. Systolic BP in the females-A was 123.9 vs 129.3 mmHg in C in the day and 118.4 vs 114.1 mmHg in the night, diastolic BP in the day – 75.8 vs 75.6 mmHg. while diastolic BP in the night in females-A was lower (62.6 ± 1.8 vs 68.8 ± 1.8 mmHg, p = 0.05). No difference in the systolic BP in the day and night (131.2 vs 134.1 mmHg in the day and 121.5 vs 122.0 mmHg in the night) and diastolic BP (76.1 vs 79.1 mmHg in the day and 67.0 vs 70.4 mmHg in the night) between male groups was found. Past A demonstrated more regular breathing during sleep (apnoea/hypopnoea index 9.4 and 15.3 in males and 5.3 and 7.6 in females, p < 0.05).

Discussion: Despite the greater prevalence of complex or polymorphous premature ventricular contractions in A, the age related decrease in heart rate variability seems to be retarded, which has a positive prognostic value and may decrease the risk of life threatening ventricular arrhythmias.

Conclusions: Sports activity in the youth has positive influence on the cardio-respiratory system in the middle-ages patients: both males and females past athletes had greater heart rate variability that may preserve from life threatening events, more regular breathing during sleep and females – lower diastolic BP at night.

RV-56
INFLUENCE OF MEAN HBA1C LEVELS ON OUTCOME IN STABLE DIABETIC OUTPATIENTS WITH CORONARY, CEREBROVASCULAR OR PERIPHERAL ARTERY DISEASE

P. Casado Escribano[1], C. Suárez[1], J. Sahuquillo[2], E. Aguilar[3], M. Piedecausa[4], M. Monreal[5] and the FRENA Investigators

[1]Department of Internal Medicine. Hospital Universitario de La Princesa. Madrid, Spain. [2]Department of Internal Medicine. Hospital Municipal de Badalona. Badalona (Barcelona), Spain. [3]Department of Internal Medicine. Hospital de Alcañiz. Alcañiz (Teruel), Spain. [4]Department of Internal Medicine. Hospital General Universitario de Elche. Elche (Alicante), Spain. [5]Department of Internal Medicine. Hospital Universitari Germans Trias i Pujol. Badalona (Barcelona), Spain.

Objectives: There is some controversy over the influence of glucose control on the risk for cardiovascular events in patients with type-2 diabetes. The aim of the current study was to compare the incidence of subsequent ischemic events (myocardial infarction, ischemic stroke or limb amputation) and death in stable outpatients with type-2 diabetes, after classifying them into quintiles of mean HbA1c levels during follow-up.

Material and method: FRENA is an ongoing registry of stable outpatients with symptomatic coronary (CAD), cerebrovascular (CVD) or peripheral artery disease (PAD). We compared the incidence of the composite outcome of subsequent myocardial infarction (MI), ischemic stroke, limb amputation or death in patients with type 2-diabetes according to quintiles of mean glycated hemoglobin (HbA1c) levels.

Results: As of November 2011, 1294 patients with type 2-diabetes were recruited. Of these, 415 presented with CAD, 356 with CVD and 523 with PAD. Over a mean follow-up of 13 months, 42 patients

(3.2%) suffered subsequent MI, 29 (2.2%) had ischemic stroke, 30 (2.3%) underwent limb amputation, and 66 (5.1%) died. The incidence of the composite outcome progressively increased, from 4.84 events per 100 patient-years (95%CI: 2.92-7.60) in patients with HbA1c levels in the first quintile to 11.4 events (95%CI: 7.89-16.0) in those in the fifth quintile. This worse outcome was mostly due to an increased incidence of subsequent MI, which increased from 0.84 events (95%CI: 0.21-2.28) to 3.20 (95%CI: 1.56-5.87). On multivariate analysis, the risk for the composite outcome progressively increased with HbA1c levels, from 1 (reference) to 1.72 (95%CI: 0.91-3.27), but with no significant differences among groups.

Discussion: Our data, obtained from a prospective series of consecutive stable outpatients with type-2 diabetes and CAD, CVD or PAD, suggest that the risk to suffer subsequent ischemic events or dying progressively increases with increasing levels of HbA1c. Among all such events, the risk to suffer subsequent MI seems to be particularly high, since patients with mean HbA1c levels in the two highest quintiles had a 4-fold higher incidence of subsequent MI than those in the first quintile. One in every 4 patients with subsequent MI died of the event. Thus, its clinical impact is considerable. The risk for subsequent stroke, limb amputation or death also increased with increasing HbA1c levels, but less evident. This worse outcome in patients with HbA1c levels in the highest quintiles persisted on multivariate analysis (although not reaching significant differences) after considering potential confounders such as the affected vascular bed, underlying diseases and pharmacologic therapies. Our data failed to confirm the existence of either a U-shaped association or an inverse correlation between HbA1c levels and all-cause mortality, as suggested in two recent studies.

Conclusions: In stable outpatients with CAD, CVD or PAD the incidence of subsequent ischemic events or death progressively increased with mean levels of HbA1c.

RV-57
CARDIOVASCULAR RISK PROFILE IN ADULTS WITH DOWN SYNDROME

R. Costa Segovia, P. Parra Caballero, D. Real de Asúa Cruzat, F. Moldenhauer Díaz, C. Suárez Fernández

Department of Internal Medicine. Hospital Universitario de la Princesa. Madrid, Spain.

Objectives: Major vascular events are practically absent in adults with Down syndrome (DS), which have been proposed as an "atheroma-free model". However, the cardiovascular risk profile in this population is unknown. We aim to 1) compare the distribution of classic cardiovascular risk factors in a group of adults with DS and a non-trisomic cohort, and 2) to subsequently stratify both populations' vascular risk according to the Framingham score.

Material and method: Cross-sectional study of 56 patients (28 adults with DS and 28 control subjects), recruited at the Adult Down Syndrome Unit of the Hospital Universitario La Princesa, Madrid, Spain between January and May 2012. Control were matched by age, gender and race. Epidemiological, anthropometric, clinical, and analytical variables were measured, and compared between both populations.

Results: We recruited 28 subjects with DS and 28 control subjects matched by age and gender, who were 40 ± 10.7 vs 43 ± 12.6 years old (p non-significant). Fourteen subjects in the DS group (50%) and 10 of the controls (36%) were males (p non-significant). Adults with DS had a significantly lower blood pressure than controls (114/71 ± 13/10 mmHg vs 130/80 ± 12/8 mmHg; $p < 0.001$). No DS adult had a diagnosis of arterial hypertension vs 3 (11%) of controls (p non-significant). Six subjects in the control group (28%) were found hypertensive in a single, casual office blood pressure (BP) measure vs 0 adults with DS ($p < 0.01$). Eleven (39%) DS adults met ATPIII criteria of dyslipidaemia vs 5 (18%) controls (p non-significant), but we found no differences in total cholesterol (204 mg/dl in two populations), triglycerides (104 mg/dl in DS individual and 102 mg/dl in control group), or cholesterol fractions' levels (HDL 60 mg/dl vs 62.8 mg/dl and LDL 122.6 mg/dl vs 121.5 mg/dl) between populations. Three (10.7%) adults with DS and 2 (11.7%) controls met ATPIII criteria of metabolic syndrome. Obesity was more prevalent among adults with DS (12/28 [43%] vs 5/28 [18%]; $p < 0.05$), who also presented a higher body mass index (29.8 ± 4.8 vs 25.8 ± 3.7 kg/m^2; $p < 0.001$). However, we found no significant differences in waist perimeter (95 ± 12.6 vs 92 ± 10.8 cm), prevalence of abdominal obesity (12/26 [46%] vs 13/27 [48%]) or in body fat percentages (28.4% vs 30%). No DS adults smoked vs 6 (21%) of controls ($p < 0.05$). All adults with DS (N = 26) were stratified as low-risk patients according to the Framingham Score (mean 2.1% ± 2.3), and none as moderate-vascular-risk subjects. In the control group, 16 subjects (94%) were classed as low-risk (mean 3.2% ± 3.7), and 1 (6%) as moderate-risk patients (p non-significant).

Discussion: Adults with DS have a substantially lower BP than controls. Although a higher number of DS adults had dyslipidemia or were obese, the prevalence of metabolic syndrome was similar in both populations. Smoking was a risk factor found only in controls. The Framingham Risk Score classed similarly both populations, underscoring the non-inferiority of the vascular risk phenotype of adults with DS.

Conclusions: The prevalence of several classic vascular risk factors in adults with DS is different than in the general population. However, this profile confers a similar cardiovascular risk according to the Framingham Score model.

RV-58
SHOULD ANTIPHOSPHOLIPID SYNDROME BE CONSIDERED A MAJOR CARDIOVASCULAR RISK FACTOR?

C. Barbosa, V. Bettencourt, A. Garrido, C. Martins, M. Bastos

Department of Internal Medicine. CHTV - Hospital de Viseu. Viseu, Portugal.

Objectives: Cardiovascular risk assessment scores value mostly metabolic and cardiovascular diseases such as dyslipidaemia and hypertension. Diabetes has been increasingly recognized as a major risk factor and additions such as smoking are also considered. However, despite the known association between Antiphospholipid Syndrome (APS) and cardiovascular manifestations, this condition is not beheld as an import cardiovascular risk factor. Our objective was to evaluate the relation between cardiovascular risk assessment by widely used scores and the evidence of cardiovascular disease in patients with APS.

Material and method: Retrospective study of 12 patients with APS. Cardiovascular risk was assessed using the Framingham Coronary Heart Disease Risk Score (F-SCORE) and the European Society of Cardiology Score for estimation of ten-year risk of fatal cardiovascular disease (E-SCORE). The evidence of cardiovascular disease was evaluated by the amount of ischemic events suffered by each patient and the number of hospitalizations for cardiovascular reasons.

Results: Nine patients (75%) were women and 3 were men. The average age was 42 years, ranging from 19 to 66 years old. Mean time from diagnosis was 2.5 years, extending from 7 years to 1 month. APS was secondary to systemic lupus erythematous in 7 patients (58.3%). The defining clinical criterion was a thrombotic event in 10 patients (stroke – 5 patients (41.7%); deep venous thrombosis – 3 patients (25%); thrombotic acute intestinal ischemia – 1 patient (8.3%) and renal vein thrombosis – 1 patient); in the remaining 2 patients the diagnosis of APS followed recurrent fetal

loss. Anticardiolipin and anti-B2-glycoprotein I antibodies were the most commonly detected (8 patients each – 66.7%) and lupus anticoagulant was isolated in 6 patients (50%). Three patients (25%) were positive for the 3 antibodies, 8 patients (66.7%) were positive for 2 antibodies and 1 patient was positive a single antibody. Cardiovascular risk evaluation using the F-SCORE was: 5 patients (41.7%) < 1%; 1 patient (8.3%) 1%; 1 patient 1.5%; 1 patient 4%; 1 patient 5%; 1 patient 6%; 1 patient 7% and 1 patient 19%. Cardiovascular risk evaluation with the E-SCORE was: 6 patients (50%) < 1%; 2 patients (16.7%) 1%; 2 patients ≥ 1.5%; 1 patient (8.3%) 6% and 1 patient 15%. Six patients (50%) were hospitalized once because of a major thrombotic event and 1 patient (8.3%) was hospitalized in two separate occasions for cardiovascular reasons. The prevalence of traditional cardiovascular risk factors was: 8 patients (66.7%) were hypertensive, 6 patients (50%) suffered from dyslipidaemia, 2 patients (16.7%) were obese, and 1 patient was diabetic.

Discussion: There is a clear discrepancy between cardiovascular risk assessment by both scores (75% of patients with a risk ≥ 5% by the F-SCORE and 83.3% with a risk ≥1.5% by the E-SCORE) and the evidence of cardiovascular disease (83.3% of patients suffered a major thrombotic event and 58.3% of patients were hospitalized at least one time for the same reason). The fact that the association between APS and an increased incidence of myocardial infarction remains controversial (in fact, none of the patients suffered a coronary event) may largely justify the divergence. The low mean age with a low prevalence of traditional cardiovascular risk factors is probably another reason for this disagreement. However, the association of APS with atherosclerosis of both peripheral and coronary arteries, accelerated atherosclerosis and a wide range of cardiovascular manifestations has been established and none of these scores appears to have sensitivity to detect it.

Conclusions: We propose that APS patients are high-risk patients for cardiovascular disease, that all traditional risk factors should be treated aggressively and that more studies should be conducted in these patients to find a more sensitive cardiovascular risk assessment score for clinical practice.

RV-59
INSULIN ADMINISTRATION TO PATIENTS WITH THE METABOLIC SYNDROME. RESULTS WITH INSULIN GLARGINE AT 12 MONTHS

A. Sánchez, I. Narrillos, C. Velasco, C. Díaz Pavón, A. Díaz, R. Torres, J. García Puig

Department of Internal Medicine. Hospital Universitario La Paz. Madrid, Spain.

Objectives: Insulin initiation is a relevant decision that may be difficult to implement due to weight gain. We have examined the efficacy and safety of an insulinization program, leaded by nurse practitioners, with insulin glargine and life style modifications.

Material and method: Unicentric study promoted by the investigators. From the general archives of the Unit (January, 2287 patients) we selected patients with the metabolic syndrome (ATP III criteria) and HbA1c > 7.5% at least on two occasions with a > 3 month interval, and who were taking at least one oral antidiabetic drug (OAD) for > 6 months. Therapeutic objectives were those established by the American Diabetes Association in 2011. Initial mean insulin glargine doses were 0.2 units/Kg weight (single morning dose), and OAD were maintained stable. Periodic visits were scheduled to revise life style modifications agreeded with each patient and pharmacologic therapy.

Results: We included 30 patients (mean age, 65 years [range, 41 to 83 years]; men, 22) with a mean BMI of 31.2 Kg/m^2. The mean time since diabetes diagnosis was 132 months. The mean number of metabolic syndrome criteria was 3.2 and the mean OAD 1.8/day. The insulin glargine initial mean dose increased from 20 units/day to 31units/day at 12 months ($p < 0.001$). Mean weight diminished at 12 months from a baseline of 86.2 Kg to 84.0 Kg (mean reduction, -2.2 Kg). Mean glucose and HbA1c concentrations decreased from 205 to 134 mg/dL ($p < 0.001$) and from 9.3% to 7.2% ($p = 0.004$), respectively. Mean systolic and diastolic blood pressures were unmodified (137/78 mmHg, in both situations). Mean triglycerides concentration decreased (baseline, 214 mg/dL; 12 months, 172 mg/dL) and c-HDL increased (basaline, 41 mg/dL; 12 months, 46 mg/dL), being c-LDL concentrations stable (basaline, 98 mg/dL; 12 months, 97 mg/dL). No hypoglycemic episodes that required someone´s help were reported.

Conclusions: In patients with the metabolic syndrome and type 2 diabetes mellitus insulin glargine, in the context of a lifestyle modification program developed by nurses, was accompanied by a substantial weight reduction at 12 months and glucose and lipid metabolism improvements.

RV-60
INTERMEDIATE PHENOTYPES IN CARDIOVASCULAR RISKS ASSOCIATED WITH FOOD PREFERENCES AND BITTER TASTE

D. Godoy[1], O. Arellano Campos[2], P. Guillém Saiz[2], E. Asensio Márquez[2], J. Sorlí[2], O. Portolés[2], D. Corella[2]

[1]Department of Internal Medicine. University General Hospital. Valencia, Spain. [2]Department of Preventive Medicine and CIBER obn. University of Valencia. Valencia, Spain.

Objectives: Diet is one of the pillars of overweight treatment and metabolic syndrome. The discrimination of different flavors strongly determines food preferences and thus these preferences might determine food selection. Genetic variation in sensitivity to PTC and PROP, is the most- studied bitter-taste phenotype in humans. The aim of the study was to evaluate the relationship between food preferences and bitter taste perception in food consumption and its association with intermediate phenotypes in cardiovascular risk.

Material and method: A cross-sectional study of the general adult population, both sexes, in the Valencia community. A food preference questionnaire with a quantitative scale of 0 = displeasure, 1 = slight liking, 2 = moderate liking and 3 = favorite taste was applied. Perception to bitter taste was evaluated by means suprathreshold concentrations of 6-n-propylthiouracil (PROP), tasters can be further classified as follows: (NT) nontaster, (MT) moderate taster and (ST) supertaster.

Results: Three hundred and thirty two subjects (332) were included: 124 males and 208 females, with an average age of 39 ± 11. Food preferences were positively correlated to food consumption in both sexes. It was found that those who prefer red meat have a higher cardiac frequency (78 ± 12 vs 69 ± 12, $p = 0.001$) and a higher percentage (%) of body fat (31 ± 8 vs 24.7 ± 11, $p = 0.006$) than those who totally dislike it. Meanwhile, those who prefer the taste of vegetables (green beans, artichoke, spinach, chard,) weigh less (70.8 ± 15 vs 78.3 ± 17, $p = 0.016$); have a body mass index of (BMI) (25 ± 5 vs 28 ± 5, $p = 0.010$), smaller waist circumference (WC) (88 ± 12 vs 96 ± 15, $p = 0.008$), lower waist-height index (WHI) (.52 ± .07 vs.57 ± .09, $p = 0.005$) and lower systolic blood pressure (SBP) (122 ± 15 vs 128 ± 17, $p = 0.024$) than those who dislike them completely.

Discussion: Consumption of these vegetables was associated with the PROP's taster status, STs with a significantly higher consumption in comparison with the NTs. Red meat consumption was not associated with the PROP's perception status of bitter taste. The literature referring to the relationship between the taster's PROP

status and vegetable consumption is controversial. These results confirm a positive association between being ST to PROP and the higher consumption of vegetable in the adult population of Valencia.

Conclusions: Food preferences are correlated to both sexes consumption; those who totally dislike vegetables have a higher weight, a higher BMI, WC and WHI in comparison to those who have them as favorite taste. Being ST for PROP is associated with a higher vegetable consumption.

This work has been supported by grants CONACYT and CIBER06_03_035.

RV-62
HDL-CHOLESTEROL AS A SENTRY ANTIOXIDATIVE PROTECTOR AGAINST SECONDARY MYELOPEROXIDASE TISSUE DAMAGE

A. Alonso, C. de la Puerta, C. Martínez, M. Fabregate, E. Tutor, J. Vilkomirskyte, R. Fabregate, J. Sabán Ruiz

Department of Endothelial Pathology. Hospital Ramón y Cajal. Madrid, Spain.

Objectives: The aim of this study was to assess the relationship between MPO and HDL, PCR levels and REGICOR score (Framingham calibrated for Spanish population) in untreated patients neither with statins nor other cardiovascular drugs.

Material and method: Population: 144 patients from the Unit who was untreated neither with statins nor other cardiovascular medication. 43.3 ± 13.0 years, 78 (54.0%) males, 19 (13%) were healthy (healthy was considered as not having Metabolic Syndrome according ATP III 2005, BMI < 30 kg/cm^2, HDL > 35 mg/dL without other SM criteria, LDL < 160 mg/dL, triglycerides < 150 mg/dL, HbAc < 5.7%, fasting plasma glucose < 100 mg/dL, ferrintin < 179 ng/mL, no cardiovascular disease, no hypertension, no hypercholesterolemia, no diabetes mellitus or not previously diagnosed of hypertrigliceridemia, impaired fasting glucose or hyperferritinemia) 65 (45%) had hypercholesterolemia, 33 (23%) had hypertension, 21 (15%) low HDL, 39 (27%) were smokers, 21 (15%) had metabolic syndrome and 27 (19%) had impaired fasting glucose. REGICOR score (only in those between 35 and 75 years old) was 1.9 ± 1.4. A sandwich enzyme-linked immunosorbent assay (BioVendor, Modrice, Czech Republic) was used to determine MPO concentrations in plasma. hs CRP was performed according to Nephelometer technique, by Siemens®. Data are presented as mean and SD or n (%). Skewed variables were natural log transformed before linear regression analyses, as in case of MPO and REGICOR score.

Results: 1. After adjustment for age and sex, a significant negative linear association between MPO and HDL was found (standardized beta = -0.187; p = 0.027). R^2 of the model was 0.041. 2. After adjustment for age and sex, a significant linear association between MPO and hsCRP was found (standardized beta = 0.282; p = 0.002). R^2 of the model was 0.084. 3. After adjustment for age and sex, a significant linear association between MPO and Coronary Risk by REGICOR score was found (standardized beta = 0.384; p = 0.015). R^2 of the model was 0.080.

Discussion: MPO activity is associated to oxidative stress and its activity increases proportionally with the number of infiltrated neutrophils, so it can be used as a leukocyte migration index and then, of oxidative stress in humans. Release of MPO by PMNs during inflammation plays an important role in the innate immune response, but MPO activity may also lead to tissue damage and precipitate atherogenesis. It was demonstrated that in metabolic syndrome patients, high MPO levels were correlated with progressive atherosclerosis. High-density lipoprotein (HDL) acts as an antioxidative protector of LDL and has a transcendental function in atherosclerosis by removing excess cholesterol from artery wall macrophages, which are a rich source of MPO, but to our knowledge, any study has linked levels of MPO and HDL. However, some observations indicate that MPO oxidatively damages HDL in humans.

Conclusions: 1. A relationship between MPO, Coronary Risk and hsCRP could be expected according to the association between MPO, the different cardiac risk factors and the atherosclerosis. 2. There is a linear association between HDL and MPO, and further studies should confirm these results and to clarify the molecular mechanisms involved.

RV-63
BLOOD PRESSURE IN DIABETIC PATIENTS: ANALYSIS OF CIRCADIAN RHYTHM

M. Esteban Moreno[1], M. Poveda García[2], S. Domingo Roa[1], A. García Peña[1], B. Hernández Sierra[1], P. Sánchez López[1], L. Díez García[1]

[1]Department of Internal Medicine, [2]Department of Nephrology. Complejo Hospitalario Torrecárdenas. Almería, Spain.

Objectives: Blood pressure (BP) has a physiological circadian rhythm with a decrease of the values during sleep. Patients with diabetes mellitus show an absence of the nocturnal physiological lowering of BP (nondipping pattern) more frequently than the rest and has been associated with an increased cardiovascular risk. The aim of our study was to observe the behaviour of the BP in a real clinical setting in a random sample of patients.

Material and method: Prospective study of 105 hypertensive patients. The sample calculation was performed on a universe of 1030 discharged patients from the emergency department of a general hospital from April until June 2010. ABPM was determined by using a device (worn by the patients) that takes blood pressure measurements over 24 hours, usually every 15 to 20 minutes during the daytime and every 30 to 60 minutes during sleep. Two comparison groups were established: patients with Diabetes Mellitus Type 2 (D Group) and nondiabetic ones (ND group). The data were analyzed by using SPSS 18.0 statistical package.

Results: In a sample of 105 hypertensive patients, 35 were diabetic (33.3%) and 70 were non diabetic (66.6%). The following variables were studied: age 63 ± 12 years DG/NDG 65 ± 11 years (p: NS) and sex DG Males: 14/Females: 16; NDG Males: 38/Females: 26 (p: NS). We analyzed the need for antihypertensive therapy: 23 patients (22.3%) with 1medicine, 45 patients (43.6%) with 2 medicines, 28 patients (27.1%) with 3 medicines and 7 (6.7%) with 4 medicine. Analyzing therapeutic families: ACE inhibitors 53% (55patients); Angiotensin 2 receptor antagonists 27% (28 patients); Diuretics 62% (64 patients); Calcium channel blockers 22% (23 patients); Alfa-Blockers 11% (11 patients); B-Blockers 17% (17 patients). Analyzing the subgroup of diabetic patients: average HbA1c 7.3%. In diabetic patients nighttime blood pressure (nondipping pattern) was observed but without reaching statistical significance (P: 0.06), probably due to the volume of the sample (n = 103).

Conclusions: ABPM is a useful technique to assess the circadian rhythm of BP, when we suspect white coat hypertension or episodic hypertension (eg, pheochromocytoma), hypertension resistant to an increasing use of medicines and hipotensive symptoms while taking antihypertensive drugs. Nondipping has also been associated with microalbuminuria and faster progressions of nephropathy in patients with diabetes mellitus. We must pay special attention to these patients to provide an individual antihypertensive treatment, thereby reducing cardiovascular complications so frequent in these patients.

RV-64
OBSERVATIONAL STUDY OF CARDIOVASCULAR RISK IN DIABETIC PATIENTS

M. Esteban Moreno[1], M. Poveda García[2], S. Muñoz Troyano[3]

[1]Department of Internal Medicine, [2]Department of Nephrology, [3]Department of Cardiology. Complejo Hospitalario Torrecárdenas. Almería, Spain.

Objectives: The role of cardiovascular risk reduction in patients with diabetes mellitus is significant. Prevention of diabetes is very important to reduce cardiovascular risk. Future therapeutic management strategies will allow us to be more effective at individualizing risk reduction. Our purpose was to analyze the control of traditional risk factors in our diabetic population.

Material and method: Retrospective study in diabetic patients of Internal Medicine, Cardiology and Nephrology of Torrecárdenas (Almería) from August 2011 to September 2011. We analyzed clinical and epidemiological variables: age, sex, comorbidity (retinopathy, kidney disease, cerebrovascular disease, coronary artery disease, peripheral arterial disease) and control of risk factors: hypertension, diabetes mellitus type 2, dyslipidemia, obesity and smoking.

Results: We analyzed 150 patients. The following variables were studied: age 68 ± 9 years, sex 85 males (56.6%)/65 females (43.4%) and comorbility: -Microvascular complications: 52 patients with retinopathy (34.6%) and 68 patients with kidney disease (45.3%): 4 patients in Stage 1 (5.8%), 14 in stage 2 (20.5%), 19 in stage 3 (27.9%), 18 in stage 4 (26.4%) and 13 in stage 5 (19.1%). -Macrovascular complications: 23 patients with cerebrovascular disease (15.3%), 48 with coronary heart disease (32%) and 8 patients with peripheral arterial disease (5.3%). We analyze the control of cardiovascular risk factors as general recommendations of the ADA (American Diabetes Association): -High cardiovascular risk: 104 patients (69.4%): 79 patients (75.9%) with systolic blood pressure < 130 mmHg; 98 patients (94.2%) with diastolic blood pressure < 80 mmHg; 34 patients (32.6%) with glycated hemoglobin < 6.5%; 28 patients (26.2%) with LDL cholesterol < 70 mg/dL; 61 patients (58.6%) with triglycerides < 150; 26 patients (25%) with BMI (body mass index) < 30 and 18 cigarette smoker (17.3%). -Low cardiovascular risk: 46 patients (30.6%): 18 patients (39.1%) with systolic blood pressure < 130 mmHg; 44 patients (95.6%) with diastolic blood pressure < 80 mmHg; 29 patients (63%) with glycated hemoglobin < 6.5%; 19 patients (41.3%) with LDL cholesterol < 70 mg/dL; 38 patients (82.6%) with triglycerides < 150; 8 patients (17.3%) BMI < 30 and 13 cigarette smoker (28.2%).

Conclusions: Our study shows a poor control of cardiovascular risk factors in diabetic patients, especially patients at high cardiovascular risk. We emphasize high rate of obesity and dyslipidemia. We must make an individualized approach in these patients, since many studies show the benefit in reducing morbidity and complications.

RV-65
PROGNOSTIC FACTOR OF AMBULATORY BLOOD PRESSURE MONITORED IN HYPERTENSIVE SUBJECTS OLDER THAN 45 YEARS

R. Ruiz Ortega, J. Ampuero Ampuero, A. Jurado Porcel, R. Martínez Fernández, M. Carracedo Melero, M. Martín Moreno, F. Gómez Delgado, M. Montero Pérez-Barquero

Department of Internal Medicine. Hospital Universitario Reina Sofía. Córdoba, Spain.

Objectives: The aim of this study was to assess the prognostic role of ambulatory blood pressure monitored in hypertensive subjects to identify factors associated with high cardiovascular risk.

Material and method: We evaluated 213 hypertensive subjects older than 45 years with 24-hours ambulatory blood pressure monitoring (ABPM). Of these 213 subjects, only 183 were selected. The incidence of cardiovascular event was assessed after at least 5 years of monitoring. We defined cardiovascular events as an acute myocardial infarction or stroke. We used test ANOVA and Chi-square test to compare the characteristics of event group and non-event group.

Results: From the 183 subjects selected, 20 of them had cardiovascular events and 163 subjects did not. There was not statistical significance between both groups in age, heart rate, body mass index (BMI), smokers, diabetes, previous cardiovascular disease, hypertension pattern or metabolic syndrome. Difference was identified between 24- hours diastolic blood pressure mean 75.9 mmHg in the non-event group and 110 mmHg in the event group (p = 0.002). There were more events in obese than in no obese (82% versus 17%; p = 0.035). The standard deviation of the activity systolic blood pressure in the event group was higher (p = 0.001).

Discussion: In patients with hypertension and homogeneous characteristics was demonstrated that high diastolic blood pressure and standard deviation of activity systolic blood pressure may predict future cardiovascular events.

Conclusions: The data captured by the ambulatory blood pressure monitoring can be used as prognostic factors in patients with arterial hypertension.

RV-66
IS THERE AN ASSOCIATION BETWEEN MIGRAINE AND CARDIOVASCULAR RISK?

B. Pardiñas Barón[1], S. Santos Lasaosa[1], Á. Flamarique Pascual[2], J. Navarro Calzada[2], E. Bellosta Diago[1], I. Torres Courchoud[2]

[1]Department of Neurology, [2]Department of Internal Medicine. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: Epidemiological studies support the association between migraine and vascular disorders. In this study we assessed the cardiovascular risk in migraineurs by analytical, anthropometric and sonographic parameters.

Material and method: We investigated 39 migraineurs and 39 controls matched for sex and age. We obtained the following vascular risks: body mass index (BMI), total cholesterol, serum levels of C-reactive protein (CRP), lipoprotein (a), homocysteine, leptin, anckle-brachial index (ABI) and carotid intima-media thickness (CIMT).

Results: Compared with control subjects, BMI, CRP and CIMT were elevated in migraine, difference was significant. Mean BMI for migraineurs was 25.77 and for controls it was 23.45 (p = 0.038), mean CRP for migraineurs was 0.37 and for controls 0.20 (p = 0.048) and mean CIMT for migraineurs was 0.547 and for controls it was 0.504 (p = 0.028). Homocysteine and leptin were increased in migraineurs compared to controls but the study exhibited no statistically significant difference, homocysteine (p = 0.052) and leptin (p = 0.077). We found abnormal values of ABI in 3 healthy subjects (7.7%) and in 7 migraineurs (19.7%) but difference was not significant (p = 0.176).

Discussion: In the last decade, there has been increasing evidence that migraine is associated with specific vascular risk profile and it seems that migraineurs develop more severe and early atherosclerosis. Besir et al found a statistically significant difference between the CIMT values of migraine patients and those of controls. Sherifa et al demonstrate strong evidence of association among migraine and increased CIMT. They also observed that migraine is associated with increased levels of CRP and this result supports the role of inflammation in migraine. Ikeda et al. described a higher frequency of pathological ABI values in migraineurs than in healthy subjects and they suggested that their finding is of relevance and may at least partially explain the increased cardiovascular risk of their population.

Conclusions: The present study indicated higher BMI, serum levels of CRP and CIMT in migraineurs. ABI did not differ statistically

between migraineurs and controls but pathological values are more common in migraineurs. We could measure ABI and CIMT as an easy way to screen cardiovascular risk in migraine patients but further studies are needed to confirm it.

RV-67
PREVALENCE OF PERIPHERAL ARTERIAL DISEASE ASYMPTOMATIC IN HOSPITALIZED PATIENTS AT THE INTERNAL MEDICINE UNIT OF THIRD LEVEL HOSPITAL

J. Ampuero Ampuero, A. Jurado Porcel, R. Martínez Fernández, R. Ruiz Ortega, M. Martín Moreno, M. Carracedo Melero, M. Montero Pérez-Barquero

Department of Internal Medicine. Hospital Universitario Reina Sofía. Córdoba, Spain.

Objectives: Known the prevalence of peripheral arterial disease (PAD) asymptomatic and the assessment of associated factors in hospitalized patients at the Internal Medicine Unit of third level hospital.

Material and method: This is a transversal descriptive study. In total 75 patients were studied, they were hospitalized for a week in the internal medicine unit. Were excluded 20 patients for severe clinical situation or previously diagnosed of peripheral arterial disease. The diagnostic was made by measurement of ankle-brachial pressure index (ABI), defined PAD as ABI < 0.9. The ABI > 1.40 was excluded. The variables were: Age, gender, antecedents and vascular risks factors, comorbidity and Edinburgh test.

Results: A total of 55 subjects (56.4% men) were included. The mean age (standard deviation) was 83 (6.4) years.10.9% (6) patients had pathological ABI, 83.3% (5) were diabetics. From the 26 diabetics patients, 21 (80.8%) had normal ABI and 5(19.2%) had pathological ABI. 12.8% (6/47) patients with arterial Hypertension had a pathological ABI, on the other hand, there were No PAD in patients without hypertension. From 100% (6) patients with Hypertension and pathological ABI, 66.7% (4) take > 3 drugs. The 83.3% (5) patients with pathological ABI are obese and the 16.7% (1) have no obesity. The glomerular filtration from the pathological ABI patients (6) was 34.70 + 13.20 ml/min versus 55.41 + 26.51 ml/min from normal ABI patients (49). The systolic arterial blood pressure of pathological ABI patients was 142.5 + 27.58 mmHg versus systolic arterial blood pressure of 125.02 + 20.33 from normal ABI patients (49).

Discussion: In our study the prevalence of PAD was 10.9%, with a greater frequency in diabetic patients. The prevalence in previous studies in Primary Care varies between 5 and 30%. In hospitalized patients the prevalence is 36%, but with a high proportion of cardiovascular diseases. One limitation of our study is the little due to the recruitment period was carried out in a week.

Conclusions: The prevalence of asymptomatic peripheral arterial disease is high. It's related with hypertension, diabetes, obesity and glomerular filtration.

RV-68
RECOMMENDATIONS FOR MODIFIABLE CARDIOVASCULAR RISK FACTORS IN PATIENTS DISCHARGED FROM AN INTERNAL MEDICINE WARD

C. Mejía Chew, G. Salgueiro, R. Mican, M. López Rodríguez, F. Barbado Hernández, F. Arnalich, J. García Puig

Department of Internal Medicine. Hospital Universitario La Paz. Madrid, Spain.

Objectives: To determine the relation between identification of modifiable cardiovascular risk factors and the recommendations reflected in the discharge reports.

Material and method: This retrospective study analyzed medical discharge reports (convenience sampling) between January 2008 and December 2010. Five modifiable cardiovascular risk factors were analyzed: hypertension, dyslipidemia, diabetes, smoking and obesity. Definition of risk factors was made on the basis of previous diagnosis or current treatment (pharmacologic and non-pharmacologic) for each individual risk factor. One point was given for the presence of each risk factor, up to a maximum of 5 points. We looked for the specific treatment recommendations (pharmacologic and non-pharmacologic) for each risk factor, reflected in the discharge report, and one point was also given for each specific recommendation for each individual risk factor. Recommendations were considered adequate if there was an equal relation between the number of risk factors and the number of recommendations.

Results: We analyzed 175 patients (54% men) who had a mean age of 67.8 years, of whom 91% had at least one cardiovascular risk factor and 45% presented two or more risk factors. Hypertension was the most prevalent (59%), followed by smoking (49%) and dyslipidemia (36%). The mean number of cardiovascular risk factors was 1.64 and the mean number of recommendations given in the discharge reports was 0.83. Treatment recommendation at discharge were given in 72% of discharge reports; being concordant to the identified risk factor in 50% of the cases.

Conclusions: Almost all patients hospitalized in an internal medicine ward of a university hospital in Madrid, showed at least one cardiovascular risk factor and nearly a third of the patients did not receive any recommendation in the treatment orders at discharge. Among the patients that received recommendations, these were incomplete in about half of the discharge reports.

RV-70
ASSOCIATION BETWEEN THE HYPERTRIGLYCERIDEMIC WAIST (HTW), DIABETES MELLITUS 2 (DM2) AND CARDIOVASCULAR DISEASE (CVD)

D. Narankiewicz, A. Villalobos Sánchez, C. Lara Rojas, V. Vallejo Herrera, V. Buonaiuto, V. Gómez Carrillo, R. Bernal López, R. Gómez Huelgas

Department of Internal Medicine. Hospital General. Málaga, Spain.

Objectives: Estimation of the prevalence of the HTW, its epidemiological and clinical characteristics and its association with DM2 and CVD in a sample group of population of the city of Malaga.

Material and method: An epidemiological and transversal study of a representative random sample of 2,492 consecutive adult patients attended in a health centre in Malaga was designed. The recruitment period was January-June of 2007 with inclusion criteria of age 18-80, possibility of access to the health centre and a signed informed consent. Pregnant women, patients with severe mental disorders, serious/terminal diseases, alcoholism/drug addiction or hospitalized during the study period were excluded. Four educational categories were established: illiteracy and primary education (classified as low educational level), secondary and university education (average-high educational level). Three physical activity levels were distinguished: no activity, occasional (< 150 min/week of a moderate pace walking) and regular activity. The first two ones were considered as sedentary lifestyle. Obesity and overweight were diagnosed by the WHO criteria. Hypertension was defined by systolic blood pressure of at least 140mmHg and/or diastolic of at least 90 mmHg or if any antihypertensive drug was used. Diabetes was diagnosed when previously reported or by the HbA1c of at least 6.5%; prediabetes when HbA1c was 5.7%-6.4% or

by fasting glucose between 100 and 125 mg/dl. The diagnosis of CVD was made if a history of ischemic cardiopathy, heart failure, aortic aneurysm, cerebrovascular disease or peripheral arteriopathy was referred. HTW was diagnosed by the WHO anthropometric criteria for the European population (waist of at least 94 cm in men and 80 cm in women) with a fasting level of triglycerides of at least 150 mg/dl.

Results: The prevalence of HTW was 14.5%, being higher in men (18.2%) than in women (10.8%) ($p < 0.001$). Patients with HTW were older (median age of 50.2 ± 14 years), with lower educational level ($p < 0.001$) and sedentary lifestyle ($p < 0.001$). They had as well mayor: BMI, waist perimeter, prevalence of obesity and higher levels of blood pressure. The levels of HbA1c, glucose, uric acid, total cholesterol, LDL were higher and the levels of HDL cholesterol were lower ($p < 0.001$) compared to those without HTW. The presence of HTW was associated with DM2, CVD and coronary disease with an OR (95%CI) of 3.61 (2.60-5.01) ($p < 0.001$), 2.63 (1.66-4.16) ($p < 0.001$) and 1.95 (1.06-3.61) ($p = 0.03$), respectively. The association between HTW and CVD was maintained after being adjusted for sex, blood pressure, smoking habit, sedentary lifestyle, glucose, LDL and HDL cholesterol, but disappeared while adjusted for age. Regarding the association between HTW and DM2, it was maintained after the adjustment for sedentary lifestyle and smoking habit, but disappeared after the adjustment for age and BMI.

Discussion: Data from transversal and prospective studies of the association between HTW and CVD are available. The CV risk associated with HTW was evidenced in normoglycaemic, intolerant to glucose and in DM2 patients. The metabolic atherogenic triad characteristic of HTW was demonstrated to be a stronger marker of the coronary disease in men than the conventional lipid triad. HTW in DM2 can identify a subgroup with mayor visceral adiposity and mayor level of subclinical coronary atherosclerosis. Moreover, it can be a good marker of glucose metabolism alterations.

Conclusions: HTW can be a useful screening tool for a group of patients with a high cardiometabolic risk and could be an alternative for metabolic syndrome. There are necessary more prospective studies to be done to evaluate its utility as a marker of the vascular risk and DM2.

RV-71
EFFECT OF GLP1 ANALOGUES ON BODY WEIGHT IN PATIENTS ATTENTED IN A GENERAL INTERNAL MEDICINE DEPARTMENT. ALCOY'S HOSPITAL EXPERIENCE

C. Pérez Ortiz, Á. Collazos Stüwe, J. Guerrero González, M. Esteban Giner, M. Nicolau Laparra, V. Giner Galvañ

Department of General Internal Medicine. Hospital Verge dels Lliris. Alcoy (Alicante), Spain.

Objectives: To show the clinical direct experience with GLP1 for the treatment of usual patients attended in a Spanish General Internal Medicine Department (older, pluripathological and plurimedicated patients) where both obesity and diabetes are very common.

Material and method: Retrospective review of medical registrations of patients attended in our General Internal Medicine Department (outpatients as well as inpatients) treated with GLP1 analogues from year 2009 to May 2012.

Results: 25 patients (aged 71.1 ± 2.2 years, 32% older than 79 years, 60% females, having 7.1 ± 0.8 drugs/day in 9.4 ± 1.0 times/day) were included for the study with near one year (11.3 ± 1.5 months) of treatment with exenatide (76%) or liraglutide (24%). All the patients had a previous diagnosis of type 2 DM and hypertension. Previous Obesity diagnosis was present in 84% of cases, and metabolic syndrome prevalence according with ATPIII, IDF2005 and 2009 Consensus were 84, 64 and 84% respectively. Sleep apnoea syndrome were present in 44% of cases, and a third of patients were on secondary cardiovascular prevention (40% peripheral vasculopathy, 28% coronary illness, 28% chronic heart failure, 12% previous stroke). Basal weight (mean) was 90.1 ± 2.5 Kg, with HbA1c 7.4 ± 0.3% and fasting glycaemia 150.5 ± 7.0 mg/dL. Weight values were 84.8 ± 2.8, 80.6 ± 3.1 and 79.4 ± 4.1 Kg after 3.2 ± 0.5, 6.2 ± 0.8 and 9.5 ± 1.3 months of follow up. The differences in weight at the visits respect to the previous one were: -4.5 ± 1.6 ($p < 0.0001$), 6.2 ± 0.8 ($p = 0.002$), 9.5 ± 1.3 ($p = 0.130$). The difference in weight at the final visit compared to the basal value was -1.5 ± 3.6 Kg with a large individual heterogeneity and a median (interval) weight loss of -0.5 (-11 to +6) Kg ($p = 0.376$).

Discussion: GLP1 analogues induce a significant and early diminution of weight in older and pluripathological patients attended in a General Internal Medicine Department, although the response is highly variable depending on each patient with weight losses greater than 10 Kg after one year of treatment.

Conclusions: GLP1 analogues seem to be a good option for the treatment of old and pluripathological obese diabetics, although the potential response is highly heterogeneous and individual.

RV-72
CARDIOVASCULAR RISK FACTORS AND PHYSICAL ACTIVITY IN INSTITUTIONALIZED PATIENTS WITH SEVERE MENTAL DISORDER

M. Lara Culebras[1], R. Huerta Ramírez[2], M. Cabello Salmerón[3]

[1]Department of Internal Medicine, [2]Department of Mental Health. Hospital Sagrado Corazón de Jesús. Complejo Asistencial Benito Menni. Ciempozuelos (Madrid), Spain. [3]Instituto Carlos III. CIBERSAM. Hospital Universitario de La Princesa. Madrid, Spain.

Objectives: Patients with psychiatric disorders (PD) have higher prevalence of cardiovascular risk factors (CRFs) than the general population, as has been analyzed by many authors. This fact is related to aspects such as: unhealthy dietary habits, use of drugs associated with development of metabolic syndrome, as in the case of neuroleptics, as well as with lower regular physical activity (PA). PA regularly executed by institutionalized patients with severe mental disorder (SMD; id est, psychotic disorders, major affective disorders and personality disorders), is expected to be effective for improve CRFs, such as control of BMI and maintaining of blood pressure levels, lipid profile and blood glucose in normal ranges. However, these factors still have not been studied on institutionalized psychiatric patients. In this study, the objective is to analyze the effect of a periodical program of PA on the CRFs in institutionalized patients with SMD.

Material and method: An interventional study with two measures before and after a usual physical activity program was performed. Sample consisted of women and men ranging from 18 to 65 years old, with SMD, who have been admited in mid-term hospital and suffer from overweight (BMI > 25). Measures were: BMI, blood pressure, cholesterol, triglycerides, fasting glucose. Comparisons pre and post intervention were performed with no-parametric Wilcoxon test.

Results: There was not a statistically significant reduction of CRFs after intervention. However, categorizing variables by their rank values, a marginal trend to improve was observed in several parameters, such as BMI (16% of patients reduced their weight to normal values after the intervention), arterial tension (100% of patients reduced it to normal values) and glucose levels (improvement from a 16.7% of high levels to an 8.3%).

Discussion: Results of this study should be interpreting in the light of these limitations: small sample size, absence of control group, no control on patient's dietetic intake and no control on

type of pharmacological treatments used. In spite of these limitations our findings highlighted that there was a high prevalence of CRFs factors in institutionalized patients. Physical programs could help to patients to reduce the risk of cardiovascular problems. In this sense, results shows the relevance of be careful about the risk of breaching treatments (dietetic or pharmacological ones) applied on CRFs, at same level than in the general population, who also has a high prevalence of treatment and preventive neglect. This is especially relevant at institutionalized psychiatric population, who have access to ordinary risk dietetic factors as part of the normalization of their lives.

Conclusions: Although this study could not demonstrate that our physical activity program reduced CRFs significant, a marginal improvement on several parameters was observed. Further studies with a greater sample size and a control group should demonstrate whether physical activity program was useful to reduce CRFs. In addition, further studies should be analyzed whether different types of physical activity programs are related to higher reduction on CRFs. It is important to develope preventive strategies on dietary and treatment neglect in order to improve cardiovascular health of patients with SMDs.

RV-73
TOLERABILITY OF GLP1 ANALOGUES IN PATIENTS ATTENDED IN A GENERAL INTERNAL MEDICINE DEPARTMENT. ALCOY'S HOSPITAL EXPERIENCE

J. Guerrero González, C. Pérez Ortiz, Á. Collados Stüwe, M. Esteban Giner, S. Martínez Tudela, M. Nicolau Laparra, V. Giner Galvañ

Department of General Internal Medicine. Hospital Verge dels Lliris. Alcoy (Alicante), Spain.

Objectives: To analyze the tolerability of GLP1 analogues in the treatment of patients attended in a Spanish General Internal Medicine Department. The expectable high age, pluripathology and polypharmacy in this kind of patients make them with a high potential low tolerability.

Material and method: Retrospective review of medical registrations of patients attended in our General Internal Medicine Department (outpatients as well as inpatients) from year 2009 to May 2012 in which GLP1 analogues were prescribed.

Results: 25 patients (aged 71.1 ± 2.2 years, 32% older than 79 years, 60% females, 7.1 ± 0.8 drugs/day in 9.4 ± 1.0 times/day) were included for the study with near one year (11.3 ± 1.5 months) of treatment with exenatide (76%) or liraglutide (24%). All the patients had a previous diagnosis of type 2 DM. Main chronic comorbidities prevalences (%) were: 100 hypertension, 84 obesity, 84 ATPIII metabolic syndrome (MS), 64 IDF2005 MS, 84 2009 Consensus MS, 44% sleep apnoea syndrome, 40% peripheral vasculopathy, 28% coronary illness, 28% chronic heart failure, 12% previous stroke. GLP1 analogues were withdrawal in 8 patients: 7 in 19 having exenatide (36.8%) and 1 in 6 having liraglutide (16.6%). The weight loss was similar during all the follow-up comparing tolerant and intolerant patients. Intolerant patients were younger (73.6 ± 11.3 vs 65.9 ± 3.6 years with 41.2 vs 12.5% older than 79 years. p = 0.115 and 0.152 respectively) and received less associated medications (7.8 ± 3.4 vs 5.6 ± 3.4 drugs/day taken in 10.3 ± 5.6 vs 7.3 ± 5.6 doses/day. p = 0.205 and 0.220). Cardio metabolic risk factors were similar comparing tolerant and intolerant patients.

Discussion: Although patients attended in a General Internal Medicine Department are potentially at high risk to in tolerate GLP1 because of very high age and multiple pharmacological treatments and illnesses, it has not been the case, with GLP1 analogues having a high tolerability. There is not a clear profile of patients especially on risk. Main reason to withdrawal such drugs is gastrointestinal intolerance.

Conclusions: GLP1 analogues are well-tolerated in patients in a General Internal Medicine Unit. Vomits are the usual reason to stop this treatment.

RV-74
OBESITY-RELATED PHENOTYPIC DIFFERENCES IN ADULTS WITH DOWN'S SYNDROME

D. Real de Asúa, R. Costa, P. Parra, F. Moldenhauer, C. Suárez

Department of Internal Medicine. Hospital Universitario de La Princesa. Madrid, Spain.

Objectives: Adults with Down's syndrome (DS) present a different cardiovascular risk profile from the general population's, mainly owing to a higher prevalence of obesity in the former group. However, major vascular events are virtually absent among adults with DS. We aim to 1) compare obesity-related phenotypes, focusing on dietary, morphologic, and metabolic differences in adults with DS versus a non-trisomic cohort, and 2) to evaluate the impact of hypothyroidism on this phenotype.

Material and method: Cross-sectional study of 62 subjects recruited at the adult Down syndrome unit of the Hospital Universitario La Princesa, Madrid, Spain, between January and May 2012. Control was most frequently siblings of these adults with DS, and was matched by age, and gender. Epidemiological (age and gender), anthropometric (height, weight, body mass index [BMI], waist circumference, and% body fat), dietary (daily dietary fat, fruit and fiber consumption), and analytical variables (fasting glucose, insulin, HbA1c, lipid profile, and TSH/free T4) were measured. Results were compared with non-parametric tests.

Results: 33 adults with DS and 29 controls were enrolled (age: DS 38 ± 11 vs controls 44 ± 13 years; gender: 19 males with DS [58%] vs 11 males in the control group [38%]; p non-significant for both comparisons). Adults with DS had a higher BMI (30.0 ± 4.7 vs 25.9 ± 3.6 Kg/m^2; p < 0.001), and were more frequently overweight or obese (p < 0.001 for the distribution). However, DS adults ate more fruit/vegetables portions daily and had a higher intake of dietary fiber than controls (fruit/vegetables portions: 4 ± 1 vs 3 ± 1; p < 0.01, daily dietary fiber 19 ± 4 g vs 16 ± 3 g; p < 0.01). We found no difference in waist perimeter, prevalence of abdominal obesity, or total body fat percentage between groups, neither did we find gender differences. Only three adults with DS (9%) and two control subjects (11%) met ATPIII metabolic syndrome criteria. Adults with DS also had higher HOMA-IR index values (3.87 ± 3.24 vs 2.35 ± 0.92; p < 0.05), and eight of them (24%) fulfilled criteria for insulin resistance (vs 0 controls; p < 0.05). Adults with DS and hypothyroidism (n = 8) had the highest BMI (33.1 ± 5.5 vs 29.0 ± 4.1 vs 25.9 ± 3.6 Kg/m^2; p < 0.001) and HOMA-IR index values (5.85 ± 3.77 vs 3.06 ± 2.7 vs 2.35 ± 0.92; p < 0.01) when compared to euthyroid adults with DS and controls. They also presented a higher prevalence of insulin resistance (4/8 [50%] vs 4/21 [16%] euthyroid adults with DS vs 0/18 controls; p < 0.01), and significantly lower serum HDL-cholesterol levels (50 ± 15 vs 60 ± 15 vs 63 ± 15 mg/dL; p < 0.01).

Discussion: Despite a slightly healthier diet than controls, obesity is a common feature in adults with DS. Although abdominal obesity was not more prevalent in this population, adults with DS presented a higher prevalence of insulin resistance. Hypothyroidism worsens this phenotype, since hypothyroid adults with DS presented even higher BMI and insulin resistance rates than their euthyroid peers.

Conclusions: Adults with DS present significant obesity-related morphologic, and metabolic differences compared to control

subjects, which are further enhanced by the presence of hypothyroidism.

RV-75
GENETICS VARIATIONS INFLUENCE POSTPRANDIAL LIPIDS OF THREE DIFFERENT POPULATIONS

P. Pérez Martínez[1], A. Pérez Caballero[1], N. Delgado Casado[1], A. García Ríos[1], A. Dembinska Kiec[2], H. Roche[3], J. López Miranda[1], J. Delgado Lista[1]

[1]Department of Internal Medicine. Hospital Universitario Reina Sofia/IMIBIC/CIBER OBN/UCO. Córdoba, Spain. [2]Department of Biochemistry. Clinical Biochemistry, Jagiellonian University Medical College. Krakow, Poland. [3]Department of Nutrition. Nutrigenomics Research Group, UCD School of Public Health and Population Science, UCD Conway Institute, University College Dublin. Dublin, Ireland.

Objectives: TCF7L2 rs7903146 is an important genetic factor predicting type 2 diabetes (T2DM), and it has also been related to higher cardiovascular risk. To date, there is little information about the additional impact of this single nucleotide polymorphism (SNP) beyond glucose metabolism. Our aim was to explore whether rs7903146 influenced postprandial lipid metabolism in three different populations (healthy young men, metabolic syndrome (MetS) and elderly persons).

Material and method: Eighty eight healthy males were submitted to a single saturated fatty acid-rich test meal. Additionally, 110 middle-aged MetS persons and 20 healthy elderly persons (≥ 65 years) were submitted to three different dietary models followed by test meals. The amount of fat given, per kg body wt, was 1 g fat and 7 mg cholesterol. The meal contained 65% of energy as fat, 10% of energy as protein, and 25% of energy as carbohydrates; it was consumed in 20 min.

Results: Minor allele homozygotes for rs7903146 showed a worse postprandial lipemia profile in young males, as seen by a lower HDL-cholesterol and Apo A1 concentration during the postprandial lipemia and a trend towards higher triglycerides (TG), than the other genotypes. In healthy elderly persons, carriers of the minor allele showed higher total cholesterol, LDL-cholesterol, Apo B and TG in the fasting state, and a higher postprandial area under the curve for total cholesterol, Apo B, small-TRL cholesterol and small-triglyceride rich lipoproteins (TRL) triglycerides. These results were accompanied by differential changes in adipokines.

Discussion: In contrast to the burgeoning existing data on the influence of TCF7L2 variations on glucose metabolism, which is the subject of over 80 studies, their influence in postprandial lipids is at present unexplored, with only one study reporting an altered postprandial lipid profile in high polyunsaturated fatty acids (PUFA) consumers. Furthermore, neither the effects on different populations nor their possible underlying mechanisms (beyond the beta-cell function) have been explored, despite the well-known regulation of adipocyte differentiation by TCF7L2. Our study shows for the first time that carriers of the rare allele of TCF7L2 rs7903146 have a disrupted lipid metabolism, which is seen in different ways depending on age and baseline conditions.

Conclusions: Healthy young males and elderly persons who are carriers of the mutant allele for rs7903146 have an impaired postprandial lipid metabolism that may be mediated by an alteration in adipokine regulation, and may be related to the higher cardiovascular risk observed in these persons.

RV-76
GENE-NUTRIENT INTERACTIONS AT THE PHOSPHOENOLPYRUVATE CARBOXYKINASE INFLUENCE INSULIN SENSITIVITY IN METABOLIC SYNDROME SUBJECTS

A. García Ríos[1], N. Delgado Casado[1], A. Pérez Caballero[1], P. Pérez Martínez[1], J. Delgado Lista[1], L. Consortium[2], F. Fuentes Jiménez[1], J. López Miranda[1]

[1]Hospital Universitario Reina Sofía/IMIBIC/CIBEROBN/UCO. Córdoba, Spain. [2]Lipgene Consortium. Lipgene Consortium. Dublin, Ireland.

Objectives: Genetic background may interact with habitual dietary fat composition, and affect development of the metabolic syndrome (MetS). The phosphoenolpyruvate carboxykinase gene (PCK1) plays a significant role regulating glucose metabolism, and fatty acids are key metabolic regulators, which interact with transcription factors and influence glucose metabolism. We explored genetic variability at the PCK1 gene locus in relation to degree of insulin resistance and plasma fatty acid levels in MetS subjects. Moreover, we analyzed the PCK1 genetic variants effect in its gene expression level in adipose tissue.

Material and method: Insulin sensitivity, insulin secretion, glucose effectiveness, plasma concentrations of C-peptide, fatty acid composition and three PCK1 tag-single nucleotide polymorphisms (SNPs) were determined in 443 MetS participants in the LIPGENE cohort.

Results: The rs2179706 SNP interacted with plasma concentration of n-3 polyunsaturated fatty acids (n-3 PUFA), which were significantly associated with plasma concentrations of fasting insulin, peptide C, and HOMA-IR. Among subjects with n-3 PUFA levels above the population median, carriers of the C/C genotype exhibited lower plasma concentrations of fasting insulin ($p = 0.036$) and HOMA-IR ($p = 0.019$) as compared with C/C carriers with n-3 PUFA below the median. Moreover, homozygous C/C subjects with n-3 PUFA levels above the median showed lower plasma concentrations of peptide C as compared to individuals with the T-allele ($p = 0.006$). Interestingly, subjects carrying the T-allele showed a lower gene PCK1 expression as compared with carriers of the C/C genotype ($p = 0.015$).

Discussion: In our study we observed a gene-fatty acid interaction among subjects with the rs2179706 SNP and plasma levels of n-3 to influence insulin resistance, suggesting the potential sensitivity of this SNP to dietary factors. Genetic variation promoting enhanced PCK1 transcription might lead to increased PEPCK-C enzymatic activity, which would increase insulin resistance through its effect on gluconeogenesis.

Conclusions: The PCK1 rs2179706 polymorphism interacts with plasma concentration of n-3 PUFA levels modulating insulin resistance in MetS subjects.

RV-77
POSTPRANDIAL LIPID METABOLISM IS INFLUENCED BY ICA1L GENE VARIANT (RS10870) IN HEALTHY MEN

N. Delgado Casado, A. García Ríos, A. Pérez Caballero, P. Pérez Martínez, J. Delgado Lista, J. Alcalá Díaz, A. Gómez Garduño, J. López Miranda

Hospital Universitario Reina Sofía/IMIBIC/CIBEROBN/UCO. Córdoba, Spain.

Objectives: Islet cell autoantigen 1(ICA1L) gene has been related to Golgi apparatus structure. However, there are not clear data on possible function of this gene in human metabolism. We studied the effect of a gene variant (rs10870) influence on postprandial lipid metabolism.

Material and method: 88 normolipidemic young men were given a fatty meal. Blood samples were drawn just prior to the meal and postprandially every hour until 6 hours, and then every 2 hours and 30 minutes until 11 hours.

Results: For rs10870 single nucleotide polymorphism, carriers of the minor allele (CT/TT) displayed lower postprandial concentrations of large triglyceride-rich lipoprotein triglycerides (Large-TRL TG) than did subjects homozygous for the major allele ($p = 0.029$). In addition, for the same polymorphism, subjects carriers of the minor allele had significantly lower amounts of accumulated postprandial Large-TRL TG compared with homozygous for the major allele ($p = 0.014$). On the other hand, the postprandial area under the curve (AUC) in study participants according to the ICA1L polymorphism were analyzed. Interestingly, the AUCs for Large-TRL TG ($p = 0.041$) were lower in persons carrying the minor T allele than in those carrying the CC genotype for rs10870.

Conclusions: The presence of the minor allele for rs10870 polymorphism at ICA1L gene, is associated with a lower postprandial response which accounts for a lower cardiovascular risk. However, due to the novelty of our findings further studies to replicate these findings may be performed.

RV-78
PRIMARY ALDOSTERONISM IN OLD AGE

N. Alonso Villaba, S. Moreno Casas, S. Suárez Ortega, J. Artiles Vizcaíno, A. Gil Díaz, Y. Hernández Aguiar, P. Betancor León

Department of Internal Medicine. Hospital Universitario de Gran Canaria Doctor Negrín. Las Palmas de Gran Canaria, Spain.

Objectives: Primary aldosteronism (PA) is an uncommon cause of hypertension in old age. We present a descriptive study about PA in the hypertensive patients over 65 years, in a hypertension office. Key words: Hypertension. Primary aldosteronism. Old age.

Material and method: Two thousand hypertensive patients have been studied in office due to resistant hypertension or suspicion of secondary hypertension. A protocol which included analytics, electrocardiogram and ultrasonic abdominal was made to all hypertensive patients. In order to realize aldosteronemia (AI) and basal plasma renin activity (PRA) we required: 1) An unknown cause of kaliemia < 4 mEq/l, 2) inappropriate kaliuria (potassium in urine collection of 24 hours urine > 30 mEq, with normal kaliemia), or 3) increased adrenal size in the ultrasonic study. Aldosteronemia and PRA were made with a diet of 200 mEq of NaCl, in supine. A ratio AI/PRA over 30, with high aldosteronemia and suppressed PRA, confirmed PA diagnosis. Other tests were made in order to differentiate hyperplasia from adenoma. Data was processed using SPSS 16.

Results: PA was demonstrated in 62 of 2,000 hypertensive adults patients; 17 (27.4%) of them were diagnosed in the geriatric age. The characteristics of geriatric cases were: Mean age 71 ± 5 years (range 65-85 years); Eight (47.1%) were women. In all cases the kaliemia was < 4 mEq/l (mean of 3.45 mEq/l, range of 2-4 mEq/l), and the aldosteronemia was higher than 17 mcg/dl (mean: 30 ± 12 mcg/dl range 17-65). The ratio A/PRA was greater than 30 in all cases (mean 113.6, range from 34-325). Low basal PRA and suppressed PRA, and inappropriate kaliuria (mean 82.2 ± 18.5 mEq/day, with range 49-122) were observed in all cases. Ultrasonic study and abdominal CT was realized to the 17 patients. Adrenal nodules were detected in: 1) 2 patients (11.7%) by ultrasonic study, and 2) 10 patients (58.8%) by abdominal CT (with a diameter bigger than one cm). The remainder patients (PA with normal-sized adrenal) were diagnosed of adrenal hyperplasia. Laparoscopic adrenalectomy was performed in 6 cases. All cases, including those which were performed adrenalectomy, needed other treatment for blood pressure control (antialdosteronic plus other antihypertensive drugs). Comparing 17 PA in geriatric age with 45 cases below 65 years old by bivariate analysis, the existence of an adrenal nodule and the need of antihypertensive treatment after surgery ($p < 0.05$) were statistically significant.

Discussion: The primary aldosteronism usually affects the middle age. In most series, PA is also diagnosed in some elderly patients. The clinical features, complementary tests and treatment are similar in old age as in adulthood.

Conclusions: 1) Potassium < 4 mEq/l has been the main guide for the diagnosing research of the PA. 2) The presence of high aldosteronemia and low basal PRA is constant in the PA. 3) These tests (associated with abdominal CT) are usually enough for the diagnosis of PA in the old age. 4) The existence of an adrenal nodule (Conn Syndrome) is more common in the PA in old age.

RV-79
CLINICAL RELEVANCE OF TREATMENT WITH HIGH DOSES OF ATORVASTATIN IN A COHORT OF PATIENTS WITH PERIPHERAL ARTERIAL DISEASE: PRELIMINARY RESULTS

M. Rico Corral[1], M. Domínguez Álvarez[1], N. Jiménez Barquero[1], M. Romero Correa[1], R. Pérez Cano[1], F. Fabiani Romero[2]

[1]Department of Internal Medicine, [2]Clinical Laboratory. Complejo Hospitalario Regional Virgen Macarena. Sevilla, Spain.

Objectives: Peripheral arterial disease is a highly prevalent entity, especially in diabetics. Statins have clinical and analitical beneficial effects in patients with coronary and cerebral atherosclerosis. We intend to study the effect of high doses of atorvastatin in the evolution of lower limbs arterial disease.

Material and method: We compared two groups of patients with lower limbs arterial disease. The study group was treated with 80 mg atorvastatin daily, and control with lower dose or another statin. Mean follow-up was close to 18 months. Vascular risk associated biochemical parameters were measured at the beginning and at the end of the study, and cardiovascular events and mortality were registered.

Results: The mean age was 67.63 years. The majority were male (77.2% in the study group, 81.6% in the control group, $p = 0.578$), with hypertension (68.3% in the study group, 71.1% in the control group, $p = 0.756$), and diabetes (82.2% in the study group, 76.3% in the control group, $p = 0.436$). In both groups occurred, at the end of follow-up, a significant decrease in serum total cholesterol (47.78 mg/dl in the study group, $p = 0$, and 57.28 mg/dl in the control group, $p = 0$), its low density fraction (44.8 mg/dl in the study group, $p = 0$, and 44.48 mg/dl in the control group, $p = 0$) and apolipoprotein B-100 (25.91 mg/dl in the study group, $p = 0.001$, and 26.2 mg/dl in the control group, $p = 0.036$) but in the atorvastatin 80 group there was also a reduction of triglycerides (31.71 mg/dl, $p = 0.033$), non-high density cholesterol (65.5 mg/dl, $p = 0$) and C-reactive protein (4.56 mg/l,$p = 0.044$). In addition, the atorvastatin 80 group had a final homocysteine serum concentration lower than the control group (respectively, 14.6 mg/dl and 30.51 mg/dl, $p = 0.008$). There was no difference in cardiovascular events in both lower limbs as brain or heart, or mortality.

Conclusions: In peripheral arterial disease, atorvastatin, at doses of 80 mgr daily, reduces serum C-reactive protein and homocysteine, in addition to its known effects on plasma lipids. Our study needs to be continued in order to find effects on cardiovascular events and mortality.

RV-80
GENETIC VARIATION AT THE CEBPA GENE MODIFIES POSTPRANDIAL LIPID METABOLISM OF METABOLIC SYNDROME PATIENTS: LIPGENE STUDY

A. Pérez Caballero, N. Delgado Casado, J. Delgado Lista, A. García Ríos, P. Pérez Martínez, F. Fuentes, A. Gómez Garduño, J. López Miranda

Hospital Universitario Reina Sofía/IMIBIC/CIBEROBN/UCO. Córdoba, Spain.

Objectives: CCAAT/enhancer-binding protein alpha (CEBPA) is a transcription factor that has been related to adipocyte differentiation from pre-adypocite. A previous work reported that a variation in the CEBPA gene (rs12691) may be associated with triglyceride fasting concentration. However, effects of this gene variation on postprandial lipid metabolism have not been studied to date. Metabolic syndrome patients (MetS) are a population at high risk for developing type 2 diabetes mellitus, and they have a disrupted lipid metabolism. LIPGENE Clinical Trials registry (NCT00429195).

Material and method: A multi-center, parallel, randomized, controlled trial conducted within the LIPGENE study randomly assigned MetS patients to 1 of 4 diets: high-saturated fatty acid, high-monounsaturated fatty acid, and 2 low-fat, high-complex carbohydrate diets supplemented with 1.24 g/d of long-chain (n-3) PUFA or placebo for 12 wk each. A fat challenge with the same fat composition as the diets was conducted pre- and postintervention, and lipid fractions were assessed.

Results: Postprandial TG were higher in the carriers of the minor allele (GA/AA) both at the pre-intervention (p 0.018) and post-intervention (p 0.033) measurements, with differences at all timepoints (0, 2, 4, 6 and 8 hours). These carriers also showed a lower HDL (p 0.026 and p 0.018), and a trend to higher large-TRL TG (p 0.092) and apoB-48 (p 0.060), irrespectively of the diet consumed.

Conclusions: CEBPA rs12691 minor allele carriers exhibit a more atherogenic postprandial lipemia. This finding suggests that the triglyceride levels of these persons should be be strictly controlled.

RV-81
COST/EFFECTIVENESS ANALYSIS OF INTENSIVE VERSUS CONVENTIONAL TREATMENT ON PATIENTS WITH TYPE-2 DIABETES MELLITUS

C. de la Puerta González Quevedo, M. Hernández Sánchez, A. Alonso Pacho, A. Esperanza Barrios, R. Fabregate Fuente, M. Fabregate Fuente, J. Sabán Ruiz

Department of Endothelial Pathology. Department of Internal Medicine. Ramón y Cajal Hospital. Madrid, Spain.

Objectives: To evaluate the costs and incremental cost-effectiveness of intensive treatment versus standard treatment in patients with type-2 diabetes mellitus (DM).

Material and method: 650 of our patients are type 2 diabetic ones. From that subgroup, we chose those of them who arrived to our unit in 2010 and were reevaluated during 2011. A retrospective observational study of these patients was performed. The costs and effectiveness of the initial treatments were estimated, as well as those of the treatments after one year of therapy. Effectiveness was defined as the decrease in clinical units after intensive treatment by a specialist. The patients data that were collected included age, sex, weight, height, BMI, years since diabetes diagnosis, family history of premature coronary disease (PCD), smoking, retinopathy, nephropathy and blood pressure, as well as analytical data: cholesterol, HDL, LDL, glucose, glycated hemoglobin (A1c), CRPhs. The costs were estimated after reviews of the clinical history and correspond to antihypertensive, lipid lowering, and antidiabetic medications. Data are presented as mean and SD or n(%); skewed variables were natural-log transformed before performing Student's t-test analysis.

Results: A total of 37 T2DM patients were analyzed, ages 59.7 ± 11.4, of which 26 (70.27%) were men. On arrival at our clinic, the patients had 7.83 ± 7.48 years since being diagnosed with their illnesses, 21.62% had a family history of PCD, and 37.83% smokers. 43.24% had some kind of renal abnormality and 8.10% had retinopathy. The patients' data on arrival at our unit were: weight 83.48 ± 14.59 kg, BMI 29.52 ± 4.18 kg/m^2. The total costs before and after the medical evaluation suffered an average increase of 30.05 ± 31.43€, distributed among pathologies as follows: antihypertensives resulted in an average incremental cost of 5.30 ± 13.43€, yielding mean decreases of 5.78 ± 19.11 mmHg in systolic pressure, which was at the limit of the statistical significance (p = 0.074), and of 2.21 ± 8.14 mmHg in diastolic pressure. Patients requiring lipid-lowering agents increased their average cost by 8.70 ± 15.31€, resulting, 8.87 ± 34.48 mg/dl of LDL (p = 0.002), and an average increase of 1.44 ± 6.60 mg/dl of HDL; and antidiabetic treatment is an average incremental cost 7.18 ± 20.56 €, with average decreases in blood glucose levels of 13.59 ± 49.25 mg/dl (p = 0.049) and in glycated Hb of 0.23 ± 0.97%, but a 29.70% of T2DM decreases their A1c levels over 0.5% and this decline has economic implications too elevated.

Discussion: Cardiovascular disease mortality is the most common cause of death in patients with type 2DM, with an incidence at least double that in the general population. The total direct annual costs of diabetes in eight European countries were estimated at €29 billion, with an estimated yearly cost per patient of €2,834. From a health care payer perspective in Steno-2 Study (Denmark), intensive therapy was more cost-effective than conventional treatment. Assuming that patients in both arms were treated in a primary care setting, intensive therapy became dominant (cost- and lifesaving). Given the recommendation of the ADA and the Steno2 regarding the treatment of patients diagnosed with DM2, through a multifactorial approach, with strict glycemic control and incisive management of cardiovascular risk factors, it is necessary to study the cost/effectiveness of interventions from specialized medical counseling in this disease.

Conclusions: 1. The most cost-effective intervention in the diabetic patient is always the LDL-target one, as occurred in our study. 2. According to the results obtained with our patients, it can be stated that the performed intensive treatment resulted in clinical benefits in all risk parameters of DM2, within an acceptable cost-effectiveness threshold. It would be advisable to perform an analysis with a larger number of patients, as well as a full economic evaluation which should take into account other costs and the patients' quality of life.

RV-82
NOCTURNAL BLOOD PRESSURE VARIABILITY CORRELATES WITH TARGET ORGAN DAMAGE IN HYPERTENSIVE SUBJECTS

A. Hermida Ameijeiras, J. López Paz, M. Romero Míguez, A. Pascual Montes, V. Martínez Durán, G. Calvo González, C. Calvo Gómez

Department of General Internal Medicine. Hospital Clínico Universitario de Santiago. Xerencia de Xestión Integrada de Santiago. Santiago de Compostela (A Coruña), Spain.

Objectives: Growing evidence associates blood pressure (BP) variability with cardiovascular events in hypertensive patients. Here we tested the existence of a relationship between nocturnal BP variability and target-organ damage (TOD) in hypertensive subjects.

Table (RV-82)

	48h-sBP SD	48h-awake sBP SD	48h-asleep sBP SD
Ankle-arm index	-0.175*	-0.321**	-0.230**
Intima media thickness	0.154*	0.318**	0.158*
Pulse wave velocity	0.255*	0.394**	0.308**
Glomerular filtration rate	-0.064	-0.243**	-0.169**
24h-microalbuminuria	0.108	0.180*	0.088

*p < 0.05; **p < 0.01.

Material and method: We studied 398 hypertensive subjects (202 men), 55.6 ± 14.93 (mean ± SD) years of age. BP was measured by 48 hours ambulatory monitoring with a Spacelabs 90207 device and systolic BP variability were assessed as the standard deviation of the mean out of 48-hour, awake and asleep BP recordings. Ankle-arm index (by echo-doppler), intima-media thickness (by carotid ultrasonography), pulse wave velocity (by applanation tonometry), glomerular filtration rate (by MDRD) and 24hour-microalbuminuria were assessed as indices of vascular and renal damage, respectively.

Results: Nocturnal systolic BP variability inversely correlates with ankle-arm index (r: -0.23; p: 0.01) and glomerular filtration rate (r: -0.169;p: 0.06), whereas we found positive correlation between nocturnal systolic BP variability and intima-media thickness (r: 0.158; p: 0.025) and carotid-radial pulse wave velocity (r: 0.308; p: 0.00). We did not found relationship between nocturnal systolic BP variability and 24hour-microalbuminuria. These correlations appears even stronger when we assess awake systolic BP variability and TOD markers, which includes 24hour-microalbuminuria.

Conclusions: The relationship between nocturnal blood pressure (BP) decline and various vascular incidences and TOD is well known. Few evidence associates nocturnal BP variability with TOD. This is the first time nocturnal blood pressure variability measured as standard deviation of 48-hour ambulatory monitoring relates to TOD. Although awake systolic BP variability seems to be a stronger predictor it could have marked effects in both research and clinical daily practice for a proper evaluation of cardiovascular risk in hypertensive subjects. Relationship between 48hour systolic BP variability (measured as 48h, awake and nocturnal systolic BP standard deviation) and several target organ damage markers.

RV-83
CENTRAL BLOOD PRESSURE MAY PREDICTS ARTERIAL DAMAGE IN HYPERTENSIVE SUBJECTS

A. Hermida Ameijeiras, J. López Paz, M. Romero Míguez, G. Calvo González, F. Lado Lado, I. Rodríguez López, C. Calvo Gómez

Department of General Internal Medicine. Hospital Clínico Universitario de Santiago. Xerencia de Xestión Integrada de Santiago. Santiago de Compostela (A Coruña), Spain.

Objectives: Large artery stiffening and the wave reflection phenomenon have been identified as being the most important pathophysiological determinants of isolated systolic hypertension and pulse pressure increases. However, the prognostic role of central as opposed to peripheral blood pressure needs to be further confirmed in more large-scale observational and interventional studies. Here we tested the existence of a relationship between central systolic/diastolic BP and pulse pressure (PP) with several markers of abnormal structure and function of large arteries in hypertension.

Material and method: We studied 398 hypertensive subjects (202 men), 55.6 ± 14.93 (mean ± SD) years of age. At Cor Medical device (Sphygmo Cor Px®, Vx®, Sidney, Australia) which uses a validated transfer function was used to derive aortic systolic/diastolic BP and central PP. Ankle-arm index (by echo-doppler), intima-media thickness (by carotid ultrasonography) and carotid-femoral pulse wave velocity (by applanation tonometry), were assessed as indices of large arteries atherosclerosis.

Results: Peripheral and central systolic BP correlate with ankle-arm index (r: -0.207; p: 0.004 and r: -0.153; p: 0.04), and pulse wave velocity (r: 0.445; p: 0.000 and r: 0.432; p: 0.00), but don´t correlate to intima-media thickness. Peripheral and central diastolic BP inversely correlate with intima-media thickness (r: -0.406; p: 0.000 and r: -0.412; p: 0.00), but don't correlate to ankle-arm index nor pulse wave velocity. Finally, peripheral and central pulse pressure inversely correlate with AAI (r: -0.207; p: 0.004 and r: -0.153; p: 0.04) and also correlate with IMT (r: 0.371; p: 0.000 and r: 0.444; p: 0.00) and PWV (r: 0.555; p: 0.000 and r: 0.575; p: 0.00).

Conclusions: Central blood pressure seems to have at least the same predictor value as peripheral BP in order to assess vascular damage in hypertensive subjects. It may help us to identify hypertensive subjects with higher vascular stiffness.

RV-84
TARGET ORGAN DAMAGE AND CIRCADIAN BLOOD PRESSURE PROFILE

A. Hermida Ameijeiras, J. López Paz, M. Pena Seijo, V. Martínez Durán, A. Pascual Montes, G. Calvo González, A. Pose Reino, C. Calvo Gómez

Department of General Internal Medicine. Hospital Clínico Universitario de Santiago. Xerencia de Xestión Integrada de Santiago. Santiago de Compostela (A Coruña), Spain.

Objectives: It has been reported the relationship between increased target organ damage (TOD) and non dipping nocturnal blood pressure. Nevertheless, increased BP variability due to a pressor effect on patient using the device for the first time has previously been reported. It has been demonstrated to diminish further lengthening the monitoring span to 48-hour. The purpose of the present study was to evaluate whether 48-hour circadian blood pressure profile correlate with TOD in hypertensive subjects.

Material and method: 340 patients with essential hypertension submitted to our Hypertension Unit (41.4% women), 55.67 years old, were included. Patients underwent glomerular filtration rate (GFR) as calculated by Modification of Diet in Renal Disease (MDRD), urinary albumin excretion rate (UAER) and microalbuminuria -MAL-, an echo-doppler study to evaluate carotid intima-media thickness (IMT) and ankle-arm index (AAI) and applanation tonometry to estimate carotid-femoral pulse wave velocity (PWV). BP was measured by 48 hours ambulatory monitoring with a Spacelabs 90207 device adjusting the diurnal and nocturnal period for each patient. We analyze differences on TOD rates regarding circadian BP pattern.

Results: 45.58% of subjects were non-dipper; a little bit elder (59.77 years old vs 52.04), with higher waist perimeter (102.7 cm vs 98.39 cm). There were no significant differences on gender, body

mass index, smoking habit, heart rate or dyslipemia prevalence. We found differences on several TOD markers as IMT (0.83 mms in non dipper subjects Vs 0.78 mms in dipper subjects; p = 0.032) or AAI (1.06 vs 1.14 respectively; p = 0.003). Carotid-femoral PWV was higher in those hypertensive subjects with impaired nocturnal BP decline (10.39 m/s vs 9.22 m/s; p = 0.002). We also found differences on glomerular filtration rate by MDRD (72.40 ml/min in non dipper subjects vs 83.89 ml/min; p = 0.000). There were no significant differences on regard of UAER nor microalbuminuria.

Conclusions: Circadian blood pressure profile may help us to identify hypertensive subjects with advance vascular damage. It may be related to increased cardiovascular morbidity and mortality in those non dipper hypertensive subjects. Further studies are necessary in order to demonstrate improving nocturnal BP falling goes with decrease arterial stiffness.

RV-85
ASSOCIATIONS BETWEEN ADIPOKINES AND CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH CHRONIC HEPATITIS C AND TYPE 2 DIABETES MELLITUS

R. Dragut[1], E. Rusu[2], F. Rusu[3], C. Parpala[1], M. Jinga[2], R. Nan[2], H. Popescu[2], G. Radulian[2]

[1]Department of Diabetes II. 1. National Institute of Diabetes Nutrition and Metabolic Diseases. Bucharest, Romania. [2]Department of General Medicine. 2. University of Medicine and Pharmacy Carol Davila. Bucharest, Romania. [3]Department of Urology I. 3. Emergency Military Hospital Carol Davila. Bucharest, Romania.

Objectives: The aims of the study were to evaluate the relationship between cardiovascular risk, insulin resistance (IR), cytokines and chronic hepatitis C (CHC), in patients with CHC and type 2 diabetes mellitus.

Material and method: Observational, multicenter study that included 113 patients with CHC and diabetes. There were followed anthropometric indicators (weight, height, waist circumference, BMI (body mass index). Biochemical parameters followed were blood glucose, glycosylated hemoglobin, lipid profile (cholesterol, trigiceride, HDL-cholesterol), liver profile (ALT, AST, GGT, bilirubin, albumin, total protein), blood count, cytokines (adiponectin, leptin, TNF-α, IL-6, resistin). IR was determined using Homeostasis model assessment (HOMA-IR). The liver fibrosis was non-invasively assessed using the Forns index; a value < 4.2 excludes liver fibrosis and a value > 6.9 is a predictor for significant fibrosis. The 10-year coronary heart disease (CHD) was calculated for each patient using the UKPDS risk engine.

Results: The average age of the evaluated patients was 53.3 ± 7.8 years, 46% females (n = 52), with type 2 diabetes for 2.3 years. Metabolic syndrome (MetS) was present in 88 patients (77.9%). Median serum concentrations of leptin, TNF-α, IL-6, resistin were higher in patients with UKPDS-CHD over 30 (all p < 0.05). Using the UKPDS score, 8% (n = 9) and 45% (n = 51) of the patients presented a high and moderat risk for CVD. UKPDS-CHD score was strongly correlated with age (r = 0.42, p = 0.02), GGT (r = 0.41, p = 0.03), HOMA-IR (r = 0.46, p = 0.001), fasting insulinemia (r = 0.215, p = 0.022), systolic blood pressure (SBP) (r = 0.32, p = 0.03), TNF-α (r = 0.38, p = 0.02), IL-6 (r = 0.28, p = 0.034), cholesterol (r = 0.29, p = 0.045) and negatively correlated with adiponectin (r = -0.315, p = 0.022) and HDL-C (r = -0.37, p = 0.001). In this population multiple regression models controlling for BMI indicated that adiponectin (R(2) = 0.16, p = 0.034), resistin (R(2) = 0.18, p = 0.045), and IL-6 (R(2) = 0.112, p = 0.048) were associated with SBP. Forns index > 6.9 was associated with increased CHD risk (r = 0.341, p = 0.0001), HOMA-IR (r = 0.47, p = 0.001), leptin (r = 0.317, p = 0.001), TNF-α (r = 0.467, p = 0.001), IL-6 (r = 0.404, p = 0.001), resistin (r = 0.361, p = 0.001), adiponectin (r = -0.352, p = 0.001).

Conclusions: It was observed that high values of Forn's index are associated with increased risk of CHC and HOMA-IR. Patients with hepatitis C and diabetes have a greater risk to develop cardiovascular diseases. CHC has an important clinical impact on cardiovascular risk in patients with diabetes. An important role in determining treatment decisions is the estimation of CHD risk.

RV-86
FASTING LIPIDS IN NORMOLIPIDEMIC SUBJECTS WITH POSTPRANDIAL HYPERLIPIDEMIA

I. Pérez Hernández[1], C. López Calderón[1], A. Ramírez Bueno[1], J. Ramírez Bollero[1], J. Carrillo Linares[1], C. García Arias[2], J. Rioja Villodres[3]

[1]Department of Internal Medicine. Complejo Hospitalario Virgen de la Victoria. Málaga, Spain. [2]Department of Internal Medicine and Dermatology, [3]Centro de Investigaciones Médico-Sanitarias (CIMES). Universidad de Málaga. Málaga, Spain.

Objectives: Postprandial particles are atherogenic. It is said that postprandial hyperlipidemia is a risk factor for arteriosclerosis. However, it has not been introduced in clinical practice due to the complexity of its assessment. The aim of our study was to identify fasting variables associated with postprandial hyperlipidemia.

Material and method: We analyzed fasting and postprandial lipids 4 hours after a mixed meal containing 50 g of fat, among subjects non-treated with lipid-lowering drugs, 121 had type 2 diabetes and 82 non diabetic controls. Clinical, anthropometric data and medications were registered. Serum lipids, apolipoprotein B, A1 and B48 were assessed by immunoturbidimetry or ELISA. Only patients with fasting triglycerides (Tg) < 200 mg/dL were included. Postprandial hyperlipidemia was considered if Tgs at 4 hours were > 200 mg/dL.

Results: Those who remaining normolipidemic after the fat load had lower levels of fasting Tg, total cholesterol, LDL cholesterol, apo B48, apo B and higher levels of HDL cholesterol than those having postprandial hyperlipidemia. In multivariate analyses, only fasting Tg > 150 mg/dL, type 2 diabetes and fasting HDL cholesterol were independently associated with postprandial hyperlipidemia.

Discussion: There is no consensus defining postprandial hyperlipidaemia. Using this simple approach, we were able to show that type 2 diabetes, together with Tg over 150 mg/dL, but not fasting apolipoproteins, mainly the apo B48, an specific marker of postprandial lipids, were significantly and independently associated with postprandial hyperlipidaemia.

Conclusions: Fasting Tgs in the range of the metabolic syndrome, type 2 diabetes and low HDL cholesterol were markers in the fasting state of postprandial hyperlipidemia.

RV-87
USUAL METHODOLOGY FOR BLOOD PRESSURE MEASUREMENT IN THE COMMUNITY PHARMACIES. FARMAPRES PROJECT

M. Reig Botella[1], M. Córcoles Ferràndiz[2], J. Amorós Mas[2], E. Aura Perol[2], J. Boronat Cortes[2], M. Cerdá Ferre[2], V. Pallarés Carratalá[3], V. Giner Galvañ[1]

[1]Department of General Internal Medicine. Hospital Verge dels Lliris. Alcoy (Alicante), Spain. [2]Community Pharmacist. Alcoy´s Health Department. Alcoy (Alicante), Spain. [3]Sociedad Valenciana de Hipertensión y Riesgo Vascular SVHTA. SVHTAyRV. Valencia, Spain.

Objectives: To assess the usual methodology applied for the measurement of BP in the Community Pharmacies (CPh) and its validity.

Material and method: A survey with 12 questions was designed to assess the usual methodology applied for BP measurements in all the CPh of the Health Department of Alcoy, in the province of Alicante. The survey was sent by conventional as well as electronic mail to the 79 CPh of the Department.

Results: The response of 39 in 79 CPh (49.4%) was obtained, with more than 95% of the population covered. BP measurement is usually (97%) made in sitting position (3% at standing position) at the brachial level (87%), although in 13% it is made at the wrist. In spite of 39% pharmacies have specific cuff for brachial perimeter > 32 cm ("obese cuff"), only 4% measured arm circumference before BP measurement, with 8% saying that "they no have this kind of client". The majority of CPh made one (62%) or two (25%) consecutive BP measurements, although it is very common (76% of those with a usual unique measurement) a second measurement "after 5 minutes of rest" in the case of a "high BP" with the first measurement. It is very heterogeneous the type of tensiometer used in each CPh, with 27 different models identified. It is noteworthy the fact that in 31.1 and 2.6% of the occasions two or three different systems are used. Semiautomatic tensiometers are the mostly used (44%), with aneroid and mercury ones used in 33 and 23% respectively. Just 52% of semiautomatic tensiometers (27.6% of total tensiometers) are validated according to adbl Education Trust criteria (http://www.dableducacional.org).

Discussion: Results are in accordance with three previous studies made in Spain in Albacete and Guipúzcoa provinces and at the city of Valencia showing a correct BP measurement just in 10% of CPh.

Conclusions: It is necessary to improve methodology for BP measurement in CPh before promote their participation in the control of hypertension through the implementation of using validate measurement systems, adjustment of the cuff to the arm circumference and systematic use of repeated consecutive measurements.

RV-88
ANTIHYPERTENSIVE TREATMENT REDUCES PULSE WAVE VELOCITY IN PREVIOUSLY NEVER TREATED HYPERTENSIVE PATIENTS

E. Rodilla, J. Costa, F. Pérez, J. Pascual

Department of Internal Medicine. Hospital de Sagunto. Sagunto (Valencia), Spain.

Objectives: Aorto-femoral pulse wave velocity (PWV) is a well established method to to evaluate vascular damage and therefore stratify hypertensive patients. Several studies in different populations have demonstrated the value of baseline measurements of PWV for assessing cardiovascular risk, but information about the influence of treatment on this variable is scarce. Our objective was to assess if antihypertensive treatment is able to reduce PWV after one year of treatment.

Material and method: This is a longitudinal study including 480 (250 men, 52.0%) non-diabetic, never treated hypertensive patients. At baseline we measured standard clinical variables, as well as PWV (Sphygmocor-System of Atcor-Medical), left ventricular mass and geometry and diastolic function (echocardiography) and renal function with microalbuminuria and estimated glomerular filtration rate (MDRD-formula) to asses target organ damage. At a median of 1.05 years, a second visit was performed, all the measures were repeated.

Results: The mean age was 49.5 ± 12 years with initial systolic and diastolic BP of 146/87 mmHg (SD ± 14/11). The initial prevalence of left ventricular hypertrophy (LVH), pathological urinary albumin excretion rate (UAER) and PWV > 12 m/sec were 31.2, 12.8 and 8.8%, respectively. We defined a decrease of 1 m/seg as a significant change in PWV. According to this definition, 41.8% of patients showed a significant improvement in PWV. In a logistic multivariate regression analysis, age (OR: -1.0; $p < 0.0001$), systolic BP reduction, considered as tertiles (OR: 4.5 and 8.8; $p < 0.001$), initial PWV (OR: 3.5; $p < 0.001$) and waist diameter (OR: -0.97; $p < 0.01$) were independently associated with a decrease of PWV. Antihypertensive treatment was analyzed, angiotensin receptor antagonists showed a trend to improve PWV, but the association did not reach statistical significance ($p = 0.07$).

Discussion: The Guidelines of the European Society of Hypertension underline the importance of identifying subclinical target organ damage to stratify cardiovascular risk. But beyond stratification at baseline, monitoring treatment has also been recognized as an important task in hypertension. Regression of left ventricular hypertrophy and microalbuminuria have shown to be associated with improvement in the prognosis of affected patients. But to which extent vascular damage, measured as PWV, is capable of regression has yet to be elucidated. Our study included naïve patients without previous antihypertensive treatment. Although age seems to be the most important factor that determines changes in PWV, our study shows that adequate antihypertensive treatment is able to reduce vascular damage, at least at initial stages of the natural history of hypertension. Treatment with ARB did not reach statistical significance, but our results suggest that there might be potential differences in the reduction of PWV between groups of antihypertensive drugs.

Conclusions: In untreated hypertensive patients, age and abdominal obesity are negative predictors of changes in PWV, whereas BP treatment and high baseline values of PWV seem to favour a significant decrease of PWV during the first year of treatment.

RV-89
CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH CHRONIC KIDNEY DISEASE

R. Martín Díaz[1], L. Lozano Maneiro[2], E. Madroñal Cerezo[1], R. Calderón Hernaiz[1], D. Rejas Velasquez[1], M. Fernández López[1], J. Canora Lebrato[1], A. Zapatero Gaviria[1]

[1]Department of Internal Medicine, [2]Department of Nephrology. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: Chronic kidney disease (CKD) is an important cardiovascular risk factor. The presence of additional factors worsens the patient's prognosis, not only at a cardiovascular level, but also at the renal pathology itself. Here we review the prevalence of the main cardiovascular risk factors.

Material and method: Descriptive review of the medical records of patients with glomerular filtration (CKD-EPI) < 30 ml/min seen in nephrology consultations between the 1/1/12 and the 30/4/12. Variables analyzed: sex, age, toxic habits, history of cardiovascular disease, cause of the CKD, creatinine, CKD-EPI, blood pressure, body mass index (BMI), LDL, TG, hemoglobin, presence of DM and HbA1c, leucocytes, ferritin, C-reactive protein (CRP), 25-OH-vitamin D, PTH and proteinuria.

Results: 60 patients were included, with median age of 72.47 years (SD 13.88), 51.7% of them male. The presence of the items evaluated was distributed in the following way: Smoking status: current 15%, never 36.7% following 35%, unknown 13.3%. Drinking habit: current 8.3%, never 61.7% following 11.7%, unknown 18.3%. Background: Stroke-TIA 15%, ischemic heart disease 25%, heart failure 18.3%, peripheral arterial disease 20%. Cause of CKD: multifactorial 21.7%, DM 20%, nephrosclerosis 20%, unknown 18.3%, glomerular nephropathy 6.6%, polycystic kidney disease 5%, vascular disease 5%, IgA 1.7%, other 1.7%. Mean creatinine 2.83 mg/dl, CKD-EPI 21.31 mg/dl. Mean proteinuria (Pr u/Cr u) 2.29. Elevated PTH in 91.4% (mean 207.95 pg/ml). BMI > 25% 82.7%, mean 29.4. Blood pressure: mean 136.14/72.49 mmHg (SD 22.88/16.75 mmHg). Lipid control: LDL 97.19 mg/dl, TG 139.85 mg/dl. Diabetes mellitus in

50%. In these, mean HbA1c 6.82 and mean baseline glucose 137.47 mg/dl. 25-OH-vitamin D deficient (< 15 ng/ml) in 45.6% of patients with a mean of 17.98 ng/ml. Anemia in 51.7%. Elevated acute phase reactants: leukocytosis in 16.7%, hiperferritinemia in 69%, elevated CRP in 44.8%.

Conclusions: There is a high prevalence of inadequate control of cardiovascular risk factors. A better control may help to reduce the comorbidity of our patients and slow the progression of the renal disease.

RV-90
ATHEROSCLEROSIS, ANTIPHOSPHOLIPID SYNDROME AND HYPERHOMOCYSTEINEMIA IN RETINAL THROMBOSIS

M. Aller Fernández, S. Neila Calvo, S. García Rubio, F. López Gutiérrez, M. García Hoyos, P. Garmilla Ezquerra, E. Cobo García, J. Napal Lecumberri

Department of Internal Medicine. Hospital Valdecilla. Santander (Cantabria), Spain.

Objectives: Retinal thrombosis is the second cause of retinal vascular disease, after diabetic retinopathy. This affects 2.1 of every 1,000 people aged 40 years and 5.4 of every 1,000 people over 64. The average age of presentation is 65 years. The existence of retinal occlusion increases cardiovascular mortality. This is a prospective study of retinal thrombosis and precipitating factors in a tertiary hospital.

Material and method: We included all patients diagnosed with retinal occlusion by the Ophthalmology Service for 38 months in our hospital. A standardized questionnaire was conducted in a computerized database that included clinical data, analytical studies, lupus anticoagulant, antiphospholipid antibodies, serum homocysteine, electrocardiogram and Doppler ultrasound of supra-aortic trunks. In patients receiving anticoagulant therapy for atrial fibrillation 7 (7.14%) could not complete the study of hipercoagulable state.

Results: The series consisted of 98 patients (56 men and 42 women) aged between 40 and 88 years (66 ± 10). Arterial hypertension affected 67 patients (68%), dyslipidemia in 67 (68%), diabetes mellitus in 27 (27%) and smoking in 43 (43%) considering active smokers and former smokers. Retinal involvement was peripheral in 69 (67 in temporal region and 2 in nasal) and central in 29. The lupus anticoagulant appeared in 6 patients (6.4%) and antiphospholipid antibodies in 6 (6%). Of the 9 patients with antiphospholipid syndrome, in 3 were positive both and the remaining 6 only one of them. Hyperhomocysteinemia (defined as homocysteine levels above 14.9 µmol/L) occurred in 24%. The Doppler ultrasound of supra-aortic trunks showed atheromatous plaques in 42%, moderate or severe stenosis in 4% and no alterations in 54%.

Discussion: The retinal occlusion is an important cause of blindness in adults. Most patients have arterial hypertension, dyslipidemia, diabetes mellitus or other vascular risk factors and therefore the retinal thrombosis is a manifestation of atherosclerosis. The hyperhomocysteinemia and antiphospholipid syndrome can cause arterial and venous thrombosis, although no prospective studies in retinal occlusion.

Conclusions: The arterial hypertension, dyslipidemia, diabetes mellitus and other vascular risk factors causing atherosclerosis are the main cause of retinal thrombosis. The presence of atherosclerotic plaques in the Doppler ultrasound of supra-aortic trunks is a sign of atherosclerotic involvement of these patients. We recommended for all patients with retinal thrombosis performed in conjunction with the study of cardiovascular risk factors, the determination of homocysteine, lupus anticoagulant and antiphospholipid antibodies.

RV-91
DOES VALSARTAN IMPROVE ENDOTHELIAL DYSFUNCTION AND VASCULAR MICROINFLAMMATION?

M. Karaman[1], S. Ay[1], Ö. Kurt[1], T. Çelik[2], H. Yaman[3], S. Demirci[1], F. Bulucu[1], K. Saglam[1]

[1]Department of Internal Medicine, [2]Department of Cardiology, [3]Department of Biochemistry. Gulhane Military Medical Faculty. Ankara, Turkey.

Objectives: Renin-angiotensin system (RAS) plays an important role in the development of hypertensive and vascular diseases. It has been shown in several studies that RAS activation makes endothelial dysfunction and inflammation. In this study, we aimed to investigate the effects of valsartan molecule as one of angiotensin receptor blockers (ARB), on vascular endothelial dysfunction and microinflammation in patients with essential hypertension.

Material and method: 34 patients who are newly diagnosed with essential hypertension and valsartan treatment was started in internal medicine and cardiology outpatient clinics, were included in the study. All of the patients 40 years old or over. None of the patients had a co-morbid disease (DM, CAD, CKD, stroke, malignancy etc.). Valsartan (80-320 mg/day) were given a single daily dose in the morning on an empty stomach. ABP measurements were performed with two weeks interval and appropriate dose titration was done. VWF as a marker of endothelial dysfunction and hscrp, pentraxin 3(Ptx3) for vascular microinflammation were studied.

Results: After twelve-week follow-up, a total of 28 patients (M: 6, F: 22) (stage-1: 13 patient, stage-2: 15) who were received only valsartan, were evaluated. Four patients whose ABP measurements were not regulated with valsartan treatment, two patients that refused to continue, were excluded from the study. ABP values were within normal limits in all patients. Marked improvement in the level of vWF was observed in all patients (change: 69% reduction, p = 0.000). Ptx3 and hscrp levels were decreased. But, while the fall in the value of ptx3 was significantly, hsCRP fall was not (respectively of change: 53%, p = 0.000 and change: 4%, p = 0.738).

Discussion: Endothelial dysfunction is an effective marker for detection of cardiovascular disease, detects prognosis and has a close relationship with in the development of atherosclerosis. Crp is the most commonly used marker to assess inflammation. PTX3 is synthesized from extrahepatic tissue, it is considered to be a more sensitive indicator of local inflammation. In our study; the improving effects of valsartan treatment on endothelial dysfunction and microinflammation was detected. A reduction of 69% were found in VWF values compared to pretreatment, that was significantly. Also, a reduction of 53% compared to pretreatment value of ptx3 and a reduction of 4% in hsCRP were observed. Considering the positive results of RAS blockage on cardiovascular and systemic effects; it can be said that the therapies aimed this blockage are more rational.

RV-92
CARDIOVASCULAR RISK FACTORS AND LEVELS OF 25-OH-VITAMIN D IN PATIENTS WITH CHRONIC KIDNEY DISEASE

R. Martin Díaz[1], L. Lozano Maneiro[2], A. Castro Gordón[1], B. Matía Hernando[1], C. Tojo Villanueva[1], L. Horrillo Sánchez de Ocaña[1], I. Navas Clemente[1], A. Zapatero Gaviria[1]

[1]Department of Internal Medicine, [2]Department of Nephrology. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: The presence of chronic kidney disease (CKD) is an important cardiovascular risk factor. Vitamin D levels have known

effects on bone remodeling, but in the last years plenty of studies have arisen evaluating the relation between deficient levels and higher morbid-mortality (both cardiovascular and global). Here we review the relation between deficient levels of 25-OH-vitamin D and other factors, specially the cardiovascular risk ones.

Material and method: Descriptive review of medical records of patients with glomerular filtration (CKD-EPI) < 30 ml/min seen in nephrology consultations between the 1/1/12 and the 30/4/12. Variables analyzed: sex, age, toxic habits, history of cardiovascular disease, cause of the CKD, creatinine, CKD-EPI, blood pressure, body mass index (BMI), LDL, TG, hemoglobin, presence of DM and HbA1c, leucocytes, ferritin, c-reactive protein (CRP), 25-OH-vitamin D, PTH and proteinuria.

Results: 60 patients were included, with median age of 72.47 years (SD 13.88), 51.7% of them male. The mean 25-OH-vitamin D was 17.98 ng/ml (SD 9.43 ng/ml). 45.6% patients had levels below 15 ng/ml. Statistical relation (or values closed to significance) was observed with (see table).

Conclusions: Our patients with advanced CKD have a high prevalence of deficient vitamin D levels -In our review we have observed that patients with lower levels of 25-OH-vitamin D have higher BMI, more frequent history of stroke or TIA and tend to have higher levels of proteinuria.

Table (RV-92)

	p	25-OH-vitamina D < 15 ng/ml	25-OH-vitamina D > 15 ng/ml
History of stroke or TIA	0.035	26.92%	6.45%
BMI	0.048	27.22	30.28
Protein (urine)/ creatinine (urine)	0.055	3.36	1.57

RV-93
STANDARDIZED MORTALITY RATIO (SMR) IN A SPANISH COHORT OF TYPE 2 DIABETIC PATIENTS

M. Bucar Barjud[1], Y. Blasco Lamarca[2], A. Mañas Martínez[2], B. Campos Gutiérrez[3], M. Serrano Herrero[1], A. Ilundain González[2], J. Pérez Calvo[1], J. Gimeno Orna[2]

[1]Department of Internal Medicine, [2]Department of Endocrinology. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain. [3]Department of Internal Medicine. Hospital de Alcañiz. Alcañiz (Teruel), Spain.

Objectives: It has been reported that diabetic subjects are at a greater risk of mortality. Our aim was to compare the mortality rate of type 2 diabetic patients with the mortality rate of the background population.

Material and method: This is a prospective longitudinal study. Patients with type 2 diabetes from Alcañiz area (Spain) were included from 1994 to 1998. The life status was ascertained on 2011. Date and cause (vascular or non-vascular) of death was obtained from hospital records and death certificates. Mortality rates are expressed per 1,000 patient-years. Age specific excess of mortality, compared with the background population, was assessed in terms of standardized mortality ratio (SMR).

Results: 463 type 2 diabetic patients (281 women and 182 men) were included. The mean age at baseline was 65 years (SD 9.2) and the mean diabetes duration was 10.5 years (SD 7.6). Prevalence of macrovascular disease at baseline was 21.4%. The median follow-up was 13.1 years. 209 patients died during the follow-up, with a mortality rate of 38.9/1,000 (35.7 women and 44.3 men). 76 deaths were of vascular cause, with a cardiovascular mortality rate of 13.4/1,000 (12.8 women and 14.4 men). The SMR for all causes of dead was 2.6 (95% Confidence interval (CI) 1.6-3.9). The highest SMRs were for the youngest patients (SMR = 3.5 in patients < 50 years old versus SMR = 1.96 in patients > 80 years old).

Conclusions: In our population, type 2 diabetes mellitus significantly increase mortality risk. The risk is higher in younger people.

RV-94
CHARACTERIZATION OF PATIENTS WITH CEREBROVASCULAR ACCIDENTS ADMITTED TO AN INTERNAL MEDICINE WARD

C. Sepúlveda, S. Cunha Martins, C. Santos Gil, M. Sousa Carvalho

Department of Internal Medicine. Centro Hospitalar Médio Tejo. Torres Novas, Portugal.

Objectives: Characterization of patients with cerebrovascular accidents admitted to an internal medicine ward.

Material and method: The authors present a retrospective evaluation of patients admitted to the Internal Medicine Department of our Hospital with the primary diagnosis of cerebrovascular accidents (CVA) during a one-year period from 01/01/2011 to 31/12/2011. Each clinical process was individually assessed.

Results: The patients admitted were characterized according to sex, age, type of CVA, presence of conventional risk factors (known and diagnosed during admission), use of anti-platelet aggregation or anticoagulation, days of admission, in-hospital mortality, and morbidity at discharge.

Discussion: Cerebrovascular disease is a leading cause of mortality and morbidity in Europe and is especially prevalent in Portugal. CVA are classified according to mechanism of injury into two large groups: ischemic and hemorrhagic. Ischemic disease is by far the most prevalent and largely preventable by controlling underlying conventional risk factors such as diabetes, hypertension, lipid disorders, arrhythmias (atrial fibrillation) and smoking. The appropriate use of anti-platelet aggregation or oral anticoagulation is also important in prevention of CVA.

Conclusions: The authors hope with this presentation to contribute in some way to a better understanding of CVA in our district, alerting doctors specifically to the need of aggressively controlling underlying risk factors, not only with life-style changes but also with appropriately prescribed medications.

RV-95
RELATIONSHIP BETWEEN GENE VAV2 (VAL 584 MET POLYMORPHISM) AND SYSTOLIC BP

J. Miramontes González, Á. Romero Alegría, D. Pescador Hernández, L. Mateos Polo, C. Montilla Morales

Department of Internal Medicine. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca, Spain.

Objectives: Essential hypertension affects more than 30% of the population of Western European countries. The high levels of systolic blood pressure increases the risk of stroke, myocardial infarction, nephropathy and peripheral vascular disease. The systolic high BP have a multifactorial etiology in the determining factors are genetic factors, have been proposed many candidate genes in association studies, and the search for new genes is focused on understanding the pathophysiology of this disorder and design of future treatments. In our study we proposed the VAV2 gene association with hypertension. We have studied a patient population with hypertension and the relationship between BP systolic values obtained and the Val584Met polymorphism of VAV2. The gene encoding the VAV-2 is located on chromosome 9, position 9q34.1. Polymorphism was studied by a single nucleotide change (SNP) gene located in the promoter region, at position 584 with a change C for T (rs 602,990).

Material and method: We studied 298 patients from a hypertension unit integrated Into M. Internal. We studied 155 men and 143 women. Were obtained from BP taken the ABPM diagnosis, have been used for 24-hour mean values to make the classification and analysis. We have excluded all patients with primary hypertension following of the protocol of the unit. Amplification reactions were performed in automatic thermal cycler (Step One Plus® Applied Biosystems) using TaqMan® probes. Statistical analysis was performed using the SPSS software.

Results: The systolic BP distributed by sex showed the following results: Men: 155 with mean of systolic BP: 141.49 mmHg and DS: 27.82 Women: 143 with mean of systolic BP: 143.69 mmHg and DS: 25.96. We obtained a sample of 118 individuals without hypertension (genotyping results: TC: 67, TT: 29, CC: 22). Individuals with high levels of systolic BP have been classified into three categories with the following results grade 1: 108 individuals (genotyping results: TC: 57, TT: 29, CC: 22), hypertension grade 2: 46 individuals (genotyping results: TC: 19, TT: 15, CC: 12) and hypertension grade 3: 26 individuals (genotyping results: TC: 14, TT: 4, CC: 8). The study of statistical association between systolic BP in hypertensive patients and hypertensive patients with the genotype results, has shown no statistical association. Chi squared test: 0.476.

Conclusions: No statistical association was found between systolic blood pressure and VAV-2 polymorphism Val584Met. The findings in animal models, in which we have based our studies encourage further studies with more extensive databases and data associated diseases.

RV-96
INTERPRETATION OF BLOOD PRESSURE VALUES OBTAINED IN A COMMUNITY PHARMACY BY THE PHARMACISTS. FARMAPRES PROJECT

M. Reig Botella[1], F. Miralles López[2], O. Jiménez Jiménez[2], F. Gozálbez Esteve[2], E. Turrión Gozálbez[2], J. Tamarit García[3], B. Roig Espert[4], V. Giner Galvañ[1]

[1]Department of General Internal Medicine. Hospital Verge dels Lliris. Alcoy (Alicante), Spain. [2]Community Pharmacist. Health Department of Alcoy. Alcoy (Alicante), Spain. [3]Department of General Internal Medicine. Hospital Universitario Dr. Peset Aleixandre. Valencia, Spain. [4]Department of General Internal Medicine. Hospital de Manises. Manises (Valencia), Spain.

Objectives: To study how a pharmacist take decisions depending on blood pressure (BP) measurements at the community pharmacy (CPh) on real-life conditions.

Material and method: As a part of a specific survey, participants (39 CPh, 49.4% of participation) were asked about BP values defining "Normal BP", "Uncontrolled BP" and "BP values for remission to a medical service".

Discussion: There is a very important heterogeneity interpreting BP values with very high subjective criteria. Pharmacists are stricter when considering DBP than systolic BP. This is especially true when defining "normotension" or considering values "for remission". When defining "uncontrolled BP" both components are equally considered.

Conclusions: There is a great heterogeneity and subjectivity when BP values are interpreted by community pharmacists. Probably a better specific formation could imporve the utility of CPh in the control of BP.

RV-97
ATTITUDES AND ACTIONS OF THE COMMUNITY PHARMACIES OF ALCOY'S HEALTH DEPARTMENT FOR THE REMISSION OF UNCONTROLLED HYPERTENSIVES TO MEDICAL SERVICES. FARMAPRES-CV PROJECT

M. Reig Botella[1], I. Llopis Boluda[2], I. Ramírez Rodríguez[2], M. Robles Sáez[2], E. Sainz Nadales[2], I. Bonig Trigueros[3], C. Sánchez García[2], V. Giner Galvañ[1]

[1]Department of General Internal Medicine. Hospital Verge dels Lliris. Alcoy (Alicante), Spain. [2]Community Pharmacist. Health Departament of Alcoy. Alcoy (Alicante), Spain. [3]Department of General Internal Medicine. Hospital de Vinaroz. Vinaroz (Castellón), Spain.

Objectives: In spite of a large number of clinical guidelines for the remission of uncontrolled hypertensive patients from the community pharmacy (CPh) to medical services, nobody knows what actions are really being taken.

Material and method: Since November 2011 until February 2012, a specific survey was sent to all CPh (n = 79) of Alcoy's Health Department, obtaining the participation of 49.4% of them.

Results: In the opinion of all participants CPh have an important/very important potential for the improvement of the control of hypertension (HT). The reasons for that are expressed in table 1. When the CPh think a patient has elevated BP (very heterogeneous and subjective criteria for it), a second measurement use to be done (87.2%), generally (63%) applying the same system. In 95% of occasions CPh refer the patient to a medical service: 44% to the Hospital Emergency Department (HED) or Primary Care Health Center (PCHC) depending on the degree of BP elevation; 40% always to PCHC and 8% always to the HED. The remission is made after giving non-pharmacological advice from 41% of CPh (83% about diet, 25% about physical activity, and 85% about fulfillment), with 5% adding pharmacological advices. When primary care physicians and nurses are asked about the remission of patients from CPh because of elevated BP, 60% think that they use to be incorrectly remitted, mainly because of an overestimated measurement and alarmism

Table 1 (RV-96). Which BP values you consider as "normal"?

ESH BP Category	Grade 3 HT ≥ 180/ 100 mmHg	Grade 2 HT 160-179/ 100-109 mmHg	Grade 1 HT 140-159/ 90-99 mmHg	High-Normal 130-139/ 85-89 mmHg	Normal 120-129/ 80-84 mmHg	Optimal < 120/ < 80 mmHg
DBP	0	0	46	26	10	18
SBP	0	0	18	13	49	20

Table 2 (RV-96). Which BP values you consider as "bad control"?

ESH BP Category	Grade 3 HT ≥ 180/ 100 mmHg	Grade 2 HT 160-179/ 100-109 mmHg	Grade 1 HT 140-159/ 90-99 mmHg	High-Normal 130-139/ 85-89 mmHg	Normal 120-129/ 80-84 mmHg	Optimal < 120/ < 80 mmHg	Other criteria
DBP	6	11	77	6	0	0	12
SBP	6	15	64	9	6	0	20

Table 3 (RV-96). Which BP values you consider for "remission"?

ESH BP Category	Grade 3 HT ≥ 180/ 100 mmHg	Grade 2 HT 160-179/ 100-109 mmHg	Grade 1 HT 140-159/ 90-99 mmHg	High-Normal 130-139/ 85-89 mmHg	Normal 120-129/ 80-84 mmHg	Optimal < 120/ < 80 mmHg	Other criteria
DBP	26	58	11	5	0	0	28
SBP	29	14	51	3	3	0	40

induced by the pharmacist to the patient. On the other hand, a significant percentage of CPh think the primary care physician does not adequately value their role in the management of BP. Finally, table 2 illustrates the potential impact on HED consultations of an improvement in the criteria for remissions from CPh considering that 40 to 45% of patients attended because of elevated BP are not referred from PCHC.

Discussion: CPh use very heterogeneous and subjective criteria for remission of uncontrolled hypertensive to medical services. They usually repeat the BP measurement and give non-pharmacological advices, although 5% of them also give pharmacological advices. There is a strong rejection from PCHC.

Conclusions: There are not objective and uniform criteria for the remission of uncontrolled hypertensive from CPh. Distrust is common between community pharmacists and PC professionals. An improvement in the remission criteria could have a significant impact.

RV-99
ADIPOCYTE FATTY ACID BINDING PROTEIN IS ASSOCIATED WITH SUBCLINICAL ATHEROSCLEROSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

S. Parra[1], A. Cabré[2], R. Ferré[3], F. Marimon[1], G. Vives[1], J. Ribalta[2], L. Masana[3], A. Castro[1]

[1]Department of Internal Medicine, [3]Department of Vascular and Metabolism Medicine. Department of Internal Medicine. Hospital de Sant Joan de Reus. Tarragona, Spain. [2]Department of Lipids and Arteriosclerosis. Universitat Rovira i Virgili. Reus. Tarragona, Spain

Objectives: To study if circulating fatty acid-binding proteins 4 (FABP4) plasma levels is a possible marker of metabolic risk in SLE patients.

Material and method: Sixty-nine consecutive patients with SLE and 34 non-SLE age matched controls were recruited for the study. Fasting venous blood samples were collected on the same day as the measurements of cIMT were performed. Total plasma lipids and the lipoprotein subclasses distribution was analysed by nuclear magnetic resonance spectroscopy.

Results: We did not find differences regarding FABP4 plasma levels between the SLE patients and the control group. The FABP4 plasma levels were identical in both SLE and control groups. In the SLE group FABP4 was associated with the presence of insulin resistance, atherogenic dyslipidemia measured by MNR and the presence of subclinical atherosclerosis. In multivariate analyses FABP4 was associated with c-IMT independently of inflammatory status.

Discussion: Patients affected by SLE show an increase of cardiovascular mortality and morbidity although this accelerated atherosclerosis cannot be entirely explained by the traditional cardiovascular risk factors. The presence of some metabolic disturbances as atherogenic dyslipidemia and metabolic syndrome seem to be more prevalent due to inflammatory mechanisms. Fatty acid-binding proteins (FABPs) are cytosolic proteins that function as chaperones and regulate fatty acid uptake and intracellular transport. The circulating levels are associated to adiposity, insulin resistance, metabolic syndrome, diabetes and cardiovascular diseases, and it's considered a marker of metabolic risk I general population. In SLE patients we confirm these previous results and we postulate that FABP4 levels in SLE could be a useful clinical biomarker of metabolic and cardiovascular risk in this usually young and non-obese patients.

Conclusions: FABP4 is involved in the metabolic disturbances in SLE patients affecting lipid metabolism and insulin resistance. Circulating FABP4 is a determinant of subclinical atherosclerosis in this population independently of the inflammatory status.

AMBULATORY BLOOD PRESSURE MONITORING (ABPM) IN HYPERTENSIVE PATIENTS TREATED IN HOSPITAL DE TORREJÓN. FIRST SIX MONTHS EXPERIENCE

I. Sanz Acevedo, A. Franco Moreno, V. Martínez Díaz, R. Segoviano Mateo, M. Lado Castro-Rial, S. Calabrese Sánchez, A. Junco García, M. García Navarro

Department of Internal Medicine. Hospital de Torrejón. Madrid, Spain

Objectives: Blood pressure (BP) measurement made by a physician generates a so-called warning reaction in most patients

Table 1 (RV-97). What can CPh offer for a better control of hypertensives? (%). N = 27

Proximity	69
Flexibility	35
Less reactive HT	23
Treatment counseling	19
Detection of new HT	11
More quality of life	4
Low cost	4

Table 2 (RV-97)

	2007	2008	2009	2010	2011
Total consultations	129	136	137	150	143
Consultations from Primary Care (PC)	53	53	56	66	64
Other origins (Home, CPh…)	41%	40%	41%	44%	45%

that provokes an increase in BP. Ambulatory Blood Pressure Monitoring (ABPM) can help to minimize the "white coat" effect and improve the accuracy of the office BP measurement. The aim of this study is to analyze the ABPM readings in patients treated in Hospital de Torrejon during its first six operating months.

Material and method: ABPM was perfomed taking blood pressure measurements over a 24 hour period. We considered as valid ABPM those with a percentage of correct measurements readings over 70%. A minimum of 14 measurements during the daytime period, and 7 measurements in nocturnal period were required as well. We calculated average values for systolic blood pressure (SBP), diastolic blood pressure (DBP) and heart rate (HR). Regarding BP circadian rhythms, we consider the following patterns: dippers (defined as those patients with average nocturnal BP 10 to 20% lower than daytime values), extremely dippers (defined as those patients with average nocturnal BP > 20% lower than daytime values), nondippers (failure of the BP to fall by at least 10% during sleep) and risers (nocturnal SBP higher than daytime values).

Results: ABPM was performed in 46 patients, 25 males and 21 females(45.6%), with 8 patients being 20 to 39 years old (17.3%), 15 patients (32.6%) being 40 to 59 years old and 23 patients(50%) over 60. Most patients (28 patients, 60.8%), underwent ABPM to study changes in BP circadian rhythm, 15 patients (32.6%) underwent monitoring to evaluate antihypertensive medication effectiveness, and in 3 cases the aim was to diagnose refractory hypertension. 14% of patients (7) presented white coat hypertension and the rest, 39 patients, (86%) were real hypertensive patients. In this group, 25 patients (64.7%) had a poor clinical control, with average BP values being 146.7 / 81.1 mmHg. 91% of patients (35) were on antihypertensive therapy (46.3% on monotherapy and 53.7% on combinations of two or more drugs). Cardiovascular risk evaluation was made, finding that 42.7% of the patients had a high or very high cardiovascular risk, 36.3% of the patients had a moderate risk and 21% of the patients had a low risk. 18% of the patients had no other cardiovascular risk factor than hypertension, while 35.8% had a second risk factor, 20.5% had a third risk factor and 25.7% had 3 or more additional risk factors. Stroke was the most frequent vascular disease antecedent (38% patients), followed by ischemic heart disease (28%) and peripheral arterial disease (13%). Concerning the circadian rhythm, it was observed that 6% of the patients had a rising pattern, 22.6% had a nondipping pattern, 69.4% were dippers and 2% were extremely dippers.

Discussion: 1. In our study, we found that most hypertensive patients are males, older than 60 years old, presenting with ahigh or very high cardiovascular risk. They have at least one more cardiovascular risk factor than hypertension, with a previous history of vascular disease. 2. Most hypertensive patients have a suboptimal clinical control of BP (grade 1) despite being treated with drugcombinations. 3. We found white coat hypertension in 14% of our patients.

Conclusions: ABPM using a device worn by the patient, taking blood pressure measurements away from external factors, such as white coat effect, improves readings accuracy and makes them similar to the real pressure in our hypertensive patients.

RV-102
PREDICTORS OF OUTCOME IN STABLE OUTPATIENTS WITH PERIPHERAL ARTERY DISEASE

C. Sanclemente[1], R. Coll[2], M. Pascual[2], J. Sánchez Muñoz-Torrero[3], L. Álvarez[4], E. Aguilar[5], M. Monreal[6], and the FRENA Investigators

[1]Department of Internal Medicine. Hospital Universitari de Bellvitge. L'Hospitalet de Llobregat (Barcelona), Spain. [2]Department of Rehabilitation, [6]Department of Internal Medicine. Hospital Universitari Germans Trias i Pujol. Badalona (Barcelona), Spain. [3]Department of Internal Medicine. Hospital San Pedro de Alcántara. Cáceres, Spain. [4]Department of Vascular Surgery. Hospital de Terrassa. Terrassa (Barcelona), Spain. [5]Department of Internal Medicine. Hospital de Alcañiz. Alcañiz (Teruel), Spain.

Objectives: Even in the absence of a history of coronary artery (CAD) or cerebrovascular (CVD) disease, patients with peripheral artery disease (PAD) have a similar risk to die from a cardiovascular cause as those with previous CAD or CVD. However, despite its frequency and severity, there is scarce information on the predictors of outcome (i.e., subsequent ischemic events, or death) in stable outpatients with symptomatic PAD. A better understanding of the factors influencing the risk for subsequent ischemic events may be helpful for better targeting of existing treatments. Background: the aim of the current study was to identify independent predictors of outcome in patients with peripheral artery disease (PAD).

Material and method: The Factores de Riesgo y ENfermedad Arterial (FRENA), is a Registry was initiated in March 2003 to prospectively record the current clinical management and outcome of patients with arterial disease in Spain. It is an ongoing, multicenter, observational registry of consecutive patients designed to gather and analyze data on treatment patterns and outcomes in stable outpatients with symptomatic ischemic disease of the heart, brain, and/or major peripheral arteries. Participating hospitals in the FRENA registry prospectively enrolled consecutive outpatients with symptomatic artery disease with at least one recent (< 3 months prior to enrollment) episode of CAD (manifesting as angina or acute coronary syndrome); CVD (manifesting as transient ischemic attack or ischemic stroke); or PAD (either intermittent claudication with an ankle-brachial index < 0.9, or previous vascular intervention or limb amputation for PAD).

Results: As of February 2011, 1205 patients with PAD were recruited, of whom 604 (50%) had Fontaine stage IIa; 336 (28%) Fontaine stage IIb; 121 (10%) Fontaine stage III; and 144 (12%) had Fontaine stage IV. Over a mean follow-up of 13 months, 172 patients (14%) developed subsequent ischemic events (myocardial infarction 40, stroke 28, disabling claudication/critical limb ischemia 115), and 83 patients (6.9%) died. In patients with Fontaine stage IIa, the incidence of MI was similar to that of disabling claudication/critical limb ischemia: 2.51 (95%CI: 1.58-3.81) vs 2.89 (95%CI: 1.87-4.26) events per 100 patient-year, respectively. The mortality rate ranged from 2.89 (95%CI: 1.87-4.26) deaths per 100 patient-year in patients with Fontaine stage IIa to 15.7 (95%CI: 1.06-22.5) in those with Fontaine stage IV. On multivariate analysis, patients with cancer, diabetes, Fontaine stages III or IV, systolic blood pressure (BP) levels < 130 mmHg, renal insufficiency, and those receiving anticoagulants were at an increased risk to die. Conversely, patients receiving statins were at a lower risk.

Conclusions: 1. In patients with Fontaine stage IIa, the incidence of critical limb ischemia is similar to that of MI. 2. Patients with cancer, diabetes, Fontaine stages III-IV, renal insufficiency, and those receiving anticoagulants were at an increased risk to die. 3. Patients receiving statins were at a lower risk to die. 4. Unexpectedly, patients with mean systolic BP levels < 130 mmHg had a 3-fold higher risk to die than those with levels > 130 mmHg.

RV-103
PREVALENCE OF TYPE-2 DIABETES MELLITUS AMONG INPATIENTS, METABOLIC CONTROL AND TREATMENT IMPLEMENTATION AT DISCHARGE

A. Hidalgo Jiménez, F. Carrasco Sánchez, H. Cachay Osorio, M. Machado Vilches, G. Mariscal Vázquez, M. de Sousa Baena, C. Díaz Pérez, C. Espejo Fernández

Department of Internal Medicine. Área Hospitalaria Juan Ramón Jiménez. Huelva, Spain.

Objectives: Type-2 diabetes mellitus (T2DM) must have increased among inpatients in the later years due to the fact that our patients have a high comorbidity. The main aim of our study was to know the prevalence of T2DM among hospitalized patients in our medical center. In addition, we wanted to determine metabolic control's degree and to evaluate the implication of physicians on hypoglycemic treatment optimization once the patient has been discharged home.

Material and method: We included all patients admitted, from March 13th to 15th 2012, at the internal medicine department in the Juan Ramón Jimenez hospital, Huelva, Spain. This is a second level hospital with just over 600 beds. We also included some general surgery-assigned patients hospitalized in our ward. We evaluated the patient's medical records using a pre-designed protocol. Glycated hemoglobin (HbA1c) was obtained from all patients. At discharge time, hypoglycemic treatment recommendations were evaluated and optimization was performed on patients with HbA1c value greater than 7.5%. For data analysis, frequency charts were created, and the prevalence with confident interval (95%) was calculated.

Results: A total of 219 patients were hospitalized in our department during the established period. T2DM prevalence ratio (84 patients) was 0.384 (95%CI: 0.448-0.320). The majority of patients were assigned to the internal medicine department (51.2%), followed by cardiology (10.7%), pneumology (8.3%) and neurology (6%) as main specialty groups. Intrahospitalary mortality rate was 6% (5 patients). In the diabetic patient's descriptive analysis, we found a mean age of 74.5 years (SD 9.8), being 56% (47) of them males. The main characteristics found were: anemia (23.8%), chronic kidney disease (29.8%), arterial hypertension (82.1%), heart failure (41.7%), obesity (26.2%), diabetic neuropathy (6%), and diabetic retinopathy (19%). The median for diabetes progression was 9.5 years (5.2–15). Regarding the mean laboratory test parameters, diabetic patients had: hemoglobin 11.04 mg/dl (SD 1.9), creatinine 1.4 mg/dl (SD 1.02), urea 77.5 (SD 51), and an HbA1c of 7.43% (SD 1.54) with a median of 7.1 (6.2-8.3). A total of 32 patients (40.5%) presented with HbA1c greater than 7.5% (excluding the laboratory test results from the 5 deceased patients). Specific recommendations for diabetes mellitus treatment optimization at discharge were done in 25 diabetic patients (78%).

Discussion: T2DM presents with a high prevalence among inpatients because of elevated comorbidity, this has a direct impact on morbi-mortality. Once optimization for intrahospitalary glycemic treatment has been established, the next step would be to evaluate the patient's previous metabolic control by systematic determination of HbA1c, in order to make changes and recommendations in treatment at discharge.

Conclusions: T2DM presents with a high prevalence among inpatients because of elevated comorbidity, this has a direct impact on morbi-mortality. Once optimization for intrahospitalary glycemic treatment has been established, the next step would be to evaluate the patient's previous metabolic control by systematic determination of HbA1c, in order to make changes and recommendations in treatment at discharge.

A PHYSICAL ACTIVITY INTERVENTION STUDY FOR THE IMPROVEMENT OF CARDIOVASCULAR RISK FACTORS IN ADULTS FROM A MEDITERRANEAN POPULATION

P. Pérez-Soriano[1], S. Llana[1], J. Sorlí[2], R. Osma[2], R. Acerete[2], D. Godoy[3], O. Portolés[2]

[1]Department of Physical Education and Sports. Faculty of Physical Activity and Sport Science. University of Valencia. Valencia, Spain. [2]Department of Preventive Medicine and CIBERobn. University of Valencia. Valencia, Spain. [3]Department of Internal Medicine. University General Hospital. Valencia, Spain.

Objectives: Clinical and epidemiological studies suggest that physical activity at any age is associated with an improvement of various cardiovascular risk factors: hyperglycemia, dyslipidemia, high blood pressure, Body Mass Index (BMI), and abdominal obesity. The extent of the intervention is a limitation in the evaluation of the results of such studies. Our aim was to carry out a pilot study to evaluate the effect of exercise in reducing these parameters, through a physical activity assisted by a physical trainer.

Material and method: We have carried out a pilot study consisting of a physical activity intervention for 7 weeks in overweighed adults (BMI ≥ 25 kg/m^2). The intervention consisted of walking on an area of land without tilt. Participants performed two practice sessions per week, one hour/day, supervised by a technician. Initial results on the test heart rate recovery were used to delimited margins of work, between 65 and 80% of maximum heart rate, individualized for each participant. To estimate body composition a scale (Tanita BC-420-S) was used. Biochemical, blood pressure and the anthropometric data were obtained at baseline and after intervention.

Results: We included 52 participants 65% women, mean age 46.6 ± 18 y. with no differences by sex (p = 0.479). The mean BMI of the population was 27.97 ± 5.3 kg/m^2 with no differences by gender (p = 0.763). Mean fat mass was 24.9 ± 11 kg with no differences between men and women (p = 0.410). Visceral fat and waist were significantly higher in men (p > 0.05). The mean of fast glucose (94.4 ± 10.2 mg/dL), total cholesterol (213.5 ± 46.3 mg/dL), triglycerides (110.4 ± 44.9 mg/dL) and LDL-chol (138.0 ± 35.4 mg/dL) did not differ by gender, however, the HDL-chol was higher in women (65.0 ± 15.7 mg/dL, p = 0.003). Mean blood systolic and diastolic pressures were 129 ± 15.5 mmgHg and 79.6 ± 9.53 mmHg, respectively, with no differences by gender (p > 0.05). After the intervention, all anthropometric and biochemical parameters studied were significantly decreased (p < 0.001), with no difference by sex (p > 0.05).

Conclusions: An easy physical activity like walking twice a week produces visible benefits even a short-term.

This work has been supported by grants EVES 2011-056.

RV-105
SENSITIVITY AND SPECIFICITY OF DIGITAL PULSE OXIMETRY AS A DIAGNOSTIC TEST FOR PERIPHERAL ARTERIAL DISEASE

C. Álvarez, G. Verdú, J. Ena

Department of Internal Medicine. Hospital de Villajoyosa. Alicante, Spain.

Objectives: Ankle-brachial index is the gold standard test for office diagnosis of peripheral arterial disease, but it requires special equipment and skills of the examiner. We evaluated the diagnostic performance of pulse oximetry as an easier method for screening of peripheral arterial disease.

Material and method: We carried out ankle-brachial index measured by handheld doppler (Minidop ES-100 VX®, Hadeco Inc.,

Japan) and handheld digital pulse oximetry (APEX Medical Corp®, SA210, Taipei, Taiwan) in 110 patients admitted to our Internal Medicine Department between March and May 2012. The ankle-brachial index was considered abnormal if it was less than 0.9. Pulse oximetry of the toes was considered abnormal if the SaO_2 was more than 2% lower from the finger or on 30 cm elevation of the foot. Patient's inclusion criteria were age greater than 50 years old with an additional risk factor (smoking, hypertension, diabetes mellitus or hypercholesterolemia) and given informed consent. We excluded patients with known history of any vascular disease and patients with limb amputations or with conditions precluding clinical examination. We calculated sensitivity and specificity of digital pulse oximetry used as index test compared to ankle-brachial index estimated by handheld doppler as reference method.

Results: The prevalence of peripheral arterial disease was 9.50% (95% confidence interval [CI]: 6.14-14.40). Pulse oximetry correctly identified 3 out of 21 patients with ankle-brachial index below 0.9 (Sensitivity 14.28%; 95%; [CI]: 3.77-37.36) and correctly ruled out the disease in 134 out of 199 patients (Specificity 67.34%; 95% [CI]: 60.29-73.70). Agreement between pulse oximetry SaO_2 gradient and ankle-brachial index categories was very low (Kappa = -0.09).

Discussion: Identifying patients admitted to internal medicine departments with unknown vascular diseases would allow to optimize treatment to achieve proposed targets of control. Previous studies showed a prevalence of undiagnosed peripheral arterial disease of 29% in elderly patients admitted to internal medicine departments. The ankle-brachial index used as reference method for diagnosis can not be easily implemented as a routine test because it is time consuming and requires skills of the examinator. Pulse oximetry is a widely available device at hospital nurse stations and may facilitate the screening for vascular disease. We hypothesized that patients with peripheral vascular disease will show a decrease in SaO_2 from the toes to the fingers. Nevertheless the diagnostic performance of digital pulse oximetry as screening for peripheral vascular disease was very poor. Additional methods should be tested in order to facilitate the diagnose of this highly prevalent condition in patients admitted to internal medicine departments.

Conclusions: Pulse oximetry based criteria yield a high proportion of false-negative test for the diagnosis of unknown peripheral vascular disease.

RV-106
DIETARY FAT MODULATES PRO-INFLAMMATORY GENE EXPRESSION IN INSULIN-RESISTANT PATIENTS WITH METABOLIC SYNDROME

N. Delgado Casado, A. García Ríos, C. Cruz Teno, A. Pérez Caballero, J. Delgado Lista, P. Pérez Martínez, J. López Miranda

Hospital Universitario Reina Sofia/IMIBIC/CIBEROBN/UCO. Cordoba, Spain.

Objectives: Metabolic syndrome (MS) is a public health problem with an increasing prevalence associated with unhealthy lifestyles and which main feature is insulin resistance (IR). Its etiology is related to a pro-oxidative and pro-inflammatory environment, produced by a high intake of nutrients, especially saturated fat. Chronic inflammatory processes may decrease insulin sensivity and are crucial in the pathogenesis of MS. Objectives: to study the differential effect of dietary fat on the expression of pro-inflammatory genes in insulin-resistant and non insulin-resistant patients with MS.

Material and method: 75 patients from the LIPGENE cohort were divided into two groups according to HOMA (homeostasis model assessment IR): HOMA < 3.2 and HOMA ≥ 3.2. Participants were randomized to receive one of four dietary intervention periods for 12 weeks: 1. Saturated fat diet (HSFA) 2. Monounsaturated fat diet (HMUFA) 3. Low fat, high carbohydrate (CH) diet (LFHCH) 4. Low fat, high CH with 1.24 g/day of polyunsaturated n-3 (LFHCH n-3). Blood samples were taken at fasting, before (pre-intervention) and after (post-intervention) dietary intervention period. We determined the expression of MMP-9 (metalloproteinase-9), TNF-α (tumor necrosis factor-α), IL (interleukin)-6, IL-1β and IL-8 genes by quantitative PCR.

Results: In pre-intervention period we observed lower levels of MMP-9 and TNF-α ($p < 0.05$) genes expression in patients with HOMA < 3.2 compared to those with HOMA ≥ 3.2. In post-intervention period we found lower levels of MMP-9 gene expression after HMUFA diet compared with HSFA diet ($p < 0.05$) in patients with HOMA index ≥ 3.2. Moreover, an increase of TNF-α gene expression was observed in patients with HOMA index ≥ 3.2 after HSFA and LFHCH diets compared with HMUFA diet ($p < 0.05$). Consumption of HMUFA diet induced lower IL-8 gene expression, compared with LFHCH and LFHCH-n3 diets, in patients with HOMA index ≥ 3.2. There were no significant differences in the rest of analyzed genes.

Conclusions: The results of our study suggest that the consumption of a HMUFA diet attenuates the inflammatory response in insulin-resistant patients with MS. This healthy diet model may be appropriated as nutritional therapy to prevent and improve IR in patients with MS.

RV-107
LIRAGLUTIDE IMPROVES THE PROFILE OF LIPID AND CARDIOVASCULAR RISK BIOMARKERS FROM BASELINE

N. Tobares[1], V. Fonseca[2], J. Devries[3], S. Bain[4], R. Pratley[5], T. Jensen[6], H. Hartvig[7], S. Marso[8]

[1]Department of Internal Medicine. Hospital Clínico San Carlos. Madrid, Spain. [2]Department of Endocrinology. Tulane University. New Orleans (Luisiana), United States of America. [3]Department of Internal Medicine. Academic Medical Centre. Amsterdam, Netherlands. [4]Department of Endocrinology. Abertawe Bro Morgannwg University Health Board. Swansea, United Kingdom. [5]Diabetes Institute. Florida Hospital. Orlando (Florida), United States of America. [6]Medical Affairs, [7]Biostatistics. Novo Nordisk. Copenhagen, Denmark. [8]Mid-America Heart Institute. St Luke´s Hospital. Kansas City (Missouri), United States of America.

Objectives: Type 2 diabetes (T2D) is characterized by increased risk of cardiovascular (CV) disease. In this analysis we assessed the impact of liraglutide therapy on lipid and CV biomarker profiles in patients with T2D.

Material and method: We conducted a meta-analysis of seven randomized controlled phase 3 trials that compared liraglutide 1.8 mg OD with other T2D therapies (glimepiride, rosiglitazone, insulin glargine, exenatide, sitagliptin) and placebo using data from 0–26 wks. The ANCOVA model used trial, previous treatment and randomised treatment as fixed effects and baseline value of outcome variable as covariate.

Results: Liraglutide treatment significantly decreased total cholesterol (TC), low-density lipoprotein-cholesterol (LDL-C) and triglycerides (TG) from baseline ($p < 0.0001$ for all) (Table 1). With comparators, only TG were significantly decreased (glimepiride and sitagliptin, $p < 0.01$ for both). Liraglutide also resulted in significant reductions in the CV biomarkers plasminogen activator inhibitor 1 (PAI-1) ($p < 0.01$), brain natriuretic peptide (BNP) and high sensitivity C-reactive protein (hsCRP) ($p < 0.0001$ for both) vs baseline. By contrast, comparator therapy reductions in PAI-1 and BNP were all non-significant and only rosiglitazone significantly decreased hsCRP vs baseline ($p < 0.0001$).

Discussion: In contrast to any of the comparators, liraglutide significantly reduced all the reported lipid and CV biomarker parameters in the T2D patients included in this meta-analysis.

Table 1 (RV-107). Change in lipids and CV biomarkers vs baseline

Lipid and CV risk biomarker change	Liraglutide n = 1496a	Rosiglitazone n = 219a	Glimepiride n = 467a	Glargine n = 225a	Exenatide n = 210a	Sitagliptin n = 201a	Placebo n = 485a
TC (mmol/L)	–0.17***	+0.24††	–0.06	0.00	–0.05	–0.03	+0.02
LDL-C (mmol/L)	–0.08***	+0.17††	+0.02	+0.07	–0.03	+0.02	+0.01
TG (mmol/L)	–0.28***	–0.09	–0.19**	–0.22	–0.09	–0.36**	0.00
PAI-1 (%)	–7.2**	–3.5	+5.2	–4.5	–9.3	+5.1	+7.2
BNP (%)	–10***	+35.8†††	+1.8	+12.8†	–3.2	+11.7	+6
hsCRP (%)	–24***	–53.3***	– 10.2	+5.5	–12.7	–10.7	–0.3

(a) n values varied depending on data availability. (*) p < 0.05; (**) p < 0.01; (***) p < 0.001 vs baseline.(† was used instead of * for p values corresponding to a significant increase).

However, further studies are needed to confirm the impact of liraglutide on lipid and CV risk protein biomarker profiles.

Conclusions: In addition to its known effects on glycaemia, weight and systolic blood pressure, liraglutide may also reduce CV risk by improving lipid and CV biomarker profiles.

RV-108
GALEN WAS RIGHT ABOUT THE PULSE DIAGNOSIS: RESTING HEART RATE PLAYS A MAJOR ROLE IN CARDIORESPIRATORY FITNESS, A USEFUL PREDICTOR OF ALL-CAUSE MORTALITY RISK

M. Fabregate Fuente, M. Murchante, R. Esteban, I. González, R. Fabregate Fuente, E. Tutor, C. Martínez, J. Sabán Ruiz

Department of Endothelial Pathology. Department of Internal Medicine. Ramón y Cajal Hospital. Madrid, Spain.

Objectives: To evaluate the main determinants factors of VO_2max, adjusted by age and sex, to know them we can correct and improve the fitness of our patients.

Material and method: N = 50, 32 males/28 females Age: 40.0 (10.5) y.o, (ranged 20 to 70). 28% hypertensives, 24% hyperglycemia, 18% smokers, 14% metabolic syndrome. Participants were eligible for CRF testing if they had no history of heart disease, no beta-blockers, blood pressure < 160/90. Biochemistry: HITACHI. Blood pressure by OMRON M10-IT. Fat mass: OMRON BF300, A1C (%): DCCT. Cardiorespiratory Fitness (CRF) testing: Rating of Perceived Exertion (RPE): Borg CR10 scale. Standard clinical treadmill: h/p/Cosmos LE 200 CE (h/p cosmos sports & medical Gmbh, Nussdorf-Traunstein, Germany). Age-predicted maximum heart rate according to Tanaka et al, 2001 (HRmax = 208 - 0.7 × age). A modified Balke submaximal exercise test on a treadmill was used to estimate maximum oxygen uptake (VO_2max) in ml/kg/min. Blood pressure was monitored by auscultation; heart rate and rhythms were recorded by Polar heart rate monitoring and h/p Cosmos Para Control software. The speed and elevation was used to convert treadmill performance to metabolic equivalents (METs). Linear regression between METS and HR at final stages (above 60% of HRmax) and to estimate VO_2max (1 MET = oxygen uptake of 3.5 mL/kg/min). Statistical analysis: continuous variables described as mean (standard deviation). Multivariate linear regression model. p < 0.1 was considered significant. Statistical analysis was performed with SPSS, version 15.0 (SPSS Inc).

Results: 1. VO_2max was inversely correlated to resting values of heart rate (standardized Beta = -0.426, p = 0.001; R^2 = 0.284), systolic blood pressure (B = -0.311, p = 0.044; R^2 = 0.181), diastolic blood pressure (B = -0.344, p = 0.018; R^2 = 0.208), after adjustment for age and sex. 2. A higher heart rate reserve (HRmax – resting HR) was associated to higher values of VO_2max (B = 0.501, p < 0.001; R^2 = 0.250) 3. Patients with a better CRF showed lower values of LDL-C (B = -0.264; p = 0.071; R^2 = 0.170) and triglycerides (B = -0.262, p = 0.082; R^2 = 0.162) independently of age and sex. 4. Percentage of Body fat mass (%) was also inversely related to VO_2max (B = -0.245, p = 0.092; R^2 = 0.140). 5. No significant association was found between CRF and waist circumference, weight, BMI, HDL-C, GLUC and A1c.

Discussion: In ancient Rome, the great physician Galen was the great master of pulse diagnosis, and wrote a treatise on the subject entitled De Pulsibus. Above-average cardiorespiratory fitness of the individual, as reflected by VO_2max (maximal oxygen uptake during incremental exercise), has been consistently shown to be associated with decreased mortality in healthy population and in patients with coronary artery disease. Recent studies (Kodama et al. JAMA, 2009) suggest that cardiorespiratory fitness could be useful for prediction of all-cause mortality risk in a primary-care medical practice. Our study supports the importance of resting heart rate in the CRF.

Conclusions: 1. A lower heart rate is good and simple-to-measure predictor of a higher level of cardiorespiratory fitness, independently of age and sex. Heart rate reserve is an age-adjusted parameter derived from resting heart rate strongly related to VO_2max. 2. Both systolic and diastolic blood pressure are closely associated with CRF. A better CFR seems to be related to lower values and/or a better control of blood pressure. 3. Also lipid profile (LDL-C and triglycerides) and body composition (% of fat mass) seems to be associated with CRF. 4-As resting heart rate plays a major role in cardiorespiratory fitness assessment, if we cannot measure VO_2max, we should give more value to this simple measurement in the office. Galen was right.

RV-109
INVESTIGATION OF AORTIC PWV IN OBESE HYPERTENSIVE AND NORMOTENSIVE PATIENTS

E. Arslan, F. Bulucu, S. Demirbas, H. Sarlak, S. Ay, M. Karaman, K. Saglam

Department of Internal Medicine. Gülhane Military Medical Faculty. Ankara, Turkey.

Objectives: Aortic (carotid-femoral) pulse wave velocity (PWV), the current "gold-standard" measure of arterial stiffness, has emerged as an important independent predictor of cardiovascular events. Obesity is often associated with cardiovascular risk factors such as hypertension and hyperglycemia. We aimed to investigate the relationship between hypertension, BMI and aortic PWV.

Material and method: 57 hypertensive-obese and 52 normotensive-obese cases- a total of 109 (males n = 48, females n = 61) patients were included in this retrospective cross-sectional study. Cases having an additional disorder other than hypertension and obesity (peripheral arterial disease, malignancy, chronic renal failure, etc.) were not included in the study. All patient records of arterial blood pressure, body mass index (BMI) values and the aortic PWV were assessed. We used Student's t test and Pearson correlation for statistical analysis.

Results: The differences of mean age (50.0 ± 12.8 and 48.7 ± 12.9 years respectively) and BMI (34.0 ± 2.8 kg/m^2, 33.0 ± 2.9 kg/m^2 respectively) were not significant between the hypertensive and normotensive obese groups (p = 0.1, p = 0.07 respectively). There

were significant differences between both groups for systolic blood pressure (153.7 ± 13.8 mmHg, 126 ± 8.5 mmHg, respectively) (p = 0.001), diastolic blood pressure (88.7 ± 9.3 mmHg, 76.9 ± 6.7 mmHg, respectively) (p = 0.001) and PWV (10.0/s, 8.5 m/s respectively) (p = 0.001). There were also significant correlations between PVW with systolic blood pressure, diastolic blood pressure and age (r = 0.301, p = 0.001/r = 0323, p = 0.001/r = 0229, p = 0.01) but BMI lacked a significant correlation (r = 0.085, p = 0.38).

Conclusions: According to these data, it could be concluded that putting on weight in obese patients does not increase aortic PWV, but in obese patients, the factor that increases PWV may be other conditions associated with obesity and hypertension.

RV-111
ASPIRIN RESISTANCE IN PATIENTS WITH RECENT ISCHEMIC STROKE: IS AN EFFECTIVE STRATEGY TO SWITCH FROM ASPIRIN TO CLOPIDOGREL?

L. Castilla Guerra[1], F. Jiménez Gonzalo[2], C. Fernández Moreno[3], E. Roldán Fontana[2], J. Álvarez Suero[1], J. Marín Martín[1], D. Jiménez Hernández[3], J. López Chozas[4]

[1]Department of Internal Medicine, [2]Department of Hematology. Hospital Comarcal de la Merced. Sevilla, Spain. [3]Department of Neurology. Complejo Hospitalario Nuestra Señora de Valme. Sevilla, Spain. [4]Department of Internal Medicine. Complejo Hospitalario Regional Virgen del Rocío. Sevilla, Spain.

Objectives: Aspirin (ASA) is a cornerstone of secondary prevention in patients with ischemic stroke. However, there is an increasing concern among physicians about aspirin resistance after ischemic events. Besides, specific treatment recommendations are not established for patients who exhibit high platelet reactivity during ASA therapy. We aimed to assess if switching to clopidogrel in patients with recent ischemic stroke and ASA resistance is an effective strategy.

Material and method: Fifty patients aged 48-85 years (mean age: 68) who had ischemic stroke in the previous 6 months were assessed in the outpatients clinic of our Hospital. ASA had been taken since the stroke episode. Resistance was analyzed using the PFA-100 aggregometer. In those patients with ASA resistance ASA was switched to clopidrogrel, and later on clopidogrel resistance was assessed.

Results: We included 43 (86%) patients with lacunar strokes and 7 (14%) patients with non-lacunar strokes. Thirty-seven (74%) patients were male. Twenty-nine (58%) patients received ASA in a daily dose of 300 mg, 5 (10%) patients 150 mg/day, and 16 (32%) 100 mg/day. Hypertension was the commonest risk factor (36 patients, 72%). Other risk factors included hypercholesterolemia (34 patients, 68%), diabetes mellitus (24 patients, 48%), smoking (20 patients, 40%), obesity (21 patients, 42%), and previous stroke (6 patients, 12%). ASA resistance was observed in 16 (32%) patients. We found no correlation between diminished response to ASA and vascular risk factors, ASA dosage, type of ischemic stroke, or sex. However, patients with diminished response to ASA presented a higher frequency of previous stroke (p = 0.01). Clopidogrel resistance was tested in 12 of these ASA resistant patients, and 4 patients were lost in the follow-up period. Six of these patients (50%) presented clopidogrel resistance.

Conclusions: A diminished response to ASA in patients with recent stroke is commonly observed. This phenomenon is clinically unpredictable. A switch from ASA to clopidogrel in patients with ASA resistance after a recent ischemic stroke doesn't seems to be an effective strategy.

RV-112
HEALTH RELATED QUALITY OF LIFE AND AGE IN HYPERTENSIVE PATIENTS: SELF-PERCEPTION AND EVALUATION BY PROFESSIONALS. THE EQUALITY STUDY

A. Roca-Cusachs[1], J. Abellán Alemán[2], D. Ruiz Hidalgo[1], B. Font[3], J. Salazar Meléndez[3]

[1]Department of Internal Medicine. Hospital de la Santa Creu i Sant Pau. Barcelona, Spain. [2]Chair of Cardiovascular Risk. Universidad Católica de Murcia. Murcia, Spain. [3]Health Outcomes. Novartis Farmacéutica SA. Barcelona, Spain.

Objectives: To analyse the association between Health Related Quality of Life (HRQoL) and age, in hypertensive patients. To evaluate the correlation between the HRQoL reported by patients and evaluated by their doctors.

Material and method: Observational, cross-sectional, multicentre national study, in Primary Care and Specialised Care. Inclusion of 5031 hypertensive patients, divided into three age groups (< 65, 65-80, ≥ 80 years) was planned. Selection criteria were: patients whose age was over 18, that were diagnosed as having hypertension at least one year before and attended a follow-up visit. Data related to hypertension, basic socio-demographic and clinical data, answers to the self-administered specific questionnaire MINICHAL for the evaluation of HRQoL (higher scores indicative of lower HRQoL), as well as scores in a visual analogue scale (VAS) for the general evaluation of HRQoL (higher scores indicative of higher HRQoL) by patients and doctors, were recorded. Data of 4,346 eligible patients was included. HRQoL-age correlation was analysed by Spearman's-rho, differences among age groups by Kruskal-Wallis and patient/doctor agreement by the intraclass correlation coefficient (ICC).

Results: Mean age (SD) was 68.35 (12.60). 38.1% of patients were under 65, 36.9% between 65 and 80, 25.0% were over 80. 54.5% were men. Mean time since diagnosis was 10.33 (7.68) years. 34.2% had a family history of high blood pressure. Mean scores in MINICHAL were: State of Mind dimension 8.07 (5.83), Somatic Manifestations dimension 3.24 (3.06). Worsening of both dimensions was found when comparing groups of increasing age (p < 0.001) as well as significant correlation of both dimensions with age (0.335, p < 0.001; 0.397 p < 0.001). Mean VAS score for doctors' evaluation was 66.84 (15.82) and 63.93 (18.46) that of patients; ICC for agreement was 0.697 (0.672, 0.687 and 0.663 by age groups).

Discussion: A clear impact of increase of age on HRQoL worsening was observed, affecting global HRQoL as well as State of Mind and Somatic Manifestations. Worsening was significant for subjects over 65, and again for subjects over 80. Doctors seem to assign slightly higher values to the HRQoL of their patients than the patients themselves.

Conclusions: Impact of hypertension on HRQoL increases with age. Patient/doctor agreement in the evaluation of HRQoL is adequate; however doctors tend to overestimate the HRQoL of patients.

RV-113
PREVALENCE OF MASKED HYPERTENSION AND WHITE-COAT HYPERTENSION BY MEANS OF AMBULATORY BLOOD PRESSURE MONITORING

M. Mellado, M. Areses, E. Ordónez, E. Bidegain, J. Aréjola, G. Tiberio

Department of Internal Medicine. Consultation. Hospital Virgen del Camino. Pamplona. Navarra, Spain.

Objectives: To determine the prevalence of masked hypertension (MH) and white-coat hypertension (WCH) in the population attending the cardiovascular-risk surgery of a tertiary care hospital

which have undergone an ambulatory blood pressure monitoring (ABPM) study.

Material and method: Descriptive study of data obtained from the ABPM made in the cardiovascular-risk surgery of a tertiary care hospital during the year 2011 in the cases referred by the World Health Organization and the clinical practice guidelines of the European Society of Cardiology and the European Society of Hypertension. Analyses were performed according to the Cardiorisc central database.

Results: Throughout the year 2001, 107 ABPM studies were made in the cardiovascular-risk consultation, 78.8% of them being of good or very good quality. There were 63 men and 44 women, mean age 60 years or more (47.7%). MH presented the 10.28% of patients (n = 11), 54.5% male, mostly aged 60 or more (54.5%). Measurements of blood pressure (BP) in the clinic and by ABPM (mean 24 hours) were respectively 11 and 128.6 126.7 ± 6.3 for systolic BP, and 10.4 ± 72.3 and 76.4 ± 8.1 for diastolic BP. Most of them had non dipper profile in the study of circadian pattern. The HBB appeared in the 14.95% of the sample (n = 16), gender differences, mainly in patients 60 years or more (62.5%). The clinic BP measurements were 155.1 ± 18.8 for systolic and 86.3 ± 11 for diastolic BP, while on the MAP resulted from 118.8 ± 70.7 ± 3.8 and 5.9 respectively. Mostly presented non dipper profile in the study of circadian pattern.

Discussion: MH is characterized by normal clinic BP and elevated ambulatory or home BP load, whereas patients with WCH have an elevation in clinic BP but normal home or ABPM values. Both entities are associated with increased cardiovascular risk and target organ failure and require high clinical suspicion and close follow-up diagnosis.

Conclusions: The prevalence of HE in this population is 10.28%, and 14.95% of WCH, similar to that described in other studies. We must consider the possibility of HE in practice, which should make us think about making more ABPM.

Table (RV-113)

	White coat hypertension	Masked hypertension
Clinic systolic BP	155.1 (18.8)	126.7 (11)
Clinic diastolic BP	86.3 (11)	72.3 (10.4)
ABPM systolic BP	118.8 (3.8)	128.6 (6.3)
ABPM diastolic BP	70.7 (5.9)	76.4 (8.1)

RV-114
CLINICAL CHARACTERISTICS OF PATIENTS UNDERGOING AN AMBULATORY BLOOD PRESSURE MONITORING STUDY ACCORDING TO THEIR CIRCADIAN PATTERN

M. Mellado, M. Areses, E. Ordóñez, R. Arnáez, J. Sánchez, G. Tiberio

Department of Internal Medicine. Consultation. Hospital Virgen del Camino. Pamplona. Navarra, Spain.

Objectives: Know the clinical characteristics of patients undergoing ambulatory blood pressure monitoring (ABPM) according to the circadian pattern they present.

Material and method: Descriptive data of the ABPM made in the consultation with cardiovascular risk of a tertiary care hospital during 2011 in the cases referred by the World Health Organization and the clinical practice guidelines of the European Society of Cardiology and European Society of Hypertension The analyses were performed according to Cardiorisc central database.

Results: During 2011, 107 ABPM studies were conducted;, 78% of them resulted in good or very good quality. 63 were men and 44 women, mean age 60 years or more (47.7%).

Discussion: The ABPM provides a method for assessing the PA that evaluates the circadian rhythms (extreme dipper, dipper, non dipper and riser). There is increasing evidence in the literature of the prognostic implications they present with Independence of the severity of elevated BP measures.

Conclusions: Non-dipper profile: male, 60 years or more, 2 or more cardiovascular risk factors besides hypertension (mainly dyslipidemia and advanced age), treated with 2 or 3 active. Dipper profile: male, 40 to 59, with low or moderate cardiovascular risk, 2 or fewer risk factors except hypertension cardiovascular (the most common age and dyslipidemia), treated with 1 or 2 active ingredients. Extrem dipper profile: male, 40 to 59, very high cardiovascular risk, at least 2 cardiovascular risk factors of hypertension (dyslipidemia, smoking, mainly), treated with 1 active. Profile riser: male, 60 years or more cardiovascular risk very high, with 2 or more cardiovascular risk factors except for hypertension (age and dyslipidemia, major), treated with 2 or 3 active.

RV-115
ANKLE-BRACHIAL INDEX AND PERIPHERAL ARTERIAL DISEASE: TWO GREAT NEGLECTED

J. Pérez Díaz, L. Pérez Belmonte, M. Blanco Díaz, M. Loring Caffarena, M. Platero Sánchez-Escribano, J. Constan Rodríguez, M. Guil García, C. San Román y de Terán

Department of Internal Medicine. County Hospital of the Axarquía. Vélez-Málaga (Málaga), Spain.

Objectives: Peripheral arterial disease (PAD) is an important marker of cardiovascular morbidity and one of the main markers to identify, in subclinical stages, patients with atherosclerotic disease. Currently we ignore how many patients are underdiagnosed in our hospital population. Therefore, the objective is to know the underdiagnosis of PAD and the burden of cardiovascular disease. So, we can stratify the risk and influence in our clinic behaviour.

Material and method: Type of study: observational, descriptive and transversal. Field of study: our Internal Medicine wards. Subjects: inpatients on May 15, 2012. Exclusion criteria: hemodynamic instability (hypoperfusion, shock, arrhythmias), severe dehydration, impaired consciousness (confusion, coma) and severe dementia. Measures and interventions: PAD was defined if the ankle-brachial index (ABI) was < 0.9 and underdiagnosis when ABI was < 0.9 and they didn't have PAD diagnosis in the medical record. We determined the intermittent claudication (IC)

Table (RV-114)

	Non dipper	Dipper	Extrem dipper	Riser
Number	46 (43%)	33 (30.6%)	6 (5.6%)	22 (20.6%)
Sex	Male (63%)	Male (57%)	Male (66%)	Male (52%)
Mean age	60 or more (47.8%)	40-59 (45%)	40-59 (83%)	60 or more (87%)
Cardiovascular risk	High-very high (52.2%)	Low-moderate (60.6%)	Very high (50%)	Very high (43.5%)
Nº CVRF appart from HTA	2 or more (52.3)	2 or less (81.1%)	2 or more (50%)	2 or less (78.3%)
Number of actives of treatment	2 or 3 (52.8%)	1 or 2 (72.2%)	1 or 2 (80%)	2 or 3 (55.3%)

using the Edinburgh claudication questionnaire. We used the oscilolometric method for measuring the ABI with a validated automatic device (microlife watch BP office ABI). We used statistical program SPSS 15.0 version and nonparametric tests to analyze the data. We divided the patients into two groups: PAD group (PADG) and non-PAD group (NPADG). We analyzed demographic, clinical and semiological data, comorbidities and cardiovascular risk factors.

Results: 61 patients were analyzed, although 9 were excluded. In both groups the average age was 75 years old and there was a clear male predominance, but not statistically significant. 33.77% has an ABI < 0.9 (16/52), including 4 patients with "index 0" or "mistake" in which the device did not register pulse in the lowers limbs. 7 patients had non-compressible ABI which indicates arterial stillness. 69% of patients were underdiagnosed, despite of 74% had symptomatic IC. Regarding to cardiovascular risk conditions and comobidities was statistically significant in PADG: diabetes mellitus (DM) (34.8 vs 24%, p = 0.03), moderate-severe chronic kidney disease (CKD) (39.1 vs 17.2%, p = 0.001), ischemic cardiomyopathy (IC) (39.1 vs 24.1%, p = 0.001) and stroke (30.4 vs 6.9%, p = 0.0001). There were also more smoking prevalence and dyslipidemia (DLP) in PADG but not statistically significant. High blood pressure (HBP) was the most common risk condition in our patients (more than three-quarters of them). 69% of the PADG had 3 or more cardiovascular risk factors. The triad with HBP, DM and DLP was the most powerful association.

Discussion: ABI determination is a simple, noninvasive and validated diagnostic test to detect arterial stenosis of 50% or higher, in lower extremities. The oscillometric method is objective, fast and improves the PAD detection respect to Doppler method if the test is not performed by trained physicians. Many of the elderly patients in our department have many TASC-III guidelines criteria. As a reflection and self-criticism, PAD is easily overlooked by patients and medical internists.

Conclusions: The underdiagnosis of PAD is really high in our patients, 69%. We have a high percentage of IC in our patients with PAD, in spite of using Edinburgh questionnaires, which is usually not a very sensitive test, what strikes us. However, we don't surprise the others vascular territories affectation and cardiovascular risk factors in this group. We recommend the ABI to use more widely in patients and evaluate the potential therapeutic impact.

RV-117
THE REFRACTARY HYPERTENSION. PERSPECTIVE FROM A VASCULAR RISK UNIT

T. Sánchez-Montón[1], D. Pujol Domínguez[1], J. Vega-Cervantes[1], N. Campillo Guerrero[1], G. Tornel Sánchez[1], M. Jiménez Pascual[1], A. Rodríguez Pavía[1], J. Ródenas Checa[2]

[1]Department of Internal Medicine, [2]Admission and Documentation. Complejo Hospitalario Universitario de Cartagena. Murcia, Spain.

Objectives: 1. Determine the prevalence and casuistic analysis of refractary hypertension. 2. Identifying the most profitable tests. 3. Establish the most effective therapeutic profile control in these patients. 4. Knowing the degree of control of these patients and its associated disorders.

Material and method: 885 patients of the Hypertension and Vascular Risk Unit. Medical records and hypertension database. Study period: 31 May 2011 to 31 May 2012. Methods: An observational, descriptive, longitudinal study. Setting: Patients attending the consultation from primary and speciality care, Health Area II of Murcia Community.

Results: We attended 885 patients with a median age of 59 years (rang: 13-90). The 26.8% under the age of 50. The distribution by sex: 54% women, 46% men. Refractary or difficult control hypertension was the main cause of consultation, established by 21% cases. The diagnosis was made with controls outpatient in 78% of cases, in consultation a 69% and 27.5% by MAPA. Risk factors more prevalent were: dyslipidemia 81%, obesity 56%, diabetes 52% and smoking 15%. The associated pathologies more important were: heart failure 28%, SAOS 27%, chronic renal failure 25%, arterial disease 22%, stroke disease 22% and atrial fibrilation 20%. Is secondary hypertension found in the 27.5%, the rest was primary hypertension. The renovascular disease and the primary hyperaldosteronism were the main causes of secundary hypertension, with a 12.5% and 10%, respectively. It had a proper control of the HTA (< 140/90) in 55% of cases. The 55.93% of diabetic patients presented HbA1c less than 7% and 42% cases of dyslipidemia had LDL less 100, it increased by 78% with levels < 120. Greater cost-effectiveness tests diagnosed were: glycohemoglobin A1c, lipid profile, cooximetry, the determination of plasma aldosterone and renin activity; proteins in urine in 24 hours, electrocardiogram, echocardiography, index ankle-brachial, ambulatory blood pressure monitoring and MRI of renal arteries. Most of the patients received 4 or more antihypertensive drugs, being the most widely used combination: angiotensin II receptor antagonist (80%), hydrochlorothiazide (60%), antagonist of calcium dihydropyridínic (57.5%) and doxazosin (55%). Other drugs: Beta blockers (47.5%), furosemide/torasemide (40%). ACE (20%), RI (17.5%), CA ND (15%), spironolactone (10%).

Discussion: The majority of patients with refractory hypertension can be controlled adequately with an association of appropriate drugs to full dose. Left ventricular hypertrophy appears in more than 50% of patients at the time of the initial consultation, as well as the renal apportionment in 25% of them. This indicates a very important delay in the control of hypertension that carries an associated organ damage. Requested many tests with a profitability diagnosed low offers opportunities of improvement in efficiency.

Conclusions: 1. Refractory hypertension is the main reason for consultation in our specialized unit. 2. The early definition of it and a quick control is possible and can prevent organic damage. 3. The prevalence of associated diseases is more high than in other grades of hypertension. 4. The delay in the diagnosis and control is associated with serious complications such as kidney disease, stroke and heart failure.

RV-118
DYSLIPIDEMIA AND GLOBAL CARDIOVASCULAR RISK IN VIH-WOMEN ON HAART ERA: IMPLICATIONS FOR PRACTICAL MANAGEMENT

J. Alzate Gallego, M. Bernardi, B. Castillo Fernández, M. Méndez Bailón, P. Ryan Murúa, N. Muñoz-Rivas, J. Troya

Department of Primary Health Care. Department of Internal Medicine. Hospital Infanta Leonor. Vallecas (Madrid), Spain.

Objectives: To know the frequency and clinical characteristics of dyslipidemia in women infected with human immunodeficiency virus (HIV) on highly active antiretroviral therapy (HAART). To detect the presence of other vascular risk factors and estimate their overall vascular risk.

Material and method: Retrospective study of 43 medical records of HIV infected women receiving HAART who have been controlled since 2008 in a specialized medical office. Variables of age, smoking, systolic blood pressure, total cholesterol, HDL, LDL and triglyceride were examined. Global vascular risk was calculated by SCORE charts for low-risk populations according to the Guidelines of dyslipidemia of the European Society of Cardiology 2011. We defined hypercholesterolemia with cholesterol levels > 190 mg/dl

and high triglycerides > 150 mg/dl. Variables were collected for viral load, CD4 and the drugs in HAART. We performed a descriptive analysis and subsequently a bivariate analysis between the levels of lipids and protease inhibitors.

Results: The mean age was 40.02 ± 9.36 years with a mean viral load of 37 cop/ml and CD4 levels of 684 cel/µl. Frequency of dyslipidemia defined by a cholesterol over 190 mg/dl was 27%. Hypertriglyceridemia (TG > 150 mg/dl) was 17%. The mean values of HDL were 59 ± 14 mg/dl and LDL 99 ± 29 mg/dl. Smoking was found in 60%. The mean systolic blood pressure was found in 14 ± 10 mmHg. The overall risk assessment by SCORE in all of them was ranged from 0 to 1%. The presence of hypertriglyceridemia was more frequent in patients receiving HAART with lopinavir-ritonavir if we compare this patients with other who are not exposed to this drug (35.3% vs 14.3%, p = 0.030).

Discussion: The presence of a cholesterol dyslipidemia defined above 190 mg/dl is common among HIV women. Despite a high frequency of dyslipidemia and smoking, the overall risk by SCORE is very low. This aspect may be mainly conditioned by the age and sex. However, being young women smokers makes interesting to use the relative risk tables by SCORE in the sense to promote the smoking cessation and dietary hygienic measures prior to the indication of lipid-lowering therapy. Lipid alteration most significant was the presence of hypertriglyceridemia associated with lopinavir-ritonavir. In this sense we should replace this drug by another with better antiretroviral lipid profile if feasible. It should be noted the need to better assess risk factors in these patients such as the presence of masked hypertension, metabolic syndrome or subclinical target organ injury. We need a more comprehensive assessment of vascular risk "individual" in HIV patients.

RV-119
ROUTINE EVALUATION OF KIDNEY FUNCTION IN HYPERTENSIVE PATIENTS – HOW IMPORTANT CAN BE A SIMPLE MEASUREMENT?

E. Badila, A. Daraban, E. Tintea, S. Frunza, C. Diaconu, M. Hostiuc, G. Oprea, D. Bartos

Department of Internal Medicine. Emergency Hospital of Bucharest. Bucharest, Romania.

Objectives: Background: Although evidence-based guidelines recommend routine evaluation of kidney function in hypertensive patients, the tests are unfortunately still too often neglected. The aim of the present study was to evaluate the prevalence and clinical correlates of CKD in patients with hypertension referred to our clinic.

Material and method: 170 subjects with treated or untreated hypertension (HTN) were included. Exclusion criteria were acute renal failure or rapid deterioration of renal function in patients with chronic renal failure, serum creatinine ≥ 3 mg/dl, secondary HTN, clinical signs of urinary tract infection, heart failure NYHA class III–IV. For each patient we recorded demographic and anthropometric data, BP values, echocardiographic data, associated clinical conditions (coronary artery disease, cerebro-vascular disease, peripheral artery disease), diabetes mellitus, concomitant medications. Serum creatinine levels were recorded, and GFR was estimated using the simplified MDRD study equation. CKD was defined as GFR less than 60 ml/min/1.73 m^2. Statistical analyses were performed using SPSS program.

Results: The patients were divided on the basis of GFR in 2 groups: I – 106 hypertensives with GFR ≥ 60 ml/min/1.73 m^2 and II – 64 hypertensives with GFR < 60 ml/min/1.73 m^2. The main differences between the 2 groups are: age (yrs) 48.9 ± 5.2 vs 56.8 ± 5.1, p 0.01; male 59 vs 42%, p 0.05; office SBP mmHg 138.6 ± 7.2 vs 142.8 ± 6.4, p 0.01; office DBP mmHg 86.4 ± 4.2 vs 88.7 ± 4, p 0.01; office PP mmHg 50.1 ± 7.4 vs 56.8 ± 7.2, p 0.01; SBP/ABPM mmHg 132 ± 6.4 vs 134.9 ± 5.2, p 0.01; LVMI g/m^2 108.8 ± 14.8 vs117.6 ± 12.3, p 0.01; duration of HTN > 5y: 30 vs 56%, p 0.01; adequate BP control achieved 53 vs 30%, p 0.01; serum creatinine(mg/dl) 0.9 +/- 0.2 vs 1.3 ± 0.3, p 0.01; hyperuricemia 21 vs 41%, p 0.01; associated clinical conditions 17 vs 48%, p 0.01; RAS inhibitor (%) 83 vs 86%, p ns; diuretics (%) 34 vs 66%, p 0.01.

Discussion: Renal abnormalities are found in a significant number of hypertensive patients (38%). One in three patients among those included in our study showed a reduced estimated GFR < 60 ml/min/1.73 m^2. CKD occurs more often in older patients and in those with associated metabolic risk factors or associated clinical conditions (coronary artery disease, cerebrovascular disease, peripheral artery disease). In our study a reduced GFR was associated also with female gender, SBP (both office and ABPM) values, office DBP (not at ABPM), PP (office and ABPM) values, LV hypertrophy (at echocardiography), duration of HTN, inadequate BP control, and diuretics use. Inadequate BP control was a relatively common finding in our study, regardless of the degree of renal impairment, and these data are in line with previously reported findings in the literature. In fact, BP values < 140/90 mmHg in the presence of CKD were only recorded in 30% of study patients.

Conclusions: These results suggest the need to improve awareness of the role of renal damage as a component of global risk. Increased awareness among physicians regarding the importance of reduced GFR as cardiovascular and renal risk markers could lead to earlier detection of patients at risk. This would improve treatment and possibly prevent or delay the progression of CKD and decrease the excess of CV risk associated with renal dysfunction.

RV-120
FRAMINGHAM PLUS. HIGH PREVALENCE OF CARDIOVASCULAR RISK FACTORS IN HIV-INFECTED PATIENTS

M. Torralba González de Suso, C. Hernández Gutiérrez, D. Rial Crestelo, P. Chacón Testor, L. Abejón López, C. Betancort Plata, E. Águila Fernández-Paniagua, A. Costa Cerdá

Department of Internal Medicine. Hospital Universitario. Guadalajara, Spain.

Objectives: The cardiovascular risk (CVR) calculated by the Framingham score (FS) has been validated in the HIV population, although it underestimates it. Our objective was to analyze the prevalence of other cardiovascular risk factors (in addition to those discussed in the FS) in our population with HIV infection and evaluate them based on how many patients should receive a theoretical pharmacotherapeutic intervention.

Material and method: Cross sectional study, with variables collected prospectively. Besides FS, we also analyzed, 14 variables that have been shown to play a role as cardiovascular risk factors (family or personal history of ischemic heart disease, cocaine, physical inactivity, waist circumference > 88 or 102 cm depending on sex, BMI > 30, TG > 200 mg/dl, CRP > 8 mg/dL, homocysteine > 12 mg/dl, renal failure, microalbuminuria, use of LPV/r, CV > 500 copies/ml, and HCV). It was proposed that a patient having > 20% in the FS or > 10% in the FS and > 2 cardiovascular risk factors qualified for a pharmacotherapeutic intervention.

Results: One hundred and thirty-three patients were analyzed. 71.4% were male with a median age of 43.5 years (IQR: 38-49). The median CD4 was 520 (IQR: 370-690) and 77% had VL < 50 copies/ml. 32% had HCV + and 6.8% HBsAg+. 61.7% were smokers with median pack-year index of 20 (IQR: 10-34). 10.5% had used cocaine in the past year. 41.4% were sedentary. 54.1% were overweight and 13.5% were obese.21.3% had a waist circumference greater than 102 or 88 cm by sex. 23% had an SBP/DBP > 140/90 mmHg and 6.7% were

diabetic. The total cholesterol/HDL was higher than normal in 25.9%, LDL cholesterol greater than 160 in 10%, triglycerides above 200 mg/dl in16.5%. 16% had a ratio of microalbuminuria/creatinuria above 25. 26.3% and 5.2% had a family or personal history of stroke or myocardial infarction. 32.1% of patients had an FS between 10-20% and 13.7% had it above 20%. The median of cardiovascular risk factors other than those included in the FS was 3 (IQR: 1.5 to 4). 10.5% were undergoing antihypertensive therapy and 11.5% were on statins. Only 17.3% (23/133) were treated with some kind of drugs. However, at least an additional 15% should be taking them.

Conclusions: The prevalence of cardiovascular risk factors is very high in the HIV population. The variables introduced in the FS underestimate cardiovascular risk in this population. Due to the high prevalence of cardiovascular risk factors in this population, pharmacotherapeutic strategies must be implemented.

RV-121
GLYCATED HEMOGLOBIN AS A MARKER OF CARDIOVASCULAR RISK IN PATIENTS ADMITTED IN INTERNAL MEDICINE

L. Ruiz Rivera[1], M. García Caballos[2], C. Lahoz García[1], I. Aomar Millán[1], A. Lluna Carrascosa[1], A. Díez Ruiz[1]

[1]Departament of Internal Medicine. Hospital de Especialidades San Cecilio. Granada, Spain. [2]Primary Care Center. Metropolitan Primary Health Care District of Granada. Granada, Spain.

Objectives: Determine the relationship between glycated hemoglobin (HbA1c) values and the presence of other cardiovascular risk factors considered, such as arterial hypertension and dyslipemia (DLP), in our patients. Evaluate its contribution to overall cardiovascular risk.

Material and method: We have conducted a prospective observational study collecting clinical and laboratory data, including HbA1c and the presence of hypertension and DLP, from patients who were admitted for any reason in the Department of Internal Medicine at the San Cecilio Hospital in Granada from April 15th to December 31st, 2010. For data analysis, patients were divided in two different groups: "DM" composed of patients with diagnosis of diabetes mellitus (DM), and "unknown DM", composed of patients without a previous diagnosis of DM. Subsequently, patients among the group "unknown DM" were divided in three subgroups according to their HbA1c levels: Group 1 (normoglycemic with HbA1c lower than 5.7%), Group 2 (prediabetic with HbA1c between 5.7 and 6.4%), Group 3 (diabetic with HbA1c equal or greater than 6.5%). We employed SPSS v.15 program, licensed by the University of Granada for data analysis.

Results: Our cohort consists of 356 patients. At the time of their inclusion in the study, 133 are "DM" and 223 are "unknown DM". The average age is 70.9 ± 17.7 years old, and 49.4% of them are men. The average HbA1c is 6.27 ± 1.36%. Patients with \"DM\" are more hypertensive than the "unknown diabetes", 83.5% (111) compared to 43.5% (97) respectively. Besides, they are more dyslipemic, 33.8% (45) vs 13.9% (31). Within the "unknown diabetes" group, there are more diagnoses of hypertension in patients in whom it has been found alterations in carbohydrate metabolism after sorting them according to their HbA1c levels, 52.2%(47) compared to 27.5% (28). In addition, the hypertensive show higher HbA1c levels compared to non-hypertensive patients with an average HbA1c, in hypertensive group, of 6.58 ± 1.45%.

Discussion: Different studies agree that HbA1c predicts cardiovascular morbidity and mortality in both diabetic and nondiabetic individuals. This evidence suggests a continuous relationship between glucose blood concentrations and cardiovascular risk. In non-diabetic population, several papers show that HbA1c levels are higher than the levels of fasting plasma glucose for the evaluation of long-term risk of developing cardiovascular disease. Individuals belonging to group 2, with HbA1c 5.7-6.4, must be paid special attention to seek cardiovascular risk factors as it has been proved that they have a high risk of developing coronary heart disease and cerebrovascular disease. In our study, among the group which unknown diabetes at the time of their inclusion, patients with alterations in carbohydrate metabolism are more hypertensive than the normoglycemic. This finding is added to their Diabetes and un-known prediabetes status, thus increasing their cardiovascular risk and hence benefiting even more from an intervention in this regard.

Conclusions: Our study supports the values of HbA1c in the quantification of cardiovascular risk not only in diagnosing and a carbohydrate metabolism disorder but also as an independent cardiovascular risk marker. This allows us to take measures to prevent cardiovascular diseases.

RV-122
INFECTIOUS COMPLICATIONS IN A STROKE UNIT

S. Mateus[2], C. Conceição[2], H. Moreira[2], N. Ferreira[2], A. Lourenço[1], F. Grenho[1], L. Campos[2]

[2]Department of Medicine IV. Hospital de São Francisco Xavier - CHLO. Lisboa, Portugal. [1]AVC Unit. Centro Hospitalar de Lisboa Ocidental. Lisboa, Portugal.

Objectives: In patients with ischemic stroke (IS), infectious complications are predictable and potentially avoidable. Studies show that organized care decreases incidence of IC and improves functional outcome. To compare length of stay, functional outcome and degree of dependence and disability in a population of patients admitted to a stroke unit (SU) with acute ischemic stroke that had infectious complications to those with acute IS that did not have any infection (CG).

Material and method: A retrospective study of patients admitted to a Stroke Unit between January and June 2011 through collection of data recorded in its database and clinical records.

Results: Of 108 patients admitted with ischemic stroke, 38% (41 patients) had infection, 18.5% urinary tract infection, 15.7% respiratory infection, 3.7% other focus. The average age of the patients in the infection group was 69.4 years vs 68.6 years in control group, with no significant difference between gender. The length of stay in infection group was 7 days (95%CI: 5.5-8.6) and in the control group was 5.3 days (95%CI: 4.7-5.8), with a p value = 0.02. At admission patients in the infection group presented a higher mean National Institute of Health Stroke Scale score (NIHSS) (10 points), and at discharge of 6.6 points, with a range of 3.4 points (95%CI: 1.9-5) compared to control group with admission NIHSSs mean value of 4.7 points, discharge NIHSSs mean value of 2.6 points and range of 2.1 points (95%CI: 1.6-2.7), all with statistically significant differences. The mean degree of dependence and disability, measured by modified Rankin Scale (mRS), was 2.9 points in the infection group vs 1.7 points in the control group, with a p value = 0.000.

Conclusions: The data analysis concluded that the presence of infectious complications was directly related to longer length of stay and worse neurological outcome. There was a strong correlation between the stroke severity, dependence and risk of contracting infections. Although it was not a primary objective of this study, we found that the incidence of infection, compared to published studies, was lower in this sample, perhaps correlated with the differentiated and standardized approach in SU.

RV-123
RELATIONSHIP BETWEEN ENOS AND HDL CHOLESTEROL LEVELS

J. Miramontes González, M. García García,
D. Pescador Hernández, L. Mateos Polo

Department of Internal Medicine. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca, Spain.

Objectives: In the development of endothelial dysfunction one of the most studied molecules is nitric oxide (NO) as an important vasodilator. It is known that in the evolution of endothelial dysfunction there is a poor production of NO. In the progress of endothelial damage and the genesis of the atheromatous plaque also contribute an important lipid levels. Lipid levels are a marker of vascular risk and one of the therapeutic goals in patients with vascular risk. We have studied the possible relationship between HDL levels and the enzyme that synthesizes NO, the endothelial isoform. To do this we select a polymorphism of the enzyme that synthesizes it. The gene encoding eNOS is located on chromosome 7, 7q35-36 location. Polymorphism was studied by changing a single nucleotide (SNP) at position 298 with a T for G. (rs 1799983).

Material and method: We studied a cohort of patients seen in a vascular risk unit. We selected 298 patients who came to control vascular risk factors. He had not previously received drug treatment. We excluded patients who had received drug treatment and those with hyperlipidemia families. Analytical extracted in the first visit to the unit. Amplification reactions were performed in automatic thermal cycler (Step One Plus® Applied Biosystems) using TaqMan® probes. Statistical analysis using the SPSS WAS Performed software.

Results: We classified the low HDL levels with lower levels 40 mg/dl for men and less than 46 mg/dl in women. High levels if are greater or equal to 40 mg/dl for men and women established limits equal to or greater than 46 mg/dl. The result 158 patients with low and 140 with very high levels. The result of the genotyping according to the HDL is as follows: Low levels: TT: 42, TG: 77, GG: 39. High levels: TT: 23, TG 70, GG: 47. The statistical association test, chi square 0.062.

Conclusions: No statistical relationship was found between HDL and eNOS polymorphisms studied. The level of statistical significance was next to p: 0.05 (p: 0.062) It is requires a study more comprehensive in the number of patients. Is necessary to study together the vascular pathology associated with endothelial damage.

RV-124
CENTRAL SYSTOLIC BLOOD PRESSURE, PULSE WAVE VELOCITY AND ABNORMAL AUGMENTATION INDEX IN THE SHOWCASE OF VASCULAR SENESCENCE

M. Fabregate Fuente[1], S. Tello Blasco[1], A. Guerri[1], A. Fernández[1], R. Fabregate Fuente[1], E. Marín[2], N. de la Torre[1], J. Sabán Ruiz[1]

[1]Department of Endothelial Pathology. Department of Internal Medicine, [2]Department of Vascular Surgery. Ramón y Cajal Hospital. Madrid, Spain.

Objectives: To evaluate the impact of different haemodynamic parameters in abnormal augmentation index of radial artery.

Material and method: N = 103. 62 males (60.2%). Age: 59.6 (13.1), 21-81 yo. 72.8% hypertensives, 70.9% hyperglycemia, 24.3% smokers Pulse wave analysis: SphygmoCor (AtCor). Augmentation Index was calculated from the central arterial waveforms as the difference between pressure at peak systolic flow and pressure at the peak of the reflected wave, divided by the central pulse pressure Augmentation index was adjusted to a standard heart rate of 75 bpm (AIx@75) at an inverse rate of 4.8% for each 10 bpm increment. Subjects were considered as abnormal AIx@75 (augmentation index adjusted to heart rate) if they were 1-standard deviation above sex-specific and age-adjusted population mean provided by AtCor from British subjects (polynomial regression). Central cardiovascular parameters: ejection duration (ED) in ms, subendocardial viability ratio (SEVR) in %, central systolic (CSBP) and diastolic blood pressure (CDBP) mmHg. Carotid-radial pulse wave velocity (PWV) (m/s) SphygmoCor system. A1c (%): DCCT; 10 years coronary Risk (%): Framingham model calibrated for Spanish population: REGICOR. Statistical: Continuous variables described as mean (Standard deviation). Multivariate linear regression model using age and gender as covariates was used to correlate AIx@75 and PWV. Multivariate: backwards method. Comparation between groups by independent samples t-test or Mann-Whitney's test as appropriate. Squared-Chi test. Two-tailed $p < 0.05$ was considered significant. Statistical analysis: SPSS(15.0).

Results: 1. The prevalence of abnormal AIx@75 was n = 29 (28.2%). The method of measure avoids the impact of age and heart rate, that are beyond question. In this study there was no significant differences in age because each abnormal case was adjusted by age and so the abnormal group had an age of 60.8 (13.4) vs 59.1 (13.0) in the normal group. 2- This prevalence is higher in males than in females: Gender: males (22 abnormal vs 40 normal); females (7 abnormal vs 34 normal). $p = 0.047$ 3-Significant differences were observed in 10-years coronary risk (%): 4.8 (2.4) vs 3.3 (2.2), $p = 0.008$, and A1c (%), both in the whole population: 6.1 (0.8) vs 5.7 (0.8), $p = 0.022$ and the hyperglycaemic group: 6.4(0.9) vs 5.9 (0.8), $p = 0.015$. 4- Among the non-invasive haemodynamic parameters measured (PWV, SEVR, ED, CSBP. CDBP), only central systolic blood pressure showed differences between the studied groups: 127.3 (14.5) vs 119.3 (14.1), $p = 0.012$. 5- No significant differences in PWV were found ((8.0 (1.4) vs 7.6 (1.1)), although a significant linear correlation between AIx and PWV was observed after adjustment by sex and age (non-standardized Beta = 2.65, $p < 0.001$¸ model $R^2 = 0.540$).

Discussion: When the heart contracts it generates a pulse or energy wave that travels through the circulation. The speed of travel of this pulse wave (pulse wave velocity or PWV) is related to the stiffness of the arteries. Moreover, by analysing the amplitude of the reflected and the first wave, the Augmentation Index can be calculated (AIx), providing information on both the stiffness of the aorta and about the peripheral vascular tone.

Conclusions: 1. Around 1 out of 3 patients with moderate-high risk have an abnormal AIx@75. 2. The prevalence of abnormal AIx@75 is higher in males. 3. The AIx is associated with glycemic metabolic control and coronary risk. 4. Central systolic blood pressure and PWV are the haemodynamic factors more closely related to AIx@75. These results are not surprising, as all of them are in the showcase of vascular senescence.

RV-125
DIFFERENCES IN BASELINE RENIN AND ALDOSTERONE CONCENTRATIONS BETWEEN EUTHYROID HYPERTENSIVE PATIENTS AND LEVOTHYROXINE-TREATED HYPERTENSIVE PATIENTS WITH SUBCLINICAL HYPOTHYROIDISM

A. Torres[1], E. Bello[1], J. Rodríguez[1], B. Mora[2], N. Aldezábal[2], M. Barrientos[2], L. Acevedo[2], L. Álvarez-Sala[1]

[1]Department of Hypertension, [2]Department of Internal Medicine IIB. Hospital General Universitario Gregorio Marañón. IiSG-M. RECAVA net member Madrid, Spain.

Objectives: The aim of our study was to compare baseline plasma levels of renin and aldosterone between euthyroid hypertensive patients and levothyroxine-treated hypertensive patients with subclinical hypothyroidism.

Material and method: In this pilot case-control study, we recruited 34 hypertensive patients from our hypertension unit.

Patients with other secondary causes of hypertension were excluded. We divided the sample into euthyroid patients (controls: n = 19) and hypothyroid patients treated with levothyroxine (cases: n = 15). We analyzed anthropometric and laboratory values and antihypertensive and lipid-lowering treatments for both groups. Baseline plasma levels of renin and aldosterone were assessed. SPSS 20.0 was used for the statistical analysis.

Results: No differences were found in plasma renin and aldosterone concentrations between hypothyroid patients and controls. Diastolic blood pressure tended to be higher in hypothyroid patients (p = 0.06). Total cholesterol and LDL cholesterol were lower in hypothyroid patients (p = 0.031 and p = 0.019). No differences were found between groups for any treatment, including lipid-lowering therapies, or for any of the other variables analyzed.

Discussion: Hypothyroidism is characterized by low plasma renin activity and dissociation in the renin-angiotensin-aldosterone system (RAAS). Thyroid hormone has an antiatherogenic effect on RAAS. It inhibits angiotensin II expression and its signal. Our hypothesis was that levothyroxine has a beneficial effect on RAAS in hypertensive patients with subclinical hypothyroidism, even though patients may not become completely euthyroid, Regardless of their subclinical hypothyroidism, levothyroxine-treated hypothyroid patients had plasma renin and aldosterone concentrations similar to those of controls. Diastolic blood pressure tended to be higher than in controls, as is the case with non-treated hypothyroid patients, although RAAS seemed to be normal. The lipid profile was better in patients treated with levothyroxine, perhaps due to the effects of this hormone on lipid metabolism.

Conclusions: Levothyroxine-treated hypertensive patients with subclinical hypothyroidism had plasma renin and aldosterone concentrations that were similar to those of euthyroid hypertensive patients, although they did not become completely euthyroid.

RV-126
IS THERE ANY ASSOCIATION BETWEEN VITAMIN D DEFICIENCY AND CARDIOVASCULAR RISK IN HIV PATIENTS?

M. Torralba González de Suso, L. Abejón López, J. García de Tena, E. Águila Fernández Paniagua, G. Hernando Benito, A. Costa Cerdá, E. Vilalta, L. Engonga Obono

Department of Internal Medicine. Hospital Universitario. Guadalajara, Spain.

Objectives: The prevalence of traditional cardiovascular risk factors in the HIV population is high. Vitamin D deficiency has been associated in several studies with increased cardiovascular risk. Our objective was to analyze the prevalence of vitamin D deficiency in the population with HIV infection and its association with other cardiovascular risk factors.

Material and method: Cross sectional study, with variables collected prospectively. We analyzed variables related to cardiovascular risks, the Framingham score (FS) and levels of vitamin D in patients with HIV infection. Vitamin D deficiency (25-OH-D3) was defined to have less than 15 ng/ml. We used univariate logistic regression to analyze the data, using vitamin D deficiency as dependent variable.

Results: One hundred and twenty-eight patients with a median age of 44 (IQR: 38-49 years) were analyzed and of which 74.2% were males. 39% had a deficiency of vitamin D. The variables that were associated with vitamin D deficiency were: lipoatrophy (OR: 0.82 95%CI from 0.72 to 0.94, p = 0.019), glycosylated hemoglobin. Out of these 5.8% accounts for patients with deficits and 5.3% for patients without deficit; (mean difference: 0.5%, 95%CI: 0.25 to 1.66, p = 0.010). The FS score was 15% in patients with vitamin D deficiency and 7.5% for those with no deficit (p = 0.10). The use of NNRTIs (EFV or NEV) was not associated with vitamin D deficiency. We did not find any association between vitamin D deficiency and sex, snuff smoking, cocaine use, physical inactivity, diabetes mellitus, hypertension, hypercholesterolemia, hypertriglyceridemia, age, hepatitis B or C, undetectable VL, waist circumference, the total cholesterol/HDL, albumin/creatinine ratio,SBP, DBP, heart rate, percentage of lean mass or fat mass percentage, the ratio of lean mass/fat mass, creatinine, CRP, CD4 count, time with HIV, or body mass index.

Conclusions: Vitamin D deficiency is highly prevalent in HIV infected population. Lipoatrophy and increased glycosylated hemoglobin is associated with vitamin D deficiency. We found a trend between a high Framingham score and the lack of vitamin D.

RV-127
CARDIOVASCULAR RISK FACTORS BEHIND THE BARS

M. Pérez Tristancho[1], P. Massi[1], J. Fajardo[2], J. Espinosa[3], M. Raffo[1], J. Morejón[3], I. Adarve[3], I. Suárez Lozano[2]

[1] Department of Internal Medicine, [2]Department of Infectious Diseases. Hospital Infanta Elena. Huelva, Spain. [3]Grupo EPRICAP. Centro de Prisión. Huelva, Spain.

Objectives: Cardiovascular diseases are the leading cause of death of Spanish population, which caused a total of 120.760 deaths until 2006. The prevalence of factors that determine the cardiovascular risk (CVRF) in the Spanish general population has been analysed previously by various authors. However there are few studies that determine its prevalence in special populations and persons arrested in a penitentiary institution. The aim of this study is to determine the prevalence of cardiovascular risk factors in a penitentiary center.

Material and method: Scope of study: Penitentiary Center. Design: cross-sectional study with data collection through a survey on cardiovascular risk factors, specifically designed for the study. We included all the prisoners who voluntarily accepted to participate through a written consent. We collected sociodemographic data, family and personal history of cardiovascular disease, weight, height, abdominal perimeter and blood pressure. We selected the cut-off points recommended by the National Cholesterol Education Program Expert Panel on Detection, Evaluation, and Treatment of High Blood Cholesterol in Adults (Adult Treatment Panel III) to determine cholesterol, triglycerides, HDL and LDL cholesterol. Measures of central tendency and proportions for a description of continuous variables or the qualitative variables were used. Ethical aspects: The study, approved by the technical Cabinet of the General Secretary of Penitentiary Institutions, was performed following the recommendations to lead physicians in biomedical research with human beings adopted by the Helsinki World Medical Assembly.

Results: We included a total of 1237 individuals (5.60% women) with a mean age of 37.2 (SD 10.31; range 19-78). 67.9% belonged to a low socioeconomic stratus, 76% only had primary education or none, 7.5% were illiterate and 24% were immigrants. 80% were smokers. 29% had high blood pressure, 31% had hypercholesterolemia, 12% triglycerides, HDL under 52%, 30.3% had a raising LDL and 6% diabetes. 54.3% had a body mass index higher than 25 and 20.6% were obese. 37.4% had a family history of cardiovascular disease, 15.4% had been diagnosed with a pre CVD. The proportion of individuals with 0, 1, +2 risk factors was of 5.50%, 23.8% and 70.6%. The percentage of individuals with dyslipidemia was 64.8%.

Conclusions: The prison population is integrated by young adults with low socioeconomic level and low level of education. These characteristics define a vulnerable group from the point of view of health. Smoking is the most common cardiovascular risk factor in

the prison and his prevalence is higher than the general population. This feature would determine future responses of health departments for the prevention and treatment of this addiction. The prevalence of other cardiovascular risk factors is similar to the general population for the same ranges of age. Taking into account their socio-demographic characteristics and the opportunity of stay in prison, it should be implemented health education programs adapted to their needs. The main weakness of this study is that it was performed in a single prison, so it would be advisable to make a multicenter study.

RV-128
ACUTE MYOCARDIAL INFARCTION WITH NORMAL CORONARY ANGIOGRAM: POSSIBLE MECHANISM OF HEROIN OVERDOSE RISK IN CORONARY ARTERY DISEASE

C. Voulgari; S. Siasiakou; L. Kalantzopoulou; S. Paximadas; S. Pagoni

3rd Department of Internal Medicine. Athens Regional Hospital G. Gennimatas, University Medical School. Athens, Greece.

Objectives: The apparent paradox of well-documented myocardial infarction with a subsequently normal coronary angiogram although no longer clinically regarded as a rarity, is still not well documented. This study was undertaken to examine the clinical features and risk factors which distinguish those patients with myocardial infarction and a normal angiogram from those whose infarction is associated with obstructive coronary disease before the age of 40.

Material and method: The coronary angiograms of 20 consecutive patients (mean age 40 ± 5 years) were examined. Ten new cases of myocardial infarction with normal coronary arteriogram were identified (group 1) and compared with 10 cases of myocardial infarction and obstructive coronary disease (group 2) matched for age and gender. The medical records of the patients were reviewed for clinical documentation of myocardial infarction (typical history, enzyme release, and the subsequent ECG development), clinical course, and presence of risk factors.

Results: Heroin overdose (Odds Ratio, 95% Confidence Interval, 1.04, 1.00-1.06, p = 0.001) and cigarette smoking (OR, 95%CI 1.4, 1.00-1.64, p = 0.01) were the main risk factors in group 1. Other factors included in the model were age, gender, obesity, hypercholesterolemia, arterial hypertension, and type 2 diabetes mellitus. Hypercholesterolemia (OR, 95%CI 1.4, 1.07-2.52, p = 0.001), arterial hypertension (OR, 95%CI 1.9, 1.05-3.45, p = 0.03) and type 2 diabetes mellitus (OR, 95%CI 3.06, 1.79-4.25, p < 0.001) were identified as main risk factors in group 2. Pre- and postinfarction angina was rare among the patients with myocardial infarction and normal coronary arteriogram (OR, 95%CI 1.02, 0.98-1.07, p = 0.22) and recanalisation after heroin and smoking-induced thrombotic occlusion was described as the most likely pathophysiological mechanism (OR, 95%CI 2.4, 1.58-3.64, p < 0.001).

Discussion: The economic crisis in Greece has adversely affected the well-being, and has ramifications for social health systems. The impact of heroin addiction has been a growing concern for all social security schemes. Acute heroin overdose has become a daily experience in the Emergency Room and accounts for many preventable deaths. Heroin-induced thrombosis is only likely to be recognised in special circumstances, when it develops in apparently normal coronary arteries, is followed by recanalisation, and is complicated by infarction as a permanent marker of previous obstruction to regional myocardial blood flow. Thrombotic occlusion of a "normal" coronary artery without recanalisation is usually recognised when myocardial ischemia is fatal. If heroin overdose can predispose to thrombosis in "normal" coronary arteries, it may be even more likely to accelerate thrombosis in atheromatous coronary arteries. Efforts to reduce the health effects of heroin use must be embedded in policies that address the underlying causes and which serve to reduce cardiovascular risk in shattered communities.

RV-129
BASELINE CHARACTERISTICS OF HOSPITALIZED PATIENTS UNDER 40 YEARS OLD WITH ACUTE CORONARY SYNDROME DIAGNOSIS

C. García Corrales, P. Márquez Lozano, C. Aranda López, P. García García, L. García Serrano, J. Nogales Asensio, J. Lopez Mínguez, A. Merchán Herrera

Department of Cardiology. Complejo Hospital Universitario de Badajoz. Badajoz, Spain.

Objectives: The incidence of acute coronary syndrome (ACS) increases with age being uncommon in the young (defined as patients under 40 years old). These young patients suffering from ACS differ by risk factor profiles, clinical presentations and prognosis. Our aim was to evaluate baseline and clinical variables of hospitalized young patients with ACS in our center.

Material and method: To evaluate this fact we performed a descriptive study including 112 young patients admitted with the diagnosis of ACS: 80 (71.4%) with ST segment elevation (-STE) and 32 (28.6%) without ST segment elevation (-NSTE). We registered classical cardiovascular risk factors, as well as toxic habits, particularly cocaine consumption, in addition with several clinical parameters such as the presence of heart failure (HF), defined in line with Killip score, at admission or complications during hospitalization. We made a descriptive analysis of the therapeutic strategy (percutaneous revascularization, PCI, or conservative treatment) and the different drugs used. Furthermore, the lipid profile was registered (table).

Results: Mean age was 36.2 ± 3.5 years. There was a higher prevalence of males (81.2%). Smoking was the most prevalent basal cardiovascular risk factor (76.8%) while only 13 patients (11.6%) were cocaine consumers. On the other hand, family history of cardiovascular disease was present in 28 patients (25%), diabetes mellitus in 10 (8.8%), dyslipemia in 27 (24.1%) and hypertension in 19 patients (17%). Most patients had not complications. We found no differences in basal and clinical variables between both types of ACS.

Table (RV-129)

Variables	STE-ACS (N = 80)	NSTE-ACS (N = 32)	p
LDL-C > 115 mg/dl	29 (36.3%)	7 (21.9%)	NS
HDL-C < 40 mg/dl	39 (48.8%)	10 (31.3%)	NS
Coronary arteriography	75 (93.8%)	28 (87.5%)	NS
No coronary lesions	16 (20%)	13 (40.6%)	NS
Multivessel disease	9 (60%)	6 (40%)	NS
LVEF	53.3 ± 10.2	57.5 ± 6.6	0.012
HF at admission	14 (17.5%)	0	0.01

Discussion: Regarding the lipid profile, we observed a high prevalence of dyslipidemia in these patients despite the fact that the prevalence of known dyslipidemia was low. So, many of these patients had previously unknown dyslipidemia. As expected, an invasive therapeutic strategy, PCI, was chosen in most cases with STE-ACS. Thrombolysis was performed in 24 patients (30%) meanwhile urgent PCI in 47 (58.8%). Long time delay from the onset of symptoms to admission (mean: 18.8 hours), could justify why some of the patients with STE-ACS were not revascularized.

Conclusions: Young patients with ACS often have a family history of premature cardiovascular disease. In addition, smoking is the most frequent risk factor. In general, the therapeutic strategy of ACS in young patients is similar to the one realized in older people. Basal lipid profile and clinical variables of hospitalized patients under 40 years old with acute coronary syndrome.

RV-131
LIPID PROFILE AT ADMISSION AND EVOLUTION AFTER DISCHARGE IN PATIENTS HOSPITALIZED WITH ACUTE CORONARY SYNDROME AT A REFERENCE HOSPITAL

P. García García, C. Aranda López, L. García Serrano, P. Mellado Delgado, L. Doncel Vecino, J. Nogales Asensio, J. López Mínguez, A. Merchán Herrera

Department of Cardiology. Complejo Hospital Universitario de Badajoz. Badajoz, Spain.

Objectives: The hypercholesterolemia, mainly increment of cholesterol associated to low density lipoprotein (LDL-C) is a known cardiovascular risk (CVR) factor. A reduction in the levels of LDL-C is one of the therapeutic goals in the treatment of patients with acute coronary syndrome (ACS) during hospitalization and at discharge. Likewise, high levels of cholesterol associated to high density lipoprotein (HDL-C) are related to a lower CVR. Our aim was to analyze the CVR according to the lipid profile as well as LDL-C/HDL-C control rates in patients with ACS during hospitalization and after discharge.

Material and method: In order to evaluate this fact we performed a retrospective cohort study that included 804 consecutive patients who were admitted to our center due to ACS: 414 (51.5%) without ST segment elevation (-NSTE) and 390 (48.5%) with persistent ST segment elevation (-STE). We analyzed the baseline epidemiological characteristics, lipid profile at admission and during hospitalization, hyperlipid therapy (HT) at discharge and the lipid profile during follow-up after discharge. We established two different prevention criteria depending on the presence of cardiovascular disease (CVD) or diabetes (DM) at admission. The LDL-C thresholds were 115 mg/dl (if no CVD nor DM) or 100 mg/dl (if CVD or DM). The point of reference for optimal HDL-C was 40 mg/dl in all cases.

Results: We observed that most of patients did not receive HT at admission although it was recommended according to their CVR in addition to their lipid profile (table). In addition, the percentage of patients who reached goals levels of LDL-C at admission did not get over 50% in both groups (primary and secondary prevention criteria). 97.2% of the patients received HT at discharge. During the follow-up after discharge, 81.2% of the patients achieved their LDL-C goals (41.2% achieving LDL-C levels under 70 mg/dl). The average of LDL-C reduction with HT was 15.19% after discharge. With respect to HDL-C, 62.3% of the patients were into optimum levels.

Conclusions: Almost half of the patients hospitalized with ACS diagnosis presents LDL-C levels at admission over the secondary prevention recommendations. An important percentage of patients did not achieved therapeutic goals after discharge despite the widespread use of HT. The achievement of optimum levels of HDL-C remains still a therapeutic challenge.

RV-132
MORNING BLOOD PRESSURE SURGE & DIPPER PHENOMENON, TWO FACES OF THE SAME COIN, THE "CIRCADIAN RHYTHM"

E. Tutor, M. Fabregate Fuente, R. Fabregate Fuente, C. Martínez Ruiz, S. Tello Blasco, S. Esteban, E. Castresana, J. Sabán Ruiz

Department of Endothelial Pathology. Ramón y Cajal Hospital. Madrid, Spain.

Objectives: 1) To assess if morning blood pressure surge (MBPS) is related to dipper phenomenon. 2) To evaluate if MBPS has a negative impact on the kidney, left ventricular hypertrophy (LVH) or vascular inflammation.

Material and method: 224 subjects, N = 191 of them with adequate recordings were evaluated, including n = 141 (73.4%) hypertensives, 106 of them under antihypertensive treatment; n = 100 (52.1%) with chronic hyperglycaemia; n = 45 (23.4%) smokers. 24-h ambulatory blood pressure: Spacelabs 90207. MBPS calculated according to Kario as: 1) Sleep-through MBPS: Morning systolic blood pressure (SBP) as the average during the first 2hours after waking, minus lowest SBP during the night (average SBP of 3 readings centred on the lowest night-time reading); 2) Prewaking MBPS: Morning SBP minus prewake SBP (the average SBP during the 2 hours just before wake-up time). Subjects classified according to average reduction in SBP and/or DBP at night compared with daytime values as: non-dipper (decrease < 10%) n = 79, and dipper (decrease ≥ 10%). Albumin/creatinine ratio (ACR) (mg/g). Glomerular filtration rate (GFR) (mL/min) by MDRD. Creatinine (Hitachi) (mg/dl).), high-sensitivity C-reactive protein (hs-CRP) (mg/L) and Cystatin C (mg/L) by Nephelometry, Siemens. Glycated haemoglobin A1C (%) (According to DCCT). LVH by echocardiography (Vivid S5, GE Healthcare). Statistical Analysis: Continuous variables as mean (Standard deviation) [minimum, maximum]. Pearson's coefficient (r). Multivariate linear regression adjusted for age, gender and antihypertensive treatment. Comparisons by t-test or Mann-Whitney's as appropriate. $p < 0.05$. SPSS v15.0.

Results: 1. Both definitions of MBPS were strongly correlated ($r = 0.821$, $p < 0.001$). 2. We split the whole population according to antihypertensive treatment. No significant differences were observed in MBPS between non-treated and treated patients. Sleep-through MBPS: 26.6 (11.5) [range: -3; 61] vs 29.1 (12.9) [-12; -59]; Prewaking MBPS: 14.1 (10.5) [-12; 37.8] vs 14.8 (12.2) [-18.7; 46.3];

Table (RV-131). Cholesterol control rates at admission depending on prevention criteria before hospitalization

Prevention criteria before hospitalization	N	Previously HT	LDL-C goal at admission (< 115 or < 100 mg/dl)	HDL-C < 40 mg/dl at admission
Primary (Not CVD nor DM)	387	20.9%	41.2%	45.7%
No hypercholesterolemia	264	NA	41.7%	48.1%
Hypercholesterolemia	123	54.5%	40%	40.6%
Secondary (CVD/DM)	417	60.7%	37.4%	55.9%
No hypercholesterolemia	166	NA	32.8%	59.6%
Hypercholesterolemia	251	75.7%	40.1%	53.5%

3. We observed a consistent relationship between the dipper phenomenon and both definitions of MBPS, independently of age, sex and antihypertensive treatment: Sleep-through MBPS: non-standardized Beta B = 9.964 with 95%CI [6.588; 13.340], p < 0.001; standardized-Beta Bs = 0.399; model R^2 = 0.166. Prewaking MBPS: B = 9.602, 95%CI [6.570; 12.634], p < 0.001; Bs = 0.414; R^2 = 0.171. 4. MBPS was not significantly related to kidney damage (ACR, creatinine, cystatin C, GFR), LVH or vascular inflammation (hs-CRP), after adjustment for age, sex and antihypertensive treatment.

Discussion: As long recognized, there is an increased risk for heart attack, stroke, and sudden death in the first few hours of the morning. In 2001, Gosse reported the phenomenon called "morning BP surge" (MBPS). It was first described in untreated hypertensive patients but later extended also to treated subjects. In 2003 Kario showed a relation between stroke risk and MBPS. For a long period, MBPS was believed systematically to increase cardiovascular disease risk, but a study in 2011 (Israel et al. Am J Hypert, 24 7, 796–801) suggested that an increase in morning BP over nocturnal levels may represent a healthier form of circadian variation.

Conclusions: 1. As previously demonstrated, the MBPS phenomenon is not exclusive to untreated patients. 2. Both definitions of the phenomenon achieve similar results, because the point is the BP sharp rise. 3. The dipper phenomenon is consistently related to MBPS, once excluded the effect of treatment, age and gender. 4. With regard to the consequences, the MBPS phenomenon had no impact on kidney damage, LVH or vascular inflammation. 5. Are both phenomena two faces of the same coin?

RV-134
OBSERVATIONAL STUDY OF HEART-HEALTHY HABITS IN A HEALTH CENTER

E. Sánchez Relinque, S. Romero Salado, M. Guzmán García, V. Lechuga Flores, V. Manzano Román, O. Mera Gallardo, G. García Domínguez, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: Cardiovascular disease is the leading cause of death and disability starting at middle age in developed countries. We propose monitoring of professionals heart-healthy habits of the health center which has to inform and advise people in this area, also who are references people of these kinds of habits.

Material and method: We have interviewed all 54 professionals who work at the Health Center of Rota and we have asked about healthy lifestyles, if they are hypertensive, diabetic or dyslipidemic. Also we measured their height, abdominal circumference and weight.

Results: 18 of 54 professional from Rota Health Center were physicians (P), 12 nurses (N), 4 Aux Nursing (A), 5 Orderlies (C), 1 dentist (DT), 1 midwife (M), 1 Ray technician (R), 1 Social Worker (T), 4 cleaners (Cl), 4 Pediatricians (Pe) and 3 Administration (Ad). Smoke 18.5%: 2 P, 3 D, 1 A, 1 C, 2 L, 1 Ad. 27% drink alcohol: 6P, 3N, 3C, 1D, 1M, 1R. They usually play sports, at least 3 times a week 57.4%: 8P, 10N, 3A, 4C, 1M, 1R, 1Cl, 2Pe, 1AD. They usually eat more than 3 eggs during the week: 18.5%: 2P, 1A, 3C, 1Cl, 2Pe, 1AD. They usually eat fish, 87% 16P, 8N, 3A, 5C, 1D, 1M, 1R, 1T, 4Cl, 1Pe, 2ad. They usually eat vegetables, 90% 18P, 12N, 3 A, 5C, 1M, 1T, 4Cl, 3Pe, 2AD. They don't feel stressed: 42% 10P, 6N, 3C, 1D, 1Pe, 1R, 1Cl, 1P, 2AD. They Sleep 7-8 hours: 55%: 8P, 8N, 3A, 4C, 1D, 1M, 1Cl, 1Pe, 2Ad. They feel physically well 66.6%: 15P, 9N, 2A, 3C, 1M, 1R, 1T, 2Cl, 1Pe, 1 Ad. The average BMI among men was 26.8 and for women 24.2. The abdominal circumference midway between the men was 94.8 (4 over 102) and 81.3 for women (6 over 88). Mean systolic is 124, with the 20% above 140. The mean diastolic tension is 72.3, with 7.5% above 84. Only 13% considered to have a sedentary lifestyle. No one is diabetic, 11% are hypertensive and 14.8 have dyslipidemia.

Discussion: Despite the increase in the population´s health knowledge, preventive awareness from public authorities and frequent campaigns, 5 million people in Spain are admitted to our hospital for coronary heart disease. In the world population smoke 32% (WHO), in Spain 17.65% (SEN), and in our Health Center 18%, slightly above the Spanish average. It is noteworthy that only 4% of men do it, increasing the percentage to 31% for women. People in Spain Play sports 40% (UV), We can see it´s much higher (57.4) in our health center, We find a big difference between men and women (49% men and 31% women). We have known than men´s percentage at health center is much higher from the Spanish one (66.6), but women fall down to 25%. Spanish sleeps an average of 7.22 (INE), we found that only half of CS professionals do it (55%) with no difference between sexes. About 87% of our professional usually eats fish and 90% fruit, well above 25% and 65% of national average (FP).

RV-135
TYPICAL AND EMERGING CARDIOVASCULAR MAIN RISK FACTORS ON PATIENTS HOSPITALIZED FOR ACUTE ISCHEMIC STROKE ON MEDICAL AREA FROM A SAS SPECIALTY HOSPITAL

M. Escobar Llompart, R. Aranda Blázquez, S. Romero Salado, G. García Domínguez, O. Mera Gallardo, V. Lechuga Flores, V. Manzano Román, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Puerto Real (Cádiz), Spain.

Objectives: Our target was to describe obesity, pathologic waist perimeter and different typical and emerging cardiovascular risk factors on patients hospitalized for acute ischemic stroke event at medical services in our hospital.

Material and method: Transversal chart study where they were revised patients hospitalized for acute ischemic stroke event at Internal Medicine and Neurology Services from our centre between December 1st 2011 and April 30th 2012. We made up a protocol to create a database with different features: age, sex, BMI, waist perimeter, DM, blood pressure, cholesterol and its fractions, triglycerides, lipoproteins and homocystein (on younger than 55), smoking and physical activity.

Results: 92 patients were included, 57 men, 35 women; age between 46 and 95 years old, hospitalized for acute ischemic stroke event (11 patients younger than 55). 54 patients (58.69%) did have IBM higher than 30, 39 obesity grade I, 11 grade II, 4 grade III. 49.01% patients had pathologic waist perimeter (more than 102 centimeters on men, more than 88 on women). Related to cardiovascular risk factors, we noticed that 67.4% were hypertensive, 53.3% smokers or did smoke before, 46.8% DM, 45.7% had high cholesterol level, 41.4% had low HDL, 35.9% had sedentary life, 32.6% had high triglycerides level. Patients younger than 55, 28.1% and 18.8% had high homocysteine and lipoproteins levels respectively.

Discussion: We see high incidence of obesity (58%) and pathologic waist perimeter on these patients. The most prevalence cardiovascular risk factors were hypertension, smoking either current or past and DM without forgetting high cholesterol levels, low HDL levels and sedentary life. Homocisteinemia medium incidence and medium/low hyperlipoproteinemia on young patients with stroke.

Conclusions: 1. Obesity and high waist perimeter appears in high number of patients hospitalized in our section for acute ischemic stroke event. 2. Other cardiovascular risk factors as blood pressure, smoking, DM and high cholesterol levels appear on a high percent

of patients. 3. It is necessary to control cardiovascular risk factors as a secondary prevention for new cardiovascular ischemic event based on clinic guidelines. 4. It would be ideal to calculate cardiovascular global risk in our patients without depending of the attributable risk of the different CVRF, in spite of this, we found the reason for the last discrepancies about definition and significance of metabolic syndrome.

RV-136
TYPICAL AND EMERGING CARDIOVASCULAR MAIN RISK FACTORS (CRF) ON PATIENTS HOSPITALIZED FOR ACUTE ISCHEMIC CORONARY SYNDROME ON A MEDICAL AREA FROM A SAS SPECIALIZED HOSPITAL

M. Escobar Llompart, S. Romero Salado, R. Aranda Blázquez, M. Guzmán, E. Sánchez Relinque, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Puerto Real (Cádiz), Spain.

Objectives: The target is to recognize obesity, pathologic waist perimeter and typical and emerging cardiovascular risk factors on patients hospitalized for acute ischemic coronary syndrome on medical area from our hospital.

Material and method: Transversal chart review from patients hospitalized for acute ischemic coronary syndrome on Internal Medicine and Cardiology Services from our centre between December 1st 2011 & April 30th 2012. We made up a protocol to create a database with different features: age, sex, BMI, waist perimeter, DM, blood pressure, cholesterol and its fractions, triglycerides, lipoproteins and homocystein (on younger than 55), smoking and physical activity.

Results: 116 patients were included, 82 men, 34 women; age between 38 and 92 years old, hospitalized for acute ischemic coronary event (21 patients younger than 55). 69 patients (59.48%) had IBM higher than 30, 41 obesity first grade, 17 second grade, 8 third grade. 50.86% patients had pathologic waist perimeter (more than 102 centimeters on men, more than 88 on women). Related to cardiovascular risk factors we noticed 61.2% were hypertensive, 56.89% were smokers or did smoke before, 53.44% DM, 43.96% had high cholesterol levels, 43.1% had low HDL levels, 34.4% had sedentary life, 42.4% had high triglycerides levels. Patients younger than 55, 28.57% and 19.04% had high homocystein and lipoproteins levels respectively.

Discussion: We see high incidence of obesity and pathologic waist perimeter on these patients. The most prevalence cardiovascular risk factors were hypertension, smoking either current or past and DM without forgetting high cholesterol levels and low HDL levels, and hypertriglicerids. Homocisteinemia, medium incidence and medium/low, hyperlipoproteinemia on young patients with acute ischemic coronary syndrome.

Conclusions: 1. Obesity and high waist perimeter appears on high number of patients hospitalized on our section for acute ischemic coronary event. 2. Other cardiovascular risk factors, such as blood pressure, smoking, DM and high cholesterol levels appear on a high percent of patient. 3. On young patients with acute ischemic coronary event, it is important to determine new factors such as homocisteinemia or lipoproteins, as well as to evaluate the presence of thrombotic pathologies. 4. It would be ideal to calculate cardiovascular global risk in our patients without depending of the attributable risk of the different CVRF, in spite of this, we found the reason for the last discrepancies about definition and significance of metabolic syndrome.

RV-137
DESCRIPTIVE ANALYSIS HOSPITALAR/CLINICAL CONTROL BY MONITORING LIPID LEVELS ON PATIENTS WITH ACUTE ISCHEMIC CORONARY EVENTS

M. Escobar Llompart, E. Sánchez Relinque, M. Guzmán García, V. Lechuga Flores, V. Manzano Román, G. García Domínguez, O. Mera Gallardo, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: Recognize monitoring degree control of lipids levels on patients who had previous ischemic coronary event.

Material and method: We included patients hospitalized on Cardiology Department from Puerto Real University Hospital (Cadiz) during 2011, for different reasons (acute coronary syndrome, pacemaker implantation, atrial fibrillation with fast response, etc.). Studied variables: monitoring lipid levels control from 3 previous months before hospitalization or during hospitalization (triglycerides - TG-,-CO-cholesterol, HDL-C, LDL-C, apolipoprotein A and/or B). Data were analyzed as a descriptive chart study.

Results: 392 patients were selected. From these, 50% with dyslipidemia. Such patients were requested for TG levels on 96.939% cases, CO at 96.684%, HDL-c on 93.878%, while LDL-c was only requested on 56.888% of patients. Apoprotein A and/or B had a minimum follow-up 4.338%.

Discussion: There is an irregular lipids levels monitoring on our area. This is mainly due to poor monitoring of LDL-c levels, essential for cardiovascular global risk decrease control. It is necessary to raise awareness among medical and hospitalary/outpatient lipids range level achieve on cardiovascular risk control through monitoring there for achieve correct treatment.

Conclusions: We must improve lipids levels control based on current recommendations. This requires making an adequate lipid level monitoring, and especially LDL-c level for an appropriate decrease cardiovascular global risk.

RV-138
CARDIOVASCULAR RISK ESTIMATION IN PATIENTS WITH SCLERODERMA

N. Martín Suñé, J. Ríos Blanco, C. Busca Arenzana, A. Gil Aguado, F. Barbado Hernández, F. Arnalich Fernández

Department of Internal Medicine. Hospital Universitario La Paz. Madrid, Spain.

Objectives: Cardiovascular disease (CVD) risk is the result of multiple interacting risk factors. SCORE (Systematic Cardiac Risk Evaluation) is a risk estimation tool to help in clinical and therapeutic management. Autoimmune diseases, such as escleroderma, are characterized by enhanced atherosclerosis and higher cardiovascular morbidity rates than the general population. Scleroderma vasculopathy, endothelial dysfunction, as well as inflammatory immune response underlying the disease may be involved in the pathogenesis of atherosclerosis. Here we present the CVD risk estimation in patients suffering from scleroderma.

Material and method: We reviewed medical records from 20 patients suffering from scleroderma who attended to Internal Medicine Outpatients Clinics. Clinical and biological data including age, gender, hypertension, dislypemia, smoking history and diabetes were recorded. Mean values for quantitative variables were calculated as well as percentage for qualitative ones. SCORE index was calculated using recommended web application of European Guidelines on Cardiovascular Disease Prevention in Clinical Practice (2012).

Results: Up to 92% of our patients were female, with mean age of 57 years. 39% had been diagnosed of hypertension and all of them were receiving angiotensin-converting enzyme inhibitors

treatment. Just 18% of them had LDL cholesterol over 160 mg/dl. None of the patients had previous diagnosis of diabetes and 7 of them were former smokers. When applying SCORE system, 35% of our patients showed moderate to high cardiovascular disease risk (5-10% and > 10%) and 65% showed low risk (1-5%).

Discussion: Patients with escleroderma have moderate or high cardiovascular risk despite diabetes or dyslipemia rates were not elevated. Some other disease-related factors such as vasculopathy, endothelial dysfunction, or inflammatory immune response could contribute to enhance cardiovascular risk. It is probable that a more strict control on classical cardiovascular risk factors could be advisable.

Conclusions: A great number of patients with scleroderma have moderate or high cardiovascular risk. Hypertension rates were elevated in this cohort, contributing to increase CVD risk. It is possible that other disease-related factors may contribute to rise cardiovascular risk in these patients.

RV-139
PERCEIVED PHYSICAL APPEARANCE COMPARED TO THE LIFESTYLE AND HEALTH HABITS IN HIGH SCHOOL STUDENTS OF A PUBLIC SCHOOL IN THE BAY OF CADIZ

S. Romero Salado, M. Guzmán García, M. Escobar Llompart, E. Sánchez Relinque, O. Mera Gallardo, G. García Domínguez, L. Fernández Ávila, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: In today's society, there is a change of lifestyle of the population over previous decades. There is a clear tendency to give great importance to the external image, and how that image can influence the daily activities of adolescents. Therefore, our goal is to know the activities of a group of teenagers and how it influences the perception of themselves for the realization of healthy practices.

Material and method: We conducted a survey of secondary school students in a public school in the Bay of Cadiz. We selected a number of variables: age, toxic habits (snuff consumption, alcohol), lifestyle, subjective view of himself and appraisal of body mass index (BMI) and waist circumference (PA).

Results: 118 surveys were conducted in adolescents aged 12 to 17 years (mean age 14.6 years). We obtained the following results: Perception of adequate physical aspect 69.49%. Consumption of toxic substances (first use of snuff: 15.75 years and alcohol: 15.38 years). Habitual physical Practice (61.86%). Poor self-perceived physical appearance (30.51%) including BMI (21.76), BMI > 25 and poor perception (41.67%), BMI < 20 and low perception (19.44%). Abdominal circumference (85.87%) Poor perception and abdominal circumference (91.15 cm) of which > 90 cm (38.89% with an average 103.21 cm) and lower than 80 cm (16.67%). Average height in poor subjective physical appearance (162.21 cm). Poor subjective and consumption of tobacco and/or alcohol (22.22% and 36.11% respectively), presence of stress 46.6%, 61.8% practiced sport.

Discussion: Stresses the early onset of drug and alcohol consumption at an early age (15.565%) with 55.92% of respondents who start an early consume. Regarding healthy habits, like good night resting, it appears in a large majority of our patients (85.59%), with 30.51% inadequate perception of its image, emphasizing parameters in this group like BMI < 20 or > 25 on 69.44% and 162.21% size (predominantly < 150 cm [68%]). Our group present regular physical activity in 61.8%.

Conclusions: There is a big change in the image profile and healthy habits (nutrition, physical exercise, health practices, etc.) present in adolescence. Currently much attention is paid to the external physical perception, offering continuous demands in an increasingly faster society, time constraints of a life more and more away from tranquility and based more on unhealthy habits. It is necessary to try to convey recommendations healthy lifestyles to promote effective primary prevention, and the role of the Internal Medicine physicians is crucial in the overall assessment of cardiovascular risk factors.

RV-140
PREVALENCE OF HYPERTENSION IN A COHORT OF SAHARAHUIS DIABETIC PATIENTS FROM REFUGEE CAMPS

J. Bernardo-Cofiño[1], F. Fernández Tamargo[2], M. Fernández Almira[1], M. Mera Fidalgo[1], A. Fidalgo Navarro[1], C. Suárez Cuervo[1], L. Trapiella Martínez[3], P. Villaverde Amieva[1]

[1]Department of Internal Medicine. Hospital General de Asturias. Oviedo (Asturias), Spain. [2]Departiment of Family and Community Care. Hospital Valle del Nalón. Langreo (Asturias), Spain. [3]Department of Internal Medicine. Hospital de Cabueñes. Gijón (Asturias), Spain.

Objectives: To assess the prevalence of arterial hypertension (AH), proportion of treated population and control rate in a cohort of patients receiving specific care for diabetes and hypertension in a Saharawi refugee population.

Material and method: It's a descriptive, observational, longitudinal and retrospective study conducted between years 2005 and 2010 of a cohort of patients Saharahuis from a refugee camp who received specific medic care for hypertension and diabetes mellitus. Quantitative variables with normal distribution were expressed as mean and standard deviation, while qualitative variables are expressed as percentages. Statistical analysis of the data was performed using SPSS Data Editor Statistics, version 17.

Results: Data were collected from 1,281 patients between 2005 and 2010. 719 (56.1%) were women, and 562 (43.9%) males. The mean age was 55.1 ± 12.7 years, 59.16 ± 10.9 in men and 53.3 ± 12.3 in women ($p < 0.001$). 69% of patients (883) were diabetic, of whom 59.5% are women. 54.2% (479) of diabetic patients were also hypertensive. Overall 733 patients (57.2%) were hypertensive (56.3% women). The mean values of blood pressure (BP) in non diabetic hypertensive patients were 159.3 ± 26.7/96.9 ± 14.0 mmHg. The mean values of BP in diabetic hypertensive patients were 24.0 ± 159.5/94.1 ± 12.5 mmHg. There is a statistically significant difference in DBP between the two groups of hypertensive patients, which could be explained by the significant difference in DBP between genders (significantly higher in women). Both weight and body mass index (BMI) were significantly associated with blood glucose and blood pressure (both systolic and diastolic). Also, age is associated with weight, BMI and BP, but not with blood glucose levels. 89.9% of hypertensive patients receive at least one drug treatment. However, the degree of control of hypertension is only 10% in Saharawi people, poor in both diabetic (7.3%) and non-diabetics (11.0%). Angiotensin converting enzyme (ACE) inhibitors are the most prescribed drugs both in monotherapy (58.3%) as part of any combination (17.2%).

Conclusions: 1. AH is a relevant disease among patients treated with a prevalence of approximately 60% in the population studied. 2. There is a poor control of BP, although the high proportion of patients receiving drug treatment. 3. The prevalence of DM in the studied population is 69%, of which over half are in addition to hypertension (54%). 4. There are significant differences in DBP among hypertensive patients without diabetes and diabetic hypertensive patients. This may be attributable to the higher proportion of female between diabetic population. 5. The ACE inhibitors are the drugs most commonly used to control BP (more than 75% of treatments). 6. The results of treatment are influenced by many variables difficult to record, as no measurable intake of salt through the water, variety of diet and physical inactivity. The study has obvious statistical limitations, given the precariousness of means, variability of observing conditions and difficulty of data collection.

RV-141
AMBULATORY BLOOD PRESSURE MEASUREMENT IN PATIENTS OF INTERNAL MEDICINE OFFICES

P. Garmilla Ezquerra, S. Qiu Liu, M. Aller Fernández, T. Tigera Calderón, M. García Hoyos, L. Corral Nieri, A. González-Torre González, J. Lozano Polo

Department of Internal Medicine. Hospital Valdecilla. Santander (Cantabria), Spain.

Objectives: To describe the cardiovascular risk factors, the Ambulatory Blood Pressure Measurement (ABPM) parameters and the degree of control of arterial blood pressure in a group of patients of Internal Medicine offices.

Material and method: 190 patients were included, aged 18 to 93 years and followed up in Internal Medicine offices in a tertiary care hospital, who had at least one of the next indications: suspected white-coat, resistant, high-risk, untreated and borderline hypertension; assessment of dipper status; assessment of drug treatment efficacy. 24hour ABPM was performed with Spacelabs 90207 devices. The monitors were programmed to obtain BP readings at 20-min intervals during the daytime and at 30-min intervals during the night-time. Four circadian patterns were defined: dipper, extreme dipper; non-dipper and riser.

Results: 57.9% men, 42.1% women with average age 59.9 ± 15.77 years. The cardiovascular risk factors are collected in the table 1. ABPM parameters are reflected in table 2. The circadian patterns obtained were: 41.71% dipper; 35.29% non dipper; 9.63% extreme dipper; 13.37% riser.

Conclusions: 1. An elevated percentage of patients had high cardiovascular risk factors. 2. ABPM system contributes to a more accurate control of blood pressure and to optimize the treatment.

RV-143
REFINING THE CARDIOVASCULAR RISK: ADVANTAGES OF SPECIALIZED EVALUATION, INCLUDING ABMP

S. Qiu Liu, T. Tigera Calderón, P. Garmilla Ezquerra, M. Aller Fernández, M. García Hoyos, L. Corral Nieri, N. Diez Herrán, J. Lozano Polo

Department of Internal Medicine. Hospital Valdecilla. Santander (Cantabria), Spain.

Objectives: To describe the cardiovascular risk before and after an advanced evaluation, including Ambulatory Blood Pressure Mesurement (ABPM) performance.

Material and method: 190 patients were included, aged 18 to 93 years, followed up in Internal Medicine offices in a tertiary care hospital. Several data were collected: anthropometric variables (age, weight, height, waist circumference, BMI), defined cardiovascular risk factors (smoking habit, diabetes mellitus, dyslipidaemia, hypertension and a family history of premature cardiovascular disease), target organ damage (left ventricular hypertrophy, microalbuminuria) or associated clinical disease (ischemic cardiomyopathy, stroke, peripheral arterial disease, renal damage...); analytic parameters (creatinine, total cholesterol, HDL, LDL, TAG). ABPM registries were performed. Details about antyhipertension treatment (statins, beta blockers, renin-angiotensin-aldosterone system inhibitors, antiplatelet agents and others) were defined.

Results: 57.9% men, 42.1% women with average age 59.9 ± 15.77 years. The distribution of the cardiovascular risk factors was: 8% family history; 14.8% smoking habit; 22.6% established cardiovascular diseases. These factors remained invariable after specialized evaluation unlike the ones collected on the table 1. Table 2 collects the cardiovascular risk variation before and after an advanced evaluation ($p < 0.01$).

Conclusions: 1. Identification of cardiovascular risk factors is more refined in specialized offices. 2. ABPM is a very useful tool for the identification of patients at cardiovascular risk. 3. The degree of risk in specialized offices is higher than the established previously.

RV-145
TREATMENT OF TYPE 2 DIABETES MELLITUS WITH A TUBULAR GLUCOSE TRANSPORTER INHIBITOR: CAN THE "DOUBLE BLIND" TREATMENT BE KNOWN?

A. Díaz Díaz, A. Sánchez, I. Narrillos, C. Velasco, C. Díaz-Pavón, R. Torres, J. García Puig

Department of Internal Medicine. Hospital Universitario La Paz. Madrid, Spain.

Objectives: Despite multiple oral antidiabetic drugs, glucose metabolism is undercontrolled in most of the patients with type 2 diabetes (T2D). Tubular glucose transporter inhibitors are being developed in Spain. These drugs may be administered at any moment in the disease evolution with any of the hypoglycaemic agents available. We have contributed to the development of one of these drugs and based on weight and HbA1c variations at 52

Table 1 (RV-141). Cardiovascular risk factors

Family history cardiovascular diseases	8%	Established cardiovascular diseases	22.6%
DM (Gluc > 125 mg/dl)	19.1%	metabolic syndrome	38.8%
Smoking habit	14.8%	Atherosclerosis	4.2%
Hypercholesterolemia (Colt > 175 mg/dl)	70.9%	Nephropathy	18.7%
LDL > 115 mg/dl	51.6%	Age (M > 55; W > 65)	52.47%
HDL < 40 mg/dl men	27.4%	Left ventricular hypertrophy	21.6%
HDL < 45 mg/dl women	24.6%	Alb/Cr (M > 22 mg/g; W > 31 mg/g)	23.25%
TAG > 150 mg/dl	24.1%		

Table 2 (RV-141). ABPM parameters

	Average	SD
SBP 24hours	128.58	14.23
DBP 24hours	76.99	10.69
SBP daytime	132.03	14.62
DBP daytime	80.18	11.14
SBP night-time	119.25	16.38
DBP night-time	68.61	10.21

Table 1 (RV-143). Variation of cardiovascular risk factors

	Before	After
DM (Gluc > 125)	21.2%	31.21%
Dyslipidaemia	51.9%	75.12%
HBP	64.7% (pre ABPM)	87.36% (ABPM)
Target organ damage	26.8%	29.05%

Table 2 (RV-143). Cardiovascular risk variation (SEH-LELHA)

	Risk previous ABPM					
Risk post ABPM	Normal	Low	Moderate	High	Very High	Total risk pre-ABPM
Normal	3.84%	3.29%	2.19%	0.55%	0.55%	10.43%
Low	1.65%	9.89%	7.14%	2.195	2.19%	23.08%
Moderate	0.55%	2.19%	12%	5.49%	0.55%	20.88%
High	0%	3.29%	4.39%	15.93%	1.65%	25.27%
Very high	0%	0%	1.65%	3.29%	15.38%	29.32%
Total risk post ABPM	6.04%	18.68%	27.47	27.47%	29.32%	182 patients

weeks we aimed to assess whether patients were assigned to the active drug or placebo arm of the "double blind" study.

Material and method: We have collaborated in a multicentric, randomized, double blind, parallel study to assess the efficacy and safety of a tubular glucose transporter inhibitor versus placebo in patients with T2D and HbA1c of 7-10.5% receiving metformin. We assumed that a given patient was randomized to active therapy if, at week 52, weight diminished > 2 Kg and HbA1c was reduced by > 0.4%. A given patient was thought to be assigned to placebo if both figures were less at week 52.

Results: We included 24 patients among which 21 were randomized (males, 8); mean age 68 years (range, 57-80 years). 18 patients concluded the 52 weeks double blind therapy period. Baseline mean blood glucose was 149 mg/dL (range, 113-242 mg/dL) and mean HbA1c concentration 7.9% (range, 6.8-9.6%). Mean baseline HbA1c decreased from 7.9% to 7.5% (mean reduction, -0.4%). We assumed that 12 patients received active therapy (mean HbA1c decrease, -0.9%) and 6 patients were assigned to placebo (mean HbA1c increase, +0.6%). Weight decreased from a mean baseline of 80 Kg (range, 57.7-102.8 Kg) to 76.3 Kg (range, 54.9-102.9 Kg; mean decrease,-3.7 Kg). We assumed that 11 patients were assigned to active therapy (mean weight decrease, -5.5 Kg) and 7 patients to placebo (mean decrease, -0.5 Kg). According to the individual decreases in weight and HbA1c 11 patients (63%) could be assigned to one of both double blind study arms. Three urinary infections were reported in the 18 patient-year period; two were attributed to patients supposedly assigned to the glucose transporter inhibitor.

Conclusions: In this double blind study comparing a tubular glucose transporter inhibitor versus placebo in T2D patients, weight and HbA1c variations at 52 weeks allowed to suspect the assigned therapy in over half of the patients.

RV-146
ADIPONECTIN: CURRENT LEVELS AND GENE EXPRESSION IN ADIPOSE AND LIVER TISSUES IN MORBIDLY OBESE WOMEN WITH NAFLD

E. Ñasco, C. Varillas, M. Molina, E. Filiu, A. Ceausu, X. Terra, T. Auguet, C. Richart

Department of Internal Medicine. Hospital Universitari Joan XXIII. Tarragona, Spain.

Objectives: To Determine the plasma levels of adiponectin and its gene expression in visceral and subcutaneous adipose tissue and liver, as well as to investigate differences among morbid obese patients (normal liver, simple steatosis, NASH) and healthy controls.

Material and method: We analyzed the livers of 90 Caucasian women: 4 lean (BMI < 25 kg/m^2) and 86 morbid obese (BMI > 40 Kg/m^2). Among morbid patients, we found 18 with normal liver (NL), 24 with simple steatosis (SS) and 44 with NASH. The liver tissues were evaluated by an expert hepatopathologist. The samples were obtained from morbid obese patients who underwent bariatric surgery and from control women who underwent liver biopsy with diagnosis purpose. Both groups were of similar ages. Those patients who had acute or chronic inflammatory diseases, infectious diseases, terminal malignancy or who took medication that could alter the metabolic and lipid parameters, were excluded. The plasma levels of total adiponectin and HMW adiponectin isoform were obtained by ELISA. Gene expression of adiponectin mRNA was performed with RT-PCR. Statistical analysis was performed using SPSS/PC + (V19.0, Chicago, Illinois, USA). P values < 0.05 were considered statistically significant.

Results: The anthropometric, clinical and biochemical parameters show significant differences between the healthy control group and morbid obese patients). Transaminase values are higher in obese patients with SS and NASH compared to obese NL ($p < 0.05$). The circulating levels of adiponectin and HMW adiponectin are lower in morbid obese patients compared to healthy subjects ($p < 0.001$). The mRNA expression of adiponectin is significantly reduced in the subcutaneous adipose tissue and the liver of morbid obese patients compared to healthy controls ($p < 0.001$), showing no differences in the visceral adipose tissue. In morbid obese patients, the circulating levels of adiponectin and HMW adiponectin are lower in SS and NASH patients compared to morbid obese with NL. There were no differences in gene expression of adiponectin among subgroups (NL, SS, NASH) in adipose subcutaneous and liver tissue. In the visceral adipose tissue, lower levels of mRNA adiponectin in subjects with SS and NASH compared to morbid obese with NL are observed ($p < 0.05$).

Conclusions: Circulating levels of adiponectin are lower in morbid obese patients versus healthy controls and in morbid obese SS/NASH patients compared to morbid obese with NL. The mRNA expression of adiponectin is decreased in the subcutaneous and liver tissue of morbid obese patients compared to healthy controls and showed no significant differences between subgroups of morbid obese patients in subcutaneous and liver tissues. In adipose visceral tissue, the mRNA expression of adiponectin is lower in morbid obese SS/NASH patients compared to morbid obese with NL.

RV-147
ASSESSMENT OF A NEW PROTOCOL FOR INPATIENTS INSULIN THERAPY

C. González Becerra[1], A. Vergara Díaz[1], M. Gómez Hernández[1], C. Pereira Delgado[1], A. Sanchís Osuna[2], S. Vidal Serrano[1], P. Gómez Rodríguez[2], M. Blanco Torró[2]

[1]Department of Internal Medicine, [2]Department of Community and Familiy Medicine. Hospital San Juan de Dios de El Aljarafe. Sevilla, Spain.

Objectives: A new protocol for inpatients insulinization has been developed and established in our center in late 2010. It is based on SAEN (Endocrinology and Nutrition Andalusian Society) recommendations. We evaluated adherence to protocol.

Material and method: 122 patients receiving insulinotherapy were randomly selected from a monthly pharmaceutical prescription list. Patients with hospital length of stay less than 24 hours; inpatient death; and single elevated glycemia without posterior confirmation were excluded from the study. We have done a descriptive study. We reviewed medical histories and we analyzed variables as age, gender, hospital service in which they were admitted, basal glycemic number, Hb A1C (in the three previously months), weight, BP rate, hospital treatment prescription and if it is agree with our protocol.

Results: A total of 122 charts were reviewed. Most of them were inpatients in Internal Medicine ward (85.25%), General Surgery ward (7.37%), Emergency Room (3.28%), Orthopaedics and Urology Ward (1.64% each one) and just 1 patient in Otorhinolaryngology Ward (0.81%). 68 of the patients were male. Mean age was 75 years, without gender differences by age. Only half of the patients had records of Hb A1C (Mean: 7.69%, range from 5.6 to 11.9%). SBP mean was 132.39 mmHg and DBP was 71.34 mmHg. Most of the patients were on intensive insulin regimen during the hospitalization (86.88%). Some charts missed the description of insulin correction doses (3.77%) (all of them using glargine as basal). It was prescribed to the most of the patient an intensive insulin regimen during the hospitalization (106, 86.88%), with priority use of basal insulin glargine as basal in 87.73% and levemir only in 8.49%. Four patients (one of them in the emergency room) (3.28%) had only scheduled fast insulin with correction regimen. 7 of these patients were on fasting insulin without prandial bolus or correction; 2 with biphasic pattern; 1 on OADs; 1 with fasting insulin without prandial bolus or correction; and 1 without any regimen. The compliance of the protocol was high, 84.42%.

Conclusions: The compliance of the protocol was high, without differences between services, in spite of a high percentage of insulin prescription in surgical patients was performed by a physician from the medical area. Generally, they had good BP and basal glycemic control during the hospitalization. Most of the patients were on glargine regimen for basal glycemic control. Few cases had mobile regimen (most of these in surgical wards). The evaluation of cardiovascular risk was incomplete. Weight values were and previous metabolic control information was incomplete.

RV-148
DO PATIENTS WITH BONE METABOLISM DISORDERS PRESENT HIGH VASCULAR RISK?

E. Puerto Pérez, N. Cubino Bóveda, A. Lérida Urteaga, A. Romero Alegría, P. Miramontes González, L. Mateos Polo

Department of Internal Medicine. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca, Spain.

Objectives: The objective of this study is to assess whether a vitamin D deficiency leads to an increase of vascular risk in relation with certain factors, such as the increase of arterial pressure values and PCR as an independent risk marker. We have also studied whether patients with chronic kidney failure and hypovitaminosis D have presented a higher number of vascular events (cerebrovascular disease and coronary disease) during one year than those who do not present those disorders.

Material and method: We have performed a transversal and retrospective study that included 98 patients (48 men and 50 women) of ages between 30 and 80 years old, who were admitted at the Unit of Internal Medicine of the Salamanca in the last year. In their first visit, they all went through the following steps: Anamnesis that includes the personal history of the patient and the history of cardiovascular events (AMI, angina, CVA) and treatment prescribed in the first visit. Physical exploration: blood pressure was determined three times, and the two last ones were considered measurements (HBP was defined as ASP > 140 mmHg and ADP > 90 mmHg). Analysis that includes levels of glycemia, urea, creatinine, PCR and vitamin D levels. It is performed after12-hours fasting. Electrocardiography. The statistical analysis was performed with SPSS version 13.0.

Results: In our 98 patients, the average age was 70.4 years. The average blood pressure levels in uncontrolled patients was 148.64/96.34 mmHg, vitamin D levels were 25.48 and ultrasensitive PCR levels were 2.7 With regard to the patients in our study, 64.28% presented chronic kidney failure, and the proportion of vascular events was ictus: 42.8%, coronary disease: 22.2% and no events: 34.92%.

Discussion: With these findings, we can see how the patients with a vitamin D deficiency present higher BP levels and a worse pharmacological control, in spite of an optimal treatment for HBP. These results are more evident in the group of women. We can also state that kidney failure is not only an independent marker of vascular risk, but it can also be enhanced by hypovitaminosis D, which further increases the appearance of events such as ictus or coronary disease. PCR is also elevated in this group of patients, which means an additional risk factor. Some observational studies have observed that hypovitaminosis D may represent a 50-80% increase of vascular risk compared with patients who do not present it, which matches the results of our study. All these findings are coherent with what was found in the literature, proving this association, although we must take into account the fact that the findings described represent associations, instead of causality.

Conclusions: The hypovitaminosis D should be taken into account in patients with poorly controlled hypertension orcoronary disease, and that a screening for this type of patients might be useful. Although there is still no consolidated scientific evidence, we might consider the use of supplementation with 1.25 (OH)2D in patients with high vascular risk in which the traditional pharmacological therapy is insufficient.

RV-149
RELATIONSHIPS BETWEEN ARTERIAL STIFFNESS AND CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH HYPERTENSION

B. Altun, F. Bulucu, S. Demirbas, M. Karaman, S. Ay, M. Cakar, M. Apikoglu, K. Saglam

Department of Internal Medicine. Gulhane Military Medical Faculty. Ankara, Turkey.

Objectives: Hypertension has been regarded as a public health problem due to its increasing prevalence all over the world. Its complications lead to morbidity and mortality. Hypertensive patients have strong evidence of endothelial dysfunction. Recently, some novel endothelial dysfunction parameters such as pulse wave velocity, augmentation index and central aortic pressure have been

investigated as predictive markers of atherosclerosis. Therefore, relationships between cardiovascular risk factors and arterial stiffness parameters in essentially hypertensive patients were investigated in the present study.

Material and method: The study population included 109 patients (63 females, 46 males) diagnosed as essentially hypertensive on outpatient clinic basis. In the all subjects were investigated according to the recommendations of hypertension guidelines. Arterial stiffness measures including pulse wave velocity, augmentation index and central aortic pressure were also applied in all the study patients. Then, the relationships between traditional atherosclerosis parameters and arterial stiffness markers were investigated.

Results: Although the systolic and diastolic blood pressures between the two groups (women and men) were indifferent from each other, augmentation index and central aortic pressure were found significantly higher ($p < 0.001$, $p = 0.03$, respectively) in women. Augmentation index was also found significantly higher ($p = 0.04$) in women smokers compared to nonsmoker ones in subgroup analyses.

Conclusions: The higher augmentation index and central aortic pressure values were observed in women than in men. These data offers new evidences for the role of sex hormones in the pathogenesis of atherosclerosis in women.

RV-150
MEDICATION ADEQUACY AT DISCHARGE ON CARDIOVASCULAR DISEASE IN AN INTERNAL MEDICINE UNIT. FOLLOW-UP THROUGH THREE YEARS

C. Rodríguez Leal, B. Sánchez Sauce, M. Monforte Gómez, L. Moreno Núñez, M. González Anglada, R. Hervas Gómez, C. Guijarro Herraiz, N. Schoebel Orbea

Department of Internal Medicine. Hospital Universitario Fundación Alcorcón. Alcorcón (Madrid), Spain.

Objectives: Medication adequacy on cardiovascular disease is the formal process of designing a treatment accord to the recommendations of current European Guidelines. We analyzed if patients with ischemic stroke, peripheral arterial disease and/or coronary artery disease had an appropriated treatment at discharge from our Internal Medicine Floor.

Material and method: We reviewed discharge reports of Internal Medicine Unit patients with cardiovascular disease during March of 2010, 2011 and 2012 at Hospital Universitario Fundación Alcorcón (Spain). These reports were collected using our hospital electronic clinical history. Each report was analyzed by two different researchers in order to detect whether it contained an accurate treatment for these pathologies. Differences between researchers were argued with a third member in order to obtain an agreement. We considered a good medication adequacy: for ischemic stroke, the use of antiplatelet drugs or anticoagulants, antihypertensives and statins; for peripheral arterial disease, the use of antiplatelet drugs and statins; and finally, for coronary artery disease, the use of antiplatelet drugs, statins, beta-blockers and angiotensina conversion enzyme inhibitor (ACEi) or angiotensin II receptor antagonist (ARA-II). In February of 2011 and 2012, we performed an informative presentation to the Unit to remind the European Guidelines for Cardiovascular Diseases. Data were collected using ACCESS 2003® database, and they were further analyzed with the SPSS 15.0® software. All patients signed a previous informed consent in order to authorize us to use their data. This study was approved by the ethical committee of the hospital.

Results: We collected 162 patients with cardiovascular disease through the three years: 65 patients in 2010, 64 in 2011 and 33 in 2012. Mean age was 81 years, and 47.5% were males. They were at hospital an average length of 7.8 days. Mean Charlson Index was 5.7. 33.3% of the analyzed patients were diabetics and 22.8% had cognitive impairment. Ratio for each pathology was: ischemic stroke, 57.4%; peripheral arterial disease, 14.2%; and, coronary artery disease, 40.1%. The least prescribed drugs were: statins, for all pathologies and years (between 40 and 60%); beta-blockers and ACEi/ARAII for coronary artery disease, both about 60%. Almost all patients who needed antiplatelet drugs or anticoagulation, had them in their treatments. More than 80% of patients with ischemic stroke had antihypertensive drugs. Global good medication adequacy was 37.7%. For each year, proportion of good adequacy was: 2010, 33.8%; 2011, 42.2%; 2012, 36.4%. There was not any statistical significant difference. We also adjusted these results with age, Charlson Index, dementia and sex with a logistic regression model. We did not obtain any statistical significant result.

Discussion: Global rate of good adequacy is very little, despite doing informative interventions last two years. Physicians usually remember to prescribe antiplatelet drugs, anticoagulants and antihypertensive drugs; but there is an unacceptable proportion of patients who do not receive statins, beta-blockers or ACEi/ARA-II when they are indicated.

Conclusions: We have to do an effort to improve appropriate medication adequacy at discharge on cardiovascular disease, because statins, beta-blockers and ACEi/ARA-II are under-prescribed.

RV-151
PROGNOSTIC IMPLICATIONS OF HYPERGLYCEMIA IN A PRIMARY ANGIOPLASTY PROGRAM

E. Cambronero Cortinas, M. Corbi Pascual, J. Jiménez Mazúecos, J. Navarro Cuartero, C. Llanos Guerrero, M. Barrionuevo Sánchez, M. Fernández Anguita, A. Gómez Pérez

Department of Cardiology. Hospital General de Albacete. Albacete, Spain.

Objectives: High levels of glycemia are closely related to a worse prognosis and progression in patients with vascular events, by the tissue damage that occurs during acute myocardial ischemia. Objectives: the aim is to analyze the prognostic value of patients (P) admitted with a myocardial infarction with ST elevation (STEMI) according to levels of blood glucose at admission, the first and second fasting glucose.

Material and method: Are realized a prospectively analysis of 312 P with STEMI undergoing primary angioplasty from June 2007 to August 2010. Admission glycemia was determined into three strata (blood glucose < 140, between 140 and 199 and > 200) and the first two basal glycemia (blood glucose < 110, between 110 and 125 and > 126). Analyzing the incidence of mortality and cardiovascular events defined as death, recurrent ischemia, revascularization and stroke during admission and follow-up. analyzed baseline variables, mortality and cardiovascular complications.

Results: 75% of P were male. The mean age was 62 years. Hypertension were 53%, 37% were active smokers, 21% were diabetic (DM) known and 10% were diagnosed during admission. The P DM had a death rate four times higher than non-DM (12% vs 3%, $p = 0.004$). The P with high levels glucose at admission had a higher mortality (2.5%, 8.9% and 15.6%, $p = 0.005$). As well as, alterations in the first fasting glucose (2.4%, 1.4% and 11.4%, $p = 0.006$). The best predictors of events were admission glycemia (long rank: 9.2, $p = 0.01$) and the first blood glucose levels (long rank: 9.5, $p = 0.009$).

Conclusions: Patients recent diagnosed of DM during STEMI had higher mortality. The first fasting glucose and first admission glucose are good estimators of this poor prognosis.

RV-152
ASSESSMENT OF SUBCLINICAL VASCULAR DISEASE IN ADULTS WITH DOWN'S SYNDROME

P. Parra Caballero, D. Real de Asúa Cruzat, R. Costa Segovia, F. Moldenhauer Díaz, C. Suárez Fernández

Department of Internal Medicine. Hospital Universitario de la Princesa. Madrid, Spain.

Objectives: Adults with Down's syndrome (DS) tend to present a different cardiovascular risk profile than general population; however, they have been proposed as an atherome-fee model, based on the absence of artheriosclerotic damage. The aim of our study was to compare the subclinical vascular disease between a cohort of DS subjects and another of individuals without the syndrome.

Material and method: Cross-sectional study of 56 patients recruited at the Adult Down Syndrome Unit of the Hospital Universitario La Princesa, Madrid, Spain between January and May 2012. Epidemiological, clinical, anthropometric, subclinical vascular damage parameters (augmentation index [AI], pulse wave velocity [PWV] and intima media thickness [IMT]), cardiovascular risk assessment (Framingham score) and analytical variables were measured. SPSS package was used for making the statistical analysis; results were compared with non-parametric tests.

Results: 28 adults with DS and 28 controls were enrolled (mean age DS 39.3 ± 10.7 vs 42.6 ± 12.6; 14 [50%] males with DS vs 10 [36%] in the control group; ns for both comparisons). DS adults had lower mean blood pressure (114/71 ± 13/10 vs 130/80 ± 12/8 mmHg; $p < 0.001$) and a higher body-mass index [BMI] (29.8 ± 4.9 vs 25.8 ± 3.7 Kg/m^2; $p < 0.001$) than controls; no differences were found between groups regarding waist perimeter [WP], total body fat percentage or prevalence of abdominal obesity, hypertension, dyslipidemia or diabetes. Aortic pressures estimated by applanation tonometry were lower in the DS group (systolic 103.9 ± 13.9 vs 119.3 ± 13.5 mmHg and dyastolic 71.8 ± 10.6 vs 81.4 ± 8.7 mmHg respectively), as well as pulse pressure (30.9 ± 9.6 vs 37.7 ± 7.7 mmHg), $p < 0.01$ for all comparisons. There was a trend towards a lower PWV in the DS group (6.3 ± 1.1 vs 7.1 ± 1.9 m/s, $p = 0.06$), and we found no differences between groups in AI or IMT mean values (AI 21.9 ± 16.4 vs 22.8 ± 15.3%, $p = 0.84$; IMT 0.55 ± 0.13 vs 0.53 ± 0.1 mm, $p = 0.55$, respectively). In the DS group the PWV values were only correlated to systolic blood pressure ($p = 0.019$) and not with age, whereas in the control group it was associated with age, WP and BMI (p 0.01, 0.05 and 0.01 respectively). IMT values were not associated with the presence of classic cardiovascular risk factors in any group, with only a non-significant higher mean value in diabetic patients (0.75 vs 0.54, $p = 0.12$) compared with non-diabetics in the DS group. In the DS group we found positive correlation between PWV and Framingham score ($p = 0.05$) and AI and Framingham score ($p = 0.03$), with a non-significant association between IMT and Framingham score ($p = 0.14$). In the control group, only AI and systolic blood pressure measured by applanation tonometry correlated with the Framingham score ($p = 0.05$ and $p = 0.01$ respectively).

Discussion: Despite a similar cardiovascular risk regarding classical risk factors, PWV seems to be lower in subjects with DS, being independent of age and obesity in this population and showing a positive correlation with BP levels, which are significantly lower in DS subjects despite similar prevalence of obesity and diabetes; PVW also correlates positively with the Framingham score. Aortic estimated pressures were all lower in DS individuals. No differences were found regarding IMT values.

Conclusions: Adults with DS seem to have lower subclinical vascular damage than controls, being this association independent of classical cardiovascular risk factors and correlating positively with the Framingham score. PWV could be useful in determining cardiovascular risk in this population.

RV-154
CLINICAL AND EPIDEMIOLOGICAL CHARACTERISTICS OF NON TRAUMATIC INTRACRANIAL HAEMORRHAGES

M. Rodríguez Arias, R. Puerta Louro, F. Fernández Fernández, M. Valle Feijoo, P. Sánchez Conde, C. Casas Hernández, L. Novoa Lamazares, J. de la Fuente Aguado

Department of Internal Medicine. POVISA. Hospital de Vigo. Pontevedra, Spain.

Objectives: The aim of this study was to analyze the clinical and epidemiological characteristics of patients with non traumatic intracranial haemorrhages (intracerebral, subarachnoid and subdural).

Material and method: We designed a retrospective study to analyze all the cases of intracranial haemorrhages in our hospital on the period comprehended from the 1 of January of 2011 to the 31 of December of 2011. All the patients discharged from hospital with diagnosis of that intracerebral, subarachnoid and subdural haemorrhages were included.

Results: We identified 60 cases with intracranial bleeding (59 patients), 58% male, mean age 70 years (31% aged > 80 years). Different types of intracranial bleeding were identified: intracerebral (44), subarachnoid (13) y subdural haemorrhages (3). The risk factors most commonly were hypertension (57%), dislipemia (27%), diabetes mellitus (22%), chronic renal failure (18%), atrial fibrillation (13.3%), haemorrhagic stroke (12%), isquemic cerebrovascular disease (10%), peripheral vascular pathology (8%), valvular disease (6.7%), coronary heart disease (5%) and heart failure (2%). Others comorbilities were anemia (30%), neoplasia (18%), alcohol intake (13%) and chronic obstructive pulmonary disease (1.7%). Regarding to treatment 37% were taking antiplatelet or anticoagulant therapy: aspirin (23%), clopidogrel (1.7%), heparin (1.7%) and oral anticoagulation (12%). Mortality was 15%.

Conclusions: Regarding to patients characteristics there were a high predominance of males, high proportion of elderly patients and intracerebral haemorrage. Hypertension was the risk factor most commonly associated with intracraneal haemorrhage. More than one third of patients were receiving antiplatelet therapy, anticoagulant or both at the moment of the haemorrhage occurrence, being aspirin the drug more frequently taken.

RV-155
ANALYSIS OF DIABETES MELLITUS PATIENTS TREATED AT A LOCAL HOSPITAL

F. García Sánchez, J. Alonso Peña, P. Ruiz Sanjuán, I. Machuca Sánchez

Department of Internal Medicine. Hospital Virgen del Puerto. Plasencia (Cáceres), Spain.

Objectives: We want to investigate: Diabetes mellitus patients profile in order to define and classify their co-morbilities, previous diseases and risk-factors. Show the relations between biometrical parameters and glycated hemoglobin. Discover which are pathologies related to patients hospitalized with diabetes mellitus.

Material and method: This study is a type of observational, descriptive and longitudinal, we have collected data from patients diagnosed with diabetes and newly diagnosed or who have entered into the beds of different medical specialties to the Hospital Virgen del Puerto of Plasencia in the last two years. We collected them from analytical and measurement of biometric parameters. That information is collected in a form with personal data, data related to the reason for admission, and hospital treatment history at home. Then, we followed the evolution of patients by primary care and

specialized tools through Extremadura Health Service to assess changes in laboratory parameters of patients with diabetes mellitus. Data collected on each patient, are processed by software SPSS 20.

Results: The highest percentage of diabetic patients in our study corresponds to males with 60.4%. It is important to note that the total sample, 73.6% of the sample or had no education or were primary, which means relevant because of the understanding, applicability and compliance with treatment. Related to previous diseases or risk-factors, hypertension was presented in 49%, closely followed by dyslipidemia, third EPOC is ahead of heart failure and peripheral arterial disease. This distributive sex, too different and so are quite similar. The most common reason for admission is related to respiratory disease with a 41.51%, second is the entrance for cardiovascular disease in 24.53% and third among the most common diseases of income, are digestive diseases with a 16.98%. As for BMI, only 18.9% was within normal weight ranges, being a relevant fact as glycosylated hemoglobin outside the normal range is evident mostly in groups of body mass index 25 and 35. It is shown that, the highest levels of HbA1c were found in patients with grade I obesity.

Conclusions: It is show a correlation between elevated BMI and HbA1c. Hypertension and dislypemia are most common risk-factor. EPOC is most common previous illness followed by cardiovascular pathology and arterial disease pathology.

RV-156
DECREASE IN DRUGS CONSUMPTION AFTER METABOLIC SURGERY IN DIABETIC PATIENTS

A. Romero Alegría[1], J. Martín Oterino[1], J. Sánchez Tocino[2], J. Fernández Rodríguez[2], E. Puerto Pérez[1], P. Miramontes González[1]

[1]Department of Internal Medicine, [2]Department of General Surgery. Hospital Universitario Virgen de la Vega. Salamanca, Spain.

Objectives: To determine the decrease in drug consumption (and the cost associated) in patients with type 2 diabetes mellitus with comorbidities, particularly hyperlipidemia and high blood pressure, after metabolic surgery.

Material and method: 12 patients (7 men and 5 women, mean age 59.1 years) with type 2 diabetes mellitus and body mass index (BMI) < 40 kg/m^2. They had metabolic surgery (gastrojejunal bypass) according to a protocol established by the recommendations of major scientific societies. We determined the number and approximate cost of the drugs they needed at baseline and follow-up year (antidiabetic, antihypertensive and hypolipidemic drugs) We established a value of 1 for low to medium doses of a drug (or < 0.3 IU insulin/kg/d) and a value of 2 for high doses or a drug (or insulin > 0.3 IU/kg/d). The cost was calculated with the mean cost of the 12 patients per month of treatment, using the cheaper drugs.

Results: Table 1.

Discussion: Metabolic surgery may be an alternative to conventional treatment of patients with type 2 diabetes mellitus. These patients require the use of multiple drugs to control the comorbidities associated with type 2 diabetes mellitus such hyperlipidemia and high blood presure.

Conclusions: Metabolic Surgery (gastrojejunal bypass) in patients with type 2 diabetes mellitus is very effective because it greatly reduce the consumption of drugs in patients, and remains the same or better metabolic control and blood pressure. As is known, the lower consumption of drugs leads to better therapeutic compliance.- By reducing the consumption of more expensive drugs (ARA II, insulin and DPP4 inhibitors) saving is around 95% of the cost prior to surgery. Although it is needed most comprehensive pharmacoeconomic studies, it seems clear that the savings in drugcosts per patient are very important.

RV-160
SHORT AND MEDIUM-TERM RESULTS OF METABOLIC SURGERY IN DIABETIC PATIENTS

A. Romero Alegría[1], J. Martín Oterino[1], J. Sánchez Tocino[2], J. Fernández Rodríguez[2], N. Cubino Bóveda[1], A. García Mingo[1]

[1]Department of Internal Medicine, [2]Department of General Surgery. Hospital Universitario Virgen de la Vega. Salamanca, Spain.

Objectives: To observe anthropometric and metabolic parameters of patients with type 2 diabetes mellitus who had metabolic surgery (gastroyeyunal bypass) short-term and medium-term.

Material and method: 12 patients (7 men and 5 women, mean age 59.1 years) with type 2 diabetes mellitus and body mass index (BMI) < 40 kg/m^2. They had metabolic surgery according to an established protocol by the recommendations of major scientific societies. All patients had a gastrojejunal bypass. All patients were taking medication for their metabolic control and blood pressure before surgery. Data obtained include anthropometric indices, fasting glucose, HbA1c, C-peptide, HOMA, blood pressure, lipids, and leptin.

Results: Table 1.

Discussion: Metabolic surgery may be an alternative to conventional treatment of patients with type 2 diabetes mellitus.

Table (RV-156)

	Number drugs/day (at the beginning)	Cost € patient/month	Number drugs/day (first year)	Cost € patient/month	Reduction (%)
Antidiabetic drugs	2.5	106.41	0.5	2.58	-97.57
Hypolipidemic drugs	1.5	35.44	0.33	3.17	-91.05
Antihypertensive drugs	3.5	35.37	1.16	3.19	-90.98
Total	7.5	177.22	1.99	8.94	94.95

Table (RV-160)

	Basal	1 month (% variation)	1 year (% variation)	p
BMI (Kg/m2)	34.7	30 (-13.5%)	25.7 (-25.8%)	< 0.01
Fasting glucose (mg(dL)	134	112 (-16.4)	103 (-23.1)	< 0.01
HbA1c (%)	7.4	7.1 (-4)	5.8 (-21.6)	< 0.01
C peptide (ng/mL)	3.25	2.6 (-20)	1.75 (-46.1)	0.001
HOMA	3.4	1.33 (-60.8)	0.6 (-82.3)	0.001
Cholesterol (mg/dL)	161	159.6 (-0.87)	170 (5.6)	ns
Blood presure (mmHg)	142/91	129/82	119/76	< 0.05

There are different surgical techniques, one of the most classic is gastrojejunal bypass.

Conclusions: -The gastrojejunal bypass shows some excellent metabolic control results in both, the short and medium term.-The data indicate an apparent decrease in insulin resistance and leptin throughout the first year of monitoring -Variations in lipids are also important. A year after surgery, no patient require lipid-lowering therapy.-The gastrojejunal bypass improves blood pressure control, especially in the first year.

RV-161
INCIDENCE, TEMPORAL PATTERNS AND CIRCADIAN VARIATION OF EMERGENCY DEPARTMENT ADMITTANCES FOR NON-HEMORRHAGIC STROKE. A HOSPITAL-BASED STUDY

S. Valero Cifuentes[1], B. Medina Tovar[1], E. García Villalba[1], M. Egea Campoy[1], C. Rosa García[1], A. Melgarejo González[1], A. Egea Valera[2], J. Fernández Pardo[1]

[1]Department of Internal Medicine, [2]Department of Clinical Documentation. Hospital General Universitario Reina Sofía. Murcia, Spain.

Objectives: To determine the incidence by age and sex, the temporal patterns and circadian variation of emergency department (ED) admittances for non-hemorrhagic stroke (NHS) episodes (including transient cerebral ischemia) in our hospital.

Material and method: Based on the computerized medical records of all assisted processes in the ED of our hospital for any cause during four consecutive years (from January 2008 to December 2011), and in preserving patients anonymity, we collected information on the age, sex, first-listed diagnosis (which was subsequently coded according to ICD-9 MC, using an application software developed by our Clinical Documentation Dept.), date and entry time of all patients attended. All these variables were imported into a database and, using the computer program SPSS® 15.0, we conducted a descriptive study and a statistical data analysis, with the objectives set out, for patients who presented an acute non-hemorrhagic cerebrovascular disease episode as main reason for attendance (ICD-9 MC codes 433 to 435).

Results: The total number of patients visiting our ED from all causes during the study period was 401678. The patients mean age (± standard deviation) was 43.7 ± 21.4 years and 50.3% were women. Among the total assisted, 1295 patients (0.32%) were mainly because of NHS. From these patients, 52.4% were men, with a mean age of 71.5 ± 13.2 years, and, 47.6% were women with a mean age of 77.3 ± 11.7 ($p < 0.001$). Nearly an 80% patients assisted by NHS were over 65 years. Season with highest NHS incidence was winter, with a 27.6%. Significant variations can be seen in the frequency of NHS during the different months of the year (December was the month with the highest incidence [9.9%] and April was the month with the lowest incidence [6.3%]). The days of the week of highest incidence were Mondays (15.3%) and Tuesdays (15.4%), whereas on Saturdays (13.3%) and Sundays (11.7%) were the days with the lowest incidence. More than a half of patients (52.6%) came to ED between 10h and 17h, with a peak between 11h and 13h (17.9%). However, in the period from 2 am to 8 am came < 5% of cases. The lowest incidence happened between 4 am and 6 am (< 1% of cases).

Conclusions: NHS is a relatively frequent and important hospital emergency, especially for those patients over 65 years old. We observe significant variations in hospital ED admissions rate for NHS among different months of the year, days of the week and hours of the day. We also find a higher incidence in winter and during the morning, and a lower incidence on Sundays.

RV-162
IS IT IMPORTANT DYSLIPIDEMIA IN A PRIMARY ANGIOPLASTY PROGRAM?

E. Cambronero Cortinas, M. Corbi Pascual, J. Jiménez Mazúecos, A. Gutiérrez Díez, G. Gallego Sánchez, D. Prieto Mateos, I. López Neyra, J. Córdoba Soriano

Department of Cardiology. Hospital General de Albacete. Albacete, Spain.

Objectives: The relationship between cardiovascular events and elevated levels of lipoprotein cholesterol (LDL-c) is clearly established. Our aim was to determine the prognostic value of patients (P) that have suffered of a myocardial infarction with ST elevation (STEMI) and to see if they show a biggest rate of mortality, during hospitalization and their following-up according to the presence of dyslipidemia (DL).

Material and method: We prospectively included 312 P with STEMI undergoing primary or rescue angioplasty from June 2007 and June 2010. We performed a prospective cohort study establishing two groups, one formed by P previously diagnosed to the event of the study or during their check in DL, compared with P without alteration of lipid metabolism. We evaluate the incidence of death according to the type of treatment performed.

Results: 40.4% of P were DL. The average age in the DL was 62.7 ± 13.4 years. 82% were male, 21% diabetics, 25% were active smokers. Average following-up was of 530 days. All baseline characteristics were similar, except the frequency of hypertriglyceridemia which was 15% vs 2.9%, $p = 0.001$. There were no significant differences in the type of revascularization treatment. The P DL showed a higher mortality to non-DL (10.5% vs 3.4%, $p = 0.005$), during hospitalization, it showed bigger levels of mortality (6.5% vs 1.2, $p = 0.038$) and it continued to rise during the following-up (4.3% vs 0.2 $p = 0.05$). The P taking statins presented a lower mortality rate (4.4% vs 27.7%, $p = 0.001$).

Conclusions: Patients with dyslipidemia show higher mortality. Therefore, we must optimize the type of treatment performed to this vulnerable group.

RV-163
IS IT IMPORTANT DIABETES IN A PERCUTANEOUS REPERFUSION PROGRAM?

E. Cambronero Cortinas, J. Jiménez Mazúecos, M. Corbi Pascual, A. Gutiérrez Díez, J. Córdoba Soriano, M. Simón García, I. López Neyra, J. Navarro Cuartero

Department of Cardiology. Hospital General de Albacete. Albacete, Spain.

Objectives: Our aim was to analyze the prognostic value of patients (P) admitted with a myocardial infarction with ST elevation (STEMI) according to the presence of diabetes (DM) and determined if they show a higher rate of mortality.

Material and method: We prospectively analyzed 231 P with STEMI undergoing primary angioplasty from June 2007 and January 2010 in a Hospital with 24 hours warning of Hemodynamics. We performed a prospective cohort study establishing two groups formed by a DM or with two basal blood glucose > 125 mg/dl or a fasting glucose > 125 and > 199 on admission and another for P without HC metabolism changes.

Results: 49.5% are diagnosed DM, still unknown for 54.4%, with an average age of 65.63 ± 12 years. 81% were male and DM known were 22.5%. All baseline characteristics were similar to those of non-DM except female gender and peripheral arteriopathy, which was higher in DM ($p = 0.019$ and 0.011). There were no significant differences in the type of treatment performed. They had a higher percentage of severe ventricular dysfunction (19% vs 3%, $p = 0.004$).

The DM had a mortality three times higher than non-DM (10.5% VS3, 4%, p = 0.016), both during hospitalization (6.5% vs 1, 2%, p = 0.038), as in the following-up (4.3% vs 0, 2%, p = 0.05).

Conclusions: During STEMI DM known and unknown show a higher level of mortality. This is true, despite having similar characteristics in the treatment performed. Therefore, we must work together to optimize the treatment performed to this vulnerable group of patients.

RV-164
LDL CHOLESTEROL IN PRIMARY AND SECONDARY PREVENTION OF VASCULAR EVENTS

R. Bagina, C. Baeta

Department of Internal Medicine. Hospital Dr. José María Grande. Portalegre, Portugal.

Objectives: We analyzed the values of LDLc in the population with cerebrovascular events, cardiovascular and metabolic events, according to risk factors and therapeutics. It was studied a sample of 176 patients followed in the Cardiovascular Risk Consulting Unit (age: 67 years, M: 78.9%, W: 21.02%). The goal was to determinate if the cLDL was a reliable predictive parameter on the cardiovascular risk.

Material and method: We used the SPSS V17.0 to analyze 54 variables (events, anthropometric indices, lipid profile, pharmacological treatment and interventional cardiology) and its relation with the values of LDLc. We studied a sample of 176 patients followed in the Cardiovascular Risk Consulting Unit (Age: 67 years, M: 78.9%, W: 21.02%).

Results: Age: 67.0 years; Gender: 78.9 M 21.1 W; CAD without ST Elevation: 23.4%; CAD with ST Elevation: 40.3%; CVA: 7.4%; AHT: 78.9%; DM2: 50.6%; BMI: 28.1; AP: 100.4 cm; Glycemia: 128.3 mg%; HBA1c: 7.4%, 22% < 6.5 mg%; Lipids (TC: 166.8 mg%; LDLc: 93.1 mg%, 56.3% < 100 mg%, 22.2% < 70 mg%; HDLc: 46.0 mg%; TG: 144.6 mg%); Treatment (Anti-platelets: 64.2%; Anti-hypertensors: 64.0%; Anti-dyslipidemics: 85.8%; Oral Anti-diabetics: 36.9%; Insulin: 8.5%; Catheterism: 68.9%; Coronary Surgery: 18.2%; Angioplasty: 38.6%). Average values of LDLc allocated per variable: CAD without ST Elevation: 91.93 mg%; CAD with ST Elevation: 91 mg%; CVA: 86.27 mg%; AHT: 91.78 mg%; DM2: 88.07 mg%; Treatment (Anti-platelets: 95.13 mg%; Anti-hypertensors: 93.73 mg%; Anti-dyslipidemics: 91.05 mg%; Oral Anti-diabetics: 91.93 mg%; Insulin: 119.43 mg%; Catheterism: 90.78 mg%; Coronary Surgery: 95.00 mg%; Angioplasty: 89.67 mg%).

Discussion: In this sample we had a very old population, majority represented by the male gender, where the prevalence of cardiovascular risk factors was very high, giving this population a global high risk for cerebrovascular and cardiovascular events. Another element that called our attention was the elevated consumption of anti-platelets, anti-hipertensors and anti-dyslipidemics drugs among these patients. When we analyze the intervention cardiology, we see that a significant percent was catheterized with consequent coronary surgery or primary angioplasty. It's also interesting observe that patients in primary and secondary prevention had a good metabolic control, better than the general population and close to the guidelines.

Conclusions: A) Secondary prevention: 1. Patients with vascular events had LDLc lower than the general average; 2. Patients treated with anti-dyslipidemics showed a lower LDLc and had less coronary surgery. B) Primary Prevention: 1. Patients with hypertension and diabetes showed a better lipid profile compared to the general population. C) In the Cardiovascular Risk Consulting Unit LDLc is a major parameter in primary and secondary prevention.

RV-165
THE EFFECT OF IRON OVERLOAD AND HFE GENE POLYMORPHISMS ON CARBOHYDRATE METABOLISM IN PORPHYRIA CUTANEA TARDA

A. González-Estrada, M. Alarcón Garcelán, L. Gómez Morales, S. Rodríguez Suárez, P. García Ocaña, E. Pamies Andreu, J. Andreu Álvarez, J. García Morillo

Department of Internal Medicine. Complejo Hospitalario Regional Virgen del Rocío. Sevilla, Spain.

Objectives: Porphyria cutanea tarda (PCT) results from a reduce activity of the uroporphyrinogen decarboxylase (UROD) enzyme, in which genetic and environmental factors are involved. It can be unleashed among others by iron overload, alcohol, estrogens and other conditions. Iron overloading is associated with hemochromatosis (HFE), and mutations in the HFE gene have been associated with the development of metabolic syndrome. The aim of this study was to describe the degree of iron loading and the Cys282Tyr and His69Asp HFE gene mutations with the development of diabetes in PCT patients.

Material and method: We conducted a transversal analysis of a population cohort of 25 patients with PCT from the Internal Medicine Department, Virgen del Rocío Hospital in Spain, recruited since 2009. The diagnosis was made measuring levels of uroporphyrinogen, coproporphyrinogen, and protoporphyrinogen in 24-hour urine samples, fluorometric blood smear, and the urodecarboxylase enzyme activity. Hemochromatosis C282T and H69A gene polymorphisms were identified. Iron overload was established by the detection of iron, transferrin saturation, and ferritin levels in blood stream. Several epidemiological and biological variables were analyzed, as well as some cardiovascular risk factors. Patients with or without metabolic syndrome were classified according to the European Diabetes Society guidelines. Data were analyzed using the SPSS Statistics Software 15.0.

Results: Patients presented a mean age of 51.06 ± 13.2 years old. Proportion men/women was 76.5%/23.5%. 64.7% of patients had a history of alcohol consumption, the rest being related to hepatitis C virus (HCV). HFE gene polymorphisms were present in 29.4%. H63D mutation was present in 20%, C282T in 6%, and double heterozygosis in 5%. Iron overload measured by transferrin saturation index (TSI) and ferritin levels, had a mean of 32.29 ± 15.87 and 410.82 ± 295.59 respectively. Results for metabolic syndrome risk factors were: mean glycemic levels 117.81 ± 38.75 mg/dl, Hb1Ac 6.7 ± 1.25%, total cholesterol 196.53 ± 33.07 mg/dl, triglycerides 134.06 ± 74.90 mg/dl, and HDL 50.21 ± 17.03 mg/dl. 17.6% of patients had arterial hypertension, treated by at least one antihypertensive drug, 41.17% had diabetes, and 7% prediabetes. Patients with more iron overload and longer treatments with hydroxychloroquine had Hb1Ac alterations and were older; the rest of cardiovascular risk factors did not maintain an association, though there was an inclination to hypertriglyceridemia. Patients with HFE mutations had more disease activity, higher levels of uroporphyrinogen, alanine and aspartate transaminases, and more tendencies to iron overload. Metabolic syndrome and iron overload did not show differences in subgroups, although we believe that the small number of patients in our study affected these results.

Conclusions: In our cohort of PCT patients, we found a tendency -which can be translated as an increase in disease activity- towards iron overload and the presence of HFE mutations. There seems to be an association between the increase in TSI levels and carbohydrate metabolism deterioration.

RV-166
TRENDELENBURG POSITIONING DURING ACUTE STROKE. HEMODYNAMIC AND CLINICAL OUTCOMES

R. Nicolas[1], A. Puy[2], C. Volkmer[2], M. García Antelo[2], D. Fernández Couto[2]

[1]Department of Internal Medicine, [2]Department of Neurology. Hospital Universitario A Coruña. A Coruña, Spain.

Objectives: Cerebral blood flow (CBF) is reduced to the infarcted area during an acute stroke. Although the classical notion is that CBF is largely controlled by arterial Pco2 and blood pressure, CBF may also be influenced by relative head position and the distribution of cardiac output. Best positioning for acute stroke patients is unknown and Trendelenburg positioning has never been used. The purpose of the present study was to investigate the potential effects of Trendelenburg positioning on systemic and cerebral hemodynamics and clinical outcomes.

Material and method: Prospective interventional cohort study set in an internal medicine department of a tertiary care hospital. 10 consecutive patients with acute stroke were immediately Brain scanned, and treated according to AHA guidelines. Hypertension was not treated except if it exceeded 220/120. All patients were placed in the Trendelelenburg position for at least 1 hour. Half of them were maintained in this position for 24 hours. Primary outcome measures were systemic blood pressures, extracranial and intracranial cerebral artery blood velocity and neurological deficits. Baseline hemodynamic measurements were performed in the horizontal and the Trendelenburg position (30 deg head-down tilt), including: blood pressure in the upper and lower limbs, respiratory rare, heart rate, O_2 saturation, end tidal CO_2, and extracranial and transcranial Doppler ultrasonography. ECD and TCD were performed immediately after admission. During admission and at a median follow-up of 2 years, new vascular events were recorded.

Results: Trendelenburg positioning did not result in major adverse events. Transitory nausea and vomiting occurred after a few hours in 20% of the patients. Most patients tolerated 24h Trendelenburg positioning without relevant discomfort. Placing the stroke patients in the Trendelenburg position resulted in a non significant increase in Systolic blood pressure in the upper arms and a decrease in systolic and diastolic pressure in the lower limbs. HR did not change during the study period in both positions. Respiratory rate, Oxygen saturation and non invasive End Tidal CO_2 did not change during the study period in both positions. A positive clinical response to the Trendelenburg position during the first hour was observed in 80% of the patients. In one patient TIBI flow improvement secondary to Trendelenburg positioning was associated with spectacular neurological recovery.

Discussion: Mechanistically there was a trend towards systolic blood pressure increase in the upper part of the body with no significant change in intracerebral arterial velocity that may be beneficial in terms of cerebral perfusion pressure. As there were no relevant changes in respiratory parameters controlling cerebral blood flow, its variation if any would be largely due to the increase in upper body blood pressure. Trendelenburg positioning may in itself be clinically beneficial or synergistic with reperfusion therapies.

Conclusions: This investigation produced two novel findings concerning Trendelenburg positioning during acute stroke: First, it is a safe manoeuvre to be applied during an acute attack, and it is well-tolerated. Second, there was a clear trend towards clinical improvement more evident in aphasia recovery, but also in the motor domain.

RV-167
DESCRIPTIVE STUDY OF THE PHARMACOLOGICAL MANAGEMENT FOR RATE CONTROL IN PATIENTS WITH ATRIAL FIBRILLATION (AF) ADMITTED TO AN INTERNAL MEDICINE DEPARTMENT

M. Gallego Villalobos[1], M. Martínez Sela[2], N. Morán Suárez[2], D. Pérez Martínez[1], J. Ferreiro Celeiro[1]

[1]Department of Internal Medicine. Hospital San Agustín. Avilés (Asturias), Spain. [2]Department of Internal Medicine. Hospital Nuestra Señora de Covadonga. Oviedo (Asturias), Spain.

Objectives: To describe the different treatments of patients with AF, with respect to rate control and associated risk factors.

Material and method: We reviewed the discharge summaries of patients admitted to an Internal Medicine Department between the period from October till December 2010 inclusive.

Results: We reviewed 863 discharge summaries and found 179 patients with AF (20.7%). The mean age was 81.6 years and 53.1% were women. Heart rate control was achieved with digoxin (54.19%), beta-blockers (35.2%), non dihydropyridine calcium channel antagonists (16.76%) and amiodarone (3.9%).

Discussion: Atrial fibrillation is the most common cardiac arrhythmia, its prevalence increases with age, as in our study we found it present in more than 20% of patients whom had a mean age of 80 years or older. Heart rate control is important in these patients, in our study the most commonly used drug was digoxin followed by beta-blockers, probably due to the high co-morbidity of our patients.

Conclusions: 1. The most commonly used rate control drug used was digoxin, in more than 50% of patients. 2. The elderly age of patients conditions treatment management.

RV-168
SEASONAL RHYTHM, WEEKLY AND HOURLY VARIATIONS IN ADMISSIONS FOR ACUTE CORONARY EPISODES IN AN EMERGENCY DEPARTMENT

B. Medina Tovar, A. Melgarejo González, C. Rosa García, S. Valero Cifuentes, J. Gómez Verdú, A. Sobrao López, C. Aguirre González, J. Fernández Pardo

Department of Internal Medicine. Hospital General Universitario Reina Sofía. Murcia, Spain.

Objectives: To determine the existence of seasonal rhythm, weekly and hourly variations, and to analyze the influence of age on admissions for acute coronary heart disease (ACHD) episodes at our hospital emergency department (ED).

Material and method: Based on the computerized medical records of all assisted processes at the ED of our hospital for any cause during four consecutive years (from January 2008 to December 2011), and in preserving patients anonymity, we collected information on the age, sex, first-listed diagnosis (which was subsequently coded according to ICD-9 MC, using an application software developed by our Clinical Documentation Dept.), date and entry time of all patients attended. All these variables were imported into a database and, using the computer program SPSS® 15.0, we conducted a descriptive study and a statistical data analysis, with the objectives set out before, for patients who presented an episode of ACHD (ICD-9 MC codes 410 to 411 and 413) as first-listed diagnosis at the hospital ED.

Results: Total assisted processes from all causes in the Emergency Department of our Hospital during the studied period were 401678. The mean age (± standard deviation) of the patients was 43.7 ± 21.4) years and 50.3% were women. A total of 418 patients were mainly assisted because of ACHD. Of these, 311 (74.4%) were men with a mean age of 62.6 ± 14.5 years, and 107

(48.3%) were women, with a mean age of 73.6 ± 12.2 years (p < 0.0001). More than half (53.1%) patients assisted by ACHD were 65 or older. The period of the year with the highest incidence of ACHD was from November to January (December was the month of highest incidence [11%]), while there was a lower incidence (21%) during the period from August to October. Sundays and Mondays were the days of further ACHD assistance (17.2% and 15.1% respectively), and Fridays had the fewest (12.2%). Almost half (49.5%) of ACHD patients went to the ED between 9 am and 6 pm, peaking at 4 pm (7.9%). The lowest attendance was between 4 am and 7 am with 5.3% of ACHD cases.

Conclusions: Important changes in hospital emergency admissions rates due to ACHD are detected among the different months of the year, days of the week and times of the day. The highest incidence is found in winter and greater attendance is found during the late morning and early afternoon, as well as on Sundays. We can confirm that women have delayed the average age of presentation ACHD episodes over a decade.

RV-170
METHODS OF ASSESSING KIDNEY FUNCTION IN A HOSPITAL CONSULTATION OF HYPERTENSION AND CARDIOVASCULAR RISK: IMPLICATIONS IN CHRONIC KIDNEY DISEASE CLASSIFICATION AND CARDIOVASCULAR RISK STRATIFICATION

M. Dias[1], P. Cunha[1], P. Oliveira[2], J. Cotter[1]

[1]ESH Hypertension Center, Department of Internal Medicine. Centro Hospitalar do Alto Ave/University of Minho. Guimarães, Portugal. [2]Instituto de Ciências Biomédicas Abel Salazar. University of Porto. Porto, Portugal.

Objectives: Cardiovascular risk of a patient should be evaluated in a global way, considering several risk factors, including chronic kidney disease. There are different equations to estimate a patient's renal function. It is not known if, for patients with increased global cardiovascular risk, the choice of different equations has any impact in estimating their renal function and therefore in the stratification of their cardiovascular risk. The objectives of this study are to assess the level of agreement between the Cockcroft-Gault, Modified Diet Renal Disease and Cystatin C equations, with respect to the classification of chronic kidney disease and cardiovascular risk stratification in an increased cardiovascular risk population followed in hospital consultation.

Material and method: Anthropometric, clinical and analytical data was collected from 228 patients with global increased cardiovascular risk. Cohen's k value analysis was used to evaluate the agreement level between equations respecting to CKD classification and CVR stratification.

Results: We verify no agreement between methods in 22.8% (n = 52) of patients in respect to chronic kidney disease stages' classification. Among these 52 patients, the method used also changed global cardiovascular risk stratification in 13.5% (n = 7) of the patients.

Discussion: There is a considerable proportion of individuals with increased cardiovascular risk classified in different states of chronic kidney disease, according to the method of renal evaluation used. In some patients the equation used to estimate glomerular function also has an impact on cardiovascular risk stratification. The lack of agreement between the methods used in this population warrants a study to compare them with a gold-standard method.

Conclusions: The equation used to estimate the glomerular function has implications in renal evaluation and cardiovascular risk stratification of patients with increased cardiovascular risk.

RV-171
DIFFERENCES BETWEEN OFFICE AND AMBULATORY BLOOD PRESSURE IN NORMOTENSIVE POPULATION ACCORDING TO GENDER AND AGE

J. Sobrino[1], M. Domenech[2], M. Camafort[2], E. Vinyoles[3], A. Coca[2] and the ESTHEN Investigators[4]

[1]ED. Fundació Hospital de l'Esperit Sant. Barcelona, Spain. [2]Department of Internal Medicine. Centre Sociosanitari Hospital Clínic i Provincial de Barcelona. Barcelona, Spain. [3]CAP. La Mina. Sant Adrià del Besos (Barcelona), Spain. [4]Estudio de la Hipertensión Enmascarada. Barcelona, Spain.

Objectives: Analyze differences between office blood pressure (OBP) and ambulatory blood pressure values (ABPM) in a cohort of normotensive subjects according gender and age.

Material and method: We included all subjects without antihypertensive treatment analyzed in previous ESTHEN studies (ESTHEN 1, ESTHEN 2 and ESTHEN 3) with OBp < 140/90 mmHg and mean 24 h ambulatory blood pressure < 130/80 mmHg.

Results: We analyze 756 subjects, with a mean age 43.7 ± 11.5 years (57.5% women). The mean values of blood pressure were upper in men than in women, with two methods, office blood pressure (125.73 ± 9.51/76.87 ± 6.89 vs 119.94 ± 11.27/74.08 ± 8.25 mmHg; p < 0.001) and ambulatory blood pressure (mean values of 24h 118.26 ± 7.42/71.83 ± 6.4 vs 113.43 ± 8.5 mmHg, p < 0.001; Diurnal 123.29 ± 7.93/75.88 ± 7.41 mmHg vs 118.28 ± 9.73/74.11 ± 7.4 mmHg, p < 0.001; Nocturnal 109.57 ± 8.86/65.13 ± 7.03 vs 104.87 ± 9.34/62.78 ± 6.85 mmHg; p < 0.001). Moreover, these differences between men and women were scarce in the elderly, even reversed in the seventh decade of life (table 1).

Conclusions: The differences in blood pressure values between normotensives men and women were independent of methodology measurement, even more pronounced with office blood pressure than ambulatory blood pressure values. These differences were more pronounced in the first decade of life, and minimize in the elderly, nearly of sixth decade of life. Women elderly than 70 years old presented blood pressure values upper tan men.

Table 1 (RV-171). Differences in blood pressure values between men and women (mmHg)

Decade (years)	SBP Office	DBP Office	24h SBP	24h DBP	SBP diurnal	DBP diurnal	SBP Nocturnal/DBP Nocturnal
20	11.6	6.3	9.4	2.9	11.3	3.8	7.2/2.7

RV-172
GLOMERULAR FILTRATION RATE AND AMBULATORY PRESCRIPTION FOR METFORMIN IN A TERTIARY IN AN INTERNAL MEDICINE SERVICE

R. Micán Rivera, R. Montejano Sánchez, A. Quesada Simón, C. Mejía Chew, G. Salgueiro Origlia, F. Arnalich Fernández

Department of Internal Medicine. Hospital Universitario La Paz. Madrid, Spain.

Objectives: Type 2 diabetes is one the most frequent pathology of internal medicine inpatients. Following ADA recommendations, metformin is the initial drug in the treatment of type 2 diabetes. Some of the diabetic patients have renal impairment related to this pathology, and treatments that they received should be prescribed depending on it, such as metformin, that is not indicated if renal impairment is present The aim of our study is to describe the characteristics of inpatient that receive treatment with metformin when they are dismissed of an internal medicine ward in a tertiary hospital. ¿Do we think about renal impairment when we prescribed metformin?

Material and method: Dismissed reports of inpatients were reviewed from 2008 to 2010. We collect data of: age, sex, ethnic group, underlying diseases (diabetes, hypertension, heart failure, ischemic cardiopathy), and some laboratory results. Patients were classified depending on their renal impairment; glomerular filtration rate was measured with Modification of Diet in Renal Disease Study Group (MDRD) equation. Data were described as mean and standard deviation for continue variables. Quality variables were described as frequencies.

Results: A total of 255 patients were included, 135 male (52.9%) and 120 female (47.1%). Mean age was 67.55 ± 18.67 years. All patients were not black. Hypertension was described in 57.6% of the patients, with systolic arterial pressure mean of 123.62 ± 23.37 mmHg and diastolic arterial pressure mean of 70.84 ± 12.98 mmHg. We found history of ischemic heart disease in 16.1% of our patients, atrial fibrillation was found in 48 patients (18.8%) and heart failure in 19%. Chronic renal failure in 8.6% (defined as a glomerular filtration rate < 30 ml/min). Obesity was described in 6.7%. Smoking habit was found in 40% of the patients. The prevalence of Diabetes Mellitus was 24.3% and metformin was prescribed in 23 patients at discharge (9%). Creatinine mean value was 1.13 mg/dl ± 0.58. To improve the analysis of the data we have separated our patients according to their glomerular filtration rate (MDRD) into three groups: < 30 ml/min, 30-50 ml/min and > 50 ml/min. Metformin prescription was found in 2 patients (0.8%) in the group of MDRD < 30 ml/min, 4 patients (1.6%) between 30-50 ml/min and 17 patients (6-7%) in the group with MDRD up to 50 ml/min.

Discussion: Metformin is considered one of the best drugs for initial treatment in type 2 diabetes in the absence of contraindications, becoming the standard of care. The available evidence supports the safety of its use in patients with normal renal function or moderate renal failure. Type 2 diabetes and its comorbidities make patients receive a lot of medications. In many of this medications doses adjustments are needed depending on glomerular filtration rate. The frequency of inappropriate prescription of metformin remains a problem (according to some series between 14-27%) mainly due to neglect of the adequate assessment of tissue perfusion and renal function of the patients. In this retrospective observational study we have found that prescription of metformin is more frequent in the group of patients with glomerular filtration rate up to 50 ml/min. However we have seen inappropriate prescription in 2 patients with glomerular filtration rate < 30 ml/min.

Conclusions: Cardiovascular risk factors were not very frequently described in the study population. Adequate prescription was more frequently observed in the analyzed patients, although 2 of the patients received inappropriate treatment. MDRD should be measured in all patients were a new drug, such as metformin, is going to be prescript.

RV-173
INFLUENCE OF SEX AND AGE ON HBA1C LEVELS IN CAMPO DE GIBRALTAR AREA

A. Michán Doña[1], J. Escribano Serrano[2], C. Casto Jarillo[3], L. García Domínguez[4], A. Blanquer Benítez[5]

[1]Department of Internal Medicine. Hospital de Especialidades de Jerez de la Frontera (Cádiz), Spain. [2]Healthcare Center San Roque. San Roque (Cádiz), Spain. [3]Laboratory. Hospital del S.A.S. la Línea de la Concepción. La Línea de la Concepción (Cádiz), Spain. [4]Healthcare Center Poniente. La Línea de la Concepción (Cádiz), Spain. [5]Healthcare Center Menéndez Tolosa. Algeciras (Cádiz), Spain.

Objectives: Some reports have stated that, in non-diabetic people, HbA1c levels increase with age, independently of their plasma glucose concentration. Aim: to determine if HbA1c levels depend on age or sex.

Material and method: We have studied fasting plasma glucose (FPG) levels and HbA1c paired determinations (D) in our Healthcare Area. This area comprises six healthcare centers (HCC), a local hospital (LH) and a hemodialysis unit (HU) (Pop 104000). All measurements were done as commonly with a HA-8160 Menarini apparatus (HPLC ARKRAY Inc., Kyoto, Japan). We have categorized age as Age groups (A_G). HbA1c levels were distributed in two groups depending if they were performed as intention-to-diagnose (ItDx) (single determinations below 7%), or as intention-to-check (ItCh) (several measurements and all above 6%).

Results: During 2011, 10,942 determinations were done in 7,948 persons. Median (Me) HbA1c 6.4% (IQR 5.7% to 7.3%). Determinations were not equally distributed along time, they were more frequent during April, May and June. 8,297 (79%) determinations came from HCC, 2,037 from RH (19.5%) and 158 from HU (1.5%). In the ItDx group there is a positive correlation between age and HbA1c, exclusively in women. By the other side, in the ItCh group HbA1c levels decrease with age, predominantly in men. All of them well correlated with FPG. According to age: Group 18 to 30 years (336 D, 3.3%) Me HbA1c 5.3% (IQR 5.1 to 5.6%), Group 31-45 (1,025, 10%) Me HbA1c 5.6% (IQR 5.3 to 6.8%), Group 46-60 (2,472, 24%) Me HbA1c 6.3% (IQR 5.7 to 7.4%), Group 61-75 (4,206, 41%) Me HbA1c 6.5% (IQR 5.9 to 7.5%) and Group 76+ (2,217, 21.7%) Me HbA1c 6.5% (IQR 5.9 a 7.3%) If Kruskal Wallis test is applied to the age group variable, a statistical significance is observed between young and old people, both for males and females. Nevertheless, this variation is different between intention-to-diagnose and intention-to-check groups, increasing or decreasing HbA1c levels respectively.

Conclusions: The number of determinations from males was inferior to those from females, although the multiplicity per person was similar. Additionally, males showed both fasting plasma glucose and HbA1c with poor control. The number of determination in older women was especially high, although they are the best controlled. Intention-to-diagnose determinations are clearly influenced by age, particularly in women. Intention-to-check determinations revealed a poor metabolic control in younger patients.

Table (RV-173)

	AGE	HbA1c	FPG	N
Woman	66	6.3	114	5,736
Men	64	6.4	121	4,595
It_Dx	64	5.8	104	5,107
W_It_Ch	69	6.9	101	3,882

RV-174
HYPERTRIGLICERIDEMIA PREVALENCE IN BARCELONA. RELATIONSHIP WITH CARDIOVASCULAR RISK FACTORS

M. García Cors[1], L. Sánchez Sitjes[1], R. Malo Barres[1], F. Del Molino Sanz[1], J. López Vivancos[1], R. Armengol Rauet[1], M. Girabent Farres[2]

[1]Department of Internal Medicine. Hospital General de Catalunya. Sant Cugat del Vallès (Barcelona), Spain. [2]Department of Epidemiology. Universitat Internacional de Catalunya. Sant Cugat del Vallès (Barcelona), Spain.

Objectives: Determine prevalence of hypertrigliceridemia in our population Asses its relationship with other cardiovascular risk factors.

Material and method: Review of clinical records of patients who come at their will for health checkup at our hospital. Data recorded and reviewed: clinical records, anthropometric data, physical exam, blood samples, elctrocardiogram, chest X-ray.

Results: 2,927 patients were reviewed, 1,871 (64%) men and 1,056 (36%) women. Ages between 20 and 85. Mean triglyceride: 111.6 mg/dL, SD 103.9, rank 20-3,100 mg/dL (men 128.2 SD 122.1; women 95.3 SD 51.2). Hypertigliceridemia following ATP-II criteria (value over 200 mg/dL) was present in 241 (8.2% patients), 205 (85%) men and 36 (15%) women. Very high triglycerides, over 1,000 mg/dL, were present in 4 males (0.1% of total population). The 241 patients with hypertrigliceridemia were matched by sex and age with 241 randomly selected non-hypertrigliceridemic patients from the database, and compared for statistical purposes. Mean triglycerides in both groups were 316.5 mg/dL (SD 258.9) compared to 102.9 mg/dL (SD 38.7). The hypertrigliceridemia group showed higher levels of alcohol intake, body-mass index, high waist perimeter, arterial hypertension, fasting glucose, incidence of type 2 diabetes mellitus. We also found increased number of patients with mild to moderate renal failure calculated by the MDRD index. There were no differences in cholesterol levels, serum creatinine levels, transaminases and alkaline phosphatase. With the reviewed data, presence of metabolic syndrome (following ATP-III criteria), presence of hepatic steatosis (fatty liver index) and presence of hepatic fibrosis index (BATT index) were assessed in the two groups, showing a higher incidence of both metabolic syndrome (56% versus 9.1%), presence of hepatic steatosis (79% versus 27%) and presence of hepatic fibrosis (41.5% versus 6.7%).

Discussion: In comparison with other population-based studies in our setting, our results show triglycerides level slightly lower, but the same level of hypertrigliceridemia (over 200 mg/dL) as found in SEA registry (Spanish Society of Arteriosclerosis) or Ibermutua registry (population of workers who underwent laboral checkup). Among our women mean values are slightly higher, perhaps due to higher age rank. With our records is very difficult to assess aethiology of hypertrigliceridemia. 90% of the patients showed also total cholesterol over 200 mg/dL, so mixed dislypidemia can be suspected. As regards to secondary causes, only 11% of the patients (all male) admit significant alcohol intake; obesity (BMI over 30 Kg/m^2) is present in 35%; type 2 diabetes mellitus in 18.7%; and metabolic syndrome in 56% of the population (72% among women). There is significant association with hyperuricemia, hypertension, metabolic syndrome and the probability of hepatic steatosis and fibrosis (using fatty liver index and BATT score respectively). The group of hypertrigliceridemia showed also slightly higher rate of renal impairment calculated by the MDRD formula.

Conclusions: Prevalence of hypertrigliceridemia in our setting is similar to previous descriptions in other Spanish populations. Hypertrigliceridemia is strongly associated to classical cardiovascular risk factors. There is also marked association with metabolic syndrome and risk for hepatic fibrosis and steatosis. We have found also higher rate of mild renal failure (calculated by MDRD).

RV-175
WEIGHT REDUCTION AFTER TREATMENT WITH TOPIRAMATE, IN MIDDLE-AGED PATIENTS FROM A CARDIOVASCULAR RISK UNIT, WHO HAD BEEN RESISTANT TO STANDARD LIFESTYLE CHANGES

C. de la Puerta, A. Alonso, R. Fabregate, N. de la Torre, M. Fabregate, A. Guerri, J. Sabán

Department of Endothelial Pathology. Hospital Universitario Ramón y Cajal. Madrid, Spain.

Objectives: To evaluate the effectiveness as a weight reductor of a low dose of Topiramate, in a sample of middle-aged patients from a Cardiovascular Risk Unit, who had been resistant to a lifestyle change treatment of 6 months.

Material and method: SAMPLE: n = 42 patients, 45 ± 12.3 years old, 27 (64%) women, 6 (14%) smokers, 18 (43%) hypertensive, 17 (41%) had chronic hyperglycemia (type 1 diabetes excluded). Basal weight was 89.0 ± 15.7 Kg and BMI 32.6 ± 6.1 of patients who were all non-responders to classic life-style changes alone, were treated with Topiramate in addition to those same life-style change measures, during 6.5 ± 2.0 months. Patients were included for the study after informed consent was signed. Overweight was defined as BMI > 28 kg/m^2). Subjects were considered non-responders to life-style changes if they had maintained a stable weight over the past 6 months while being under treatment (within a variation range of < 3%). Subjects with a history of myocardial infarction (within the last 6 months), anemia, plasma creatinine levels > 1.5 mg/dL or concomitant chronic diseases (e.g. cirrhosis, chronic obstructive pulmonary disease, heart failure) were excluded. Life-style change measures included recommendations of regular exercise and dietary advice (coherent to the Steno-2 Study). Treatment: from a starting dose of 25 mg/day, dosage was titrated upward by weekly increases of 25 mg/day over a 7-week period (according to Rosenstock [Diabetes Care. 2007;30(6):1480-6) and continued afterwards up to a target dose of 150-200 mg/day during the maintenance phase. Patients were considered as "responders" if their weight reduction was ≥ 5% of their initial weight and "hyper-responders" if it was ≥ 10% of initial weight. Statistical analysis: Continuous variables were described as mean ± SD. Wilcoxon signed-rank test was used to assess median differences.

Results: 1- Weight reduction was of 5.48 ± 4.12 Kg ($p < 0.001$), and that of BMI of 2.0 ± 1.46 ($p < 0.001$). Average reduction in bioimpedance values was of 2.7 ± 3.3 Kg of body fat (2.3 ± 2.5% of initial value, ($p = 0.002$) 2- 9 0ut of 10 patients lost more than 5% of their initial body weight, and almost 2 out of 10 lost more than 10% of it. 3-Tolerance to topiramate: 6 out of 10 patients suffered adverse events (AE), being paresthesia the most frequent one (36% of the whole sample). Only 5 of the 42 patients abandoned the treatment. 4 of them due to moderate AEs and only 1 due to inefficacy of treatment after a period of 6 months.

Discussion: While awaiting the release of new drugs, topiramate has been proposed as a novel anti-obesity drug. Previously, among obese patients with binge-eating disorder, topiramate treatment was associated with significantly greater reductions in BMI, body weight, and improvement in obsessive-compulsive scores. The most commonly reported side effects of topiramate are central nervous system negative effects which generally occur at high doses, being paresthesia the most frequent one. Other rare adverse reactions include cough, leukopenia and thrombocytopenia, osteoporosis, and ocular disturbances (acute myopia, secondary angle-closure glaucoma, maculopathy). Up to date, the use of topiramate to treat obesity is controversial. Nevertheless, our study yields a very favorable result regarding both its efficacy in reducing weight as well as its tolerance.

Conclusions: 1. Tolerance to topiramate is fairly good, being the adverse events occurred mild to moderate. 2. Percentage of patients with a weight reduction ≥ 5% of their initial weight was

considerable high: 9 out of 10. 3. In subjects at cardiovascular risk, a context in which obesity is much more than an aesthetic issue: Is there anything to lose where all other measures have failed?

RV-176
SCORE UNDERSTIMATES CARDIOVASCULAR RISK OF HIV INFECTED PATIENTS

R. Ramírez Montesinos, V. Moreno Arias, E. Martín Mojarro, O. Araujo Loperena, L. Tikhomirova, A. Delegido, S. Hernández Toboso, E. Pedrol

Department of Internal Medicine. Sant Pau i Santa Tecla Hospital. Tarragona, Spain.

Objectives: New European Guidelines of Dislipemia Management of European Society of Cardiology (ESC) and European Artheriosclerosis Society (EAS) consider HIV as patients at high risk of developing cardiovascular events and deaths. Probably previous cardiovascular risk charts were underestimating cardiovascular risk in those patients. The objective of our study was to evaluate cardiovascular events and deaths in the series of HIV infected patients followed in our hospital. SCORE of these patients was assessed 4 years ago.

Material and method: Observational, cross-sectional study, including a cohort of HIV+ve infected patients from an internist's office and a cohort of controls non-HIV-ve infected from a primary care setting during 2008. Sociodemographic and clinical variables (cardiovascular risk factors, lipid profile and treatment) were collected from an electronic medical record. Cardiovascular risk was calculated using the SCORE cardiovascular risk chart. Variation on lipid profile after 4 years and incidence of cardiovascular events (stroke, acute miocardic infarction or angina or peripheral arterial disease), cardiovascular death or death related to any cause were recorded. Data were analyzed using SPSS version 20.0 for MAC.

Results: 154 HIV+ve and 155 HIV-ve patients were included. Mean age was 44.8 ± 9.5 years vs 55.2 ± 14.3 years and 69.5% vs 49% males respectively ($p < 0.01$). Mean time since HIV diagnosis on HIV+ve infected was 11 ± 6.2 years. Mean body mass index (BMI) and systolic blood pressure (SBP) were lower in HIV+ve (25.1 ± 6.7 kg/m^2 vs 28.7 ± 5.1 kg/m^2, ($p < 0.01$) and 119.6 ± 19.4 vs 124.7 ± 14.7 mmHg, ($p = 0.044$), respectively). A lower proportion of hypertense, diabetic and obese patients were observed in HIV+ve (26.5% vs 6.5%, 20.6% vs 3.9% and 36.8% vs 12.3%) but a larger proportion of smokers (68.8% vs 29.7%) was observed ($p < 0.01$ in all cases). Mean cholesterol and low-density lipoprotein cholesterol (LDLc) were lower in HIV+ve (191.2 ± 41.4 vs 218.5 ± 44.6 mg/dl and 109.5 ± 33.9 vs 134.6 ± 37.7 mg/dl, $p < 0.01$ respectively) but with a lower mean high-density lipoprotein cholesterol (HDLc) and higher triglycerides (TG) (50.3 ± 19 mg/dl vs 55.2 ± 14.9 mg/dl, $p = 0.013$ and 156.7 ± 85.7 vs 135.8 ± 66.2 mg/dl, $p = 0.017$, respectively). There was no significant difference in mean cardiovascular risk SCORE in both cohorts (3.5 ± 3.6% vs 4.4 ± 3.8%, $p = 0.091$). With this SCOREs 5´2 ± 5.3 and 6´7 ± 5.8 cardiovascular events or deaths should be expected in HIV+ve and non HIV patients respectively at 10 years. Four years later total Cholesterol, LDLc, HDLc, TG (190.56 ± 43.4, 106.53 ± 37.1, 50.22 ± 13.9, 175 ± 114.4) in HIV+ve patients did no variate compared with those obtained years before ($p < 0.05$ for of them). The same occurred in nonHIV patients (205.57 ± 43.56, 123.70 ± 40.22, 56.05 ± 13.09, 134.06 ± 62.09, $p < 0.05$ for all of them). 5 events and 1 death were seen at 4 years following in HIV+ve, and 3 in non HIV patients.

Discussion: The incidence of events in HIV+ve patients is similar to the expected according to his SCORE at 10 years. We could suppose that once the 10 years following is reached, this incidence will be higher. In the other side, in nonHIV patients at four years just 3 events occurred, far from the 6´8 events expected. There were no significant differences between lipid profiles in none of the cohorts.

Conclusions: 1. Lipid profile with low HDLc and high TG is persistent in HIV patients at 4 years of following. 2. Undestimation of cardiovascular risk in HIV patients by SCORE charts could be present as soon as at 4 years. 3. This could reaffirm the stratification of HIV patients as high risk patients in new guidelines.

RV-177
ARE THE DPP4 INHIBITORS IN DIABETES MELLITUS REALLY EFFECTIVE?

E. Puerto[1], N. Cubino[1], A. Romero[1], S. Carrero[2], P. Miramontes[1]

[1]Department of Internal Medicine, [2]Department of Surgery. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca, Spain.

Objectives: This study aims to assess the number of patients, treated with DPP4 inhibitors in association with other antidiabetic drugs and insulin, who are well-controlled according to the objectives of the current American Diabetes Association to maintain a glycosylated hemoglobin (HbA1c) below the 7%. In addition, we have also tried to determine which are the most commonly used DPP4 inhibitors (sitagliptin, vildagliptin o saxagliptin) for the treatment of diabetes present today in the Spanish market. We also seek to evaluate if a higher consumption is related to the glycosylated hemoglobin decrease or with the onset of side effects.

Material and method: A 91-patient (between 45-80 years) transversal and observational study has been carried out at the Risk Vascular Unit of Salamanca Hospital for the last two years. The subsequent protocol has been followed during the visits: medical and personal history, current treatment and drugs side effects. Physical examination including blood pressure and HbA1c (%) analytical. Patients used a treatment with DPP4 inhibitor a year prior to their inclusion in the study. Finally, a SPSS program has been used to analyze data.

Results: 67.03% of the patients were treated with sitagliptin, 26.37% with vildagliptin and 6.59% with saxagliptin. According to treatment, the following average number of glycosylated hemoglobin was showed in patients: DPP4 Inhibitor with metformin showed an average of HbA1c 7.43%, DPP4 Inhibitor with metformin and insulin showed an average of HbA1c 8.92%, DPP4 Inhibitor with sulfonylurea showed an average of HbA1c 7.75%. The most common pharmacological association: metformin + sitagliptin 42.8%, metformin + vildagliptin 13.8%, metformin + saxagliptin 4.3%, sulfonylurea + sitagliptin 7.6%, sulfonylurea + vildagliptin 2.19%, sulfonylurea + saxagliptin 1.09%, metformin + insulin + sitagliptin 20.8%, metformin + insulin + vildagliptin 7.6%. Patients with HbA1c < 7% according to pharmacological association used: 57.14% with sulfonylurea + sitagliptin, 48.7% metformin + sitagliptin, 66.6% metformin + vildagliptin, 21.05% metformin + sitagliptin + insulin. The most frequent side effects; 9.89% hypoglucemya, 5.49% headache, 7.69% urine infection and 3.29% stomach sickness.

Discussion: In relations to results, we consider that the sitagliptin is the most commonly used drug in association with metformin, probably because it was the first to emerge on the market. The best glycosylated hemoglobin levels were achieved combining insulin with metformin and the worst results originated from DPP4 inhibitors with insulin. These results could originate in the fact that, at the beginning of the treatment, a DPP4 inhibitor was added to patients treated with insulin resulting in a poorer metabolic control. The association of metformin with vidagliptin obtained the best results according to the goals of de ADA.We believe that the drug selected is not related to side effects, since they are very scarce.

Conclusions: This study concludes that, although in the literature, the decrease in HbA1c is the same for DPP4 inhibitors (between 0.5-1%), vildagliptin in association with metformin is recommended

since it reduces glycosylated hemoglobin more effectively. Although it would require a study with more advanced statistical data, we would like to state that DPP4 inhibitors are high-quality drugs for the initial stages of diabetes mellitus.

RV-178
COPD PREVALENCE IN HEALTHY SPANISH POPULATION AND ITS RELATIONSHIP WITH CARDIOVASCULAR RISK FACTORS

M. García Cors[1], L. Sánchez Sitjes[1], M. Girabent Farres[2], S. Martín Fuste[1], J. Herranz Pérez[1], R. Malo Barres[1], J. López Vivancos[1]

[1]Department of Internal Medicine. Hospital General de Catalunya. Sant Cugat del Vallès (Barcelona), Spain. [2]Department of Epidemiology. Universitat Internacional de Catalunya. Sant Cugat del Vallès (Barcelona), Spain.

Objectives: Asses COPD prevalence among asymptomatic people attending at their own will a health check-up program in a private hospital. Analyze relationship between COPD and traditional cardiovascular risk factors.

Material and method: Review of clinical records of patients attending the Preventive Medicine clinic of our hospital, of age between 40 and 80. Demographic data were collected, along with spyrometric values to classify patients as COPD/non-COPD according to Gold criteria (FEV1/FVC < 70%). In the COPD group, age, BMI, smoker status, waist perimeter, blood pressure, glucose, lipid levels, creatinin and MDRD, AST/ALT/GGT, uric acid were also collected.

Results: Patients attending the Preventive Medicine clinic from 1998 to 2004. 2,166 had age 40-80. 35 (1.61%) presented FEV1/FVC < 70% and were classified as "COPD". 28 (80%) men and 7 (20%) women. Among smokers, rate of COPD was 2.4%. Mean age was 62 years (SD 10). Mean MBI: 27.29 Kg/m^2 (SD 4.6). The rate of smokers was 25% and ex-smokers 19%. Obesity (BMI > 30 Kg/m^2) was present in 18% of the men and 57% of women. 63% had hypertension, 5.7% type 2 diabetes mellitus (3.6% men, 14.3% women). Hypercolesterolemia was present in 71% of men and 100% of women Renal impairment (MDRD < 60 ml/min) was found in 16% of the patients without sex differences. Metabolic syndrome, defined by ATP-III criteria, was present in 4 patients (11%), 3 men (10%) and 1 woman (14%). Calcification of aortic arch, assessed by chest X-ray, was present in 3 patients (8%). After statistical analysis, association was found between COPD and the presence of hypertension and hypercolesterolemia in both sexes. An association was found also between COPD and central obesity only in women.

Discussion: Our results are consistent with other groups that show independent association between COPD and cardiovascular risk factors such as hypertension and hypercolesterolemia. What is highly surprising in our data is the relatively low prevalence of COPD found in our population, only 1.6%, as compared with other Spanish works, as the IBERPOC study of 1997 (prevalence 9.1%) or the EPI-SCAN Survey 2006-2007 (10.2%). Our data are more consistent with other published works, in UK in 2000 and 2008, and in Germany in 2009; the investigators find rates of COPD amongst general population in a rank between 1.36% and 1.5%, and only of 6.9% in German smokers (2.4% in our smokers) Discussion exists between strategies that could over- or under-estimate the real prevalence of COPD, important in terms of excessive medicalisation in the first case, or excess of pulmonary function loss due to delayed diagnosis in the second. The difference lies in the method of selection of the "study population". In the Spanish studies, randomly selected population of one area is contacted and requested to visit the investigators, with a bias depending on willingness to attend. In the UK/German studies, all population attending a specified clinic in specific dates is reviewed. Our design is similar to the second approach.

Conclusions: COPD is associated with hypertension, hypercolesterolemia, and central obesity in women COPD prevalence in our study population is of 1.6%, lower compared to other works in our setting A clear method needs to be defined to accurate assessment of COPD prevalence.

RV-179
DIFFERENCES ON THE DIAGNOSIS AND THERAPEUTIC MANAGEMENT OF PATIENTS WITH ACUTE CORONARY SYNDROME ACCORDING TO THE DEPARTMENT ADMISSION

C. Espejo Fernández, J. García Moreno, M. Alcoucer Díaz, M. Machado Vílchez, C. Leyva Prado

Department of Clinical Management and Internal Medicine. Área Hospitalaria Juan Ramón Jiménez. Huelva, Spain.

Objectives: Explore the patterns of management of patients hospitalized for acute coronary syndrome (ACS) as well as to determine the influence of the department admission over the consequent hospital management and discharge.

Material and method: All patients diagnosed of ACS whose were treated in the Internal Medicine (IM), or Cardiology (CA) department during the first 3 months of 2012 were included in the analysis. We performed a descriptive analysis of demographic, clinical, diagnostic and therapeutic management after reviewing discharge reports.

Results: 100 patients were included in the study. 39% were admitted in CA and 61% in IM departments. The mean admission stay per patient was 9.95 days for IM and 8 for CA. Mean age was 66.6 years old for patients in IM and 64.3 for CA. Gender distribution was 61% males in IM and 72% in CA. Previous pathologies registered are shown in Table 1. We have observed differences in the number of test assessed according to the place of entry, with a greater number of diagnostic and therapeutic tests among CA patients (92.3% percutaneous coronary intervention, PCI) compared to those whose did it in IM (77% PCI), $p < 0.05$. Among the PCI performed, 89.4% were therapeutic in IM and 99.4% in CA. The treatment administered is shown in Table 2.

Discussion: Our study represents the hospital management of ACS, even with the design limitations. Numerous studies have established the efficacy of antithrombotic and beta-blocker therapy and the interventional strategy. There are major differences in the treatment of patients with ACS according to geographical areas, hospitals and services in which are handled. In our study the differences in hospital management depending on the department where they entered, lay in the PCI or not. The application of proven

Table 1 (RV-179)

Previous pathologies	Internal Medicine	Cardiology	p
Previous ischemic heart disease (%)	42.6	23	0.46
Heart failure (%)	24.5	20.5	0.63
Chronic obstructive pulmonary disease (%)	13.1	2.5	0.72
Cognitive impairment (%)	3.2	5.1	0.64
Other (%)	24.5	20.5	0.88

Table 2 (RV-179)

Treatment	Internal Medicine	Cardiology	p
Beta-blockers (%)	96.7	92.3	0.32
Aspirin (%)	97.7	97.4	0.24
Clopidogrel/Prasugrel (%)	81.9	94.8	0.06
Statins (%)	91.8	84.6	0.26

treatments for this disease were very similar in both groups, although IM patients had a diagnostic and therapy less intense.

Conclusions: No differences found in medical treatment of ACS conducted by internists or cardiologists. Differences on more aggressive intervention applied to patients admitted in CA, due to the more conservative strategy of IM when treating patients with major underlying disease.

RV-181
SECONDARY PREVENTION OF CARDIOVASCULAR DISEASE IN DIABETIC PATIENTS WITH ANTICOAGULANT THERAPY

J. Constan Rodríguez[1], C. Calleja Rodríguez[2], M. Herrero García[1], M. Loring Caffarena[1], C. de la Torre Solís[2], M. Guil García[1], C. San Román y de Terán[1]

[1]Department of Internal Medicine. Hospital de la Axarquía. Vélez-Málaga (Málaga), Spain. [2]Department of Primary Care. Centro de Salud de Torre del Mar. Vélez-Málaga (Málaga), Spain.

Objectives: Main target: we want to know if our diabetic patients with anticoagulant therapy and established cardiovascular disease receive or not antiplatelet therapy. Secondary targets: know the profile of this patients and the reason of their anticoagulant treatment.

Material and method: It´s a descriptive and transversal study made with all diabetics patients who come to our health center in Torre del Mar for checking their anticoagulant therapy (acenocumarol). We collect demographic data (gender, age, evolution time of diabetes) if they have cardiovascular diseases (ischemic heart disease or/and, stroke, transient cerebral ischemia, heart failure, intermittent claudication, amputation, creatinine > 1.2 mg/dl or glomerular filtration < 60 ml/mto, microalbuminuria or proteinuria positive, pathological pedal pulse and retinopathy). In addition we look into the reason for anticoagulation, their anticoagulant and antiplatelet treatment and the high risk of bleeding (ulcer and previous gastrointestinal bleeding).

Results: A total of 70 diabetic patients were included: 41 women (58.6%) 29 men (41.4%). Mean age was 76.04 (± 8.5). Evolution time of diabetes was 10.44 (± 5.76). The anticoagulant therapy was deep vein thrombosis in 3 (4.3%), pulmonary embolism in 4 (5.7%), thrombophilia in 1 (1.4%) and atrial fibrilation in 62 (88.6%). 61 of them (87.14%) had at least one of major cardiovascular diseases: myocardial infarction 15 (24.6%), ischemic heart disease 24 (39.3%), stroke 11 (18%), transient cerebral ischemia 4 (6.6%) heart failure 17 (27.9%), intermittent claudication 9 (14.8%), amputation 2 (3.3%), creatinine > 1.2 mg/dl 16 (26.2%), glomerular filtration < 60 ml/mto 19 (31.14%), microalbuminuria positive 26 (42.6), proteinuria positive 19 (31.1%), pathological pedal pulse 9 (14.8%) and retinopathy 13 (21.3%). Only 2 patients (3.2%) had previous gastrointestinal ulcer and 1 (1.6%) gastrointestinal bleeding. The whole of 61 (100%) received treatment with acenocumarol and 6 of them (9.8%) antiplatelet therapy: 4 (6.5%) acetylsalicylic acid in low dosis and 2 (3.2%) triflusal. In these 6 patients 4 had peripheral arteriopathy and 2 myocardial infarction more than one year before. There is no contraindications in the remaining 52 patients (85.2%) for double teraphy.

Discussion: Cardiovascular disease is the leading cause of mortality in patients with diabetes accounting for an estimated 65-80% of death. Antiplatelet teraphy is the gold treatment for prevent major adverse cardiovascular events. However there´s no consensus for the combination of the anticoagulation and antiplatelet therapy, and the recommendations are based on the expert opinions and data derived from large prospective studies are lacking. We think there is too much fear of bleeding.

Conclusions: The primary care physician and the internal medicine have a significant responsibility in cardiovascular prevention of the patients affected by this problem. Each patient must be individualized for his best therapy but now, they probably would be undertreated.

RV-182
PREVALENCE OF PCSK9 GENETIC VARIANT R46L IN A SPANISH POPULATION AT MODERATE-HIGH CARDIOVASCULAR RISK

A. Alonso Pacho[2], D. Rey Zamora[1], R. Fabregate Fuente[2], M. Fabregate Fuente[2], S. Tello Blasco[2], C. Martínez Ruíz[2], N. de la Torre Alonso[2], J. Sabán Ruiz[2]

[1]Department of Medical Genetic, [2]Department of Endothelial Pathology. Hospital Universitario Ramón y Cajal. Madrid, Spain.

Objectives: To determine the prevalence of the PCSK9-R46L allele in Spanish subjects with moderate-high cardiovascular risk without statins treatment and its association with low-LDL levels.

Material and method: N = 248 patients, 57.2 ± 13.2 years, 22% were females, 51% had chronic hyperglycemia, 61% hypertension, 17% coronary disease and 20% were smokers. A lipid profile was carried out including total-cholesterol (t-C), HDL-cholesterol (HDL-C) and triglycerides (TG), measured by Hitachi autoanalyzer. LDL-cholesterol (LDL-C) was calculated in subjects with TG < 400 mg/dl (< 10.3 mmol/L) using the Friedewald equation. LDL-target: < 100 mg/dl (2.58 mmol/dl). Genotyping of R46L (rs11591147) was done by TaqMan®, ABI Prism 7300 (Applied Biosystems). Data were analyzed with SPSS V15.0. Chi-square test to evaluate the Hardy-Weinberg equilibrium.

Results: 1. We have identified 7 heterozygote R46L allele carriers and there were no homozygous. The frequency of the R46L allele was 2.8% in the 248 individuals examined. Genotype distributions were in Hardy-Weinberg equilibrium (p > 0.051). 2. All 7 patients were male. Two patients had coronary artery disease (CAD) and DM2 (one died from myocardial infarction at age of 59 and the other one has 74 years old) and the other 3 had hyperglycemia, 3 had hypertension and 2 were smokers. Five of them had LDLc < 100 mg/dL. Although two of them were under treatment with statins, it was due to their CAD. 3. Among noncarriers R46L allele patients, the prevalence of LDL lower the target and without statins treatment was 8%, while 5 out of 7 carriers (71.43%) were within this target.

Discussion: Proprotein convertase subtilisin/kexin type 9 (PCSK9) modulates plasma levels of low-density lipoprotein cholesterol (LDL-C) by promoting the degradation of low-density lipoprotein receptors (LDLRs), the primary pathway for the removal of low-density lipoprotein (LDL) from the circulation. Loss-of-function mutations in the PCSK9 gene appear to be more common than gain-of-function mutations, which are responsible for hypercholes-

terolemia (linked to familiar hypercholesterolemia with autosomal dominant inheritance). The loss-of-function mutations are associated with reduced plasma levels of LDL-C and protection from CHD. Concerning PCSK9 loss-of-function mutations, there are three main mutations, two described in Afroamericans (Y142X and C679X) and one in Caucasians (R46L). So, R46L in PCSK9 gene is more common among white people (prevalence 3.2%) than among black people (0.6%). The R46L polymorphism in PCSK9 has been associated with reductions in LDL-C of 9% to 15% with a 47% reduction in risk of CAD in carriers versus noncarriers.

Conclusions: 1. In our Spanish population, prevalence of PCSK9 genetic variant R46L was below 3%, similar to that described in Caucasian people in other studies. 2. 5 out of 7 patients were within target-LDL without treatment versus 1 out of 12 in non-carriers. 3. The presence of the allele does not protect itself for the development of coronary heart disease, at least in the presence of diabetes mellitus (at least if diabetes mellitus is associated with it).

RV-183
EFFECT OF PHENOLIC COMPOUNDS OF OLIVE OIL ON POSTPRANDIAL INFLAMMATORY RESPONSE IN PATIENTS WITH METABOLIC SYNDROME

J. Alcalá Díaz, A. Camargo García, A. García Ríos, J. Delgado Lista, N. Delgado Casado, A. Pérez Caballero, P. Pérez Martínez, J. López Miranda

Department of Lipids and Atherosclerosis, Department of Medicine. IMIBIC/Hospital Universitario Reina Sofía. Universidad de Cordoba, Cordoba, Spain and CIBER Fisiopatologia Obesidad y Nutricion (CIBEROBN), Instituto de Salud Carlos III, Madrid, Spain.

Objectives: Metabolic syndrome is a constellation of several factors which increase the risk of developing cardiovascular disease and type 2 diabetes mellitus. Atherosclerosis is an important pathogenic substrate for cardiovascular disease in patients with metabolic syndrome and it is known that phenolic compounds of olive oil and its concentration could be important factors in preventing the development of atherosclerosis. To assess the postprandial effect of consumption of olive oils with different phenolic compound content in the state of chronic inflammation characteristic of patients with metabolic syndrome.

Material and method: In a randomized crossover design, 52 patients with metabolic syndrome received two types of olive oil which differ in the content of phenolic compounds (396 ppm, 70 ppm). The oils were administered as separate different breakfast in two different days, separated by 1 week. We analyzed the postprandial inflammatory response by measuring plasma cytokines IL-1B, IL-6, TNF-α and MCP-1 and the measurement of gene expression and the regulatory genes of IkKa, IkKb, NF-kB p65 and IkBa in peripheral blood mononuclear cells by qRT-PCR.

Results: Consumption of high phenolic compounds oil reduced postprandial plasma levels of IL-6 and TNF-a ($p = 0.004$ and $p = 0.023$, respectively) and gene expression of IL-6 ($p = 0.016$) compared to consumption of low phenolic compounds oil. Likewise, the consumption of high phenolic compounds oil reduced gene expression of IkBa ($p = 0.025$). In addition, there was a postprandial increase in the expression of NF-kB p65 ($p = 0.007$), regardless of the oil consumed. No changes in the expression of regulatory genes IkKa and IkKb were found.

Conclusions: Phenolic compounds in virgin olive oil reduces postprandial inflammatory response. This anti-inflammatory effect would explain the preventive effect of consumption of virgin olive oil against cardiovascular risk.

RV-185
THE RELATIONSHIP BETWEEN NEWLY DIAGNOSED HYPERTENSIVE WOMEN AND MICROALBUMINURIA, LEFT VENTRICULAR HYPERTROPHY, RETINOPATHY, SEX HORMONES STATUS

M. Apikoglu[1], F. Bulucu[1], S. Demirbas[1], S. Ay[1], M. Karaman[1], B. Altun[1], G. Gokce[2], K. Saglam[1]

[1]Department of Internal Medicine, [2]Department of Ophthalmology. Gulhane Military Medical Faculty. Ankara, Turkey.

Objectives: An increased incidence of hypertension (HT) in postmenopausal female population has been shown in the previous studies and this has been ascribed to an association with altered status of estrogen (E2) and the other female sex hormones. HT is associated with certain target organ damage (TOD) and related clinical conditions. The purpose of this study was to determine the relationship between microalbuminuria, left ventricular hypertrophy, retinopathy and their female sex hormones status in newly diagnosed hypertensive women.

Material and method: Sixty-six hypertensive women (39 postmenopausal/27 premenopausal) were included into the study. The patients were divided into the two groups according to their menopausal status. Left ventricular hypertrophy (LVH), hypertensive retinopathy and microalbuminuria along with the tests recommended in the hypertension guidelines were investigated in all of the patients. Sex hormones follicle stimulating hormone- FSH, luteinizing hormone -LH, progesterone-P, E2) of the patients were also measured.

Results: No statistically significant difference between the two groups in regard of TOD, except microalbuminuria. The rates of microalbuminuria in premenopausal group patients were higher than those of the postmenopausal group patients ($p = 0.038$). In the premenopausal group, a statistically significant negative correlation with serum LH levels and left ventricular posterior wall thicknesses (PWT) was detected ($p = 0.003$). It was observed that the serum levels of progesterone were higher in the patients without hypertensive retinopathy when compared to women with hypertensive retinopathy ($p = 0.038$) within the in the postmenopausal group. In the correlation analysis, there were statistically significant negative relationship between the septal wall thicknesses on echocardiography and the serum follicular stimulating hormone levels ($p = 0.028$) in postmenopausal hypertensive women. There was also a negative correlation between serum LH levels and microalbuminuria rates ($p = 0.032$) in postmenopausal hypertensives.

Conclusions: Conclusively, this study suggests that target organ damages caused by hypertension, they are very important health problems, seem to be related with female sex hormones.

RV-186
DIFFERENCES BETWEEN CLINIC PROFILE OF THE PATIENTS WITH ACUTE CORONARY SYNDROME ACCORDING TO CLINIC DEPARTMENT

M. Machado Vílchez, J. García Moreno, C. Espejo Fernández, M. Alcoucer Díaz, C. Leyva Prado

Department of Clinical Management and Internal Medicine. Área Hospitalaria Juan Ramón Jiménez. Huelva, Spain.

Objectives: Establish the clinical characteristics of patients admitted for acute coronary syndrome (ACS) in our hospital and check the differences in clinical profile of these patients by entry into Internal Medicine (IM) or Cardiology (CA).

Material and method: Patients admitted to CA and IM during the first 3 months of this year, with a discharge diagnosis of ACS. Patients were classified into 2 groups according to the department

in which they were admitted, CA or IM. Clinical characteristics were obtained from a review of their discharge reports. Included the following variables: age, sex, average stay, cardiovascular risk factors, underlying chronic disease, ischemia tests performed.

Results: 39% of patients with final diagnosis of ACS were admitted to CA, 61% to IM. The mean age of patients admitted to IM was 66.5 and the patients admitted to CA was 64.26. Cardiology patients were somewhat younger, although not significantly. Gender distribution was 61% males in IM and 72% in CA. The average stay of each department was 9.95 days for patients with IM and 8 for CA. The distribution of cardiovascular risk factors (CVRF) is contained in Table 1. MI patients admitted had a higher risk profile due to the predominance of CVRF: hypertension, tabaquism, dyslipemia. Diabetes mellitus distribution was similar in both. Previous ischemic heart disease and heart failure were more frequent in IM patients.

Discussion: The main population admitted with ACS in a hospital are elderly patients and have poor prognosis (underlying chronic disease and high CVRF). Those admitted to IM had a worse risk profile than those to CA. Is significantly higher average stay of patients admitted to IM, due their comorbidities. The admission to different departments might be influenced by multiple factors, in addition to strictly medical indication. Patients who had some other medical condition or increased cardiovascular risk profile were admitted to IM.

Conclusions: Our study shows that the initial admission department of patients with ACS are properly adjusted to the baseline risk profile. CA beds are usually reserved for patients with increased cardiovascular risk and no other chronic disease, while MI beds were assigned to patients with higher underlying chronic disease.

Table1 (RV-186)

Cardiovascular risk factors	Internal Medicine	Cardiology
Hypertension (%)	65.5	61.5
Diabetes mellitus (%)	37.7	38.46
Dyslipemia (%)	59	46.1

RV-187
CARDIOVASCULAR RISK IN A COHORT OF SYSTEMIC LUPUS ERYTHEMATOUS PATIENTS WITH NORMAL RENAL FUNCTION

S. Rodríguez Suárez, L. Beltrán Romero, A. González Estrada, L. Gómez Morales, R. Muñoz Hernández, J. García Morillo

Department of Internal Medicine. Hospital Virgen del Rocío. Sevilla, Spain.

Objectives: 1. To evaluate the demographic characteristics and the cardiovascular risk factors prevalence in a clinically stable systemic lupus erythematous (SLE) population with preserved renal function. 2. Analyze the correlation between classic and emerging cardiovascular risk factors with a personal history of lupus nephritis. 3. Analyze the correlation between classic and emerging cardiovascular risk factors with serum TWEAK levels.

Material and method: We conducted a prospective, descriptive, cohort study in a population of 26 clinically stable SLE patients with normal renal function, attending the Internal Medicine Department (Colagenosis and Pulmonary Hypertension Unit) at the "Virgen del Rocío" Hospital, Spain. We studied the prevalence of classic (arterial hypertension, diabetes mellitus, smoking, LDL, HDL, and triglycerides), and emergent cardiovascular risk factors (high-sensitivity C reactive protein (CRP-hs), homocysteinemia, fibrinogen, blood glucose and insulin values, and HOMA index), investigating possible correlations among these factors, a previous personal history of lupus nephritis, and the serum TWEAK values. Data was analyzed using the Mann Whitney U non-parametric test (SPSS Statistics Software 15.0). The association between serum TWEAK values and continuous quantitative variables were done applying the Spearman Rank Correlation. The p-value significance was considered at 0.05.

Results: 1.Patients characteristics and classical/emergent cardiovascular risk factors prevalence. 86.4% women, mean age 43.54 ± 14.93 years old, mean progress disease 14.71 ± 9.24 years. 27.3% received corticoid treatment (lupus nephritis history). 27.3% arterial hypertension, 31.8% hyperlipidemia, 0% diabetic, 9.1% smoked, 102.36 ± 26.03 LDL (mg/dl), 51.73 ± 11.63 HDL (mg/dl), 98.18 ± 42.28 triglycerides (mg/dl), 84.32 ± 6.73 mg/dl fasting glucose levels, 14.86 ± 6.21 homocysteinemia (mcmol/l), 47.59 ± 46.75 lipoprotein (mg/dl), 6.03 ± 8.51 mg/l high sensitivity C reactive protein (), 8.23 ± 2.70 insulin (µmol/ml), 1.71 ± 0.59 HOMA index, 26.96 ± 26.83 (mm/h), 3.96 ± 1.15 fibrinogen (g/l), 852.09 ± 292.30 TWEAK (pg/ml). 2. Classical/emergent cardiovascular risk factors and lupus nephritis. There was a tendency in patients that had a previous history of lupus nephritis to present high levels of LDL (113.25 ± 37.63 vs 96.45 ± 19.086), HDL (52.75 ± 10.75 vs 50.45 ± 10.89), triglycerides (120.50 ± 76.54 vs 85.82 ± 31.41), homocysteinemia, CRP-hs, ESR, lipoprotein, and serum creatinine (1.06 ± 0.31 vs 0.69 ± 0.14, p 0.019). In these patients there were also low levels of serum fasting glucose (84.25 ± 3.09 vs 86.36 ± 8.67), insulin (6.38 ± 3.36 vs 8.93 ± 2.19), HOMA index (1.34 ± 0.74 vs 1.90 ± 0.51), fibrinogen (3.70 ± 1.80 vs 3.92 ± 1.06), and creatinine clearance test measured by MDRD method (66.25 ± 19.56 vs 112.18 ± 20.28, p 0.007). 3. Classical/emergent cardiovascular risk factors and serum TWEAK values. Higher serum TWEAK levels correlated (without statistical significance) to higher levels of the next values: LDL (107 ± 30.18 vs 96.00 ± 18.88), triglycerides (99.58 ± 51.88 vs 84.50 ± 16.52), fasting glucose levels (86.08 ± 5.94 vs 83.75 ± 11.70), homocysteinemia (16.74 ± 7.08 vs 11.80 ± 2.73), lipoprotein (50.33 ± 33.03 vs 22.25 ± 18.24), CRP-hs (1.79 ± 1.58 vs 1.17 ± 0.66), insulin (8.41 ± 2.89 vs 6.70 ± 2.38), fibrinogen (4.02 ± 1.28 vs 3.36 ± 1.43), HOMA index (1.79 ± 0.65 vs 1.38 ± 0.52), and ESR (26.41 ± 19.19 vs 8.25 ± 5.05). A positive linear correlation between TWEAK and ESR was statistically significant.

Conclusions: 1. The prevalence of classical cardiovascular risk factors was the same as that observed in healthy patients, but an important higher prevalence of emergent risk factors was detected in SLE patients, this may have an important role in the evaluation of cardiovascular disease of the population studied. 2. Patients with a previous history of lupus nephritis maintain a tendency to higher lipid levels, with elevated prevalence of emergent cardiovascular risk factors and a decline in insulin resistance. 3. High TWEAK values tend to have a worst metabolic profile. TWEAK levels are usually elevated in SLE patients, especially when associated to vascular inflammation.

RV-188
DIABETES, CORONARY RISK FACTORS AND VASCULAR EVENTS

R. Bagina, C. Baeta

Department of Internal Medicine. Hospital Dr. José María Grande. Portalegre, Portugal.

Objectives: We analyzed the diabetic population followed in the Cardiovascular Risk Consulting Unit, identifying their prevalence of coronary risk factors and their vascular event's rate. The goal was to determinate if an adequate risk factor control had a positive impact on the vascular events rate.

Material and method: We studied a sample of 91 patients followed in the Cardiovascular Risk Consulting Unit (Age: 66.7 years, Male: 78%, Female: 22%) in which 44% of the population was diabetic. We used the SPSS V17.0 to analyze variables such as coronary risk factors, anthropometric indices, lipid profile, intervention cardiology and events in the diabetic and non diabetic population.

Results: Diabetic Population and Risk Factors: Age 68 years; Gender 80% Masculine; Arterial Hyper Tension (AHT) 87.5% (Mean Blood Pressure (BP) 137.7/76.4 mmHg); Dyslipidemia 45% (Total Cholesterol 143 mg%; HDLc 42.3 mg%; LDLc 75.13 mg%; Triglycerides 125 mg%); Body Mass Index (BMI) 27.35. Diabetic Population and Events: Coronary Artery Disease (CAD) without ST Elevation 20%; CAD with ST Elevation 27.5%; Stroke 10%. Diabetic Population and Intervention Cardiology: Catheterism 62.5%; Percutaneous Transluminal Coronary Angioplasty (PTCA) 35%, Coronary Artery Bypass Graft (CABG) 10%. Non Diabetic Population and Risk Factors: Age 66.9 years; Gender 78% Masculine; AHT 81% (Mean BP 139.3/79.3 mmHg); Dyslipidemia 41% (Total Cholesterol 139.3 mg%; HDLc 40.9 mg%; LDLc 85.8 mg%; Triglycerides 122.5 mg%); BMI 27.9. Non Diabetic Population and Events: CAD without ST Elevation 19.78%; CAD with ST Elevation 41.76%; Stroke 7.69%.Non Diabetic Population and Intervention Cardiology: Catheterism 72.5%; PTCA 39.2%, CABG 23.53%.

Discussion: This is a very specific sample, it's important to add that this population is referred to the consult for having risk factors difficult control, in primary prevention, or after a vascular event, in secondary prevention. The diabetic population was older; had a higher prevalence of AHT (with better tensional profile); had a higher prevalence of dyslipidemia (with better lipid profile); and a lower BMI, which represents an adequate risk factor control achieved by the patient's and physician's compliance. The diabetic population had also less coronary events, especially CAD with ST Elevation (with statistic signification at.05 level). On the other hand, the diabetic population had a slighter higher prevalence of Stroke. As result of the inferior event's rate, the diabetic population consumed less intervention cardiology resources.

Conclusions: 1. The diabetic population had a higher prevalence of coronary risk factors and a better control than the nondiabetic population; 2. The inferior rate of coronary events in diabetics may be a result of the risk factor's control; 3. The risk factor's control in diabetics may attenuate their natural tendency for coronary events.

RV-189
NON TRAUMATIC INTRACRANIAL HAEMORRHAGES MORTALITY AND FACTORS OF WORSE PROGNOSIS

R. Puerta Louro, M. Rodríguez Arias, L. González Vázquez, F. Fernández Fernández, A. Sanjurjo Rivo, C. Casas Hernández, A. Arca Blanco, J. de la Fuente Aguado

Department of Internal Medicine. POVISA. Hospital. Vigo (Pontevedra), Spain.

Objectives: The aim of this study was to analyze non traumatic intracranial haemorrhages mortality and the identification of factors of worse prognosis.

Material and method: We have performed a retrospective analysis of the hospital discharges in with diagnosis include intracerebral, subarachnoid or subdural haemorrhages from 1 of January of 2011 to the 31 of December of 2011.

Results: We identified 60 cases with intracranial haemorrhage (59 patients), male (58%), mean age 70 years. Mortality was 15%, 9 patients: 7 intracerebral (7/44, 16%), 1 subdural (1/3, 33%) and 1 subarachnoid haemorrhages (1/13, 8%). Five of the dead patients were taking anticoagulant (2), antiplatelet (2) or both treatments (1). The mean age of those dying are greater with 75 years while those who survive have an mean age 69 years. The indication for anticoagulation of the 3 patients who died was 2 atrial fibrillation and 1 (with clopidogrel) for coronary heart disease (subdural haemorrhage). Those factors of poor prognosis are male 17% vs 12%, coronary heart disease 67% vs 12% taking antiplatelet or anticoagulants 24% vs 11% (28.5% taking anticoagulants, 15% taking aspirin), hypertension 21% vs 8%, diabetes mellitus 31% vs 11%, atrial fibrillation 37% vs 11.5%, history of ischemic cerebrovascular disease 33% or haemorrhagic stroke 14% vs no stroke 13% (3 patients of 6 with history of ischemic cerebrovascular disease are taking antiplatelet and 1 anticoagulant; only 1 patients of 7 with history of haemorrhagic stroke are taking low molecular weight heparin). In the multivariate analysis showed risk factors associated with mortality were coronary heart disease [OR 45, 95%CI: 2.77-730] and atrial fibrillation [OR 17, 95%CI: 2.15-132].

Conclusions: The mortality in non traumatic intracranial haemorrhages was 15%, lower than in other series, higher prevalence in patients previously treated with antiplatelet or oral anticoagulants therapy. The risk factors associated with mortality were coronary heart disease and atrial fibrillation.

RV-190
VENTRICULAR HYPERTROPHY STUDY IN A COHORT OF HYPERTENSIVE PATIENTS

L. Acevedo, N. Matskiv, M. Barrientos, B. Mora, N. Aldezabal, E. Donis, E. Bello, J. Rodríguez

Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: Previous studies have shown the relationship between left ventricular hypertrophy (LVH), left ventricular geometry and cardiovascular risk. The aim of our study is to analyze the presence and type of LVH in a cohort of hypertensive patients and its relationship with other cardiovascular risk factors.

Material and method: Echocardiographic data were analyzed from 85 patients seen in a Hypertension Unit. Hypertensive patients were classified into four groups according to echocardiographic findings: normal geometry, concentric remodelling, eccentric hypertrophy, or concentric hypertrophy taking into account left ventricular mass index and relative wall thickness. LVH was measured by the ASE method and corrected by Devereux. We studied the correlation between HsCRP, diastolic dysfunction, non-dipper pattern, UAE, hypertensive retinopathy and history of cardiovascular events (ischemic heart, cerebrovascular and peripheral arterial diseases) and the different patterns of LVH. All statistical analyses were performed using SPSS version 18.0.

Results: The prevalence of LVH was 51.4% Among hypertensive patients, left ventricular mass index and relative wall thickness were normal in 34.3%, whereas 14.3% had increased relative wall thickness with normal ventricular mass (concentric remodelling), 17´1% had increased mass with normal relative wall thickness (eccentric hypertrophy) and 34´3% had typical hypertensive concentric hypertrophy. No statistical associations were found between different patterns of LVH and other cardiovascular risk factors and cardiovascular events.

Discussion: It is known that the presence of LVH is an independent cardiovascular risk factor. The geometry of hypertrophy also has prognostic significance, as has been demonstrated in many studies. Patients with concentric hypertrophy and remodelling have a higher rate of cardiovascular events than patients with eccentric hypertrophy. In our study the majority of hypertensive patients had concentric LVH, as expected. However we did not find statistically significant association between different geometric patterns of LVH and other studied cardiovascular risk factors.

Conclusions: 1. LVH is highly prevalent in our population of hypertensive patients.2. The most prevalent type of hypertrophy is concentric.3. No correlation was obtained between different patterns of LVH and other cardiovascular risk factors, possibly due to the small sample size.

RV-191
CLINICAL AND EPIDEMIOLOGICAL CHARACTERISTICS OF PATIENTS WITH ISCHAEMIC STROKE AND TREATMENT AT DISCHARGE

M. Rodríguez Arias, R. Puerta Louro, H. Enríquez Gómez, L. González Vázquez, F. Fernández Fernández, S. Araujo Fernández, C. Casas Hernández, J. de la Fuente Aguado

Department of Internal Medicine. POVISA. Hospital Vigo. Pontevedra, Spain.

Objectives: We have performed a retrospective analysis of the hospital discharges in with diagnosis include ischaemic stroke from 1 of January of 2011 to 31 of December of 2011.

Material and method: We have performed a retrospective analysis of the hospital discharges in with diagnosis include ischaemic stroke from 1 of January of 2011 to 31 of December of 2011.

Results: We identified 198 hospital stays with ischaemic stroke (194 patients), 56% women, mean age 76 years (age ranged 41-102), 62% aged > 75 years, 21% aged > 85 years and 10% aged > 90 years. The affected vascular territory was 62% anterior circulation, 16.6% vertebrobasilar, 6% both and 14.6% lacunar stroke. Subtypes of infarction were cardiogenic embolism 21% and atheroma thrombosis 24%. Others comorbilities most commonly associated were hypertension 70%, dislipemia 34.4%, diabetes mellitus 26%, atrial fibrillation 25.8%, ischaemic cerebrovascular disease 21%, chronic renal failure 17.2%, peripheral vascular pathology 13.6%, valvular disease 12.6%, coronary heart disease 8.6% and heart failure 8%. Others diagnosis were anemia 23%, alcohol intake 13%, neoplasia 10.6% and chronic obstructive pulmonary disease 4.5%. Mortality was 12.6%. Forty percent was taking antiplatelet or anticoagulant therapy, 22% aspirin, 7% clopidogrel and 14.6% oral anticoagulation (4 patients aspirin with clopidogrel and 2 patients clopidogrel with anticoagulant). Fifty percent patients with history of atrial fibrillation was taking anticoagulation treatment. Treatment at discharge were 66.5% aspirin, 18% clopidogrel and 22% anticoagulation (11 aspirin with clopidogrel and 7 aspirin with anticoagulant).

Conclusions: Ischemic stroke patients presented high proportion of elderly patients, anterior circulation vascular territory affected and receive antiplatelet or anticoagulant on admission (half of patients with atrial fibrillation were anticoagulated).Hypertension was the most common associated comorbidity. Although 40% were taking antiplatelet or anticoagulant therapy suffered an ischemic stroke. Aspirin is the most widely used drug treatment at discharge.

RV-192
EFFICIENCY OF MICROCURRENTS USE ON DIABETIC NEUROISCHEMIC ULCERS HEALING

J. Garcia-Klepzig, E. Calvo Manuel, L. Escobar Curbelo, J. Trippe, J. Atance García de la Santa, I. Calero Paniagua

Department of Internal Medicine. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: 1. Evaluate the clinical effect of PhyBack PBK-2C device on neuroischemic ulcers in diabetic patients compared to placebo by measuring the ulcer size and transcutaneous oxygen pressure levels. 2. Determine the release and the effect of VEGF produced by the action of this device on the ulcers. 3. Establish the clinical correlation between serum levels of VEGF and wound healing.

Material and method: Experimental, prospective, triple, randomized, placebo-controlled study which tries to analyze two groups of diabetic patients with neuroischemic ulcers (some treated with microcurrent and other treated with placebo) Target population: Patients with confirmed diagnosis of diabetes mellitus with neuroischemic ulcers. Sample: a total of 17 were included. They met the inclusion criteria and present no exclusion criteria.

Results: Transcutaneous oxygen pressure (TcpO2): Regarding the TcpO2, their average levels at day zero in the control group and experimental group were 37.4 +/- 3.6 and 23.83 ± 13.5 mmHg, respectively. On day 5, TcpO2 in the control group is 41.4 ± 7.6 mmHg with a p-value = 0.230. In the experimental group the value of this parameter on day 5 is 37 ± 15.1 mmHg (p = 0.02) In the experimental group, TcpO2 level is still increasing today 30 (43.9 ± 10.1 mmHg) This is higher than those found for the same group on day 0 and day 5. At day 90, the findings obtained by day 30 were confirmed with parameter values analyzed of 39.2 ± 9.5 mmHg for the control group. The group receiving electrotherapy presented at day 90, TcpO2 levels of 43.2 ± 5.9 mmHg (p value 0.039) While not greater than 30 days, their value is higher than those found for the control group and furthermore, it is almost 20 points higher than that observed in this group at day 0. VEGF values: These values, which were collected only three days (0, 5, and 30) also have been more favorable in the experimental group. At day 0, VEGF levels were higher in the experimental group. Thus, values in this group were 191.81 ± 316 pg/ml, whereas in the control group were 104.2 ± 93.7 pg/ml. VEGF values in the control group at day 5 and day 30 were 179.07 ± 164.6 and 112.26 ± 101.1 pg/ml respectively with a p value of 0.101 for day 5 and 0.669 for day 30 In the group receiving the device application PhyBack PBK-2C there was a progressive and statistically significant rise in the VEGF levels. Thus, levels at days 5 and 30 were 250 ± 465.39 and 316.39 ± 829.9 respectively with values of p = 0.008 and 0.021. These values show a clear increase in VEGF levels after application of microcurrents. Ulcer size and healing: At day 90, 100% of patients in the experimental group had presented complete healing of the ulcer, while only 60% of patients in the control group had. This probably has important implications, both in quality of life and in reducing pain and complications of these patients in the short to medium term.

Discussion: Microcurrents use in diabetic neuroischemic ulcers improves healing process. However, the number of patients included in this study, is not enough to asseverate this fact and more studies are necessary.

Conclusions: Microcurrents use in diabetic neuroischemic ulcers induces a clinical improvement, accelerating the healing process, due to an increase in VEGF levels.

RV-193
CARDIOVASCULAR RISK IN THE FIRST VISIT OF A HYPERTENSION UNIT

N. Aldezabal[1], B. Mora[1], M. Barrientos[1], L. Acevedo[1], N. Matskiv[1], A. Torres[2], L. Álvarez-Sala[2], E. Bello[2]

[1]Department of Internal Medicine 2B. Hospital General Universitario Gregorio Marañón. Madrid, Spain. [2]Department of Internal Medicine. Hospital General Universitario Gregorio Marañón and Instituto de Investigaciones Sanitarias Hospital Gregorio Marañón. Facultad de Medicina, Universidad Complutense Madrid. RECAVA Network. Madrid, Spain.

Objectives: To describe the cardiovascular risk (CVR) in a hypertensive population in the first hospital visit and its relationship with non-dipper pattern, high sensitive C reactive protein (hsCRP) and urinary albumin excretion rate (UAE).

Material and method: We performed a retrospective study of patients seen for the first time in a hospital hypertension unit in 2011. We collected the following variables: age, sex, body mass index (BMI), smoking habits, diabetes, dyslipidaemia, chronic kidney disease, history of ischemic heart, cerebrovascular and peripheral arterial diseases. hsCRP, UAE, ambulatory blood pressure monitoring (ABPM), echocardiogram, fundus and CVR calculated by SCORE (spanish specific calibrated version, 2007, published by the 4th Joint European Societies' Task Force on Cardiovascular Disease Prevention in Clinical Practice) were determined. All statistical analyses were performed using SPSS version 18.0.

Results: We included 83 patients, mean age 55 ± 16 years, 43% men. Total cardiovascular risk was stratified into low (20%), moderate (47%), high (20%) and very high (14%). 11% were diabetic and 5% had a previous cardiovascular event. 51.4% had left ventricular hypertrophy (LVH) (measured by the ASE method and corrected by Devereux) and 36% had diastolic dysfunction. 40% of patients had microalbuminuria and 32% hypertensive retinopathy. 32% of patients had non-dipper pattern. 16% had hsCRP > 0.5 mg/dl, which was associated with the presence of DM ($p = 0.016$). We obtained a moderate direct linear relationship of hsCRP with age ($r = 0.3$) and UAE ($r = 0.7$). We found a statistically significant association of hypertensive retinopathy grade 3-4 with stroke and peripheral arteriopathy ($p < 0.01$). Microalbuminuria was associated with high waist circumference (105.7 ± 13 cm vs 85.7 ± 11.2 cm, $p = 0.002$). There was also a statistically significant relationship between microalbuminuria and male sex ($p = 0.034$), smoking habits ($p = 0.003$), LDL increased ($p = 0.002$) and non-dipper pattern ($p = 0.047$).

Discussion: Hypertension is an asymptomatic disease. Many studies show that it is important to stratify cardiovascular risk in hypertensive patients, but this is not often done. In our study we try to assess cardiovascular risk status of patients in the first visit to our unit. We found that moderate-high cardiovascular risk and target organ damage are very common.

Conclusions: 1. In our study, the prevalence of cardiovascular events among patients attending for the first time in a hospital hypertension unit is low, possibly because they are referred to other specialists. 2. Many patients have asymptomatic cardiovascular risk factors such as LVH, non-dipper pattern and high UAE, requiring more aggressive attitude. 3. In our study, the elevated hsCRP is more common in patients with DM in our population but is not associated with other cardiovascular risk factors.

RV-194
ISCHAEMIC STROKE MORTALITY AND ASSOCIATED FACTORS OF WORSE PROGNOSIS

M. Rodríguez Arias[1], R. Puerta Louro[1], S. Araujo Fernández[1], C. Casas Hernández[1], L. González Vázquez[1], J. Paz Ferrín[1], D. María del Carmen[2], J. de la Fuente Aguado[1]

[1]Department of Internal Medicine. POVISA. Hospital. Vigo (Pontevedra), Spain. [2]Encoding Service. POVISA. Hospital Vigo (Pontevedra), Spain.

Objectives: The aim of this study was to analyze ischaemic stroke mortality and the identification factors of worse prognosis.

Material and method: We have performed a retrospective analysis of the hospital discharges in with diagnosis include ischaemic stroke from 1 of January of 2011 to 31 of December of 2011.

Results: We identified 198 cases with ischaemic stroke in 194 patients, 56% women, mean age 76 years. Mortality was 12.6%, 76% female, mean age 85 years (75 years in survivors) and 88% aged > 80 years. Atrial fibrillation was present in 60%. Although 50% patients with history of atrial fibrillation were taking anticoagulation treatment, they had an ischaemic stroke. Those factors of poor prognosis are aged > 75 years (19% vs 3%), female (17% vs male 7%), heart failure (37.5% vs 10%) and atrial fibrillation (29% vs no atrial fibrillation 7%). The multivariate analysis showed as risk factors associated with mortality aged > 75 years [OR 6, 95%CI: 1.34-27] and atrial fibrillation [OR 4, 95%CI: 1.73-10.5].

Conclusions: The mortality in ischaemic stroke was 12.6%, similar than in other series. The risk factors associated with mortality were coronary heart disease and atrial fibrillation.

RV-195
PREVALENCE OF HYPERTENSION ONE YEAR AFTER DELIVERY IN WOMEN WHO DEVELOP PREGNANCY GESTATIONAL HYPERTENSION

M. Núñez Rodríguez, R. Quirós López, D. Urdiales Castillo, A. Aguilar López, L. García de Lucas, A. Blázquez Puerta, M. Martín Escalante, J. García Alegría

Department of Internal Medicine. Costa del Sol Hospital. Marbella (Málaga), Spain.

Objectives: To analyze the prevalence of hypertension one year after delivery in women who develop pregnancy gestational hypertension.

Material and method: A retrospective cohort study, including patients diagnosed during pregnancy of gestational hypertension during the inclusion period from January 1, 2007 to June 31, 2011. The diagnosis of gestational hypertension was established for those women from 20 weeks of gestation had blood pressure > 140/80 mmHg classifying them as mild to moderate hypertension, and > 160/100 mmHg severe hypertension. Analysis of demographic variables, comorbidity, laboratory, and treatment. We conducted a follow-up period of 1 year.

Results: A total of 138 women with a mean age of 30 years were included. The diagnosis of hypertension was established on average at 36 weeks gestation (SD 3,837), labor happening at 38 weeks on average (SD 1,928). With regard to obstetric history, 44% had had previous pregnancies (57% one pregnancy, two pregnancies 27.5%, 7.2% three pregnancies, 5.1% four pregnancies, 2.9% five pregnancies), of which 23.7% had been diagnosed of gestational hypertension (66.7% had required treatment). In 27% of patients had developed complications during the pregnancy, the most frequent preeclampsia (56.3%).Up 80.7% had no family history of hypertension. 1.4% had a history of diabetes mellitus prior to pregnancy, and 11% were diagnosed with gestational diabetes. 81% of pregnant women were diagnosed with mild-moderate gestational

hypertension, and the remaining 18.9% severe hypertension requiring treatment, 55.4% (labetalol (90%), alpha methyldopa (6.7%), nifedipine (1.7%), other (1.7%)). In 87.9% of patients in our study the pregnancy ended at term (from 37 weeks of gestation); intrapartum complications arise in 62.7% of cases, most of them in the form of preeclampsia (88.1%), followed by other complications like premature rupture of placenta (7.1%) and eclampsia (4.8%). In the laboratory, level of urea were 22 mg/dl, creatinine 0.65 mg/dl, and quantified proteinuria presented a median of 410 mg/g. 33% of the women in our study continued antihypertensive treatment after birth, although only 11.3% reported having made outpatient controls blood pressure. At three months postpartum 22.2% remained hypertensive, and at one year only 3.3%.

Conclusions: 1. The diagnosis of gestational hypertension is usually close to delivery. 2. About a quarter of women had gestational hypertension presented in previous pregnancies, complications occurred in 66.7% of cases, the most common pre-eclampsia. 3. In our study the majority of women had a moderate mild gestational hypertension (81%), requiring treatment in 55.4% of cases, being the drug of choice labetalol. 4. In 62.7% of pregnant women found complications, most of them in the form of pre-eclampsia, with proteinuria numbers around 410 mg/g. 5. The prevalence of hypertension one year after the development of gestational hypertension is very low.

RV-196
EARLY STAGE OF HYPERTENSIVE RETINOPATHY. IS IT REALLY IMPORTANT?

M. Karaman[1], S. Ay[1], Y. Bozkurt[2], Ü. Yolcu[3], Ö. Kurt[1], F. Bulucu[1], L. Yamanel[1], K. Saglam[1]

[1]Department of Internal Medicine, [2]Department of Radiology, [3]Department of Ophtalmology. Gulhane Military Medical Academy. Ankara, Turkey.

Objectives: HT, which has an important role in pathogenesis of atherosclerotic cardiovascular diseases (CVD) affects the whole arterial system, not only the coronary arteries. Plays a role in atherogenesis by causing endothelial dysfunction (ED) and increasing vascular microinflammation. Retina; is the only place in the body which vascular structures can be seen and assessed with the naked eye. Retinopathy;is a disease that defines the changes at retinal arteries and venules caused by chronic diseases; and known since the mid-1700s. Hypertensive retinopathy (HTRP) was described by Marcus Gunn in 1936 for the first time. Ophthalmoscopic examination is a simple, easy to administer and cheap procedure that can give important information about disease activation and prognoses for Following-up the diseases affecting vascular structures. In this study, we aimed to investigate the relationship between markers of endothelial dysfunction and vascular microinflammation, which has quite an important place at process of early hypertensive retinopathy and atherogenesis; and to determine the potential clinical benefit with a larger-scale studies if there is a relationship.

Material and method: A total of 99 people consisting of patients with a diagnosis of essential hypertension (n = 73), healthy (n = 26) were included to the study. Patients had no diseases other than HT. The routine laboratory tests which recommended ESC/ESH and JNC VII guidelines were done, also fundoscopic evaluation for organ damage, microalbuminuria, left ventricular hypertrophy and carotid intima-media thickness (CIMK) investigated. FMD and NMD process which are non-invasive methods described by Celermajer et al were performed to determine the ED in patients. ADMA as a marker of ED, and hsCRP, sTWEAK levels were measured with as a marker for vascular microinflammation. Retinopathy screening were done by same person with Canon CR-1 Mark II'' Digital Non-mydriatic fundus camera after photographing the fundus by Keith-Wagner-Barker staging. Statistical analyzes were performed using SPSS 15.0 program.

Results: 73 patients (f: 44 m: 29) and 26 healthy subjects (f: 20 m: 6) in the total 99 people attended. The mean age of the patient group was (48.74 ± 12.2), the mean age of the control group was (38.62 ± 8.7). Hypertensive patients mean disease duration was (6.7 ± 5.7). The average arterial blood pressure (ABP) of hypertensive patients and control group were respectively (140.1 ± 13.7/86.1 ± 10.7) (107.12 ± 10.0/65.38 ± 10.2) were detected. 60.3% of hypertensive patients (n = 44) had HTRP, 39.7% (n = 29) had not. 52.1% of those with retinopathy were stage 1, 8.2% were stage 2, found to be. Hypertensive patients compared with controls; hsCRP, ADMA and sTWEAK (p: 0.011, p = 0.000, p: 0.000) levels were significantly higher in hypertensive group. FMD-NMD measurements were lower in the hypertensive group as expected but it was not statistically significant (p: 0.36/0.85). FMD and NMD rates were significantly lower in patient with retinopathy. (p = 0.033). And also hsCRP, sTWEAK and ADMA levels were significantly higher in patients with retinopathy (p: 0.039, p: 0.000, p: 0.000). Also, at assessment among the patients with retinopathy and no retinopathy; FMD-NMD measurements were significantly lower at retinopathy group, and this was statistically significant. (p: 0.12, p: 0.12).

Discussion: As it is expressed before; there is a close relationship between progressed retinopathy at hypertensive patients and CVD as with CAD, CVA. But the relationship between the current situation with early-stage retinopathy is still not fully elucidated. At this study; patients with stage 1 and stage 2 HTRP compared with healthy control group there is more increase in endothelial dysfunction, in comparison to the patients without HTRP. And it was found to be statistically significant. atherogenesis and vascular micro-inflammation which has an important role in endothelial dysfunction were shown to be impaired in patients with early-stage HTRP.

RV-197
HOW DO WE DIAGNOSE RENAL INFARCTION?

A. Castro, I. Navas, M. Fernández, L. Lozano, J. Ruiz, L. Horrillo, C. Tojo, B. Matía

Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: Renal infarction is a disease with high mortality and morbidity that frequently leads to delayed diagnosis due to its low clinical expression, low diagnostic suspicion and clinical mimicry as a banal and common pathology such as ureteral colic. The pathogenic mechanisms are very common and are related to frequent diseases such as cardioembolism (atrial fibrillation) and hypercoagulable states.

Material and method: Retrospective descriptive study including all cases of renal infarction diagnosed at the Universitary Hospital of Fuenlabrada from the opening date (2004) until 2010. It describes the epidemiological, clinical, and laboratory outcomes.

Results: Of the 16 cases diagnosed during these 6 years, we observed a clear predominance of males (62%). Etiologically, cardiovascular risk factors were associated in up to 75% of the patients (hypertension 56%), neoplasms and hypercoagulable states in up to 62%. Of all de cases described, 10 cases presented symptoms of abdominal pain (in the remaining 6, it was an incidental diagnosis). Of the 10 cases, 3 were early diagnosed, with a global diagnostic delay ranging from 2 to 6 days. Of the classically described analytical findings, high LDH was evident in 100% of the patients.

Conclusions: The diagnosis of renal infarction is complicated by the non-specific symptoms and the need for unusual imaging tests for confirmation (CT, arteriography...), and its precocity is crucial in order to improve the patient's renal function. However, there are epidemiological, analytical and clinical factors that are especially useful to enhance our clinical suspicion. Furthermore, their

detection is a warning sign that should raise suspicion and condition further studies to rule out other possible diseases that are associated such as underlying neoplasms.

RV-198
INFLUENCE OF OBSTRUCTIVE SLEEP APNEA SYNDROME ON METABOLIC SYNDROME

E. Nadal, E. Rovira, M. Abdilla, R. Julve, Z. Pla, I. Ezquerra

Department of Internal Medicine. Hospital Universitario de la Ribera. Valencia, Spain.

Objectives: The aims of the study were to assess if obstructive sleep apnea syndrome (OSAS) may increase the risk of developing metabolic syndrome and to determine the prevalence of metabolic syndrome in patients with OSAS.

Material and method: In cross-sectional study (case-control) during 6 months in the hypertension and cardiovascular risk unit were recruited cases defined as patients with an apnea-hypopnea index (AHI) > 5 events/h and controls were designed as suggestive OSAS clinic and AHI < 5 events/h. Exclusion criteria were as follows: OSAS with CPAP therapy, COPD patients and patient refuse to participate in the study. 158 cases and 32 controls at 0 and 6 months were evaluated on cases and control subjects: physical examination, smoking and alcoholism habits, EKG, ankle-brachial index (ABI), office blood pressure (BP), ambulatory BP monitoring (ABPM), 24 hours BP and hemogram and biochemical blood and urine test. Metabolic syndrome was defined according to 2009 AHA consensus document.

Results: 53.2 ± 8.7 year-old on average were in cases and 52.6 ± 9.9 year-old in controls. Smoking and alcoholism were more numerous in the group control (43.8% vs 38.6% and 25.0% vs 17.1% respectively; p = 0.292). Cases group had a statistically significant higher BP (50% vs 31%; p = 0.045) and dyslipidemia (32% vs 12%; p = 0.024). Biochemical parameters related with metabolic syndrome showed significantly higher values in cases: fibrinogen (385.71 vs 393.00 mg/dl; p = 0.043), glucose (113.47 vs 101.79 mg/dl; p = 0.025), HbA1c (5.959 vs 5.793 g/l; p = 0.009), LDL cholesterol (124.19 vs 112.40 mg/dl; p = 0.019) and creatinine (0.906 vs 0.847 mg/dl; p = 0.009). No significant differences were observed in remaining analytical variables. On logistic regression analysis, given the presence of metabolic syndrome as a dependent variable, OSAS presence predicted significantly the existence of metabolic syndrome (95%CI: 1.10-5.52; p = 0.028) regardless of sex, age, BMI and alcoholism. Therefore the presence of OSAS multiplied by 2.5 the risk of metabolic syndrome.

Discussion: This study shows how OSAS is associated with the developing risk of metabolic syndrome. OSAS was related with 2 components of the metabolic syndrome: hypertension and dyslipidemia. There was a greater number of components of the metabolic syndrome in OSAS patients which indicates that in patients with greater severity of apnea, the likelihood of metabolic syndrome is higher. This interrelationship was independent of confounding factors such as sex, age, body mass index and the consumption of tobacco and alcohol. It demonstrates metabolic syndrome by itself, may enhance the effects of OSAS in cardiovascular disease through the activation of the sympathetic nervous system (mediated by hypoxia and hypercapnia), triggering the cascade of inflammatory response and its consequences on the components of the metabolic syndrome.

Conclusions: The presence of OSAS is an independent risk for developing metabolic syndrome. This increase of risk is independent of gender, age, BMI and consumption of alcohol. OSAS patients had higher BP levels with less decline nocturnal BP and worse glycemic and lipid control. Minor metabolic control may be released with the hiperinsulinemia and hiperfibrinogenemia. Inadequate hemodynamic and metabolic control regardless of waist circumference in OSAS patients may contribute to an increased of cardiovascular risk.

RV-199
CARDIOVASCULAR RISK FACTORS (CVRF) AMONG PATIENTS NOT REFERRED BECAUSE OF CV RISK

J. Medina García, C. Hernández Carballo, M. Dávila Ramos, A. Castellano Higuera, M. López Gámez, J. Romero Pérez, F. Martín Hernández, P. Láynez Cerdeña

Department of Internal Medicine. Complejo Hospital Universitario Nuestra Señora de Candelaria. Santa Cruz de Tenerife, Spain.

Objectives: To describe the CVR profile among patients referred to a Clinic for problems not related with CVR.

Material and method: Data from patients attending for any reason other thant CVR management were recorded. Numerical variables are expressed by means ± SD (range) and compared using Spearson's correlation coefficient. Categorical variables are expressed in absolute numbers (percentage) and compared by means of Chi-square test or U-Mann-Whitney test when this was deemed appropiate.

Results: A total of 191 were yielded. Patients were 61 ± 19.7 years old, with 83 (43.5%) women. Most of the patients were either illiterate (31; 16.2%) or attended only primary school (83; 43.5%). 33 patients (17.3%) admitted drinking more than 40 g/day. 31 (16.2%) were current smokers and 59 (30.9%) were former smokers. There was a clinical history of blood hypertension (BHT), diabetes mellitus (DM) or dyslipidemia in 111 (58.1%), 49 (25.7%) and 83 (43.5%) cases, respectively. 60 patients (31.4%) were obese. Mean body mass index (BMI), systolic blood pressure (SBP) and glucose levels were 27.55 ± 5.4 kg/m^2, 133.25 ± 20.79 mmHg and 103.17 mg/dl respectively. Mean HbA1C, LDL-cholesterol, HDL-cholesterol and triglycerides levels were 5.94 ± 0.95%, 108.45 ± 43 mg/dl, 48 ± 18.3 mg/dl and 124.15 ± -66.97 mg/dl. Mean ultra-sensitive CPR was 3.01 ± 8.61mg/dl. CV damage in the form of ischaemic cardiomyopathy, congestive heart failure, atrial fibrillation and chronic kidney disease showed a relatively high prevalence (13.6%, 24.1%, 13.1 and 12.6% respectively). CPR levels showed a mild positive significant correlation (r = 0.198; p = 0.035) with triglycerides levels and a negative one with HDL levels (r = -0.321; p = 0.001). SBP closely correlated (r = 0.301; p = 0.001) with BMI and with HbA1C levels (r = 0.316; p = 0.002). There was a marginal correlation with CPR levels and CVR estimation measured by SCORE (p = 0.069). Cultural background closely correlated with CVR (Chi-Square = 48.89; p = 0.001).

Discussion: CVRF and CV damage show a relative high prevalence among patients not referred because of CVR assessment to a general Internal Medicine Clinic. Classical and novel biomarkers show good reliability in assessing CVR.

Conclusions: Despite not being referred to the clinic because of CVRF, among the general population in the Canary Islands, especially among individuals with lower social status, CVR is a prevalent reality that should always be assessed, whatever the cause for the patient to be in the clinic. In times of economical crises, special attention should be paid to high risk population.

RV-201
EVALUATION OF GLUCEMIC CONTROL WITH A NEW PROTOCOL FOR INPATIENTS INSULIN THERAPY

M. Gómez Hernández, C. González Becerra, A. Vergara Díaz, A. Sanchís, M. Blanco, P. Gómez Rodríguez

Department of Internal Medicine. Hospital San Juan de Dios de El Aljarafe. Sevilla, Spain.

Objectives: A new protocol for inpatients insulinization has been developed and established in our center in late 2010. It is based on SAEN (Endocrinology and Nutrition Andalusian Society) recommendations. We evaluated the glucemic control, as well as hypoglycemia rate in our patients.

Material and method: 122 patients receiving insulinotherapy were randomly selected from a monthly pharmaceutical prescription list.

Patients with hospital length of stay less than 24 hours; inpatient death; and single elevated glycemia without posterior confirmation were excluded from the study. We have done a descriptive study. We reviewed medical histories and we analyzed variables as age, gender, hospital service in which they were admitted, basal glycemic number, capillary blood glucose control, glycemia in the morning; premeal mean glycemia in the noon; premeal mean glycemia in the afternoon; and bedtime glycemia, Hb A1C (the three previously months), weight, BP rate and hypoglycemia rate in our patients.

Results: Mean value of fasting glucose level on admission was 165.13 mg/dl, premeal (30 minutes before) mean glycemia in the morning was 167.65 mg/dl; premeal mean glycemia in the noon was 189.38 mg/dl; premeal mean glycemia in the afternoon was 204.77 mg/dL; and bedtime glycemia was 205.04 mg/dl. Glycemia records were 93.4% for premeal mean glycemia in the morning, 92.62% for premeal mean glycemia in the noon; and 91.80% for premeal mean glycemia in the afternoon. However only a small percentage of patients (34.43%) were checked before sleep, they were the same who had high premeal mean glycemia in the afternoon. We've only documented 13 cases of hypoglycemia (10.65%); 43.84% were at night; 30.77% were on fasting; and 15.38% were of severe grade.

Conclusions: Generally, they had good BP and basal glycemic control during the hospitalization. In spite of intensive glycemic control, hypoglycemia rate was low.

RV-202
EVALUATION OF TREATMENT PLANNING AFTER DISCHARGE WITH A NEW PROTOCOL OF INSULIN THERAPY

A. Vergara[1], M. Gómez Hernández[1], C. González Becerra[1], C. Pereira[1], A. Sanchís[2], S. Vidal Serrano[1], P. Gómez Rodríguez[2], M. Blanco Torró[2]

[1]Department of Internal Medicine, [2]Department of Community and Family Medicine. Hospital San Juan de Dios de El Aljarafe. Sevilla, Spain.

Objectives: A new protocol for inpatients insulinization has been developed and established in our center in late 2010. It is based on SAEN (Endocrinology and Nutrition Andalusian Society) recommendations. We evaluated treatment at hospital discharge.

Material and method: 122 patients receiving insulinotherapy were randomly selected from a monthly pharmaceutical prescription list. Patients with hospital length of stay less than 24 hours; inpatient death; and single elevated glycemia without posterior confirmation were excluded from the study. We have done a descriptive study reviewing medical charts and analyzing variables including age; gender; basal glycemic levels; Hb A1C (any in the last three months); weight; Blood Pressure previously; home treatment; hospital prescription and adherence to protocol; treatment at hospital discharge; (oral antidiabetic drugs (OADs); OADs + insulin or insulin; and kind of regimen.

Results: Home treatment was performed mostly with OADs (51.64%); 32.79% were on insulin therapy alone; 13.93% were on insulin plus OADs; and only 2 patients were not receiving any treatment but hypoglycemic diet. Most of the patients were on intensive insulin regimen during the hospitalization (86.88%). Most patients were on ADOS at discharge (46.72%). 18.03% were on metformin; 2.46% were on sulfonylureas; 2.46% were with glinides; none of them were receiving incretin mimetics. The 36.89% were prescribed insulin (22.95% with intensive regimen, 15.57% basal insulin and 11.47% with biphasic).

Conclusions: Most patients were previously on ADOS. Most of home treatments were unchanged, but insulin had to be initiated in 17.21%. Around 5% of patients were discharged with intensive regime indications, keeping the same prescribed during admission.

RV-203
HAEMODYNAMIC INSTABILITY FOLLOWING BARIATRIC SURGERY: AN UNUSUAL COMPLICATION?

M. Zigenhorn[1], S. van de Poll[2], J. Wiebolt[1], J.W.F. Elte[1], A.P. Rietveld[1], G. Mannaerts[3], M. Castro Cabezas[1]

Departments of Internal Medicine[1], Cardiology[2] and Surgery[3], Sint Franciscus Gasthuis, Rotterdam.

Objectives: Bariatric surgery (BS) is a popular and effective method in the treatment of morbid obesity. In the majority of patients BS results in significant weight loss. Symptoms and signs of orthostatic hypotension following rapid weight loss have been described especially in starvation, but may also occur after BS. We describe three patients with severe orthostatic intolerance after BS.

Results: Case report: three patients (two males and one female; mean age 44.3 ± 2.9 years) who had undergone BS and developed clear symptoms of orthostatic intolerance and were admitted to the hospital. On average they lost 54.0 ± 20.2 kg body weight (representing 37.4 ± 9.9% of their original body weight). Their initial BMI was 42.2 ± 3.2 kg/m^2 which decreased after laparoscopic sleeve resection to 26.1 ± 2.9 kg/m^2. All three subjects developed new-onset syncope, near-syncope and dizziness within a mean term of 13.3 ± 8.1 months after surgery. Their mean systolic blood pressure decreased from 132.5 ± 10.6 mmHg to 117.5 ± 24.7 and their heart rate decreased from 81.0 ± to 55.5 ± 14.8 bpm. ECG, electrocardiography and 24h holter registration were normal. None of the patients had deficiencies of vitamins or minerals and there were no other biochemical abnormalities responsible for their symptoms. Based upon these results all three patients were diagnosed with (postural) orthostatic hypotension following excessive weight loss.

Discussion: BS is an effective method to treat (morbid) obesity. Orthostatic hypotension can be a severe side-effect of BS and has been described previously. Its exact incidence and etiology is unknown. The likely mechanism of orthostatic failure is autonomic insufficiency combined with reverse course of obesity-related hypertension. In general, the orthostatic hypotension disappears if the patient regains weight. As BS is getting more popular in the Netherlands, more people presenting with orthostatic intolerance following rapid weight loss are expected. Further investigations will be necessary to determine the exact incidence of orthostatic intolerance and to identify those patients at greater risk for developing orthostatic intolerance following BS.

VTE

T-1
THROMBOPROPHYLAXIS IN HOSPITAL AT HOME UNIT

P. Marchena Yglesias, M. Vives Fernández, M. Ríos, J. Burillo Lorente, X. Martret Redrado, G. Donaire Sanso, A. Gómez, E. Bragulat Baur

Department of Internal Medicine. Parc Sanitari Sant Joan de Déu. Sant Boi de Llobregat (Barcelona), Spain.

Objectives: To assed our Hospital at Home Unit (HHU) level of thromboprophylaxis fulfilment and relationship with a description analysis of the unit.

Material and method: Descriptive analysis of HHU: age, length of stay, admission illness, fulfilment of thromboprophylaxis.

Results: Between July 2011 to January 2012 was admitted in HHU 259 patient with mean age 71 years old and length of stay of 6.2 days. During that period, return to hospital 37.8% (n = 38) patients. 14.8% were visited in emergency department and 12.1% readmitted in conventional hospitalized (that represented 81% of emergency visited). 7% had a programmed visiting. Only 2% needs an image test. 0.8% death (N = 2). The more frequent illness was pneumologic disease -15.7%- (COPD, asthma, pneumonia), infectious disease -5.31%- (urinary, soft tissues, abscess) and cardiovascular (3.2%). We made thromboprophylaxis in 42.1% of the patients when was indicated in 90%. The patients who made it have the same mortality, readmission and length of stay than who has not made it.

Discussion: The Hospital at Home Unit is an alternative to conventional hospitalization in chronic disease when are decompensate, mild infectious disease with needing antibiotic therapy. The risk of venous thromboembolic disease is the same than in conventional hospitalized hence thromboprphylaxis follow indicated. A despite this, the realization of thromboprophylaxis in HHU is low.

Conclusions: There is a low ratio of thromboprophylaxis in our Unit despite of high level of indication.

T-2
EPIDEMIOLOGICAL CHARACTERISTICS OF PATIENTS WITH SUPERFICIAL VEIN THROMBOSIS OF THE THROMBOEMBOLIC DISEASE UNIT OF HOSPITAL GENERAL DE CIUDAD REAL

J. Castro, J. Portillo, C. Muñoz, F. González, I. de la Rocha, I. Clemente, M. Mañas, A. Sáenz

Department of Internal Medicine. Complejo Hospitalario de Ciudad Real. Ciudad Real, Spain.

Objectives: Determine the epidemiological characteristics of patients seen in the thromboembolic disease unit of the Hospital General of Ciudad Real who have suffered a superficial vein thrombosis between January 2011 and April 2012.

Material and method: All patients who have had superficial vein thrombosis of the official record of the thromboembolic disease unit of the Hospital General de Ciudad Real were studied retrospectively. The information was extracted from the patients´ medical records. A data collection protocol was developed and it included the following variables: age, sex, origin of the patient, varicous vein, recurrence, hypercoagulable state, idiopathic (those with healthy vein without known predisposing factors), previous surgery of varicose veins and treatment. We excluded patients whose data could not be collected. About 90% was derived from the vascular surgery consultation, 10% from internal medicine hospitalization and all the rest from the emergency room.

Results: Data was collected from 33 patients. The 84.4% of the patients were female and the remaining 15.6% men. The mean age of patients was 56.27 years with a standard deviation of 15.35. The minimum age was 29 years and maximum 85 so the range was 56. About 85% had varicous vein prior to superficial vein thrombosis, the rest appeared on healthy vein. In 30.3% of patients it was the first episode of superficial vein thrombosis, the rest had submitted at least one other before. In 6% documented history of varicous vein surgery was found. The treatment was very heterogeneous 48.5% were treated with LMWH (Low-medium weight heparin), followed by 27.3% of patients who were treated with elastic stockings. 9.1% of patients were treated with acenocoumarol and another 9.1% of them with diosmine plus hesperidin, 6.1% of patients were treated with aspirin.

Discussion: Superficial vein thrombosis is a condition that has traditionally been considered a harmless and banal entity, thus, in some cases it was not diagnosed and when it was not referred to the specialist for evaluation. In recent years some studies that have been published prove that this belief is not well supported because thromboembolism can be secondary to superficial vein thrombosis. Despite this, there are still few studies on the subject or at least not of the desired quality. The best treatment still remains unknown.

Conclusions: Superficial vein thrombosis´s real prognosis and treatment still remains unknown so we need more studies to discover it so we can give patients a best assistance.

T-3
COMPARISON OF DIFFERENT D-DIMER ASSAYS FOR THE PROGNOSIS OF PATIENTS WITH ACUTE PULMONARY EMBOLISM: FINDINGS FROM THE RIETE REGISTRY

A. Maestre Peiro[1], J. Bascuñana[2], M. Peris[3], J. González-Martínez[4], A. Ruiz-Gamietea[5], O. Madridano[6], M. Monreal[7] and the RIETE Investigators

[1]Department of Internal Medicine. Hospital del Vinalopó. Elche (Alicante), Spain. [2]Department of Internal Medicine. Hospital Infanta Leonor. Madrid, Spain. [3]Department of Internal Medicine. Consorcio Hospitalario Provincial de Castellón. Castellón, Spain. [4]Department of Internal Medicine. Althaia - Xarxa Assistencial de Manresa. Manresa (Barcelona), Spain. [5]Department of Internal Medicine. Hospital Universitari Joan XXIII. Tarragona, Spain. [6]Department of Internal Medicine. Hospital Infanta Sofía. Madrid, Spain. [7]Department of Internal Medicine. Hospital Universitari Germans Trias i Pujol. Badalona (Barcelona), Spain.

Objectives: We tried to assess the predictive value of D-dimer levels measured by five different assays at baseline for the 15-day outcome in acute PE.

Material and method: RIETE is an ongoing, prospective registry of consecutive patients with acute, objectively confirmed, symptomatic VTE. Patients were classified in five groups, attending to the D-dimer assay used. We considered those D-dimer assays used in at least 500 patients (Vidas D-dimer, IL Test D-dimer, STA-Liatest D-D, D-dimer plus and Turbiquant).

Results: Up to January 2012, 20151 patients with acute symptomatic PE have been enrolled in RIETE. Of these, 9073 patients underwent D-dimer testing on admission by one of the five assays chosen for the study: 3340 patients with IL-Test D-dimer, 1722 with Vidas D-dimer, 2431 with STA-Liatest D-D, 931 with D-dimer plus and 649 with Turbiquant. Multivariate analysis showed that patients with D-dimer levels in the fourth quartile determined by IL-Test D-dimer had an increased risk for major bleeding (odds ratio: 3.4; 95%CI: 1.8-6.4) and fatal bleeding (odds ratio: 6.6; 95%CI: 1.2-36), not for the other assays. D-dimer did not independently predict mortality, fatal PE (odds ratio: 1.7; 95%CI: 0.9-3.3) and overall death (odds ratio: 1.3; 95%CI: 0.8-2.0), in any subgroup.

Discussion: In this cohort with PE, D-dimer levels determined by IL-Test D-dimer at baseline were significantly associated with major and fatal bleeding during the first fifteen days of therapy. Previous reports showing an independent prognostic significance on mortality or adverse outcome are not confirmed by the present study in any of the subgroups. These results may be explained by an overshadowing of the prognostic potential of D-dimer level by the presence of other more potent recognized prognostic factors, such as presence of cancer, metastases, age or some PE characteristics.

Conclusions: Only D-dimer levels in the fourth quartile at baseline determined by IL-Test D-dimer had an increased risk for major bleeding and fatal bleeding during the first fifteen days of therapy, although we found no differences in mortality.

T-4
USEFULNESS OF TUMOR MARKERS IN SCREENING FOR OCCULT NEOPLASMS IN IDIOPATHIC VENOUS THROMBOSIS

L. Fons, M. Mafe, A. Ventura, M. Bourguet, I. Poquet, C. Tornero

Department of Internal Medicine. Hospital Francesc de Borja. Gandía (Valencia), Spain.

Objectives: Fifty percent of all cases of deep venous thrombosis (DVT) present no known risk factors, and in 10% of the cases neoplastic disease is detected in the course of the episode or in the following year. The strategy for discarding malignancy is subject to debate and can include imaging techniques and the evaluation of different tumor markers (TMs). The present study examines the usefulness of TM detection in patients with DVT in the absence of known risk factors.

Material and method: A retrospective study was made of the patients admitted to a second level hospital over a two-year period with a diagnosis of DVT of uncertain origin, and subjected to follow-up over the subsequent year. The case histories were used to analyze the usefulness of TM detection in relation to the tests that initially yielded an orientation, and the new diagnoses made. A control group of patients with idiopathic DVT without TM determination and subjected to follow-up over the subsequent year was also included.

Results: Of the 221 patients diagnosed with DVT, predisposing factors were identified in 122 (already known neoplastic disease, immobilization, hypercoagulability, etc.). Tumor marker determinations were requested according to supervising physician criterion in 52 of the 99 patients with idiopathic DVT. TM elevation was detected in 17 cases (PSA in 7 subjects, CEA in 7, Ca-12.5 in 2, Ca-19.9 in 2, and Ca-15.5 in 1 case). As a result of these findings, 9 ultrasound explorations were made, along with 7 CAT scans, 4 colonoscopies, 3 gastroscopies and two MRI studies. Two prostate neoplasms, one colon tumor, two urothelial neoplasms and one case of disseminated metastatic disease were identified. Furthermore, in the following year, one patient with CEA elevation and initially normal colonoscopic findings was diagnosed with colon cancer. In the year following the DVT episode, one gastric cancer, two bladder neoplasms and a prostate carcinoma were detected in the 47 patients not subjected to TM determination.

Discussion: In our experience, 10% of the patients with DVT in the absence of risk factors were diagnosed with neoplastic disease in the course of the thrombotic episode or in the following year. The detection of TM elevation led to many complementary explorations, many of which were of little help – though in some cases a diagnosis was established. The presence of normal TM findings does not rule out the possible appearance of tumors in the following months.

Conclusions: In patients with DVT in the absence of risk factors the detection of TM led to many complementary explorations, many of which were of little help – though in some cases a diagnosis was established.

T-7
TREATMENT AT HOME VS A SHORT HOSPITAL STAY FOR LOWER EXTREMITY DEEP VEIN THROMBOSIS (LEDVT) IN DAILY CLINICAL PRACTICE

M. Ruiz, M. Torralba, R. Llanos, O. Casado Meseguer, I. Puche, F. Herrero

Department of Internal Medicine. Hospital Universitario J.M. Morales Meseguer. Murcia, Spain.

Objectives: Comparing LEDVT treatment without admission and with short stay admission.

Material and method: A prospective observational study during of 199 patients with LEDVT over a period of a year. Patients with known neoplasia, associated pulmonary embolism or who only received heparin were excluded. Those who were not given a clinical or ultrasound follow-up at one year (9 in the non-admission group, 16 in the admission group) or who died (0 in the non-admission group, 2 in the admission group), were excluded from the statistical analysis. leaving 133 admissions and 39 non-admissions to be analyzed. The continuous variables were analyzed using Student's t-test and the qualitative variables using the chi-squared test.

Results: The following baseline differences were found between the groups: age (admission: 62 ± 18.8, non-admission: 55.9 ± 16, p = 0.047), the Charlson Index (admission: 0.6 ± 0.9, non admission: 0.23 ± 0.5, p = 0.02) and prior symptomatic time (admission: 8.3 ± 9.6, non-admission: 20.3 ± 36.0 p = 0.047) and no differences were found in the remaining baseline parameters or treatment characteristics (sex, nº of risk factors, nº of affected areas, dimer D, prior venous thromboembolic disease, idiopathic disease, proximal/distal location, days of heparin, total days of treatment, % INR in the correct range or the use of Compression stockings). The evaluated results after one year are shown in table 1.

Discussion: The new treatment of LEDVT has made its management possible with less hospital resources, opting for short admissions or treatment without admission. We have presented our experience of non-admitted patients compared with patients admitted into a short stay medical unit, a decision that was taken in the emergency department at the discretion of the physician who treated the patients. We did not find any differences in the evolutive parameters analyzed. The deficiencies found in age and the Charlson Index could be due to the tendency to admit more elderly patients with more comorbidity.

Conclusions: 1. Admitted patients tend to be elderly and have more comorbidities. 2. There were no significant differences in the evolution of non-admitted patients compared to patients given a short admission time. 3. Most of the patients who had a short admission time could benefit from complete home treatment.

Table 1 (T-7). Results

	% admitted	% non-admitted	p
Ultrasound resolution after one year of follow-up	61	74	< 0.119
Post-thrombotic syndrome (Villalta > 4 points)	19	11	0.55
Slight hemorrhage	19	21	0.8
Severe hemorrhage	3.1	0	0.27

T-8
MANAGEMENT OF ORAL ANTICOAGULATION WITH DICOUMARINIC DRUGS IN HOSPITALIZED PATIENTS FROM AN INTERNAL MEDICINE UNIT IN SPAIN

I. Losada[1], A. Hernández[1], C. Gallego[1], S. Torres[2], A. de la Peña[1]

[1]Department of Internal Medicine, [2]Department of Pneumology. Hospital Son Llàtzer. Illes Balears, Spain.

Objectives: Internal Medicine (IM) patients often need the use of oral anticoagulants (OCA), more often dicoumarinics (DC), with the inconvenience of their narrow efficacy range and variable safety.

Table 1 (T-8). Relationship between therapeutic range and other factors

	No therapeutic range. N/media (%/SD)	Therapeutic range. N/media (%/SD)	p
Institutionalized	6 (3.2)	7 (7.6)	0.13
Pers/perm AF	124 (66.7)	64 (69.9)	0.75
Parox AF	29 (15.6)	15 (16.3)	
New AF	3 (1.6)	0 (0)	
AAS	18 (9.7)	8 (8.7)	0.8
Clopidogrel	5 (2.7)	3 (3.3)	0.72
Double antiplatelet	21 (11.3)	11 (12)	0.85
Bleeding	41 (22)	23 (25)	0.65
Age	79.3 (8.5)	78.8 (8.6)	0.69
Chads Vasc2	4.7 (1.5)	4.7 (1.5)	0.92
HasBleed	2.2 (0.9)	2.2 (0.9)	0.87
GFR	62.2 (27.9)	62.6 (24.6)	0.91
Number drugs	8.8 (3.6)	9.1 (3.3)	0.4

Aim: 1) To establish the characteristics of the patients discharged from an IM Hospitalization Unit treated with DC, and their indications. 2) To analyze the proportion of patients within a therapeutic range at admission and its relationship with other clinical factors.

Material and method: Observational, descriptive, retrospective study of patients admitted to the IM Unit of Son Llàtzer Hospital (Balearic Island, Spain) in 2010 and discharged from hospital in treatment with DC.

Results: Three hundred and ninety six patients were discharged in treatment with DC. One hundred and twenty five (31.5%) of them, were discharged more than once during this year, accounting for a total of 616 discharges. The total number of discharges in the Unit were 2758, thus the percentage of patients receiving DC at discharge was 22.3%. Mean age was 77.6 (SD 9.9), 311 (78.5%) had hypertension and 367 (92.7%). In 301 of 396 patients (76%) the indication was atrial fibrillation. In 117 (29.5%) the treatment was started for the first time (de novo); the remaining 279 were receiving the treatment previously to admission. 92 (33.3%) of them were within the therapeutic INR; 102 (36.6%) were below and 84 (30.1%) were above that range. The mean number of drugs taken by the patients was 8.04 (3.9). Sixty eight (17.2%) patients received also double antiplatelet therapy (aspirin and clopidogrel). Seventy three (18.4%) haemorrhages were documented. There was no clinical association between the lack of INR within therapeutic range and other clinical factors (table 1).

Conclusions: At least 1 of every 5 patients admitted to an IM unit received DC when discharging from hospital, most of them because of atrial fibrillation. Two of every 3 patients did not have an INR within therapeutic range when admitted to hospital and almost 20% of them had a haemorrhagic event. These results confirm the fact that the management of DC is difficult and unsafe.

T-9
CARDIOVASCULAR RISK FACTORS AS PREDICTORS OF IDIOPATHIC VENOUS THROMBOEMBOLIC DISEASE RECURRENCE

A. Franco Moreno[1], I. Sanz Acevedo[1], J. Ortiz Sánchez[1], E. Madroñal Cerezo[2], R. Martín Díaz[2], V. Martínez Díaz[1], C. de Ancos Aracil[2], M. García Navarro[1]

[1]Department of Internal Medicine. Hospital de Torrejón. Madrid, Spain. [2]Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: Venous thromboembolic disease (VTED) is a frequent and growing pathology, presenting with a high morbidity and mortality. Thromboembolic recurrence is one of the long-term complications. Up to 10% of patients present a thromboembolic recurrence in the next five years after the initial event, this recurrence being most frequent in those with a idiopathic VTED. The aim of this study is to analyze this possible association between cardiovascular risk factors and VTED after the cessation of anticoagulant treatment.

Material and method: This is a cohort, observational, prospective and multicentre study comprising 375 patients diagnosed by idiopathic acute VTED between 2004-2012. Patients were followed up for recurrences of thromboembolic disease after the initial event. All patients had received anticoagulant treatment for at least 3 months after initial event. In all patients, (whether or not with thromboembolic recurrence), arterial hypertension, smoking, diabetes, obesity and microalbuminuria were analized, as well as previous cardiovascular events, presenting as stroke or miocardial infarction.

Results: 375 patients were collected in Hospital de Torrejón and Hospital Universitario de Fuenlabrada in the period between 2004 and 2012. The recurrence of thromboembolism occurred in 42 patients (10.9%). Descriptive study of non-recurrence group (333 patients): They were 172 males (51.7%) and 161 female(48.3%) with an average age of 58.1 ± SD 18.2 years. 71% presented at least one of the mentioned cardiovascular risk factors. 10.5% of patients presented hypercholesterolemia, 22.8% were smokers, 40.5% had hypertension and 14.7% had diabetes. Microalbuminuria was positive in 14.2%, and obesity was present in 22. 8% of the patients, average body mass index being 25.7 kg/m^2 (SD 5.3). Previous stroke and miocardial infarction were present in 5.7% and 4.8%, respectively. Descriptive study of the recurrence group (42 patients): They were 25 males (59.5%) and 17 females (40.5%) with an average age of 66.1 ± SD 16.5 years. 83.3% presented at least one cardiovascular risk factor. 65% had hypercholesterolemia, 58.8% were smokers, 47.6% had hypertension, and 33.3% had diabetes. 45.2% of patients were obese, average body mass index being 31 kg/m^2 (SD 7.9). Microalbuminuria was positive in 76.2% of the patients. Previous stroke was present in 9.5% and previous miocardial infarction in 14.3%.

Discussion: The thromboembolic recurrence after discontinuation of anticoagulant treatment in our study was similar to that found in previous reports, though our cohort was comprised only of patients with idiopathic VTED. Recurrence percentage was higher in males than in females, as previously described. In the recurrence group 83.3% of the patients had at least one cardiovascular risk factor, while in non-recurrence group this percentage was 71% (p = 0.40); In the univariate analysis we found that smoking (p = 0.001), hypercholestrolemia (p = 0.002), diabetes (p = 0.002), obesity (p = 0.002) and positive microalbuminuria (p = 0.001) had statistical association with recurrence. On the other hand, age and

hypertension did not show to be related to recurrence. No relation was found between previous cardiovascular events and idiopathic thromboembolic disease recurrence.

Conclusions: Patients with idiopathic VTED present a high percentage of recurrence after discontinuation of anticoagulant treatment. We found a significant association between recurrence and smoking, obesity, diabetes, hypercolesterolemia and microalbuminuria. We believe more clinical and epidemiological studies are needed to confirm these findings, and to identify more possible factors linked to VTED recurrence, in order to establish the optimal duration of anticoagulant treatment.

T-10
FREQUENCY AND CLINICAL FEATURES OF PATIENTS WITH DELAYED DIAGNOSIS OF ACUTE PULMONARY EMBOLISM

J. Torres Macho[1], A. Mancebo Plaza[2], S. García Ramos[1], B. González Herrero[1], J. Calderón Parra[1], J. de Miguel Yanes[2]

[1]Department of Internal Medicine-Emergency. Hospital Infanta Cristina. Madrid, Spain. [2]Department of Internal Medicine. Hospital del Sureste. Arganda (Madrid), Spain.

Objectives: The aim of this study was to describe de frequency of delay or misdiagnosis of acute pulmonary embolism (PE) in the Emergency Department (ED) and to identify clinical predictors of this situation for defining the clinical profile of these patients.

Material and method: This was a retrospective observational study performed at two University affiliated Hospitals. We retrospectively evaluated the clinical charts of patients who were hospitalized due to an acute PE diagnosed by chest computed tomography from April 2008 to December 2011. The records were analyzed in terms of age, sex, risk factors for PE, clinical presentation, laboratory findings, radiologic and electrocardiographic results. We categorized each patient into one of three groups: 1. ED diagnosis: PE was diagnosed by chest CT that was ordered while the patient was still in the ED. 2. Delayed diagnosis: PE was diagnosed by chest CT ordered after the patient had left the ED (the predefined study protocol required that all patients in this group have one predefined symptom consistent with PE written on the ED chart) and 3. Patients who were sent home with a wrong diagnosis and returned to the ED with the same complaints and were diagnosed of PE.

Results: 139 patients were included, 69 patients (49.6%) were male. Mean age was 66.8 ± 19.1 years. 93 patients (67%) were diagnosed correctly at initial presentation. 27 patients (19.4%) were admitted to hospital and had a delayed diagnosis and 19 patients (13.6%) were sent home with a wrong diagnosis. The most frequent wrong diagnoses in patients who were admitted to hospital were: respiratory tract infection/pneumonia (25.9%), heart failure (18.5%) and COPD exacerbation (15.9%). The presence of COPD (37 vs 4.3%), cough (37 vs 14.2%) and the absence of signs of DVT (3.8 vs 20.6%) were univariate predictors of delayed diagnosis in this group of patients. The presence of COPD was the only independent factor associated with delayed diagnosis in the multivariate analysis (OR: 12.7 95%CI 6.5-15.2; $p < 0.05$). Patients who were sent home had an initial wrong diagnosis of respiratory tract infection/pneumonia (31.6%), mechanical chest pain (15.8%), asthma or COPD exacerbation (30.6%) and heart failure (15.3%). This group of patients was significantly different in gender (68% women vs 45%), absence of dyspnea (33.8 vs 80.2%), fever (31.5 vs 10.8%), pleuromechanic chest pain (36.8 vs 1.9%) and absence of signs of DVT (0 vs 20.6%) with statistical significance in the univariate analysis. The absence of dyspnea (OR: 9 95%CI 4.3-12.6; $p < 0.05$) or signs of DVT (OR: 10.7 95%CI 5.8-14.2; $p < 0.05$) were independent predictors of misdiagnosis in this group of patients in the multivariate analysis.

Discussion: Prompt recognition of pulmonary embolism remains a challenge. Despite advances in diagnosis, delays or misdiagnosis of acute PE are still common. Factors associated with this situation are not well defined. We found a high incidence of delayed or missed diagnosis (33%), which is similar to previous reports. We also found that patients who are sent home with a wrong diagnosis are more frequently women without manifest symptoms of PE while patients who are admitted to Hospital and are diagnosed of PE after they leave the ED have unespecific symptoms and comorbidities like COPD.

Conclusions: In this multicenter study, the diagnosis of PE was frequently delayed (one third of patients). There are some clinical characteristics that are associated with this delay in diagnosis which are different depending on if the patient is sent home or is admitted to hospital.

T-11
AGE ADJUSTED D-DIMER CUT-OFF VALUE VS CONVENTIONAL METHOD: A RETROSPECTIVE STUDY

I. Pons[1], A. Calaf[1], E. Sanchís[2], V. Nováková[3], P. Comas[1]

[1]Department of Internal Medicine, [2]Department of Radiology. Hospital d'Igualada. Barcelona, Spain. [3]Department of Preventive Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: Levels of D-dimer increase with age, thus reducing its sensibility for pulmonary embolism (PE) diagnostics in older patients and making it a less useful tool for the early diagnostics of PE in the elderly. Recently, some authors have postulated an age-dependent new value of D-dimer (positive D-dimer: age × 10 in older than 50 years) that should increase the sensibility without losing specificity.

Material and method: All patients in which we performed a high-resolution computerized tomography (CT) to exclude PE during the year 2010 and which had the D-dimer values available were included in this retrospective study. The D-dimer examination was made with the quantitative method Innovance. We registered clinical data, age and the clinical probability of PE according to the scale of Wells. Patients were classified according to this probability and those with non-high probability were stratified with two D-dimer cut-off values (age × 10 in older than 50 years compared to the standard cut-off value, expressed in micrograms/milliliter). We have calculated and compared the sensitivity (S), specificity (E), positive predictive value (PPV) and negative predictive value (NPV) with both cut-off values. Statistical analysis was performed using SPSS 18.0.

Results: A total of 160 CT were performed in order to rule out PE. D-dimer was determined in 125 patients. Of these 125, only 6.4% had a high clinical probability, leaving 117 patients with low or intermediate probability (114 older than 50 years). 29.6% (37) of 125 CT performed were positive for EP. The distribution of patients according to the standard cut-off value and the age × 10 (in older than 50 years) is shown in Tables 1 and 2. With the standard cut-off value, we had: S 100% E 3%, PPV 28%, NVP 100%. With the cut-off age × 10, we had: S 100% E 8%, PPV 29%, NPV 100%. We could not appreciate any statistically significant differences between these 2 methods.

Discussion: We observe that our S and NPV are equivalent or better and the E and PPV are significantly lower (35-50% and 50-70%) when compared to the values that we found in the literature. These results should be taken with caution due to the small number of patients with values under the cut-off point value with the two methods that we used in our study.

Conclusions: Our series does not find differences in the S, E, PPV and NPV between both cut-off values. However, with the new method, we have a higher number of healthy patients with D-dimers values under the cut-off point, and this could have avoided 4 (3.2%) chest CT's when compared to the fixed cut-off method. It would be

convenient to increase the cohort size in order to reach statistically significant conclusions.

Table 1 (T-11). Standard cut-off value

	EP confirmed	EP discarded
D-dimer > 500	31	83
D-dimer < 500	0	3

Table 2 (T-11). Age × 10 (in older than 50 years) cut-off value

	EP confirmed	EP discarded
D-dimer > age × 10	31	76
D-dimer < age × 10	0	7

T-12
VENOUS THROMBOEMBOLIC DISEASE (VTD) IN A COHORT OF PATIENTS ADMITTED TO A PALLIATIVE CARE UNIT

G. Delgado Cárdenas[1], V. Rojo Valencia[1], P. Sánchez Chica[1], C. Vicente Martín[1], J. Marco Martín[2], S. Plaza Canteli[1]

[1]Department of Internal Medicine. Hospital Severo Ochoa. Leganés (Madrid), Spain. [2]Department of Internal Medicine. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: The Internal Medicine Department of our hospital has a Palliative Care Unit since 2002. Our aim is to analyze the characteristics of patients admitted to this Unit with the diagnosis of venous thromboembolic disease (VTD).

Material and method: Descriptive and retrospective study by revision of clinical records of patients admitted to the Palliative Care Unit with a diagnosis of VTD between November 2003 and December 2011. Variables recorded were age, sex, thrombus location, main symptom at admittance, predisposing factors, mean stay, type of discharge, survival time, VTD recurrence and hemorrhagic complications. An Access data base was created and SPSS was used for analysis.

Results: A total of 117 episodes in 111 patients (incidence of 6%) were identified. Mean age was 68.2 years (SD 10.9) with 66.7% males. VTD was the main diagnosis at admittance in 80 cases (68.4%). The diagnosis of VTD was made during hospitalization in 8 patients (6.8%) and 18 (15.4) had had a recent admittance. Pulmonary embolism (PE) was also present in 59 (50.4%) patients, deep venous thrombosis of the lower extremities in 47 (40.2%), thrombosis of the vena cava in 3 (2.6%) and both PE and DVT in 4 (3.4%). Related symptoms were present in 35 patients with VTD, 59.3% with PE, and 44 (75.3%) with DVT. Dyspnea (72.8%) and pain (58.6%) were the most frequent complains in each group. All patients had neoplasic disease being in order of frequency lung (25.2%, n = 28), colorectal (13.5%, n = 15), pancreas (9%, n = 10) and stomach (8.1%, n = 9). Chemotherapy was active in 56 (47.9%) patients and immobilization was considered the predisposing factor in 17 (14.5%). Mean stay was 6 days (p25-p75: 4-8) for PE and 5 days (p25-p75: 3-8.2) for DVT. In-hospital mortality was 25.6% (n = 30) while 64.1% (n = 75) went home and 10.3% (n = 12) to other centers. Anticoagulant treatment (low molecular weight heparin) was administered to 48 (43.24%) patients. Only in 2 cases placement of a filter in the vena cava was necessary and 5 (4.3%) mayor hemorrhagic events were recorded. There were 14 recurrences (12%): 3 PE and 11 DVT.

Conclusions: Incidence of VTE is 1.6 per 1.000/year and in our study it reaches 6.08% of admittances, a rate that can be attributed to the 100% of incidence of concomitant neoplasic disease in our patients. VTD was asymptomatic in 32.4% of our cases and as is the case with other published works, colorectal and lung were the most frequent thrombi generating tumours. Thromboembolic prophylaxis must be taken into account in these patients if there are other risks factors, especially after surgery and when under active chemotherapy. The decision to treat patients with cancer must be individualized and is especially difficult in patients under palliative care which should be considered not to initiate anticoagulation in terms of non therapeutic advantage (risk of bleeding, limited survival, not planned oncologic chemotherapy), not benefit palliative (eg Alleviate dyspnea) and unreasonable burden of anticoagulant treatment (painful injections, need for follow-up visits…).

T-13
SAFETY OF CHRONIC ANTICOAGULANT THERAPY OF ABDOMINAL VISCERAL VENOUS THROMBOSIS: RETROSPECTIVE STUDY OF TWENTY-FIVE CASES

E. Sánchez-García[1], Á. Blanco-Molina[1], I. Domínguez-Fernández[2], B. García Olid[1], C. Arenas Muñoz[1], I. Ramírez Lara[1], J. Ogea García[1]

[1]Department of Internal Medicine. Reina Sofía University Hospital. Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), University of Córdoba. Córdoba, Spain. [2]Department of Internal Medicine. Hospital Universitario Reina Sofía. Córdoba, Spain.

Objectives: Anticoagulant therapy duration in abdominal visceral veins thrombosis (AVVT) is not well-defined. For this reason, we report the safety and effectiveness of prolonged chronic anticoagulant therapy in the treatment of AVVT, independent of the site of it and the underlying conditions.

Material and method: We retrospectively reviewed twenty-five cases of AVVT that were diagnosed and treated with chronic anticoagulant therapy in our Unit from 1996 to the date.

Results: Twenty-five cases of AVVT were analysed [12 men (48%) and 13 women (52%)]. The mean age at diagnosis was 53.3 ± 19.2 (45.4-61.2) years. The main symptom at presentation was abdominal pain that was present in 18 patients (72%). Portal-splenic-mesenteric (PSM) axis was the most frequent site (18, 72%) but other locations were present [renal vein (6, 24%) and ovaric vein (1, 4%)]. In 14 patients a risk factor was identified. Cancer (7, 28%) was the most frequent associated risk factor and the diagnosis of the tumour was established after the thrombotic event in all cases. The presence of thrombophilia was studied in 22 patients. Inherited procoagulant mutations were found in 6 cases (27.3%) (1 factor V Leiden, 4 prothrombin gene mutation G20210A, 1 other) and 3 patients presented more than one (13.6%). Three patients were diagnosed as having an antiphospholipid syndrome (13.6%). Among patients with portal vein thrombosis, four (28.57%) of them developed cavernomatous formation and esophagogastric varices grade I of Los Angeles classification but they do not showed neither progression or bleeding with chronic anticoagulant therapy. Low molecular weight heparin (LMWH) was the elected acute anticoagulant therapy in all cases (23/23; 100%). Two patients were not anticoagulated because of active haemorrhage and poor prognosis of a metastatic cancer. Chronic anticoagulation was maintained in the rest of cases (LMWH 5, 21.7%; acenocumarol 18, 78.3%). In one case anticoagulant treatment was discontinuated by patient´s decision and recurrent thrombosis in the same site was developed. Rethrombosis was solved after anticoagulant therapy reinitiation. Radiological control tests showed no progression or partial resolution of the thrombosis in 3 cases (17.5%) and a complete one in 12 cases (70.6%). Only one patient (5.9%) developed radiological worsening and it was associated with the progression of a diffuse hepatocarcinoma. All patients remain asymptomatic after treatment beginning without rethrombosis and/or major bleeding after a median followed-up period of 43.7 ± 58.9 (19.3-68) months.

Discussion: Our study shows that chronic anticoagulant therapy is a safe therapy in the treatment of AVVT, despite the existence of

procoagulant conditions, its location or the presence of signs of acuticity or chronicity. Furthermore, when portal hypertension and/or cavernomatous formation were present, anticoagulant therapy was associated with a clinical stabilization of these complications. The presence of esophagogastric varices was no associated with digestive bleeding. That is why we consider that it is not a limitation for prolonged anticoagulation. However, a careful assessment of the risk of bleeding must be performed before starting the therapy.

Conclusions: Our experience suggests that prolonged anticoagulant therapy is safe in the treatment of AVVT and it is not related to major bleeding. As a result, we think that anticoagulant therapy should be started and maintained for an extended period if there are no high risk-bleeding factors.

T-14
DEGREE OF CONCORDANCE IN THE THROMBOEMBOLIC PROPHYLAXIS PRESCRIBED IN AN EMERGENCY SERVICE

T. Blanco Moya[1], L. Cortejoso Fernández[2], A. de Lorenzo Pinto[2], E. Duran García[2], M. San Julian Romero[1], M. Gómez Antúnez[1], A. Muiño Miguez[1], M. Sanjurjo Sáez[2]

[1]Department of Internal Medicine 2A, [2]Department of Pharmacy. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: Venous thomboembolism (VTE) is considered the main preventable cause of death in hospitalized patients and an important health problem. The PRETEMED clinical practice guide on prevention of VTE in medical patients allows the establishment of recommendations according to combined risk factors. The objective of the study is to assess the degree of concordance in the thromboembolic prophylaxis prescribed in an Emergency service according to the PRETEMED guide.

Material and method: Observational, longitudinal and prospective study carried out from September 2011 to May 2012 in an Internal Medicine unit. Inclusion criteria were: adult patients from an Emergency service and the exclusion criteria: patients receiving one of the habitually prescribed drugs for thromboprophylaxis but with an exclusively therapeutic intention. The following variables were collected: demographic data, VTE risk factors, hospitalisation diagnosis and antithrombotic prophylaxis prescribed in the Emergency service. The Internal Medicine pharmacist compared the prescribed prophylaxis with the recommended by the PRETEMED 2007 guide and assessed concordance.

Results: 73 patients were included (54.8% male). Mean age was 81 years (minimum 25, maximum 105 years). The most frequent diagnosis was respiratory disease (36.4%) and 60.3% of patients were classified as high risk for VTE. The most used prophylactic dosage was enoxaparin 40 mg/24h sc (45.2% of patients), followed by enoxaparin 20 mg/24h sc in 15.1% of patients (of these, 54.5% were at low risk for developing VTE according to clinical judgement, 36.4% displayed a creatinine clearance lower than 30 ml/min and 9.1%, suspicion of haemorrhage). 34% of the prophylaxis was not in agreement with that established in the PRETEMED guide. Reasons for non concordance were: no indication for mechanical/pharmacologic prophylaxis (11%), prophylaxis omission (16.4%), no indication for pharmacologic prophylaxis but mechanical (11%) and overdose (1.4%). 23% of patients classified as high risk for VTE were not prescribed thromboprophylaxis in the Emergency service.

Discussion: Studies show that between 5% and 10% of all inhospital deaths are directed result of pulmonary embolism. Randomized clinical trials over the past 30 years provide irrefutable evidence that primary thromboprophylaxis reduces DVT and pulmonary embolism (PE), and there are studies that have also shown that fatal PE is prevented by thromboprophylaxis. PE is the most common preventable cause of hospital death and the number-one strategy to improve patient safety in hospitals. Almost all hospitalized patients have at least one risk factor for VTE, and approximately 40% have three or more risk factors. Unfortunately, despite the hundreds of randomized trials demonstrating the benefit of thromboprophylaxis and > 20 practice guidelines recommending the use of thromboprophylaxis since 1986, low adherence with evidence-based thromboprophylaxis compromises the optimal benefits of this key patient safety practice. A UK survey suggested that 71% of patients assessed to be at medium or high risk of developing deep vein thrombosis did not receive any form of mechanical or pharmacological VTE prophylaxis.

Conclusions: A high number of patients do not receive adequate thromboprophylaxis on admission, probably because physicians undervalue the risk for VTE. For this reason the development of prescription support tools to aid prescription and warn physicians on individual VTE risks is of paramount importance.

T-15
IS AN INITIAL MINIMUM 5-DAY TREATMENT WITH HEPARIN NECESSARY IN LOWER EXTREMITY DEEP VEIN THROMBOSIS (LEDVT)?

I. Puche, M. Torralba, O. Casado, R. Llanos, M. Ruiz, F. Herrero

Department of Internal Medicine. Hospital Universitario J.M. Morales Meseguer. Murcia, Spain.

Objectives: To assess the follow-up of patients administered with less than 5 days of heparin as their initial DVT treatment.

Material and method: A prospective observational study of LEDVT over one year to compare the results of the treatment of 17 patients who received less than 5 days of heparin with the group of 207 who received it for at least 5 days. Patients with known neoplasia or who only received heparin were previously excluded. Those who did not undergo clinical or ultrasound follow-up at one year (2 in the group with < 5 days (11%) and 31 (15%) in the group of at least 5 days) or who died (0 in the group < 5 days, 3 (1.7%) in the group of at least 5 days), were excluded; leaving 173 for the analysis with at least 5 days of heparin and 15 with < 5 days. The continuous variables were analyzed using Student's t-test and the qualitative variables using the chi-squared test.

Results: No differences were found in the baseline or treatment characteristics of both groups (sex, age, mean stay, nº of risk factors, clinical time, nº of affected areas, Charlson Index, D-dimer, prior thromboembolic venous disease, idiopathic disease, proximal/distal location, associated pulmonary embolism, total days of treatment,% of INR in the correct range or the use of compression stockins). The results after a year are shown in table 1.

Table 1 (T-15). Results

	5 or > 5 days%	< 5 days%	p
Post-treatment ultrasound resolution	52	46	0.89
Post-thrombotic syndrome (Villalta > 4 points)	16.8	13.3	0.9
Slight hemorrhage	17.8	26.7	0.39
Severe hemorrhage	3	0	0.49
Relapse	7.5	0	0.27
Pulmonary embolism	0	0	

Discussion: Since the beginning of the 90's, based on studies of non-fractionated intravenous heparin, a minimal initial treatment period of at least 5 days with heparin followed by oral anticoagulation has been widely recommended for the treatment of LEDVT with both therapies being initiated on the same day. Since the introduction of this combined treatment, a reduction in this period has not been contemplated. However, in daily practice, whether due to error or because of reaching an excessively high INR during the first few days, heparin has been suspended in some patients before the fifth day. We decided to assess the consequences of this situation and to compare the follow-up of these patients with those who were maintained on standard treatment for at least 5 days, and no differences were found between the groups. Although the treatment group of < 5 days is too small to reach definitive conclusions it suggests that large registries could be used to evaluate this situation and confirm the same results through a clinical trial.

Conclusions: 1. The 3-4 days of initial heparin treatment could be enough, provided oral anticoagulation is initiated simultaneously and 2-3 INR is achieved quickly. 2. Reaching an adequate INR could be more important than the days heparin is administered, except for the first 2 days of dicumarinic procoagulant tendency.

T-16
MALFORMATIONS OF INFERIOR VENA CAVA AND DEEP VEIN THROMBOSIS

R. Calderón Hernáiz, J. Ruiz Ruiz, O. Mateo Rodríguez, D. Rejas Velásquez, E. Madroñal Cerezo, M. Fernández López, J. Canora Lebrato, A. Zapatero Gaviria

Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: The abnormalities of inferior vena cava (IVC) constitute a large group of malformations and anatomic variants, usually called "IVC agenesis". Sometimes, these may be confused with abdominal tumoral masses or lynphadenophaties, so an invasive vascular technique is necessary to reach de right diagnosis. The flow stasis and turbulences generated in venous system condition thrombotic phenomenous, especially in the iliac system of young patients, though most of them never give symptoms and provide a casual diagnosis (up to 69%). It is described its association with other vascular malformations, but also with visceral anormalities such as pulmonary dysgenesis and polysplenia. Treatment is controversial with insufficient evidence. In most cases, lifelong anticoagulation is recommended to avoid recurrent thrombosis. The malformation is usually not surgically repairable. Our objective is to describe all cases of IVC malformations and deep vein thrombosis (DVT) detected at the Fuenlabrada University Hospital (FUH).

Material and method: Retrospective analysis of cases of IVC abnormalities and DVT detected in the Internal Medicine Service of FUH, since its opening in 2004.

Results: We detect three cases during this period: The first one is a smoker 26 years old men with a cerebral cavernoma that bled one year earlier. He enters for groin pain and doppler indicates extensive DTV of left femoro-iliac axis to IVC. The angioTC detects IVC hypogenesis and cerebral MR shows the presence of cerebral cavernoma and a cerebellar venous angioma. The thrombophylic study was not abnormal. The patient undergoes surgery of cerebral cavernoma three months later and he remains anticoagulated since then. The second is a 38 years old man with operated right temporal lobe epilepsy and two previous episodes of DVT with known homozygous mutation of MTHFR 677T (normal homocysteine levels) and anticoagulated indefinitely. He enters again becasue of extensive femoro-popliteal DVT. Hypoplasic IVC is incidentally detected in a cavography while trying to place vein cava filter that finally was impossible. Months later, during another admission to the hospital due to pneumonia, we detect megaesophagus and esophageal achalasia. The last one is a healthy 21 years old woman with mediastinal widening detected on a conventional chest radiography performed during the study of epigastric pain. Chest CT showed IVC malformation with persistance of supra and subcardinal veins. No other malformations were detected in this case. She never had episodes of thrombosis. Her doctor indicates thromboprophylaxis measures at risk situations.

Conclusions: We must consider IVC malformations in those young patients with DTV, especially when they occur in the iliac system. These malformations are usually associated with another vascular and visceral abnormalities, as showed in our patients. We wonder if it is cost-effective to systematically investigate IVC malformations in these cases because they are generally non-repairable deffects, although it may be useful to decide the anticoagulation duration.

T-17
INFERIOR VENA CAVA CONGENITAL ANOMALIES-ASSOCIATED DEEP VEIN THROMBOSIS: 4 PATIENTS AND REVIEW OF THE LITERATURE

A. Díaz[1], E. Montero[1], C. Gómez[1], C. Castillo[2], M. Carreño[1], P. Durán[1]

[1]Department of Internal Medicine, [2]Department of Family Medicine. Hospital Universitario Puerta De Hierro Majadahonda. Majadahonda (Madrid), Spain.

Objectives: Inferior vena cava agenesis (IVCA) is a rare congenital abnormality, with an estimated prevalence of 0.0005-1% in the general population, found in almost 5% of patients under 30 years old with unprovoked deep venous thrombosis (DVT). Only 72 IVCA cases have been described in th English literature. We present 4 cases of clinically extensive DVT associated with IVC thrombosis in patients with unknown IVCA.

Material and method: We revised medical histories of the 30 patients with criteria for IVC thrombosis between 1990 and 2012 at our tertiary-care university hospital, which serves a population of about 600,000 inhabitants, and selected only those with IVC malformations (4 of 30). They underwent thrombophilia screening. Acquired risk factors for DVT and family histories were always sought. A follow-up period of at least 12 months after discharge was performed.

Results: Patient 1: a 45 year-old computer engineer presented with a 1-week history of lower back pain, edema of lower extremities and dyspnea. He used to cycle in his spare time. Full-body CT scan revealed bilateral pulmonary embolism (PE), IVC thrombosis (IVCT), agenesis of suprarenal IVC and horseshoe kidneys. Doppler ultrasound showed DVT of both iliac and femoral veins. Thrombophilia blood testing highlighted heterozygosity for a factor V Leiden (G169A) mutation. The patient was treated with high-dose unfractionated heparin followed by oral anticoagulation. Subsequent IVC Doppler showed poor resolution of IVC thrombosis 1 year later. Patient 2: a 26 year-old waiter was admitted with a 10-day history of abdominal pain (located in the lower right side) and fever. Abdominal CT-scan revealed a right retroperitoneal mass (possibly lymphoma). Abdominal MRI angiography showed thrombosis of IVC from iliac to renal veins and saccular dilatations of vessels coming from IVC (congenital malformation of IVC). CT-guided mass biopsy could not find tumoral cells. Iliocavography was performed to apply local thrombolysis. The patient works and does his normal life 2 years later (with oral anticoagulation). Patient 3: a 48 year-old postman suddenly suffered pain, edema of right low extremity and fever 2 days before admission. There was neither dyspnea nor chest pain but CT scan showed bilateral PE. Doppler ultrasound revealed right iliac vein thrombosis. Both Doppler of IVC and abdominal MRI angiography showed IVCT and agenesis of suprarenal segment, with left renal vein thrombosis. He was treated with high-dose unfractionated heparin, and oral anticoagulation for 52 months, with no morbility. Patient 4: a 43 year-old female

cashier developed high temperature, both lower limbs edema and right abdominal flank pain 14 days before diagnosis. Doppler ultrasound showed both iliac veins and IVC thrombosis. CT scan revealed IVC trombosis and intrahepatic segment agenesis. She received oral anticoagulation for 6 months and has continued with acetylsalicylic acid for the last 15 years.

Discussion: In the present study, as in literature, we find that most patients are male under 50 years old. Compensatory drainage thru the thoracic-lumbar, pelvic, and abdominal veins can cause symptoms prior to those typical of DVT of the lower extremities. Although some authors believe cava malformation alone can provoke DVT, all patients should undergo thrombophilia screening. Recurrent thrombotic occlusion occurs only in patients whose anticoagulation treatment is suspended.

Conclusions: We should suspect the presence of IVC malformation in patients < 30 years with DVT of the lower extremities when the iliac veins are affected. No precise duration of anticoagulation has been established.

T-18
THROMBOPROPHYLAXIS OF VENOUS THROMBOEMBOLIC DISEASE IN ACUTE MENTAL DISORDERS

P. Marchena Yglesias[1], S. Ramírez Perdomo[2], A. Serrano[2], E. Bragulat Baur[1]

[1]Department of Internal Medicine. Parc Sanitari Joan de Déu. Sant Boi de Llobregat (Barcelona), Spain. [2]Acute Psychiatric Unit. Parc Sanitari Sant Joan de Déu. Sant Boi de Llobregat (Barcelona), Spain.

Objectives: To assess the level of fulfilment of thromboprophylaxis in acute psychiatric disorders admitted in our psychiatric acute unit, analyzed the risk factors and the better way to improve.

Material and method: Descriptive, observational and transversal study carry on one day of may 2012 in Acute Psychiatric Unit of our hospital. We analyzed all patients admitted that day and review intake of antipsychotics, other risk factors, intake of chronic anticoagulants and acute mental disorder and the level of fulfilment of thromboprophylaxis.

Results: In 61 patients admitted 7 May 2012, 52% were women with mean age of 44 years old. 4.9% had a previous VTD and only 1.6% was a chronic anticoagulation user. 88% use antipsychotics and 36% antidepressant. 8.2% were immobilized by agitation. The mainly diagnosis were acute psychotic disorder, bipolar disorders and depression and the admission cause was behavior disorder and psychotic outbreak. The mainly antipsychotics use during the admission were atypical: olanzapin, risperidon and quetiapin. A 26.2% of patients had indication of thomboprophylaxis, whom only 37.5% really made. Exists a 56% of patients with indication whom not realized tromboprophylaxis.

Conclusions: In our acute psychiatric unit, there are a low level of thromboprophylaxis despite of the indication is low too.

T-19
ASSESSING VENOUS THROMBOEMBOLISM RISK AND PROPHYLAXIS IN PATIENTS ADMITTED TO AN INTERNAL MEDICINE WARD OF A UNIVERSITY HOSPITAL

M. Carvalho, A. Silva, C. Pereira, I. Chora, J. Urbano, M. Ferreira, S. Silva, M. Patacho

Department of Internal Medicine. Centro Hospitalar São João. Porto, Portugal.

Objectives: Venous thromboembolism (VTE) is a major cause of preventable in-hospital death; according to the ENDORSE study, a large proportion of at-risk patients is not receiving recommended prophylaxis. The goal of this study was to assess the prevalence of VTE risk in acutely ill medical patients and to determine the adequacy of VTE prophylaxis received.

Material and method: Patients aged 18 or older, admitted to an internal medicine ward of a Portuguese university hospital, were assessed on the basis of chart review, on a preset day (5th April 2012). VTE risk and prophylaxis were evaluated according to Caprini's VTE Risk Assessment Tool and to 2004 American College of Chest Physicians (ACCP) guidelines.

Results: From 159 inpatients studied, 91 fulfilled inclusion criteria (56% male, median age 74, range [24-91]). 88 patients were judged to be at Caprini's risk for VTE (21.6% moderate, 26.0% high, 53.4% highest risk); from these, 64 (72.7%) were under VTE prophylaxis (pharmacological or not), which was according to ACCP recommendations in only 70.3% of the cases. Considering all at-risk patients for VTE (n = 88), 43.2% (n = 38) were not under recommended prophylaxis: in 21.6% (n = 19) of the cases prophylaxis was absent and in 21.6% (n = 19) it was inadequate (incorrect posology 57.9%, non-adjustment to renal function 10.5%, presence of contraindications 21.1%, non-pharmacological measures when pharmacological were indicated 10.5%). The major pharmacological prophylaxis used was low molecular weight heparin (98.4%). None of the patients in which anticoagulation was contraindicated received non-pharmacological measures.

Discussion: Scarce data available on VTE risk and prophylaxis in Portuguese studies reinforce the relevance of this assessment. In this study, almost all patients were at Caprini's risk for VTE - these results are consistent with the finding that 5-10% of in-hospital deaths are due to thromboembolic events. In spite of numerous published guidelines addressing this issue, the proportion of at-risk patients under correct prophylaxis is still lower than it would be expected. Our series found that only 56.8% of the patients received adequate prophylaxis according to ACCP guidelines. Possible explanations for these results may include the underestimation of VTE risk, which can lead to underprescription of prophylaxis, and the non-consideration of all clinical factors when prescribing pharmacological or non-pharmacological measures. The type of pharmacological VTE prophylaxis found in this study is in agreement with other European series.

Conclusions: Almost all patients hospitalized for acute medical illness were at risk for VTE but there was still a considerable proportion of them in whom the prophylaxis received was not according to ACCP recommendations. These results emphasize the need to reassess and optimize daily clinical practices, ensuring that at-risk patients receive appropriate VTE prophylaxis, in order to decrease VTE related in-hospital morbidity and mortality.

T-22
INFERIOR VENA CAVA FILTERS: A RETROSPECTIVE STUDY

A. Sáenz Gutiérrez[1], C. Lozano Cejudo[2], M. Zarca de la Espina[3], A. Pinar Ruiz[3], J. Castro Giménez[1], J. Portillo Sánchez[1]

[1]Department of Internal Medicine, [3]Department of Radiology. Hospital General de Ciudad Real. Ciudad Real, Spain. [2]Department of Radiology. Hospital Santa Bárbara. Puertollano (Ciudad Real), Spain.

Objectives: To review a 12-year single-center clinical experience with inferior vena cava filters. To determine, with a retrospective study, the characteristics of patients undergoing implantation of an inferior vena cava filter, indications and complications of this procedure and its effectiveness along 12 last years in our center.

Material and method: All filter placements were performed at our hospital (3rd level. 600 beds). We identified those patients who underwent inferior vena caval filter placement during 1997-2009 in order to prevent pulmonary embolism. Caval filters were placed by vascular radiologists in an angiography procedure room, with the use of imaging guidance. Inferior vena cavography was performed prior

Table 1 (T-22). Underlying disease at the time of venous thromboembolic event

Disease	Neoplasm	Diseases of the blood	Diseases of the digestive system	Diseases of the digestive system	Injury	Diseases of the nervous system	Total
N. of events	39	2	10	5	15	7	78

Table 2 (T-22). Indications for filter placement

Contraindication to coagulation (41 patients)	53%
Complication of anticoagulation (18 patients)	23%
Failure of anticoagulation (11 patients)	14%
Added coagulation (8 patients)	10%

to and following filter insertion with Seldinger technique to discard congenital anomalies of the vein and assess diameter and location of renal veins. The aim was to place the filter just below the renal veins. We analyzed demographic data, clinical characteristics of the patients including the underlying disease, nature of thromboembolic events. The type of filter, indications for the procedure, effectiveness and complications were also analyzed. Computations were performed with the use of statistical software (SPSS 12.0).

Results: During a 12-year period, 78 patients were referred for placement of a caval filter. 44.8% (35 of 78) were female with a mean age of 68.2 years. For male patients (55.2% 43 o 78 patients), the mean age was 63.4 years. Table 1 shows the underlying disease at the time of venous thromboembolism. The largest group was neoplasms (39 [50%] of 78) and other large groups were injury (15 [19.2%] of 78) and cardiovascular diseases (10 [12.8%] of 78). Contraindication to anticoagulant therapy was the most common reason for filter placement. Complication of anticoagulation, failure of anticoagulation and added protection were the others indications. Several types of permanent and temporary filters were implanted. All of them were in the infrarenal cava, close to the point of entry of the renal veins by percutaneous insertion. No major complications occurred during or immediately after the procedure, only hematomas at the puncture site, without hemodynamic impact. Imaging techniques in the follow-up of patients included conventional abdominal radiography and CT. The prevalence of postfilter pulmonary embolism was 1.28% that occurred within 48 hours after filter placement and it led to the patient's death. 10 patients died in the early months of filter placement. Neoplasia was the cause of death in 5 of them, and we could not establish the cause of deaths in other patients because of the confluence of factors as advanced age, poor general condition and severe comorbidity (diabetes, brain strokes, heart disease…). The prevalence of caval thrombosis below the filter was 2.56%. During the follow-up filters did not show significant migration, fracture o deformity.

Conclusions: Inferior vena caval filters provide protection from life-threatening pulmonary embolism with minimal morbidity but the procedure carries risk of serious complications. In recent years there has been a remarkable growth in the number of filter implantations due to the increased incidence of venous thromboembolism and the emergence of temporally filters that allow recovery after a variable period of time.

T-23
PULMONARY THROMBOEMBOLISM IN PATIENTS WITH PREVIOUS HISTORY OF VENOUS THROMBOEMBOLISM

R. Macías Casanova, A. Prolo Acosta, J. Torres Triana, L. Manzanedo Bueno, P. Crecente Otero, J.G. Rivero, S. Gómez Lesmes, A. Barbosa Ventura

Department of Internal Medicine. Hospital Universitario de Salamanca. Hospital Clínico. Salamanca, Spain.

Objectives: Determine prothrombotic risk factors in patients with diagnosis of pulmonary thromboembolism (PTE).

Material and method: This descriptive, retrospective study was done at the University of Salamanca Clinic Hospital in which 846 patients with diagnosis of PTE were analyzed from January 2009 to December 2011. Of 846 patients 93 were found with previous history of venous thromboembolism (VTE), risk factors for prothrombotic state were analyzed in those with recurrent thromboembolic disease, also signs and symptoms and the WELLS scale were determine during the beginning of the new episode.

Results: Of the 846 patients with diagnosis of PTE, 93 (10.99%) had previous history of VTE and were included in our study. 30 (32.2%) patients had risk factors for prothrombotic state; 20 patients presented with previous history of cancer and 11 presented with history of active malignant neoplasm. Solid tumors were more frequent (90%) meanwhile hematologic processes were only 10%. Primary hypercoagulable state was found in 7 (23.3%) patients and 3 (10%) cases presented history of autoimmune disease. The mean age was 73.2 and the sex distribution was 54.8% males and 45.2% females. At the moment of the acute PTE episode, 6 patients presented a high risk for PTE according to the WELLS scale, 51 patients had intermediate risk and 36 had low risk for PTE. The most frequent symptom found was dyspnea (68.8%), followed by chest pain (35.5%) and cough (15%); tachycardia was present in 23.6% of the cases at the moment of the diagnosis. 11 patients were receiving anticoagulant treatment with aceno-coumarol; 3 were in therapeutic range, 7 below the therapeutic range and 1 patient presented blood levels over the therapeutic range. 3 patients were treated with low molecular weight heparin at therapeutic dose. In 20 patients DVT was confirmed with Doppler ultrasound, of this 20 patients 35% of them did not presented any signs or symptoms of thrombosis.

Discussion: The incidence of DVT and TEP in hospitalized patients is very high. Studies show a mean annual incidence for DVT of 48 per 100,000 and for PTE 23 per 100,000. The exact incidence and mortality is unknown due to the lack of good screening and confirmatory diagnostic methods for the diagnosis of these diseases. Advanced age is the most important risk factor (the incidence of VTE exponentially in ages above 50 years). Previous history of VTE doubles or triples the risk for a new episode even in the absent of other risk factors. Other clinical entities considered risk factor for VTE are: cancer (increasing the risk if there is evidence of tumor spread and the patient is receiving chemotherapy), primary and secondary hypercoagulable states, traumas with or without bone fracture, congestive heart failure, myocardial infarction, cerebrovascular disease, sepsis, and others.

Conclusions: A high percentage of patients with pulmonary thromboembolism had previous history of venous thromboembolism. The most important risk factors are: age, history of malignant neoplasm and hypercoagulable states. The WELLS scale serves as an important diagnostic tool for PTE during the clinical suspicion in the acute episode. In patients with history of VTE and high risk factors, they should receive the option of indefinite anticoagulant therapy.

T-24
ACUTE PULMONARY EMBOLISM: DIAGNOSIS RECOGNITION AND CLINICAL OUTCOME

P. Barata[1], C. Torre[2], C. Coelho[2], R. Lucas[3], C. Patrício[2], F. Silva[2], C. Meireles[2], S. Oliveira[1]

[1]Department of Medical Oncology, [2]Department of Internal Medicine, [3]Department of Radiology. Hospital Santo António dos Capuchos, CHLC. Lisbon, Portugal.

Objectives: Acute pulmonary embolism (PE) remains a challenging diagnostic problem since it mimics other cardiopulmonary disorders. Although clinical and laboratory data are usually performed, computed tomographic pulmonary angiography (CTPA) remains the preferred imaging test for diagnosing PE. The purpose of this study was to study the prevalence of acute PE in patients suspected of having acute PE in a tertiary university hospital center (CHLC). Secondary end-point was to study possible relation between demographic, clinical and laboratory data and clinical outcome.

Material and method: A retrospective review was performed on a consecutive series of 183 patients that underwent CTPA assuming a suspected acute PE diagnose; both inpatient and outpatient were included between January 2008 and December 2011. Imaging was performed using multi-detector scans (GE and Toshiba) with 8, 16 or 64 detectors. PE was defined as pulmonary artery filling defect within a segmental or larger vessel on CTPA. Demographic and clinical characteristics were analyzed as well as laboratory tests. Follow-up data were collected on medical files or by telephone interview with patients or relatives. SPSS 17th edition was used to perform statistic analysis.

Results: Over a 4-year period, 183 patients underwent CTPA for possible acute PE, a total of 44 (24.0%) cases were positive. Mean PE rates were higher for women and patients over 65 years old, with 32 (72.7%) and 31 cases (70.5%), respectively. Bilateral PE was the most common event being present in 24 patients (54.5%) and right PE was seen in 17 patients (38.6%). Dyspnea was the most frequent initial symptom, present in 16 patients (38.1%). Tachypnea was seen in 17 (48.6%) patients at presentation and tachycardia in 13 (37.1%). Hemoptyses were not found in this population (0%) and body temperature was normal in almost every patient (95.5%). Screening testing with D-dimers was negative in only one patient (2.6%). C-reactive protein (CRP) and lactate dehydrogenase (LDH) serum levels were increased in 39 (88.6%) and 30 patients (68.2%), respectively. No relation was found between side of PE and sex, age and laboratory data. The 30-day all cause mortality was 53.8% (7/13). At 12 months of follow-up, median overall survival was 70.5% (31/44).

Conclusions: PE is a clinical relevant diagnosis with high mortality, affecting women and older people more often. The initial presentation of tachypnea, tachycardia and elevated PCR, LDH and D-dimers on admission can be used to improve diagnostic suspicion. Further studies comparing clinical outcome of the subset of patients suspected of having acute PE and excluded by CTPA will be performed.

T-25
LONG-TERM ORAL ANTICOAGULATION TREATMENT OF PATIENTS WITH DEEP-VENOUS THROMBOSIS AND MALFORMATION OF THE INFERIOR VENA CAVA

M. Fernández Quevedo[1], M. Fanlo[1], R. Barranco[2], C. Sancho[2], S. García[3], A. Romera[3], A. Riera Mestre[1], R. Pujol[1]

[1]Department of Internal Medicine, [2]Department of Angioradiology, [3]Department of Angiology and Vascular Surgery. Hospital Universitari de Bellvitge. L'Hospitalet de Llobregat (Barcelona), Spain.

Objectives: The inferior vena cava malformation (IVCM) is a rare congenital anomaly that affects 0.001-1% of the population. When associated with genetic polymorphism or other hypercoagulable states, the risk of deep-venous thrombosis (DVT) can increase. We analyzed a series of consecutive patients from our center with IVCM and DVT and their outcome with or after withdrawal long-term oral anticoagulation.

Material and method: Between 1979 and 2009 patients attended in a university tertiary care hospital with first acute lower-extremity DVT episode and subsequently found to have IVCM on computed tomography (CT) scan or magnetic resonance imaging (MRI). Patients were followed-up until April 2012. The data was collected retrospectively from medical records. Clinical variables and venous thromboembolism (VTE) recurrences were registered. Statistic analyses were calculated using SPSS v.15 software.

Results: Seven patients were included, four were men. The mean age at the diagnosis was 36.8 (range 31-51) years. In 71% of the cases (five patients) the thrombosis was bilateral. In one of the six cases analyzed we have found a thrombophilic disorder (Factor V Leiden heterozygous mutation). In four of the patients were found factors associated with VTE (smoking in three patients, oral contraceptive in one patient). One of the cases had family history of VTE. The diagnosis was done in six patients using CT scan and MRI in the remaining patient. Only one of the patients had a DVT recurrence seventeen years after oral anticoagulation withdrawal. No patient had evidence of pulmonary embolism (PE). The six patients who discontinued oral anticoagulation therapy indefinitely have had no evidence of recurrent VTE during follow-up with a mean of 22.2 (range 4-57) months.

Discussion: IVCM is a rare congenital anomaly associated with DVT in young patients, increasing the diagnostic suspicion when the thromboembolic event in such patients occurs bilaterally. The management of DVT associated with IVCM is controversial. According to our results, there is low risk of recurrence after withdrawal oral anticoagulation in DVT associated with IVCM.

Conclusions: In our series the withdrawal of oral anticoagulation treatment was safe with low risk of DVT recurrence and no case of PE.

T-26
INCIDENCE OF VENOUS THROMBOEMBOLISM IN MALIGNANT PLEURAL EFFUSIONS AND IMPACT ON SURVIVAL

M. Civit, S. Bielsa, J. Porcel

Department of Internal Medicine. Hospital Universitari Arnau de Vilanova. Lleida, Spain.

Objectives: 1) To know the incidence of thrombotic events (TE) in patients with malignant pleural effusions (MPE), according to the primary tumour. 2) To compare the survival in 3 groups of patients: 1) MPE without TE, 2) MPE with TE before or at the diagnosis of MPE and 3) MPE with TE during chemotherapy.

Material and method: Retrospective study of all patients who were diagnosed of MPE in a university hospital (Lleida, Spain) between January 2006 and February 2012.

Results: Two-hundred and twenty-five patients with MPE were included, of whom 29 (13%) developed a TE (17 pulmonary embolisms and 14 deep venous thrombosis). Nineteen TE appeared less than 1 year before MPE diagnosis and 10 were directly related to the chemotherapy agents (8 platinum analogues and 2 gemcitabine). Lymphoma and gastrointestinal cancers were the tumour types more frequently associated with thromboses (Table). The survival of patients with MPE without TE was 203 days, compared with 104 days among patients with TE before or at the diagnosis of MPE ($p = 0.05$). The survival of patients who developed TE during chemotherapy was 184 days.

Discussion: There are no studies analysing the frequency of TE in patients with MPE. Thrombosis has been classically considered as a

Table 1 (T-26). Incidence of venous thromboembolism in malignant pleural effusion

Tumor origin	No. of patients	No TE No. (%)	TE before MPE No. (%)	TE during chemotherapy No. (%)
Lung	84	71 (85)	8 (10)	5 (6)
Breast	39	37 (95)	1 (3)	1 (3)
Unknown primary	21	18 (86)	2 (10)	1 (5)
Lymphoma	18	15 (83)	3 (17)	0
Gastrointestinal	15	11 (73)	2 (13)	2 (13)
Others	48	44 (92)	3 (6)	1 (2)
Total	225	196 (87)	19 (8.5)	10 (4.5)

poor prognosis factor in cancer, although in our study this was true only in cases of thrombosis not related with chemotherapy.

Conclusions: Up to 13% of the patients with MPE developed a thrombotic event, particularly in lymphomas or gastrointestinal cancers. Thrombosis not related with chemotherapy appeared to be a poor prognostic factor in patients with MPE.

T-27
VENOUS THROMBOEMBOLIC DISEASE IN A COMMUNITY HOSPITAL

P. Olcina Lloret, N. Lozano Cortell, M. Gomis Mascarell, N. Macias Vega, S. Pintos Martínez, P. Martín Rico

Department of Internal Medicine. Hospital de Dénia. Dénia (Alicante), Spain.

Objectives: Analysis of clinical and epidemiological characteristics and secondary complications of patients admitted to internal medicine department with a diagnosis of venous thromboembolism (VTE) in a period of 3 years.

Material and method: Retrospective analysis using medical records of patients admitted to our hospital from January 2009 to December 2011 with a diagnosis of VTE at discharge. Analysis using SPSS 20.

Results: Of a total of 143 patients, 81 (56.6%) were male, mean age of 69.19 years (range 23-97 years). VTE presented a history of 20.3%. The risk factors were: bed rest and immobilization 23.1%, 21.7% malignancy, recent major surgery 11.2%, 6.3% COPD, travel and DM 3.5% respectively, previous trauma, congestive cardiac and catheters 2.8% respectively, obesity and venous insufficiency 2.1%, stroke and previous hormone treatment 1.4% respectively. Of the cases analyzed, 51% were pulmonary thromboembolism (PE), 30.1% deep vein thrombosis, preferably with proximal location (77.1%) and 18.9% both simultaneously. Thrombophilia was performed at 30 21.3%. D dimer was determined in 121 patients (84.6%). Was negative in only 4 patients. The treatment used was the low molecular weight heparin (LMWH) 58.7%, 40.6% followed by acenocoumarol, fondaparinux in one case, and in only one case was thrombolysis. The relapse rate was 6, 3%. Hemorrhagic complications 4.2%; 4.2% were exitus. The average stay was 8.6 ± 5 days.

Discussion: VTE is a relevant disease. The most common styles are PE and DVT. We found a similar distribution in age and sex, according to literature. We describe the presence of risk factors in over 85% of patients, the most common are immobilization, malignancy and recent history of major surgery. The most widely used diagnostic procedure remains CT angiography of pulmonary arteries, sought after high clinical suspicion. The treatment of choice is LMWH and oral anticoagulants in proportions similar to those obtained in our analysis. In the literature reviewed, the average stay ranges from 9 to 13 days for VTE, being less in our case. Mortality is similar to that described in the literature.

Conclusions: VTE is a disease very prevalent in our environment, especially in institutionalized elderly patients with reduced mobility, with high morbidity and mortality, it forces us to make a correct prophylaxis. It is important to individualize the management and treatment of our patients to avoid complications.

T-29
THE MANAGEMENT OF CHILDREN`S THROMBOSIS BY THE INTERNAL MEDICINE PHYSICIAN

A. Hernández Molina, V. Rosa Salazar, M. Hernández Contreras, M. García Méndez, B. García Pérez

Department of Internal Medicine. Hospital Universitario Virgen de la Arrixaca. Murcia, Spain.

Objectives: Describing the patient care of children consulted to specific venous thromboembolism disease (VTE) Unit dependent of the Internal Medicine Department by the pediatric unit during the period of one year.

Material and method: We report four cases of deep vein thrombosis (DVT) found in children aged between 2 and 4, accepted to the pediatric services of our hospital.

Results: In all of the four cases it was the first VTE episode. In 2 cases thrombosis was located in the cerebral sinovenous (CSVT), another in the upper limb (right internal jugular) and the last in both territories (right internal jugular and cavernous sinus). Three of the four cases involved a secondary thrombosis, with an infection of the orofacial area as the only precipitating factor and in the other case no predisposing factor was founded. In all of them the management was the same: due to suspected diagnosis in addition to a positive value of D Dimer in the coagulation test, we confirmed de diagnosis of DVT with imaging: compression ultrasound, magnetic resonance (MRI) and magnetic resonance angiography (MRA) and treatment was started with low-molecular weight heparin (LMWH); subcutaneous enoxaparin with dose of 1 mg per kg every 12 hours monitored to a target AntiXa activity range of 0.5 to 1.0 units/mL. The clinical progress was appropriate and after initial anticoagulation we proposed maintaining the treatment with LMWH for 3 months in ambulatory mode, with subsequent change to an only daily dose of enoxaparin adjusted to 1.5 mg/kg after verifying proper anticoagulation levels of AntiXa.

Discussion: We conducted regular surveillance of the patients in a specialized VTE unit. During the follow up, new imaging was included and also coagulation tests with D-Dimer as well AntiXa levels. A study of thrombophilia was applied to all patients, once made discontinuation of enoxaparin treatment after a three-months anticoagulant therapy, In the 3 cases in which venous thrombosis was secondary to an infectious cause, both values of D Dimer and imaging tests had normalized, so, after getting a negative thrombophilia study, anticoagulation was discontinued definitely. In the only the case in which there was found no predisposing factor for thrombosis, including the negative thrombophilia study, we assume the episode as an idiopathic DVT. A new MRA compared with the older ones showed changes suggestive of chronic CSVT and the lab tests revealed a weakly positive D-Dimer. After considering risk-benefit, it was decided to suspend anticoagulation and closely review the patient. At the first visit, just one month after discontinuation of LMWH, D Dimer remained stable and a year later our patient has not presented symptoms or signs suggestive of recurrent thrombosis.

Conclusions: The internal medicine physician as consultant and as a fundamental part of cross-department units, short-stay or

home care units but especially when working in specific care units for treatment of diseases such as VTE, should be familiar with the management of patients like children, who were not traditionally assisted by this specialty. Children who have problems related with thrombosis, although this is an uncommon pathology at that age, benefit from a first care and follow-up carried out jointly by pediatricians and physicians experienced in the treatment of VTE.

T-31
CHRONIC THROMBOEMBOLIC PULMONARY HYPERTENSION

J. Alonso Martínez[1], F. Anniccherico Sánchez[1], S. Pérez Ricarte[1], M. Urbieta Echezarreta[1], F. Olaz Preciado[2]

[1]Department of Internal Medicine A, [2]Department of Cardiology. Hospital de Navarra. Pamplona/Iruña (Navarra), Spain.

Objectives: Chronic thromboembolic pulmonary hypertension (PH) (class 4 of current classification of PH) is defined as mean pulmonary-artery pressure (MPAP) greater 25 mmHg that persists 6 months after pulmonary embolism is diagnosed, and it has a prevalence of 2-4%. Typically, patients have a honeymoon period after acute pulmonary embolism without symptoms despite the existence of pulmonary hypertension, and its natural history is not well-known.

Material and method: In consecutive patients diagnosed of acute pulmonary embolism by chest computed tomography angiography (CTA), a trans-thoracic echocardiography with doppler imaging was made in order to evaluate data of pulmonary hypertension (right ventricular dilatation, hypertrophy and hypokinesis, right atrial enlargement, right ventricular pressure overload signs) and to measure systolic pulmonary pressure (mean gradient method) and to calculate mean pulmonary pressure applying the Chemla equation (0.61 × systolic pulmonary artery pressure + 2 mmHg). We interpretate as pulmonary arterial hypertension when one or several factors above mentioned, or mean pulmonary artery pressure > 25 mmHg were present. We also recorded data related to gaseous exchange, plasma ProBNP and troponin values and clinical antecedents of previous cardiac and chronic respiratory disease and resolution of pulmonary thrombi evaluated by (CTA). Dyspnea was categorized with NYHA class.

Results: Sixty eight patients were evaluated, mean age 70 ± 13 years, men 32 (47%). Previous cardiac disease occurred in 9 patients and chronic respiratory disease in 2 patients in which pulmonary hypertension were shown and they were ruled out for evaluation. Thus, 18 (31.5%) patients had some degree of PH, while 39 patients had normal MPAP and right ventricular function. Globally, echocardiography was made in a median time of 4 (interquartile range 8) months after acute episode. In patients with some data of PH echocardiography was made 6.25 ± 6 months after acute episode. Echocardiography showed a dilatated right ventricle in 9 patients, hypertrophic right ventricle 2 patients, right ventricular hypokinesis 2 patients, tricuspid regurgitation in 3 patients and right atrial enlargement in 2 patients. Systolic pressure of pulmonary artery was recordable in 47 patients (mean 41.08 ± 14.84 mmHg) with a mean pulmonary artery pressure of 26.4 ± 8.98 mmHg. Patients with PH had plasma Pro-BNP 873 (IQR 1,891 ng/l, delay in diagnosis 9 (IQR 19) days, PaO_2 58.76 mmHg, $PaCO_2$ 32.97 mmHg, and A-aO_2 49.33 mmHg; while patients without PH had plasma Pro-BNP 527 (IQR 1,803) ng/l (p = 0.07), delay in diagnosis 7 (IQR 12) days (p = 0.05), PaO_2 65.54 mmHg (p = 0.09), $PaCO_2$ 36.31 mmHg (p = .07) and A-aO_2 39.44 mmHg (p = 0.019). MPAP in patients with PH was 28.93 ± 4.62 mmHg, while in patients without PH was 20.40 ± 2.86 (p < .001) In patients with PH, NYHA class was I 6 (33%) patients, II 8 patients, III 2 patients and IV 2 patients while patients with normal MPAP and right ventricular function was I 23 (59%) patients, II 15 patients, III 1 patients and any patient in class IV. The proportion of patients in NYHA class I was lower in the cases of PH (p = 0.05, 95%CI -0.05-0.56). Sixteen (89%) patients with PH had clinically evident deep venous thrombosis, while 23 (59%) patients without PH had deep venous thrombosis (p < 0.01).

Conclusions: Chronic thromboembolic pulmonary hypertension could be more prevalent than the previously accepted despite the good functional status of the patients. Patients with deeper failure in gaseous exchange and clinically evident DVT could have a greater risk to develop future PH.

T-32
VENOUS THROMBOEMBOLIC DISEASE. ANALYSIS OF 300 CASES ADMITTED TO A METROPOLITAN HOSPITAL IN MURCIA

E. García Villalba, M. Egea Campoy, C. Rosa García, A. Pérez Pérez, F. Sarabia Marco, C. Aguirre Martínez, M. Meseguer Frutos, F. López Andreu

Department of Internal Medicine. Hospital General Universitario Reina Sofía. Murcia, Spain.

Objectives: Explain the epidemiological, clinical, analytic, therapeutic characteristics and secondary complications in patients with venous thromboembolic disease admitted to a metropolitan hospital in Murcia.

Material and method: We conducted a retrospective study of a series with 300 patients admitted to General Hospital Reina Sofia University of Murcia, between years 2009-2011, whose primary or secondary diagnosis shows venous thromboembolism (VTE) in some of its manifestations. Statistical analysis was performed using SPSS 15 for Windows.

Results: Of the total series studied (n = 300), 46.3% were male and 53.7% female with mean age 68.5 ± 35.5 years. The 16.3% of patients had a VTE history and only 3.7% had a family history. Among the most common risk factors, we have to stress prolonged immobilization (29.7%), obesity (26%), existence of chronic venous insufficiency (21.7%), diabetes mellitus (20.7%), smoking habit (18.8%) and existence of simultaneous neoplasia (15.2%). 14% of patients had a stroke history, 13% had heart failure and 9% had lung disease. Less frequently, we found other risk factors such as history of major surgery (9.1%), use of hormone therapy (6%), trauma history (6%), use of intravascular devices (4%) and history of more than 6-hour trip (1.7%). From the sample, 44.7% were diagnosed with deep vein thrombosis (DVT), 37.7% of pulmonary embolism (PE) and 17.6% of both simultaneously. Thrombophilia was performed in 30.3% of cases being positive 10.7%, with predominance of the positivity of anticardiolipin antibodies and lupus anticoagulant. Inpatient treatment at the beginning was mostly with low molecular weight heparin (LMWH) (95.3%) compared to sodium heparin (4%). From analytical alterations, it is remarkable the negativity of D-dimer in 3 patients. Major bleeding complications appear in 6% of cases and lower bleeding in 5.3%. At discharge, most patients (75.3%) were treated with acenocoumarol. Relapse rate was 3.7% during treatment and only 4 patients after treatment. The average stay was 12.46 ± 25 days, with an average DRG weight (Diagnosis Related Groups) of 1.56. The hospital mortality was 9%.

Discussion: VTE is a significant public health problem and an important cause of avoidable death, with an incidence of 0.1%. Most common presentation is DVT and PE. The distribution by sex and age observed in our study is similar to the literature reviewed, with a slightly higher prevalence in women. Approximately 80% of patients with VTE has any risk factors, being the most common: prolonged immobilization or bed rest (45%), major surgery (34%), neoplasms (34%), history of VTE (18-30%), stroke or heart failure (10.8%) and hormonal treatment (9.4%). We found a similar distribution of risk factors, being remarkable the high value in history of cardiovascular risk and chronic venous insufficiency and lower frequency in history of neoplasm, surgery, prolonged bed rest

and congenital thrombophilia. The most widely used treatment described is LMWH (96%) and oral anticoagulants (76%), with similar proportions in our analysis. The average stay described is 9 and 13 days in DVT and PE, respectively, being necessary to consider including all VTE (both DVT and PE) and the high weight of DRG in longer stays that are present in our study. Exitus rate similar to the one observed in the literature.

Conclusions: In VTE, it is especially important exposure to risk factors both hereditary and acquired. Our study highlights the low prevalence of a history of prolonged bed rest, major surgery and neoplastic disease. The determination of D-dimer has a high negative predictive value, being remarkable the negativity in 3 patients in our series.

T-33
RELATIONSHIP BETWEEN CLINICAL VARIABLES AND GENETIC THROMBOPHILIC DISORDERS IN PATIENTS WITH VENOUS THROMBOEMBOLIC DISEASES

M. Pérez Pinar[2], I. García Cuartero[1], J. Solís García del Pozo[2]

[1]Department of Internal Medicine. Hospital General de Albacete. Albacete, Spain. [2]Department of Internal Medicine. Hospital General de Villarobledo. Albacete, Spain.

Objectives: Our aim is to check the relationship among different risk factors or clinical symptoms in patients with venous thromboembolic disease (VTD) and different genetic alterations.

Material and method: We have reviewed the medical records of patients with VTD, diagnosed at the hospital of Villarrobledo (Albacete, Spain) since its opening in 2007 until the present. We have collected data of patients with a thrombophilia study which determined a mutation in genotype of factor V Leiden, prothrombin genotype and MTHFR genotype as well as a deficit of protein C, protein S, and antithrombin III. We have collected clinical variables such as age, presence of malignancy, oral contraceptive use, obesity, bed resting prior to the VTD, presence or absence of pulmonary embolism, bilateral deep vein thrombosis (DVT), need for intensive care unit (ICU) admission. The frequency of genetic alterations and relationship among clinical variables collected and genetic alterations are described.

Results: We identified 122 patients. Out of these 122 patients, 21 (17.2%) had a malignancy, 67 (54.9%) were male and 21 (17.2%) had previously suffered another episode of VTD. Only 1 case (0.8%) was heterozygous carrier of factor V Leiden mutation, 10 cases (8.2%) were carriers of mutation of the prothrombin gene and 21 cases (17.2%) were homozygous for MTHFR mutation. Decreased levels of protein C were detected in 12 patients (9.8%) and decreased levels of protein S were detected in 27 patients (22.1%). Deficiency of antithrombin III level was found in 12 patients (9.8%). One of these disorders was found in forty one patients (33.6%), two of them were found in 10 patients (8.2%), three of them were found in 6 patients (4.9%) and four conditions were found simultaneously in one patient (0.8%). A possible relationship between the presence of at least one of these disorders and a history of malignancy ($p = 0.054$) was detected. Besides, a relationship between patients who suffered VTD after bed rest over 4 days with the presence of some of these thrombophilic disorders was also detected ($p = 0.006$). Out of the four patients who had bilateral DVT, one of them had three of these genetic disorders, a second patient had two of them and a third one had four of these disorders. It seems there is a relationship between the history of more than one episode of VTD with protein C deficiency ($p = 0.051$) and antithrombin III deficiency ($p = 0.003$). No differences were found between genetic alterations with other clinical variables such as age, sex, presence or absence of pulmonary embolism and need for ICU admission or death.

Discussion: This study asks about the relationship between some clinical data with the presence of genetic abnormalities predisposing to VTD. The fact of the coexistence of risk factors such as prolonged bed rest or neoplasm does not rule out the presence of these genetic alterations. These abnormalities may be responsible for the development of deep vein thrombosis as well as other risk factors present in these patients.

Conclusions: Certain clinical features may be related to underlying genetic alterations in VTD. The presence of certain risk factors does not exclude the possibility of genetic predisposition for thrombosis as an added risk factor.

T-34
IS THROMBOPROPHYLAXIS DONE CORRECTLY TO THE INTERNAL MEDICINE PATIENTS OF THE REGION OF MURCIA'S HOSPITALS?

L. Guirado Torrecillas[1], V. Rosa Salazar[1], A. Verdú Berenguer[2], M. Torralba Saura[3], J. Trujillo Santos[4], S. Herrera Adán[4], M. Artero Castro[4], G. Tornel Sánchez[4]

[1]Department of Internal Medicine. Hospital Universitario Virgen de la Arrixaca. Murcia, Spain. [2]Department of Internal Medicine. Hospital Virgen del Castillo. Yecla (Murcia), Spain. [3]Department of Internal Medicine. Hospital Universitario Morales Meseguer. Murcia, Spain. [4]Department of Internal Medicine. Hospital Universitario Santa Lucía. Cartagena (Murcia), Spain.

Objectives: To evaluate the thromboprophylaxis (TP) in medical patients admitted to Internal Medicine Services (IMS) in several hospitals in the Region of Murcia both at the admission time and during their hospital stay.

Material and method: A multicenter observational study has been performed in four Spanish hospitals of the Region of Murcia about prophylaxis for venous thromboembolism (VTE) scheduled to patients admitted from the emergency services in the IMS during the month of November 2011. Five consecutive patients were selected daily from Monday to Friday where the TP was assessed after being scheduled by their physicians (unaware of the study) according to the parameters indicated on the Pretemed Scale (PS)

Table 1 (T-34). Pretemed criteria

	Low risk (1st day)	High risk (1st day)	Low risk (4th day)	High risk (4th day)
Not prescribed TP	52 (35%)	30 (21%)	58 (39%)	43 (30%)
Prescribed TP	97 (65%)	112 (79%)	91 (61%)	99 (70%)

Table 2 (T-34). Medenox criteria

	Low risk (1st day)	High risk (1st day)	Low risk (4th day)	High risk (4th day)
Not prescribed TP	49 (40%)	27 (18%)	60 (49%)	36 (24%)
Prescribed TP	73 (60%)	122 (82%)	62 (51%)	113 (76%)

and the criteria of Medenox (MX) and Exclaim studies. The hospitals that participated in the study were: Morales Meseguer (HMM) and Virgen de la Arrixaca (HUVA) from Murcia, Santa Lucia (HUSL) from Cartagena, and Virgen del Castillo (HVC) from Yecla.

Results: A total of 396 patients were evaluated. 105 (27%) of them were anticoagulated and they were not included in the TP study. Tables 1 and 2 show the data for the included 291 patients. The prescription of TP on admission (day 0) was: 204 drug (70%), 5 mechanical (1.7%), 82 not prescribed prophylaxis (28%). The prescription on the 4th day was: 186 drug (64%), 4 mechanical (1.4%) and 101 unprescribed (35%).

Discussion: The previous study showed the underutilization of TP in medical patients. There are several guides in the literature used to frame the risk of VTE in medical patients; the Spanish PS guide and the internationally validated MX are the most used ones. Data from our study, based on both guides, show that TP regimen figures for patients at high risk have increased from the previous studies (79% PS, 82% MX), dropping these figures on day 4 of hospitalization (65% PS, 76% MX) without any apparent cause that justifies it. Some, even more concerning, figures are obtained by analyzing patients at low risk for VTE where we see that TP is predicted in very high figures both at admission (65% PS, 60% MX) and on day 4 (61% PS, 51% MX).

Conclusions: According to PS and MX guidelines, the absence of TP in patients at high risk for VTE in the IMS in our region at admission time and during hospital stay is lower than in published studies but there is a fairly high percentage (> 50%) of patients at low risk that receive it even when they should not receive it, both at their arrival and during their stay in our services. The low use (< 2%) of physical measures is a common pattern in all our patients. To sum up, we might say that inadequate thromboprophylaxis is greater in excess than in defect.

T-35
LOW-MOLECULAR-WEIGHT HEPARINS IN VTE PREVENTION - AN INQUIRY IN INTERNAL MEDICINE WARD

T. Garcia, P. Cachado, Z. Vesza

Department of Internal Medicine 4. Hospital de Santa Marta - CHLC. Lisboa, Portugal.

Objectives: It's well known that low-molecular-weight heparins (LMWHs) have proven effectiveness in the prevention of venous thromboembolism (VTE), being VTE responsible for high morbility and mortality during in-hospital admittance. Prevention has the best cost-effectiveness ratio. Nevertheless, published data has shown that just about half of the patients that should be taking LMWHs are in fact doing so. Taking these facts into account, the authors will present the prevalence for the prescription of LMWHs in an Internal Medicine ward and its relationship with the adapted algorithm from the ACCP 2008 guidelines for VTE prevention.

Material and method: The authors applied an inquiry that was carried out without prior notification and included all patients admitted at the time in this Internal Medicine ward. Adaptted algorithm in accordance to the ACCP guidelines 2008 was applied.

Results: Study included 27 patients – 61% male; average age of 74.7 years (13 patients older than 80 years-old). The average admittance time was 9.7 days. Of the 27 patients, 16 were under LMWHs and they all fulfilled the criteria for prevention. Of the other 11 patients that weren't, we concluded that 9 should have been, according to the ACCP algorithm; nevertheless 3 of them were under oral anti-coagulation, 2 with anti-platelet therapy and the other 2 presented thrombocytopenia. With respect to dosage, the majority of the patients were under prophylactic dose (14 patients) - 12 under 40 mg and 2 under 20 mg (renal insufficiency with GFR less than 30), once daily.

Discussion: The authors call attention to the fact that 10-30% of in-ward patients develop one or more presentations of VTE. In spite of this data, not all the patients are submitted adequate prevention. In this inquiry 89% of the patients had criteria for VTE prevention therapy and 65% of them were in fact doing so. Of the 35% of patients that weren't under prevention therapy we concluded that 3 had anti-coagulant therapy and 2 had thrombocytopenia, conditions that increase the hemorrhagic risk.

Conclusions: The results presented, although encouraging, reinforce the need of calling attention to the problem and to the established protocols taking into account the high efficacy of this preventive measure and VTEs high mortality.

T-37
EPIDEMIOLOGIC ANALYSIS OF PULMONARY EMBOLISM IN AN INTERNAL MEDICINE DEPARTMENT

L. Pérez Lluna, I. Torres Resta, B. Antequera, C. Castellanos, M. Escrivà, P. Gimeno, P. Porcar, A. Saura

Department of Internal Medicine. Hospital Sagunto. Sagunto (Valencia), Spain.

Objectives: The aim of this study is the knowledge of the risk factors of pulmonary embolism, as well as the presentation, complications and mortality of these patients.

Material and method: We retrospectively reviewed the medical records of patients admitted for pulmonary embolism, during the period between January 2010 and January 2011. Data on risk factors, comorbidity, clinical presentation, complications, treatment and outcome were collected from clinical history. Clinical probability scales Wells and Ginebra were used. To perform the analysis the statistical package SPSS version 19.0, for qualitative variables, have been calculated frequency tables, while for quantitative measures of central tendency most common location.

Results: A total of 41 patients were diagnosed of pulmonary embolism during the period of the study; 68% of whom are women (28), with a mean age of 73 (31-97). Age > 75 years (66%) was the risk factor more frequent collected followed by neoplasm (31.7%), immobilization of more than 4 days (22%) and previous deep venous thrombosis (14.6%). The most common symptom of presentation was dyspnea (87%), followed by deep vein thrombosis (31.7%), syncope and pleuritic pain (22%), fever (19.5) and hemoptysis (19.4%) As for the chest X-ray, the most common radiological finding is pleural effusion (17.1%), followed by pulmonary infiltrates (14.6%), although most of them had a normal chest radiograph (58, 5%). The most frequent ECG finding was the right bundle branch block (14.6%), followed by alterations of repolarization in right precordial leads (12.2%), pattern SIQIIITIII (7.3%), and atrial fibrillation (4.9%). Analytically noted that 100% of patients have a higher D-dimer to 0.5. Regarding the arterial blood gas analysis, 41% have respiratory failure at admission (17). The distribution of patients by clinical probability scales were for Wells scale: low probability 9 (22%). Intermediate probability 25 patients (61%), and high 6 patients (14.6%). And for Ginebra scale: low probability 13 (31.7%), intermediate risk 23 (56.1%), and high probability 1 (2.4%). Regarding computerized axial tomography central artery embolism were found in 26 patients (63%), lobar arteries embolism in 27 patients (65.9%), and segmental arteries embolism in 6 patients (14.6%). Regarding treatment 24 patients (43.9%), were treated with LMWH followed by acenocoumarol, 14 patients (34%) were treated with LMWH most of them had an active neoplasm. Only in 3 (7.3%) patients fibrinolysis was indicated. 5 patients (12%) died.

Conclusions: The risk factor most associated with pulmonary embolism, was age over 75 years. The most common symptom was dyspnea, the majority RX and ECG had not pathological findings. Most commonly arteries affected were central and lobar. The most frequently used treatment is LMWH followeb by acenocoumarol. Only 12% of patients died.

T-38
PROPHYLAXIS FOR THROMBOEMBOLIC DISEASE AT DISCHARGE

M. Martínez[1], G. Muñoz Gamito[2], I. Arancibia Freixa[2], A. Álvarez Soto[2]

[1]Department of Intensive Care, [2]Department of Emergency Medicine. Hospital Mutua de Terrassa. Barcelona, Spain.

Objectives: Prophylaxis for thromboembolic disease (TD) in hospitalized patients with PRETEMED index ≥ 4 has proven to be effective. However, their effectiveness at discharge is not well established. The aim of our study is to describe the characteristics of patients admitted for major thromboembolic event (MTE).

Material and method: Retrospective descriptive study. From 1st January 2010 to 31st December 2011, we identified all patients admitted to our center with diagnosis at discharge of MTE (pulmonary embolism –PE- or deep vein thrombosis (only femoral and popliteal)-DVT-). Demographic data (age and gender), PRETEMED index, previous hospitalization (PH) within the previous 12 months, the reason for admission, length, prophylaxis at discharge or not, time to MTE and 30-days mortality were reported.

Results: 172 patients presented MTE (112 PE, 60 DVT). The median age was 70 ± 16 years old and 48% were men. The most frequent risk factors were age > 60, neoplasm, immobilization > 4 days and prior TD in 73%, 23%, 20% and 16%, respectively. 70 patients (41%) had PH. The most common reasons of income were traumatology (21%), pneumological (17%) and cancer (14%). TD represented 6%. The median income was 9.7 ± 8.1 days and 14% were prescribed prophylaxis at discharge. 58% of the patients with PH, presented the MTE within 30 days. The global PRETEMED index was 3 ± 2 points (2.7 if no PH vs 3.3 in PH, $p > 0.05$). Mortality at 30 days was 7% in no PH vs 15% in PH patients ($p > 0.05$).

Conclusions: The most common risk factor in patients with MTE was the age. Nearly half of patients with MTE have a history of PH, especially within the first month. However, no prophylaxis at discharge is prescribed. According to our study, it would seem advisable to assess prophylaxis at discharge in patients with high PRETEMED index. More studies in this regard, with larger samples are needed.

T-39
VENOUS THROMBOSIS, DON´T LOOK AT THE LEGS, DO IT IN TO THE ABDOMEN!

C. Smilg Nicolás, M. Artero Castro, S. Herrera Adán, A. Trujillo Santos, G. Tornel Sánchez, J. Vega Cervantes, A. Moreno Hernández, M. Mozo Cuadrado

Department of Internal Medicine. Hospital General de Área Santa María del Rosell. Cartagena (Murcia), Spain.

Objectives: To know the clinical features, diagnosis and treatment of a rare cause of persistent venous thrombosis of the left iliac.

Material and method: A two diagnosed cases report in 2011 at "Hospital de Santa Lucía", Cartagena.

Results: Case 1: A 33-year-old woman consults to our department for a left lower limb swelling that lasted for a week. She had a L4-L5 herniated disc and she was taking oral contraception for the last 10 years. When the swelling started she associated it to her disc disease, so she rested and took painkillers. A week later, she checked for persistent pain and swelling in the left lower limb. A Doppler ultrasound was performed showing a deep vein thrombosis (DVT) of the left iliac and superficial femoral vein and she was treated with acenocumarol. 3 and 6 months control Doppler showed persistence of thrombus. In order to study the persistence of the thrombus, we asked for an abdomino-pelvic CT which reveals extrinsic compression of the left common iliac vein at its origin – between the right common iliac artery and the spine. Case 2: A 22-year-old woman consults to our department about persistent pain in her left thigh. She had a right hemithyroidectomy for a thyroid nodule. She had been using a vaginal ring (etinilestradiol-etonogestrel) during the last year. The examination revealed an increase in left thigh perimeter, erythema, also warmth and pain at palpation. A Doppler ultrasound showed venous thrombosis in the common and superficial femoral; left distal superficial femoral vein; proximal arch of great saphenous vein and external iliac. Due to the location of proximal thrombosis we decided to ask for an abdomino-pelvic CT to keep up with our study. That CT shows acute venous thrombosis in iliac sector common femoral and superficial, with stenosis of the iliac vein origin, mostly caused by extrinsic compression between the right common iliac artery and the spine.

Discussion: The May-Thurner syndrome is a deep venous thrombosis of the left iliofemoral vein being compressed between the right primitive iliac artery and the fifth lumbar vertebrae. The friction between both vessels and the constant transmission of the pulse of the artery over the vein produces an irritation on the endothelium, therefore it proliferates. This fact predisposes to thrombosis. The May-Thurner syndrome could be responsible of 1 to 5% of DVT. Diagnosis is made by CT, but the gold standard is flevography. Being diagnose, if there are no contraindications, it may start oral anticoagulation at least for 6 months. Nowadays, new therapeutic techniques, such as direct thrombolysis catheterization and stent placement, are been tested.

Conclusions: We should keep in mind May-Thurner syndrome as a possible cause of left iliac vein thrombosis. It should be highly suspected in patients with symptoms of persistent edema and pain in the left leg.

T-40
PHARMACOLOGICAL VENOUS THROMBOPROPHYLAXIS (PVT) IN INTERNAL MEDICINE (IM). DOSAGE ANALYSIS

M. Torralba[1], V. Rosa[2], L. Guirado[2], S. Herrera[3], M. Artero[3], G. Tornel[3], J. Trujillo[3], A. Verdú[4]

[1]Department of Internal Medicine. Hospital Universitario J.M. Morales Meseguer. Murcia, Spain. [2]Department of Internal Medicine. Hospital Universitario Virgen de la Arrixaca. Murcia, Spain. [3]Department of Internal Medicine. Hospital Santa Lucía. Cartagena (Murcia), Spain. [4]Department of Internal Medicine. Hospital Virgen del Castillo. Yecla (Murcia), Spain.

Objectives: Evaluation of the doses of PVT administrated in IM and the implementation of the guidelines.

Material and method: Observational study of PVT in patients admitted in IM departments of 4 hospitals in the region of Murcia, in November 2011. We recruited 5 patients that were admitted daily from Monday through Friday, without the knowledge of the doctors assigned to each of them. Using the treatment sheets, the PVT and the doses was compared according to the Pretemed parameters during the 1st and 4th day of admission. Renal failure was defined as a creatinine level greater than 1.3. Patients anticoagulated for other reasons were excluded from the study.

Results: Of a total of 291 patients, PVT was administered to 205 (70%) of them, these are the subjects included in the study. The most commonly used drug for prophylaxis was enoxaparin (95%), with doses ranging from 20 to 160 mg daily, nonetheless 90% corresponded to the 20 mg (17%) dose and 70% to 40 mg. Second most commonly used drug was bemiparin 3,500 units in 4%. Table 1 shows the dose according to risk on the 1st and 4th day after admission.

Discussion: In our study, the doses of PVT used vary among patients, although the most current doses are 20 and 40 mg of enoxaparin. In high-risk patients the dose administered (40 mg) is adequate in 80%, and up to 90% is considered correct if the 20 mg dose is used in patients with renal impairment. The prescription does not change during the first days of admission, which may reflect a lack of reconsideration of this matter.

Conclusions: 1) 90% of the high-risk patients hospitalized in Internal Medicine department receives the correct dose of pharmacological venous thromboprophylaxis.2) A high percentage of the low-risk patients receive a similar dose of pharmacological thromboprophylaxis as high-risk patients. 3) The dosage of venous thromboprophylaxis does not often change during the first days of hospitalization.

Table 1 (T-40)

Day 1	Low risk	High risk	Total
40 mg/day (or 3,500 IU)	70(74%)	88(80%)	158
Other dosage	25(26%)	22(20%)	47
p = 0.28	95(46%)	110(54%)	205
4th day			
40 mg/day (or 3,500 IU)	68(74%)	73(76%)	141
Other dosage	24(26%)	23(24%)	47
p = 0.74	92(48%)	96(51%)	188

EVALUATION OF THROMBOPHILIA SCREENING IN A TERTIARY HOSPITAL OF THE METROPOLITAN AREA OF BARCELONA

G. de la Red[1], E. Niño[1], B. Batalla[1], Y. Loza[1], N. Jové[1], A. Culla[1], M. Torres[1], I. Portal[2]

[1]Department of Internal Medicine, [2]Department of Hematology. Fundació Hospital de l'Esperit Sant. Barcelona, Spain.

Objectives: To determine the most frequent abnormalities in the thrombophilia screening among patients who have suffered a thrombotic event in a metropolitan area of Barcelona, Spain.

Material and method: The results of all consecutive, thrombophilia studies of the last two years (2010 and 2011) were obtained by the service of Hematology of our Hospital. All of them belonged to patients who had thrombosis. There were analyzed the frequency and type of alterations of hemostasis. In the study of thrombophilia was analyzed protein C, protein S, antithrombin III, factor V Leiden mutation, mutation of the prothrombin gene G20210A, lupus anticoagulant, anticardiolipin antibodies IgG and IgM, anti-beta-2-glycoprotein IgG and IgM antibodies, and homocysteine.

Results: A total of 74 patient samples were included in a thrombophilia screening during the following years 2010 and 2011 at the Esperit Sant Hospital, Santa Coloma de Gramenet, Barcelona, Spain. Among the 74 patients, 48 (64.87%) were females and 26 (35.13%) were males. The medium age was 51.82 years (range 16-80). Half of the patients (37) had any alteration in the thrombophilia study. Protein S was analyzed in 59 patients and 4 (6.78%) had protein S deficiency. Protein C was analyzed in 58 patients and 1 patient (1.72%) had its deficiency. Antithrombin III was analyzed in 61 patients, and 3 patients presented antithrombin III deficiency. Factor V Leiden mutation was analyzed in all 74 patients, appearing in 10 patients (13.51%), all of them heterozygotes. G20210A prothrombin gene mutation was analyzed in 66 patients, appearing in 4 patients (100% heterozygous). 1 patient had both mutations simultaneously. Lupus anticoagulant was analyzed in 63 patients, being positive in 12 (19.5%). Anticardiolipin antibodies were analyzed in 70 patients, 17 of them (24.28%) were positive, 7 (10%) IgG positive, and 10 (14.28%) IgM positive. Anti-beta-2-glycoprotein antibodies were analyzed in 14 patients, being IgG positive only in one patient (7.14%). In 64 patients homocysteine was analyzed, being altered in 13 (20.31%), 12 (92.31%) of whom had vitamin deficiency and 1 patient (7.69%) was heterozygous.

Discussion: The thromboembolic disease is a serious clinical problem because of its high incidence and its important morbidity. In addition to the classic predisposing factors, such as elderly, immobilization, trauma, malignancy, surgery or contraceptive drugs, it is possible to identify abnormalities in hemostasis mechanisms, which may favor thrombotic process. The results of this study confirm the importance of investigating possible causes of thrombophilia in patients who suffered a thrombotic event.

Conclusions: 1. In half of the cases analyzed there are alterations in the mechanisms of hemostasis that involve a prolonged anticoagulant treatment. 2. Thrombophilic disorders occur mainly in women with 52 years on average. 3. The most frequent alteration in our environment are hyperhomocysteinemia (20.3%) and antiphospholipid syndrome -with increased frequency of anticardiolipin antibodies (24.28%) and lupus anticoagulant (19%)-, followed by factor V Leiden mutation (13.51%). 4. It is important to make a thrombophilia screening in all patients who have a thrombotic event.

T-42
DESCRIPTIVE STUDY OF 345 PULMONARY EMBOLISMS

C. Rodríguez Blanco, E. Rodriguez Beltrán, M. Budiño Sánchez, C. Sánchez Sánchez, L. Andreu Urioste, C. Machado, J. Barragán Casas and other authors*

Department of Internal Medicine. Complejo Asistencial de Ávila. Ávila, Spain.

Objectives: The aim of study was to know and analyze the epidemiological characteristics of the patients with pulmonary embolism (PE) in our hospital.

Material and method: We studied 345 patients in a retrospective study of patients with PE from 2005 to 2010 at the Hospital Nuestra Señora de Sonsoles (Ávila, Spain). There were excluded those patients without certainty PE diagnosis.

Results: Patients: 345. Males: 190 (mean age: 68.9 +/-15.3 years). Women: 155 (mean age: 60.5 ± 15.8 years). The initial clinical symptoms were: symptoms related to the PE (262), symptoms related to PE and DVT (76) and incidental findings (7). The diagnosis was realized by CT-angiography in 340 patients, ventilation-perfusion scan in 4 and autopsy in 1 patient. Predispoising factors for PE were: immobilization (34), obesity (29), thrombophilia (29) and contraceptives (7). D-dimer > 500 was in 288/294 (97.3%). Mortality patients were 73 (21.2%), being in 7 cases related to the PE and the rest for other causes. Anticoagulant therapy was carried outusing low molecular weight heparin in 74 (21.5%) and acenocumarol in 271 (78.5%), withdrawn in 17 patients (6.3%), 11 for hemorrhagic causes (two of them lethal) and 6 for other causes. Filter of cava vein was placed it in 2 patients (0.6%).

Conclusions: PE is more frequent in males and these are older than women. Initial clinical symptoms are related with PE, without DVT. Usually, the diagnosis method is CT-angiography. D-dimer is raised in 97.5% of patients. Mortality was 21.2%, related one to PE 2%. Thrombophilia was present in 8.4% of the patients. The treatment is usually acenocumarol.

T-43
RESIDUAL VEIN THROMBOSIS (RVT) AFTER 6 MONTHS OF ANTICOAGULANT TREATMENT

G. Delgado Cárdenas[1], P. Sánchez Chica[1], V. Rojo Valencia[1], P. Del Valle Loarte[1], M. Cervero Jiménez[1], P. Rondón Fernández[1], M. Joya Seijó[2], J. Jusdado Ruiz-Capilla[1]

[1]Department of Internal Medicine. Hospital Severo Ochoa. Leganés (Madrid), Spain. [2]Department of Internal Medicine. Hospital Rey Juan Carlos. Móstoles (Madrid), Spain.

Objectives: Nowadays, RVT is considered an additional factor to estimate the risk of recurrence of deep vein thrombosis (DVT), but not enough to strongly influence recommendations on length of therapy. Our objective was to analyze the clinical and epidemiological differences between patients who had RVT in ultrasound and those of patients whose ultrasound was reported as patent (PV) after 6 months of anticoagulant treatment.

Material and method: In May 2010, we started an outpatient-based deep vein thrombosis management protocol in our Internal Medicine Unit. After the acute phase, patients were referred for follow-up in a monographic DVT office. Doppler ultrasound was performed before the treatment withdrawal, usually 3 or 6 months after starting anticoagulant therapy. Variables recorded were: age, sex, location, predisposing factors and the result of Doppler ultrasound control (RVT or PV). Qualitative variables were expressed as frequency and quantity variables, according to their symmetry with the average and standard deviation or median and inter-quartile range. The comparison of hypotheses was performed using the Chi^2 test and Pearson's correlation. We performed a multivariate logistic regression analysis with variables expressing OR and his confidence interval. All data was stored in Access database and analyzed using the statistical package SSPSS 11.

Results: A total of 84 patients were diagnosed in the Emergency Unit of lower limb DVT during the period from May 2010 to April 2012. 38 patients underwent ultrasound scans. The average time to perform the Doppler ultrasonography was 196.85 days (95%CI 160.73 to 232.97). In 47.4% of the patients RVT was showed, the thrombosis was supra-popliteal in 12 (66.67%). The median age was 58.64 years, with a 52.6% of patients below age 65. The location of the DVT was: supra-popliteal vein 23 (60.5%), under-popliteal vein 14 (38.8%) and iliofemoral 1 (2.7%). A predisposing factor was found in 9 patients with RVT (50%) and in 13 with PV (65%). The only factors associated with RVT after 6 months of anticoagulant treatment were the history of thromboembolic disease and the absence of immobilization as the underlying cause to unchain venous thrombosis.

Conclusions: In this study RVT was present in 47.4% of patients 6 months after starting anticoagulant therapy regardless of age and sex. These results confirm, as other studies, the need to check Doppler ultrasound thrombous resolution before the end of treatment. Immobilization as the underlying cause of venous thrombosis was the only factor associated with lower risk of RVT, indicating that in these patients the anticoagulant treatment can be shortened. At the moment, our limited number of patients does not allow us to draw conclusions for other predisposing factors.

T-44
ASSOCIATION OF INCREASED D-DIMER (DD) LEVELS WITH VENOUS THROMBOEMBOLISM DISEASE (VTD) AND OTHER CAUSES

P. Martínez García[1], A. Arenas Iglesias[1], I. Maderuelo Riesco[1], M. Villanueva Montes[2], L. Alcuria Ledo[1], K. El-Boutaibi Faiz[2], J. Ferreiro Celeiro[1], M. de Zárraga Fernández[1]

[1]Department of Internal Medicine, [2]Department of Respiratory Medicine. Hospital San Agustín. Avilés (Asturias), Spain.

Objectives: Analyze if high DD levels are associated with a higher probability of suffering from VTD, as well as the influence of other factors on DD level increase.

Material and method: A descriptive study was performed in 691 consecutive patients with the determination of DD levels using ELISA (Enzyme-Linked ImmunoSorbent Assay) in a regional hospital in Asturias between the period of January inclusive till 15th of March 2010. Demographic data, sex, age, DD levels, diagnosis on admission, and other causes of DD level increase were analysed using SPSS 19.0 (Statistical Package for the Social Sciences).

Results: A total of 691 consecutive DD determinations were identified, of which 51.6% were women and the average age was 68.7 years (50.7-86.8). In 238 cases (34.4%), the DD level was within the normal range (< 275 ng/mL), and elevated in 453 (66.6%). VTD was found in 46 patients (6.6%), of which 27 had DVT (deep venous thrombosis), 15 had PE (pulmonary thromboembolism) and 4 had both DVT and PE. There were 5 VTD (2.1%) with normal DD levels, and 41 (9%) with elevated DD levels ($p < 0.001$). There was an association between high DD levels and VTD, we observed that as values increased the likelihood of VTD was higher. For normal DD levels, only 2.1% of the cases had VTD, 5.9% for values between 276-1,920, 17.2% between 1,921-3,560, 19% between 3,561-5,200, and finally 20.7% for DD > 5,200. Taking as reference the first interval (OR = 1), the values of OR are respectively 2.91, 9.67, 10.96 and 12.16 ($p = 0.001$). Other causes of increased DD levels that were statistically significant include heart failure ($p = 0.001$), sepsis ($p = 0.001$), surgery and traumatism ($p = 0.001$), malignity ($p = 0.0001$) and acute renal failure ($p < 0.01$). We found no statistically significant association between high DD levels and atrial fibrillation, acute myocardial infarction, stroke, disseminated intravascular coagulation, fibrinolysis, eclampsia, sickle cell anemia, SIRS (systemic inflammatory response syndrome), severe liver disease, nephrotic syndrome, chronic renal failure and cardiovascular disease, pregnancy or venous malformations. There were 402 patients with high DD levels who had not suffered from VT; 330 (82%) of them had at least one of the five factors that were statistically significant: heart failure 22.39%, sepsis 48.51%, surgery or traumatism 16.91%, malignity 17.16%, acute renal failure 5.75%. The remaining 72 patients did not have any of these causes for increased DD levels.

Discussion: As in other studies, DD levels have shown to be useful to exclude VTD, with a negative predictive value of 97.89%. However the low specificity found (36.12% in our study) makes it a poor tool to support the diagnosis of VT, as there are other factors which raise levels in the absence of VTD. Other studies show that 22% of patients with high DD levels without VTD are explained by the presence of underlying diseases, whilst it was 82% in our study. Analyzing factors that can increase DD in the absence of VTD, we found statistically significant associations with SIRS, surgery, trauma, acute renal disease and malignancy. Results in other studies are contradictory, in one study a statistical significance was found for recurrent VT and elderly people whilst a statistical non significant association with malignancy. In another study there was a significant association with malignancy and non significant with previous surgery and acute medical illness. We found as in other studies a strong association between higher DD levels and the presence of VTD.

Conclusions: 1. D-Dimer levels are associated with a higher probability of suffering from venous thromboembolic disease. 2. Heart failure, sepsis, surgery and traumatism, malignancy and acute renal failure are associated with high D-dimer levels in patients without venous thromboembolic disease.

T-45
APPROPRIATENESS OF THE THROMBOPROPHYLAXIS IN PATIENTS ADMITTED AT AN INTERNAL MEDICINE DEPARTMENT OF A TERTIARY SPANISH HOSPITAL

J. Praena Segovia[1], R. Álvarez Marín[2], M. Martínez Rísquez[1], M. García Gutiérrez[1], S. Rodríguez Suárez[1], E. Montero Mateos[1], M. Gómez Hernández[3], F. Medrano[1]

[1]Department of Internal Medicine, [2]Department of Infectious Diseases and Microbiology. Hospital Virgen del Rocío. Sevilla, Spain. [3]Department of Internal Medicine. Hospital San Juan de Dios de El Aljarafe. Sevilla, Spain.

Objectives: The aim of this study was to evaluate the appropriateness of the thromboprophylaxis to the PRETEMED 2007 guideline criteria in medical patients admitted to two units of an internal medicine department.

Material and method: In this cross-sectional study were included patients the first 100 consecutively admitted at two medical units (internal medicine ward and short stay ward) of an internal medicine department in a tertiary hospital from March 1, 2012. Inclusion criteria were: age over 18 years-old and being admitted to one of the studied units. Exclusion criteria were: need of full-dose anticoagulation, hypersensitivity to low-molecular-weight heparins, history of heparin-induced thrombocytopenia, active hemorrhage, history of digestive tract hemorrhage in the last three months, severe hepatic dysfunction (Child B or C) and/or previous coagulation disorder (INR > 1.5 or TPTA > 60 seconds). A standardized form was filled to identify risk factors for venous thrombosis, adjusted risk of thromboembolic disease: medium-high ≥ 4 (pharmacological prophylaxis is recommended) or low < 4 (only physical measures of prophylaxis are recommended) and appropriateness of pharmacological prophylaxis. Statistical analyses were performed using IBM SPSS Statistics version 19 software.

Results: A total of 102 patients were consecutively evaluated, but finally just 62 were included (39 patients were excluded because of needing full-dose anticoagulation and one because of active digestive tract bleeding). Among these 62 patients, 17 were admitted at the short stay unit and 45 at the conventional internal medicine ward. No significant differences in demographical and clinical variables were found between patients admitted at the two units. Among the 17 patients admitted at the short stay unit, appropriateness of pharmacological prophylaxis to PRETEMED-2007 guideline was 47.1% and overuse and underuse was observed in 41.2% and 11.8% of cases, respectively. Among the 45 patients admitted at the conventional internal medicine ward, the overall appropriateness was 46.7% and overuse and underuse was observed in 35.6% and 17,7of cases, respectively.

Discussion: Despite recent advances in venous thromboembolism (VTE) prophylaxis, this disease is still nowadays a major problem of public health. The indication of thromboprophylaxis in non-surgical patients is difficult and many different risk factor must be taken into consideration. The recently developed PRETEMED-2007 Guideline was the first evidence-based-guide on VTE prophylaxis that allows to stratify the risk and to establish the indications of prophylaxis in medical patients. Nonetheless, this audit demonstrates the absence of fulfillment of these indications in our department. With the limitations of low number of subjects evaluated the study suggests that without the use of a risk scale increased awareness to the problem determines an overuse of pharmacological prophylaxis. Efforts should be made to implement the PRETEMED-2007 guideline in order to optimize the prevention of VTE in medical patients.

Conclusions: The appropriateness of thromboprophylaxis to PRETEMED-2007 is low in medical patients of our department, being overuse in low risk-patients the main problem.

T-46
FACTORS ASSOCIATED TO RADIOLOGICAL EXTENSION OF PULMONARY EMBOLISM

S. García Rubio[1], F. Arnaiz de las Revillas Almajano[1], L. Corral Nieri[1], A. Sánchez González[1], V. Pardo Gutiérrez[2], D. Nan[1], M. Múgica Estébanez[3], M. Valero Diaz de Lamadrid[1]

[1]Department of Internal Medicine, [3]Department of Oncology. Hospital Valdecilla. Santander (Cantabria), Spain. [2]Department of Internal Medicine. Hospital Santos Reyes. Aranda de Duero (Burgos), Spain.

Objectives: To establish risk factors for greater radiological extension of pulmonary embolism (PE) in our center. As secondary objectives we studied the relationship between radiological extension of PE and radiological data of right ventricle dysfunction (right-to-left ventricle index, RVI) and pulmonary artery obstruction (Qanadly score).

Material and method: We studied data from clinical charts of 33 consecutive patients admitted for PE in Marqués de Valdecilla Universitary Hospital (Santander, Spain) between May and September 2007. We recorded data concerning age, sex, presence of active malignancy, lung or heart diseases and previous history of venous thrombosis (VT). We registered radiological findings of right ventricle dysfunction (RVI > 1) and pulmonary artery obstruction (Qanadly score > 40%) in the spiral lung CT scan performed for PE diagnosis. We defined PE as extensive if one or both pulmonary main arteries were affected and not-extensive for the remaining pulmonary circulation (lobar and segmentary arteries). We evaluated the need of ICU admission and the fatality rate.

Results: We found 10 extensive PE (30%). No death cases were found in the extensive group while 5 patients (22%) from the not extensive group died. The distribution of the remaining clinical variables studied in both groups is shown in table 1. The only variable associated to a extensive PE was active malignancy (OR = 1.62, 95%CI = 1.19-2.2; p = 0.04). In the multivariate analysis we found no independent statistically significant association for the previously named variables. We found no statistically significant association between radiological extension of PE and the need of ICU stay or fatality. Extensive PE were associated with RVI > 1 (OR = 6.11, 95%CI = 1.28-34.14; p = 0.02) and Qanadly score > 40% (OR = 1.91, 95%CI = 1.29-2.83; p = 0.01).

Discussion: Patients with active malignancy disease had extensive PE more often. Greater radiological extension of PE was associated with radiological data of right ventricle dysfunction and pulmonary

Table 1 (T-46). Distribution of variables. n (%)

	Age > 65 years	Female sex	Malignancy	Lung disease	Heart disease	Previous VT	Need of ICU stay
Extensive 10	6 (24%)	8 (80%)	10 (100%)	0 (0%)	0 (0%)	1 (10%)	2 (20%)
Notextensive 23	19 (76%)	12 (52%)	7 (30%)	6 (26%)	10 (43%)	4 (17%)	3 (13%)

artery significant obstruction but not with the need of ICU stay or death. Patients in the not extensive group were older and this may influence in the greater fatality rate found in that group.

Conclusions: Patients with active malignancy may present with extensive PE more often. Extensive PE were associated with poorer radiological outcomes but not with worse clinical course. Further research needs to be done to confirm these findings.

T-47
RELATIONSHIP BETWEEN D-DIMER LEVEL, RESIDUAL THROMBOSIS AND POST-THROMBOTIC SYNDROME AFTER DEEP VENOUS THROMBOSIS AT 6 MONTHS OF ANTICOAGULANT THERAPY

C. Barbagelata López, C. Mella Pérez, B. Buño Ramilo, E. Fernández Bouza, B. Vázquez Vázquez, L. Vilariño Maneiro, G. Rivas Costa, P. Sesma Sánchez

Department of Internal Medicine. Complejo Hospitalario Arquitecto Marcide-Prof. Novoa Santos. Ferrol (A Coruña), Spain.

Objectives: Introduction: After a deep venous thrombosis (DVT) risk of recurrence is approximately 40% in 10 years. Have been described as risk factors of recurrent thromboembolic event the presence of residual thrombosis (TR) in ecodoppler control and high D-dimer (DD) levels. Post-thrombotic syndrome (PTS) shows the development of symptoms or signs of chronic venous insufficiency after DVT, being an important negative factor in the perception of quality life. Objectives: a possible relationship in the follow-up after DVT between the presence of DD high levels at 6 months, before stopping anticoagulant therapy (ACO) and the presence of TR or SPT.

Material and method: Prospective observational study of patients diagnosed with DVT first episode between January 2009-June 2011, performing at six months DD, doppler monitoring in the affected limb and clinical control before stopping anticoagulation. We performed a descriptive analysis of the variables included in the study. Qualitative variables are expressed as percentages and quantitative variables as averages and standard deviations, for the mean comparison Student's t test was used and for proportions comparison the Chi square test using SPSS 11.0 software package.

Results: 44 cases were analyzed, mean aged was 62 years, 59% female. DVT was induced in 61.4% of cases, 13.7% history of fracture or trauma surgery in previous month, 38.6% over 3 days immobilization, 9.1% were taking oral contraceptives, 6.8% active neoplasia, 2.3% antiphospholipid syndrome. Other risk factors were: 36.4% varicose veins, obesity 47.7%, 41% basal limited mobility. The event features TVP showed: 79% total occlusion, several territories 66% (18% iliac-femoral, femoro-popliteal 47.7%) and one territory 34% (12% femoral, popliteal and 15.9% of junction saphenous 6.8%). TR was detected at 6 months in the 43´2% and SPT in 59%. Mean level follow-up of DD was 348 ng/ml (range 31-850), while in 25% DD < 150 and 52% DD < 250. Regarding the association between TR and the value of DD at 6 months before stopping anticoagulant therapy, DD breakpoints > 250 and > 500 did not find statistical significance, with p values 0.54 and 0.36 respectively. Regarding the association between SPT and the value of DD for the same cut points, we found no statistical significance with p values 0.163 and 0.141 respectively.

Conclusions: In our patients follow-up with DVT at 6 months of anticoagulant therapy, 43´2% shown TR and 59% SPT. Regarding the value of DD, 48% of patients have a value higher than 250 before the end of anticoagulation. We did not find association between DD high levels for breakpoints > 250 or > 500 and TR or SPT, although there is a trend towards greater partnership figures DD > 500 being more significant this association for SPT than for residual thrombosis. In the literature, recently have been described the lack of relationship between TR and DD elevation, as we observed in our series. Although the risk of recurrence has been reported in literature with elevated DD after ACO suspension, studies begin to appear also relate it to their elevation before suspending ACO. In our series, a high number of patients showed DD high levels therefore would have higher risk of recurrence after stopping ACO.

T-48
THROMBOEMBOLIC DISEASE RELATED WITH HORMONAL CHANGES IN WOMEN AT THE MONOGRAPHIC CONSULTATION OF THROMBOSIS AT UNIVERSITY GENERAL HOSPITAL OF CIUDAD REAL, 2010-2011

I. de la Rocha Vedia, E. Bencosme de Méndez, G. Abataneo, F. González Gasca, C. Muñoz Hornero, J. Castro, A. Sáenz Gutiérrez, J. Portillo Sánchez

Department of Internal Medicine. Hospital General de Ciudad Real. Ciudad Real, Spain.

Objectives: Identify the thrombotic events associated with hormonal changes in women at the monographic consultation of thrombosis at University General Hospital Of Ciudad Real, 2010-2011.

Material and method: Descriptive, retrospective study and observational of the patients diagnosed of thrombosis related to hormonal changes, that were attended in the monographic consultation of thrombosis of the University Hospital General of Ciudad Real in January from the 2010 to December of 2011.

Results: They were included a total of 25 patients, in 11 of them the phenomenon thrombotic had appeared associate to it takes of contraceptive oral, and in the 13 remainders to pregnancy or postpartum. The rank of age in the patients that took contraceptives was among 25 to 30 years (5 patient 41.7%), In pregnancy was of 35-40 years (5 patient 38.5%) and of 40-45 years (4 patient 30.5%). No significant association was found in relation to the obesity neither with the tobacco. The patients that had been in rest were 2 (16.7%) for the ones that took contraceptive and 4 (30.8%) for the pregnancy. A total of 5 was identified (41.7%) patient with thrombophilia of the patients that took contraceptive and to 5 (38.5%) in the pregnancy. In patients contraceptive takers deep vein thrombosis was present in 10 (83%), followed by superficial thrombosis in 2 (16.6%) and pulmonary embolism in 1 (8.3%) In the group of pregnant found DVT in 7 patients (53.8%), 2 (15.4%) pulmonary embolism, 1 (7.7%) venous thrombosis cava and 1 (7.7%) superficial thrombosis. The events occurred mostly in the second trimester 4 (30.8%), followed by the third and postpartum with 3 patients (23.1%) in each case. We found only 1 (7.7%) patient in the first quarter. Termination of labor so eutócica in 6 patients (46.2%), cesarean in 6 (46.2%) and 1 (7.6%) abortion. Treatment during pregnancy was in 12 patients (92.3%) with low molecular weight heparin, and one we opted for the temporary placement of a vena cava filter (7.7%).

Discussion: Is currently considered thromboembolic disease as a multicausal disease and several studies suggests that contraceptives use increases by 4 times the risk of thrombosis, thus blocking the chromosome 5 of dihydrofolate reductase by altering the metabolism of homocysteine. All the venous system of the lower extremities is vulnerable to thrombosis resulting from compression by the gravid uterus, especially during last trimesters, as in this study. It is considered that the older age group is associated as risk factor, but in this case, in patients taking oral contraceptives, the predominant range was 25 to 30 years. In pregnant between 35 and 45. Thrombophilia has been described as a risk factor but in these cases, it has been found in fact less than 50% The treatment of choice during pregnancy is the low molecular weight heparin, because of its greater plasma half-life, do not require laboratory testing of control and do not cross the placental barrier. In patients taking contraceptives and after

birth, treatment was individualized according to the type of thrombosis and associated risk factors.

Conclusions: The occurrence of thrombotic events with hormonal changes, such as oral contraceptives, pregnancy and puerperium, forces his close monitoring during this period to identify potential risk factors and use preventive measures if possible. The initial and early appropriate treatment is essential to avoid further complications.

T-49
PULMONARY EMBOLISM AND TUMORS. STUDY OF 345 PATIENTS

J. Barragán Casas, E. Rodríguez Beltrán, C. Rodríguez Blanco, C. Sánchez Sánchez, D. Sánchez Fuentes, R. Velasco Domínguez, M. Pedromingo Kus and other authors*

Department of Internal Medicine. Complejo Asistencial de Ávila. Ávila. Madrid.

Objectives: The aim of study was to know and analyze the relation between pulmonary embolism and tumors in our patients.

Material and method: We studied 345 patients in a retrospective study of patients with PE from 2005 to 2010 at the Hospital Nuestra Señora de Sonsoles (Ávila, Spain). There were excluded those patients without certainty PE diagnosis.

Results: Patients: 345. Males: 190 (mean age: 68.9 ± 15.3 years). Females: 155 (mean age: 60.5 ± 15.8 years). There are 91 (26.4%) patients with PE and tumors. We classify according to the moment that they appear in: a) Before PE: 59/345 (17.1%). Distribution according to histological race: adenocarcinoma (30), epidermoid (6), ductal carcinoma (6), haematological malignancies (5) and other (13). According to the anatomical location: digestive system (12), prostate (12), breast (7), lung (6), oropharyngeal (5), hematologic system (5), others (10). b) Simultaneously with PE: 18/345 (5.2%). Distribution according to histological race: adenocarcinoma (11), epidermoid (1) and other (6). According to the anatomical location: lung (5), digestive system (3), ginecologic tumors (2) and others (8). c) Later to PE: 14/345 (4.1%). Distribution according to histological race: adenocarcinoma (8), bladder (2) and other (4). According to the anatomical location: lung (5), digestive system (2), prostate (2), bladder (2) and others (3).

Conclusions: Patients with PE and tumors were 26.4%, predominantly adenocarcinoma. 1 of every 9 patients with EP will diagnose a tumor during the revenue or his follow-up. *Other authors: J. Sesma, M.A. Budiño, C.L. Machado, H. Mendoza, M.C. Calleja, M.J. Álvarez-Moya, T. Carmona, E. Barroso, M. Cañizo, M.D. López-Fernández and J. Arnáiz.

UPPER-EXTREMITY VEIN THROMBOSIS NOT ASSOCIATED WITH INTRAVASCULAR DEVICES

R. Santalla Fernández[1], S. García Mendoza[2], M. León Téllez[3], C. Rodríguez Blanco[4], S. Martín Rodríguez[5], L. Mateos Polo[1], J. Barragán Casas[4] and other authors*

[1]Department of Internal Medicine. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca, Spain. [2]Department of Internal Medicine. Complejo Asistencial de León. León, Spain. [3]Department of Internal Medicine. Hospital Santa Bárbara. Soria, Spain. [4]Department of Internal Medicine. Complejo Asistencial de Ávila. Ávila, Spain. [5]Department of Internal Medicine. Hospital General. Segovia, Spain.

Objectives: Analyze the characteristics of the patients with upper-extrelity vein thrombosis who are not related to intravascular devices.

Material and method: Retrospective multicenters study with follow-up of the patients' cohort of the people of Salamanca, León, Soria, Ávila and Segovia (Castilla y León, Spain). The cases were obtained of the Department of Clinical Documentation of the each Hospitals. We evaluated the clinical histories of patients. Patients with intravascular devices were excluded.

Results: Patients: 40. Males: 20 (mean age 59.1 ± 21.9 years). Females: 20 (mean age 64.4 ± 21.8 years). Location of the thrombosis: subclavian vein (21), basilic, cephalic and brachial veins (13), axillary vein (4) and yugular vein (2). The diagnosis methods were: ultrasound scan doppler: 34 (85%) and CT-angiography: 6 (15%). D-dimer was raised in 19/22 patients (86.4%). Eight patients (20%) have had thombophilia. Five patients (12.5%) has previous thromboembolic disease, three of them with thrombophilia. Twelve patients (30%) received previous thromboprophylasis. In 16 patients (40%) they associated to tumors. The histological race were: adenocarcinoma (5), epidermoid (5), haematological malignances (4), small cell lung (1) and papillary (1). The anatomical location were: lung (6), oropharyngeal (3), haematological (3), thyroid (1), bladder (1), breast (1) and prostate (1).

Conclusions: The subclavian vein is the most affected. Oncologic disease was present in 40% of the patients, prevailing lung and oropharyngeal locations (56%). 1 of every 5 patients have had thrombophilic situation. *Other authors: E. Fernández Pérez (León), V. del Villar Sordo (Soria) and C. Sanz Lobo (Segovia).

T-51
SUSPICION OF PULMONARY EMBOLISM IN THE EMERGENCY DEPARTMENT: WHEN IS IT NECESSARY TO ASK FOR D-DIMER TEST?

C. Gómez del Valle, C. Josa Laorden, M. Matía Sanz, M. Bucar Barjud, B. Amores Arriaga, M. Torralba Cabeza, M. Aibar Arregui, J. Pérez Calvo

Department of Internal Medicine. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: Analyze the requests for D-dimer (DD) asked from the Emergency Department in patients with suspected pulmonary embolism (PE), evaluating the indication according to the current guidelines.

Material and method: Descriptive study which analyzes the DD requests from the Emergency Department of the Lozano Blesa Universitary Clinical Hospital, during the period of 30 consecutive days (October 2011). Medical reports have been reviewed considering epidemiological data, comorbidity, PE clinical probability according to Wells scale, complementary tests, final diagnosis and clinical course.

Results: 100 requests were made during this period. Suspicion of PE was the reason for 72 patients, deep vein thrombosis (DVT) for 22 and no clear cause for 6. The mean age was 68.8 years (range 23-91), being 57% of them male. The main symptoms were dyspnea (62.5%), chest pain (27.7%) and syncope (22.2%). 7% of the patients presented hypotension (SBp < 90 mmHg), 35.2% tachycardia (HR > 100), and 44.8% basal O_2 saturation below 95%. DD was "negative" (< 500 µg/l) for 16 patients (22.2%). 15 of them (93.7%) had a low probability of PE according to Wells score (< 2 points). No CT pulmonary angiogram (CT-PA) was request. 80% of the patients were discharged from the Emergency Department with different diagnosis. Just one patient (6.3%) had intermediate probability of PE according to Wells score (2-6 points). EP was discarded by CT-PA, and the patient was discharged. DD was "positive" (> 500 µg/l) for 56 patients (77.8%). 44 of them (78.5%) had a low probability of PE according to Wells score. CT-PA was done in 6 patients (13.6%), confirming pulmonary embolism in 1 case (2.2%). 12 patients (29.6%)

were discharged. Another 6 patients (10.7%) had an intermediate probability of PE according to Wells score. CT-PA was made in 1 case (16.6%), confirming the diagnosis of PE. All the patients were hospitalized. Just 2 patients (3.5%) had high probability of PE according to Wells score (> 6 points). No CT-PA was requested. Both patients were hospitalized. No PE diagnosis was confirmed for the admitted patients. None of the discharged patients were readmitted within 6 months with diagnosis of PE.

Discussion: Pulmonary embolism is the most serious manifestation of venous thromboembolism (VTE), with an incidence of 1 case/1,000 people/year, and 12% mortality at 30 days. Early diagnosis is as important that there are several clinical probability scales. One of those is Wells score, which incorporates clinical items and risk factors. D-dimer test has a sensitivity above 95% for VTE, but low specificity (< 50%). It has a high negative predictive value, so < 500 µg/l levels discard the diagnosis of PE, but only when clinical probability is low. As recommended by the SEPAR guidelines, CT-PA must be indicated in moderate or high clinical probability cases, or in low clinical probability with high DD test. In the group of patients with negative DD, diagnostic attitude was according to current recommendations. However, the diagnostic procedure for the group of patients with positive DD should be noted, especially for those with intermediate or high clinical probability and with no CT-PA that discard EP. It is relevant to consider that DD is requested at the same time than another complementary test, which results can lead to the diagnosis of other pathologies.

Conclusions: According to data from our study, current guidelines are not followed for the diagnosis of pulmonary embolism in the Emergency Department of our Hospital. Therefore, we suggest creating a protocol for all cases of suspected pulmonary embolism, in order to improve the management of these patients.

T-52
DIFFERENCES IN THROMBOEMBOLIC DISEASE AMONG YOUNG PATIENTS AND PATIENTS OLDER THAN 50 YEARS OLD

M. Egea Campoy, E. García Villalba, M. Meseguer Frutos, C. Vera Sánchez-Rojas, R. Millán Rodríguez, E. Rashid Jiménez, M. García Puche, C. Royo-Villanova Reparaz

Department of Internal Medicine. Hospital General Universitario Reina Sofía. Murcia, Spain.

Objectives: To analyze clinical and epidemiological differences of venous thromboembolic disease (VTD) among patients older and younger than 50 years.

Material and method: Review of medical records of admissions with a diagnosis of VTD at discharge, for a period of two years.

Results: The results matched, placing first the group of patients younger than 50 years. The gender distribution was similar in both groups, about 50%. Stay average was 10.93-12.8 days. The weight average GRD was (1.4-1.59). Differences were statistically significant ($p < 0.05$) for those younger than 50 years; family history of VTD (1.9-0.4%), highest percentage of smokers (48-13.2%), hormonal contraceptives (20.4 -0%) and hormonal replacement therapy (HRT) (1.9-0.8%) We observed a tendency to suffer from thrombophilia disease on younger people and statistically significant findings for the presence of lupus anticoagulant (6.7-2.5%), protein C deficiency (3.8-0%) and protein S (3.8-0.4%), anticardiolipin antibodies (7.5-2.1%) and 20210 gene mutation (1.9-0.4%), with greater presence in over 50 years of heterozygous Factor V Leiden (0-1.6%). People younger than 50 years old present a predominance of deep vein thrombosis (DVT) infrapopliteal (22-6.8%) and upper extremity (4.9-0%) and higher percentage of treatment with acenocoumarol (90.7-71.8%) In elderly patients, we observed higher comorbidity: heart failure (0-15.9%), COPD (1.9-10.6%), stroke (1.9-16.9%), diabetes mellitus (5.6-24%), varicose vein (7.4-24.8%), predominance of DVT suprapopliteal (65.9-82.2%) and bedridden (1.9-16.3%). In the younger people group, there were no bleeding complications (0-7.3%), deaths (0-11%) or pregnancies. In all other variables studied, the differences were not statistically significant ($p > 0.05$). We observed more frequently in the younger people a personal history of DVT (13-10.2%), recent travel (3.7-1.2%), trauma (11.1-4.9%) and immobilization (24.1-14.2%). However, in people older than 50 years, there was a higher frequency of PH of pulmonary thromboembolism (0-4.1%), obesity (15/07/28%), orthopedic (0-1.2%) or abdominal surgery (1.9-3.3%) Young patients had no indications of cava filter, there were no cases of hematologic malignancy (0-3%) and only 2 cases were solid neoplasia of gynecological origin. Patients under 50 years old were admitted more frequently in the Short Stay Unit (SSU) (24.1-12.2%), predominantly in the month of June (20.4-7-7%), while older, were hospitalized in ward (74.1-80.5%) or home (1.9-5.7%), preferably in the month of April (3.7-13%).

Discussion: VTD is a serious and potentially deadly process. The series show a linear correlation between age and incidence, which is correlated in this group to found more patients older than 50 years (54-246 patients). In our analysis, there were more studies of inherited thrombophilia in the younger GROUP because these pathologies debut early. However, it WAS noted the increased frequency of heterozygous Factor V Leiden in patients over 50 years. As expected, in young patients, hormonal contraceptive use was more common, with a tendency to use HRT in the same group, associated, probably, to the treatment of early menopause. Treatment duration was longer in patients under 50 years because the presence of non-modifiable risk factors and increased frequency of bleeding complications in the longest-lived (involving the suspension of anticoagulation). Due to comorbidity, older patients were less frequently admitted to the SSU and their average stay was longer.

Conclusions: VTD is a common disease that presents high mortality and its incidence increases with age. Our series of patients show a higher frequency of inherited thrombophilia in young patients. In patients over 50 years, there is a higher presence of Factor V Leiden with a greater comorbidity, severity of disease and presence of precipitating factors.

T-53
TROMBOPROPHYILAXIS IN THE INTERNAL MEDICINE SERVICES OF THE REGION OF MURCIA. IS THE ADEQUACY OF TROMBOPROHYLASIS WITH LMWH MODIFIED AFTER AN EDUCATIONAL INTERVENTION?

M. Artero[1], G. Tornel[1], C. Smilg[1], S. Herrera[1], J. Trujillo[1], V. Rosa[2], M. Torralba[3], P. García[1]

[1]Department of Internal Medicine. Hospital Universitario de Santa Lucía. Cartagena (Murcia), Spain. [2]Department of Internal Medicine. Hospital Universitario Virgen de la Arrixaca. Murcia, Spain. [3]Department of Internal Medicine. Hospital Universitario Morales Meseguer. Murcia, Spain.

Objectives: To evaluate the adequacy of thromboprophylaxis in admitted patients and the influence of an educational intervention in its prescription.

Material and method: An observational study of thromboembolic prophylaxis was carried out in patients admitted to the Internal Medicine Service during the month of november (preintervention phase). Thromboembolic prophylaxis was evaluated once a day, from Monday to Friday, in 5 patients. The Pretemed scale and the Medenox and Exclaim criteria were used. Subsequently, the results of the observational study were reported to the doctors of the internal medicine service insisting in the need of evaluating the adequacy of thromboprophylaxis of admitted patients. Another

data collection was carried out following the same systematic as in the previous phase. Morales Meseguer, Virgen de la Arrixaca and Santa Lucia hospitals took part in this study. All three hospitals are located in the Region of Murcia.

Results: From a total of 291 patients evaluated in the first phase, pharmacological thromboprophylaxis was prescribed in 186 patients (64%) . It was not prescribed in 101 (36%). According to the scales used: PRETEMED, MEDENOX and PADUA, pharmacological thromboprophylaxis was used in 62%, 53% y 50% (respectively) in low-risk patients and in 67%, 72% y 86% (respectively) in high-risk patients. After the educational intervention and according to the previously referred scales, from a total of 271 patients pharmacological thromboprophylaxis was prescribed in 47%, 44% y 21% of low-risk patients and in 39%, 42% and 48% of high-risk patients.

Discussion: According to the Pretemed scale, after the informative intervention, thromboprofilaxis was less prescribed both in high-risk patients (adequate prescription) and in low-risk patients (inadequate prescription). According to the Medenox criteria, the results obtained were the same as those obtained by Pretemed: after the educational intervention thromboprofilaxis decreased in high-risk patients (adequate prescription) and in low-risk patients (inadequate prescription). The results obtained following the Padua criteria were the same as those of Medenox and Pretemed: after the educational intervention prescription decreased in those patients classified as high-risk patients (adequate prescription) and also in low-risk patients (inadequate prescription). As a general assessment, any of the three scales used in the educational intervention entails decreasing of inadequate prescriptions (in low-risk patients) but it also reduces adequate prescriptions (in high-risk patients).

Conclusions: 1. An adequate prophylaxis is only achieved in 67-86% of high-risk patients according to the different scales used in the preintervention phase. After the explanatory intervention, adequate prophylaxis in high-risk patients decreased to 39-48%. 2. As for low-risk patients, inadequate prescription was used in 50-62% of the cases. After the intervention, inadequate prophylaxis decreased to 21-47%. 3. These data take us to reflect on the adequate knowledge of the risk scales among doctors and to avoid indiscriminate prescription of this prophylaxis. 4. After the intervention, inadequate prescriptions decreased, but it contributed as well to avoid some adequate prescriptions in high-risk patients.

T-54
UTILITY OF THE IMPROVE RISK SCALE AND DOSE MODIFICATION OF THROMBOPROPHYLAXIS ACCORDING TO THE RISK OF BLEEDING

M. Artero[1], G. Tornel[1], S. Herrera[1], J. Trujillo[1], V. Rosa[2], L. Guirado[2], M. Torralba[3], M. Ruiz[3]

[1]Department of Internal Medicine. Hospital Santa Lucía. Cartagena (Murcia), Spain. [2]Department of Internal Medicine. Hospital V. Arrixaca. Murcia, Spain. [3]Department of Internal Medicine. Hospital Morales Meseguer. Murcia, Spain.

Objectives: To evaluate whether the reduction of the doses of LMWH thromboprophylaxis in patients at increased risk of bleeding according to the risk scale of Improve study and validate the utility of this risk scale.

Material and method: Observational study of patients admitted to Internal Medicine service. The first 5 consecutive patients who did not need anticoagulant therapy were collected daily and the Improve risk score was considered. Diagnostic characteristic of this score was also evaluated. The following hospitals from the Region de Murcia participated in the study: Hospital Santa Lucía (Cartagena) and Hospitals Morales Meseguer and Virgen de la Arrixaca (Murcia).

Results: On admission day, 44% of patients with a high-risk scoring in Improve scale were prescribed a dose of 20 mg of enoxaparin, while this doses was used in 28% of patients with a low-risk. On the fourth day of admission, 62% of patients with a high-risk received doses of 20 mg of enoxaparin, while this doses was considered in 20% of patients with a low-risk. In those four days there were 5 bleeding, 4 of them in patients with a high-risk, only one of them on 20 mg/d of enoxaparin doses. Improve risk scale showed a sensitivity out of 80%, 92% of specificity, and a positive likelihood ratio of 9.9, which implies that it is able to predict bleeding in patients at high risk. The area under the ROC curve was excellent, 0.86 (0.65-1.00).

Discussion: Although the Improve risk scale of bleeding has been useful in predicting bleeding, in medical patients estimated with an increased risk of bleeding, a lower doses of LMWH is given. Similarly, the majority (80%) of patients in whom bleeding occurred in the early days of thromboprophylaxis were at high risk of bleeding.

Conclusions: the risk scale of bleeding described in Improve study could be useful to consider a dose reduction of thromboprophylaxis with LMWH in hospitalized medical patients.

Table (T-54)

p < 0.001	High-risk IMPROVE	Low-risk IMPROVE
Bleeding in 4 days	4 (22%)	1 (0.6%)
No bleeding	14 (78%)	160 (99%)
Total	18	161

T-57
STUDY OF VENOUS THROMBOEMBOLIC DISEASE AT A SHORT STAY WARD OF INTERNAL MEDICINE

N. Moya Notario, N. Jaén, L. Suárez Hormiga, F. Acosta de Bilbao, A. Martín Sánchez, J. Muñoz de Unamuno[1], J. Pérez Marín, J. Gómez Díaz

Department of Internal Medicine. Complejo Hospitalario Universitario Insular-Materno Infantil. Las Palmas, Spain.

Objectives: Short Stay Wards of Internal Medicine department represent an alternative to conventional admission and performs a close ambulatory follow up which allows a reduction of admission length. One of the pathologies which may be managed at those units is venous thromboembolic disease (VTD). Our objective is to describe the experience of the Short Stay Ward of Internal Medicine at Hospital University Insular of Las Palmas de Gran Canaria in relation with this disease, between March 1st, 2010 and February 29th, 2012.

Material and method: Descriptive study of characteristics of VTD admitted during one year at the Short Stay Ward, which consists of six beds (one hundred and twenty-six patients out of a total of eight hundred and fifty-one). Statistical analysis was performed using SPSS 19.0.

Results: The pathologies which are found include deep venous thrombosis (DVT) (83.3%) and pulmonary embolism (EP) (16.7%). During hospitalization, a 4% of the patients diagnosed of DVT presented EP as complication. Average age of VTD patients is 59.3 years (range: 16-95), 49.2% of whom were males. Average stay is four days (range: 0-29), being median and mode of 4.75% of patients stays four or less days. Most frequent risk factors are: hypertension (38.9%) tabaquism (38%), obesity (29.4%), dyslipidemia (25.4%), diabetes mellitus (19%), previous venous thromboembolic disease (VTD) (12.7%), immobilization (16.7%) and active neoplasia (12%). In order to analyze the basal situation of the patients, Barthel scale or basic activities of daily living (70% independent), instrumental activities of daily living or

Lawton scale (53% autonomous) and Pfeiffer scale for cognitive state evaluation (86.4% free of cognitive impairment) were used. By analyzing the Charlson comorbidity index, we find 73.9% patients free of comorbidity and 15.2% patients with high punctuation. In terms of ethiology, a 52.4% of idiopathic VTD is found. The rest of VTD is associated to immobilization (12.7%), active neoplasia (11.1%), hormonal-related disorders (androgenism, contraceptives use…) (5.6%), lower extremities trauma (4%), lower extremity fracture (3.2%), thrombophilia, postsurgical and recent medical pathology (2.4%). The study of idiopathic VDT consists of a screening for neoplasia and/or thrombophilia. 45.5% idiopathic VDT patients are studied for neoplasia screening. 7.6% idiopathic VDT patients are diagnosed of neoplasia (gastric cancer, pulmonary cancer and unknown origin metastatic liver). Thrombophilia study is performed in 27.3% of idiopathic VTD, 36% of which shows abnormalities (ATIII deficiency, hyperfibrinogenemia, S and C protein deficiency, hyperhomocysteinemia, 20210 A protein, combined thrombophilias). 79% idiopathic VTD no abnormalities are found.

Conclusions: Venous thromboembolic disease is a pathology which allows a short admission for most of the patients without short term readmission demand related to recurrence. The profile of the patient who is admitted consists in most of cases of autonomous and independent patient so that is a good candidate for ambulatory follow up. In half of the patients an evident trigger is not found at admission, so further investigations are needed for neoplasia and thrombophilia screening. Nevertheless, a high percentage of cases continues without an evident ethiology.

T-58
THROMBOPHILIAS IN PATIENTS WITH VENOUS THROMBOEMBOLIC DISEASE AT HOSPITAL UNIVERSITY INSULAR OF GRAN CANARIA

N. Jaén, N. Moya Notario, L. Suárez Hormiga, A. Martín Sánchez, F. Acosta de Bilbao, J. Pérez Marín, J. Muñoz de Unamuno, J. Gómez Díaz

Department of Internal Medicine. Complejo Hospitalario Universitario Insular-Materno Infantil. Las Palmas, Spain.

Objectives: Thrombophilias are characterized by a predisposition to hypercoagulability state and therefore to venous thromboembolic disease (VTD). Those are classified as inherited and acquired. Main inherited thrombophilias include: antithrombin deficiency, S protein deficiency, Leiden's V factor, 20210A mutation of prothrombin, hyperhomocysteinemia secondary to C677 gene mutation (metyltetrahydrofolate reductase), incremented levels of VIII factor. Acquired ones include: antiphospholipid syndrome, lupus, hyperhomocysteinemia and Behçet disease. Determine the clinical characteristics of VTD inpatients admitted at the Short Stay Ward of the Hospital University Insular of Gran Canaria whom presented a primary or secondary thrombophilia: risk factors, comorbidity, methods used for diagnosis, type of thrombophilia and complications next 6 months after discharge.

Material and method: Retrospective study of VTD patients admitted at the Short Stay Ward of the Hospital University Insular of Gran Canaria between March 1st, 2010 and February 28th, 2012; both included. Statistical analysis was performed using SPSS 19.0.

Results: The number of patients admitted with diagnosis of VTD was 126. Deep venous thrombosis (DVT) represented in 83.3% of the cases and Pulmonary Embolism (PE) in 16.7% of them. By the other hand, 52.4% of those patients were classified as idiopathic VTD. In 27.3% of these patients, a thromphilia screening was performed, with positive findings in 20 (36%). In relation to basal characteristics of those patients with thrombophilia, the average age was 53 ± 19.2 years old (mode: 40 years old). There was a predominance of male gender (55% against 45%). The most common comorbidities were: dyslipidemia (15%), obesity (25%), hypertension (25%), diabetes (15%) and previous VTD (10%). The mean hospital stay was 3.75 days. The most prevalent thrombophilias were: lupic anticoagulant (25%), Leiden's factor V (15%), antithrombin III deficiency (10%), S protein deficiency (10%) and combined thrombophilias (15%). Less common cases of C protein deficiency, elevated VIII factor, hyperhomocysteinemia, hyperfibrinogenemia and 21210 prothrombin gene mutation were described too. Analyzing the prevalence of thrombophilias by gender, we find up to 50% of lupic anticoagulant in men, compared to 14% in women. Finally, the incidence of complications was very little. Only one patient (5%) required readmission within the first three months after discharge because of DVT recurrence.

Conclusions: In opposition to data published in previous scientific literature, our study showed a higher prevalence of thrombophilia in men, being lupic anticoagulant the most common abnormality. The Short Stay Unit of Internal Medicine provides a close ambulatory follow up which minimize the risk of complications. That explains a lower rate of readmission than expected for this ward.

T-59
ACUTE PULMONARY EMBOLISM: PULMONARY HYPERTENSION AND COMPLICATIONS

L. Clavel Conget[1], I. Pascual Calleja[2], R. Pelay Cacho[1], M. Matía Sanz[1], M. Aibar Arregui[1], M. Iguzquiza[1], M. Bucar Barjud[1], F. Conget Lopez[3]

[1]Department of Internal Medicine, [3]Department of Pneumology. Hospital Clínico Lozano Blesa. Zaragoza, Spain. [2]Department of Cardiology. Hospital General de Asturias. Oviedo (Asturias), Spain.

Objectives: To evaluate the clinical and haemodynamic features of the pulmonary embolism (PE) in our setting, the distribution of the risk factors for PE, its ecocardiographic profile, the use of diagnostic tests and the treatments applied.

Material and method: This is a observational descriptive and longitudinal prospective study. We recorded 140 consecutive patients with acute symptomatic PE confirmed by clinical tests plus chest CT and/or perfusion scintigraphy that were admitted at hospital from February 2004 until November 2008 and not hospitalized at the time of diagnosis. We recorded clinical, tests, laboratory, treatment and monitoring variables to fill up the specifically designed form. The monitoring time lasted 4 months or until the patient died. Data were analysed with SPSS 19.0.

Results: The mean age was 66 years (SD 16.3) and the 51.4% were female. The 87.9% had previous diseases: 77% had Body mass index > 25 (and 37% BMI > 30), 43% hypertension and 9.3% diabetes. PE risk factors: cancer 12.1%, surgery 7.9%, immobilization 12.9%, previous PE or deep venous thrombosis 12.9%, air travel 1.4%, contraceptives 4.3%, varicose veins 17.9%, thrombophilia 16.4%. Clinical variables: leg edema 21.4%, chest pain 50.7%, haemoptysis 12.1%, fever 10%, dyspnea 78.6% and syncope 22.9%. Tests variables: echocardiogram performed in the 71.4%: right ventricular (RV) diameter 24.15 mm (SD 6.9), pulmonary artery systolic pressure (PASP) 45.29 mmHg (SD18.1). ECG (99.3%): mean heart rate 95.3 bpm, right bundle branch block 32.1%, S1Q3T3 22.5%, negative T waves V1-V4: 38.7%. Arterial blood gases (80%): mean pO2 63.18 mmHg (SD 14.6), pCO2 34.12, O2 sat 90.52%. Perfusion scintigraphy (69.1%): high probability for PE 62.4%. Pulmonary angiography (22%): PA pressure (mmHg): systolic 60.38, mean 36.63. Chest CT (59.3%): main arteries multiple thrombosis 50%, multiple lobar arteries 25%, multiple segmental arteries 15.3%, single mean artery 2.8%. Chest radiography (97.1%):

cardiomegaly 42.3%, Hampton's hump 3.6%, pleural effusion 21.9%. Venous US (83.6%): proximal veins thrombosis 30.7%, distal veins 7.1%. Laboratory: mean D-dimer value 2.285, creatinine 1.06, troponine-I 0.20. Treatment variables at the acute phase of PE: inferior vena caval filter 18.6%, low-molecular-weight heparin (LMWH) 70.7%, unfractioned heparin (UFH) 54.3%, oral anticoagulants (OA) 1.4%, thrombolysis 17.3%. Chronic phase: compression stockings 25.2%, LMWH 26.1%, OA 89.1% (mean duration 7.17 months). Monitoring variables: mean duration 8.58 months, cause of cessation: death 10%, consultation 90%, relapse 2.9%, adverse effects: haemorrhage 17.3% (mean INR 3.42).

Discussion: Comparing to other studies, the distribution of the risk factors for PE is homogeneous, except for the high rate of thrombophilia. The CV risk factors are concordant with the age, but high BMI is more frequent in our study. Basing on the clinical variables, we can say that these PE are of great magnitude. We have found a mortality of 10% that seems high bearing in mind the age and low comorbidity, but the number of patients isn't high enough to make mortality curves.

Conclusions: In our study, the population that suffers a PE isn't old, but almost 88% had previous disease, among which elevated BMI stands out (overweight 77%, obesity 37%). We have found a high percentage of thrombophilia carriers (16.4%). Dyspnea is the most frequent symptom (78.6%) but the syncope (22.9%), chest pain (50.7%) and tachycardia rates also are important. Concerning the diagnostic tests, the elevated PASP detected by ecocardiogram, the high percentage of ECG abnormalities, proximal thrombi in extremities at US and in proximal pulmonary arteries at CT and the high values of troponin and d-dimers are highlight too.

T-60
ANALYSIS OF TREATMENT AND COMPLICATIONS OF THROMBOEMBOLIC DISEASE

M. Areses Manrique[1], M. Mellado Ferreiro[1], E. Bidegain Garbala[1], B. Lacruz Escalada[1], J. Oteiza Olaso[4], M. J. Paloma Mora[3], H. Palacios Feria[2], G. Tiberio López[1]

[1]Department of Internal Medicine-B, [4]Department of Internal Medicine-A, [3]Department of Hematology-B. Complejo Hospitalario de Navarra. Pamplona Iruña (Navarra), Spain. [2]Department of Emergencies. Hospital García Orcoyen. Estella/Lizarra (Navarra), Spain.

Objectives: To analyze the treatment and complications of patients diagnosed with thromboembolic disease (TED) in the area of Pamplona after three months follow-up.

Material and method: We have collected all new cases diagnosed, treated and followed at the department of Internal Medicine-B of Complejo Hospitalario de Navarra and registered at RIETE until March 1, 2011. We included patients of both sexes, regardless of age, with objective diagnosis of TED based on at least one imaging test.

Results: We analized 669 cases. 44.46% (297/669) were deep vein thrombosis (DVT), 42.6% (285/669) pulmonary embolism (PE) and 12.85% (86/669) both DVT/PE. In the acute phase low molecular weight heparin was used in 90% of cases, especially enoxaparin (639/669). Unfractionated heparin (30/669), fibrinolytic (2/669) and pentasaccharides-fondaparinux (2/669) were used in the remaining 10% cases. For the long-term therapy oral vitamin K antagonist was used in 86.4% (578/669) and enoxaparin in 11.6% (78/669). Only the 0.9% (6/669) underwent insertion of vena cava filters for recurrent thromboembolism despite anticoagulation therapy. During the three month follow up, 31.8% (213/669) had some type of complication. The most common was bleeding which occurred in 19.2% patients (41/213). The 36.6% (15/41) had gastrointestinal origin, 24.4% (10/41) from muscle and the remanding cases 39% (16/41) of urological location, cerebral, retroperitoneal and others. There was major bleeding in 41.5% cases and severe in 58.5%. The 39% (16/41) cases presented bleeding despite having the INR below the therapeutic range. The next most common complication, thromboembolic recurrence, occurred in 18.3%. 59% (23/39) which as DVT and 41% (16/39) the form of PE. When relapse happened, only 30.7% (12/39) completed anticoagulant therapy. Mortality was 16.74% (112/669). The causes of death were as follows: 19.6% (22/112), 11.6% (13/112) PE, 10.7% (12/112) bleeding and 58% (65/112) other reasons.

Discussion: The analysis of the type of treatment and complications during follow-up three months show that the characteristics of patients admitted in our department is very similar to validated national studies.

Conclusions: Enoxaparin was used in 90% of cases in the acute phase of treatment and vitamin K antagonist in 86.4% of cases in the long-term treatment. In the 3 months follow up, 31.8% of patients had some type of complication after the initiation of anticoagulant therapy. Bleeding was the most prevalent complication (19.2%), especially of gastrointestinal origin (36.6%). Mortality was 16% and in contrast to the complications, the cause bleeding was the less frequent cause of mortality (10.7%).

T-61
THROMBOEMBOLIC DISEASE IN PREGNANCY

M. Areses[1], M. Abínzano[1], M. Ruiz[1], M. Roche[2], E. Huarte[1], M. Mellado[1], R. Arnáez[1], G. Tiberio[1]

[1]Department of Internal Medicine-B, [2]Department of Obstetrics and Gynecology. Complejo Hospitalario de Navarra. Pamplona (Navarra), Spain.

Objectives: Thromboembolic disease (TED) is 10 times more common during pregnancy and puerperium than in nonpregnant women. It is preventable and treatable, but in spite of maternal mortality have decreased in recent years, it is still the most common cause of death in pregnant and puerperal women. We describe the clinical and epidemiological features of pregnant and puerperal women who develop TED during last 6 years in our hospital. We review the predictive factors for developing during pregnancy and puerperium and analyze the role of the multidisciplinary approach in these patients.

Material and method: Retrospective and descriptive analysis of pregnant and puerperal women with TED that were cared for directly by the department of Internal medicine or consulting for obstetrics during last 6 years (January 2007-May 2012). We included pregnant and puerperal women with objective diagnosis of TED based on at least one imaging test.

Results: 9 patients were analyzed with mean age of 29.2 years. 6 of the events occurred during pregnancy and 3 in puerperium.

Table (T-61)

vein thrombosis	Pulmonary embolism Total			Deep venous thrombosis		Cava vein thrombosis	Ovaric
Pregnancy	1	4	0	1	6		
Puerperium	1	0	1	1	3		
Total	2	4	1	2	9		

4 of the patients had obstetric history: 3 of them had history of abortions and 1 had severe preeclampsia during a previous pregnancy. Only one of the 9 patients had kept rest for muscle problems before the thromboembolic event. 1 of the events was located on cave and iliac veins, 4 of them were deep vein thrombosis (DVT), 2 on one iliac vein and femoral system, other 2 on femoral system without affectation of the iliac vein, other 2 were ovarian vein thrombosis and last 2 pulmonary embolism (PE). In 4 patients there was a lupus anticoagulant positive determination in the acute phase, but it was negative in the second. Only in the patient who had thrombosis in the cave vein was performed fibrinolysis followed by intravenous heparin. The other 8 patients received low molecular weight heparin in the acute treatment. In puerperal women simultaneously began treatment with acenocumarol. During admission patients were followed by both internist physician and obstetrician. Short term outcome was favorable except for cave vein thrombosis, which developed a postphlebitic syndrome.

Discussion: The clinical assessment scales available outside pregnancy are not validated in pregnancy so that the diagnosis of TED should be made based on clinical suspicion using the diagnostic tools available at each hospital. It can be used the necessary radiological tests assessing the risk-benefit for the mother and fetus. The management of TED in pregnancy is similar to nonpregnant patients. They should be treated in the acute phase with low molecular weight heparin or sodium heparin.

Conclusions: It is necessary to evaluate all suspected TED during pregnancy and puerperium due to high morbidity and mortality involving the mother and fetus. This is a clinical situation that requires multidisciplinary approach between internist physician and obstetrician. Also we want to note the unusual location of thrombosis in 3 of our patients confirming the tendency extensive thrombosis and involvement of the pelvic region.

T-62
NON-PROVOKED VENOUS THROMBOEMBOLISM: OUTCOMES AT FIRST THREE MONTHS OF DIAGNOSIS

J. Pedrajas[1], V. Sendín[1], R. Jiménez[1], E. Salgado[2], M. Ciammaichella[3], G. Barillari[4], M. Monreal[5] and the RIETE Investigators

[1]Department of Internal Medicine. Hospital Clínico San Carlos. Madrid, Spain. [2]Department of Intensive Care. Hospital Clínica La Merced. Quito. Ecuador. [3]Department of Emergency Internal Medicine. Ospedale St. John. Rome. Italy. [4]Department of Internal Medicine. Center for Hemorrhagic and Thrombotic Disorders. Uridine. Italy. [5]Department of Internal Medicine. Hospital Universitari Germans Trias i Pujol. Badalona (Barcelona), Spain.

Objectives: Non-provoked venous thromboembolism (VTE) has a high incidence of recurrence after anticoagulation (AC) is stopped. It increases continuously with time, and there is no clear data on what group of patients could discontinue AC with a low risk of recurrence. Moreover, scarce information is available about outcome of non-provoked VTE in the first 3 months, when the patient is still on AC. Therefore, we evaluated the clinical characteristics, co-morbidity and prognosis of non-provoked VTE and compared it with a group of patients with secondary VTE at the first three months of diagnosis.

Material and method: Registro Informatizado de Enfermedad Tromboémbólica (RIETE) is an ongoing, prospective registry of consecutively enrolled patients with objectively confirmed, symptomatic, acute VTE. We compared the clinical characteristics of patients diagnosed with non Provoked VTE with those of patients with secondary VTE in the first three months of treatment.

Results: 39,921 patients were included. 18,029 (45.1%) were non-provoked VTE and 21,902 (54.9%) were secondary VTE. In the non-provoked VTE group, 8,922 (49.5%) had pulmonary embolism (PE) and 9,107 (50.5%) had deep vein thrombosis (DVT) while in the secondary group 10,766 (49.2%) had PE and 11,126 (50.8%) patients had DVT. Median age for non-provoked PE was 70 years, 48.5% was men, 14.8% had chronic heart failure, 19.5% chronic renal failure and 0.7% recent major bleeding, while secondary PE median age was 66 years, 44.2% was men, 8.5% had chronic heart failure, 17.5% chronic renal failure, and 3.5% had recent major bleeding (RMB) ($p < 0.001$). Data for Non-provoked DVT were as follows: 59.3% were men, median age was 64 years, and 0.5% had RMB ($p < 0.001$) while for secondary DVT were: 46% men, median age: 63 years, and 3.4% had RMB ($p < 0.001$). There were more patients with previous VTE in the non-provoked VTE group ($p < 0.001$). The initial treatment was similar in both groups, but more inferior vena cava (IVC) filters were used in secondary VTE patients ($p < 0.001$). At long term, LWMH was more used in secondary VTE than in idiopathic VTE. LWMH Doses were similar in both groups, as was the median INR.Multivariate analysis confirms that non-provoked VTE is associated with less major or mortal bleeding, fatal PE and recurrent VTE in patients with EP an in patients with DVT.

Discussion: 45% of patients had non-provoked VTE. The percentage of patients with previous VTE was higher in non-provoked VTE and initial treatment was similar in both groups, but more IVC filters were used in patients with secondary VTE. Recurrence, bleeding and death at 90 days were much more frequent in patients with secondary VTE. Multivariate analysis confirms that idiopathic VTE is associated with better prognosis both in patients with EP and in patients with DVT.

Conclusions: Our study confirms that non-provoked VTE is associated with better prognosis than secondary VTE.

T-63
VALUATION OF THE RESULT OF A TRAINING PROGRAM IN TROMBOPROFILAXIS IN THE LAST 6 YEARS IN A SERVICE OF INTERNAL MEDICINE

O. Gavín Blanco, J. Vela Moreno, J. Velilla Marco, N. Gómez Aguirre, M. Odriozola Grijalbam, N. Guiral Fernández, P. Casanova Esteban, J. Aguirre Errasti

Department of Internal Medicine. Internal Medicine/Hospital Universitario Miguel Servet. Zaragoza, Spain.

Objectives: This is a valuation of fulfillment of prophylaxis of venous thromboembolic disease in patients admitted to an Internal Medicine Service and a valuation of the degree of improvement that involves the implementation of training activities.

Material and method: Review of the medical histories and treatments of the patients admitted in the Internal Medicine Service of the Hospital Universitario Miguel Servet of Zaragoza, in 4 moments: The first in October 2006. The second in December 2006 after the completion of a clinical session on trombophrophylaxis. The third in June of 2011. The fourth in May of 2012 after creation and teaching of a protocol of thromboprophylaxis The indications and dose of low molecular weight heparin is decided on the basis of the recommendations of the ACCP and PRETEMED criteria.

Results: 1) October 2006: 100 patients. 12% oral anticoagulation with acenocoumarol or low molecular weight heparin at therapeutic doses. The prophylaxis of VTE in 70% of the patients was considered correct and in the 30% incorrect. 2) December 2006: 80 patients. 20% oral anticoagulation with acenocoumarol or LMWH at therapeutic doses. The prophylaxis of VTE in 76.3% of the patients was considered correct and incorrect in the 23.7%. 36.3%, of which 13.8% in the dose was not recommended 3) June 2011: 96 patients. 35.4% oral anticoagulation with acenocoumarol or LMWH at therapeutic doses. Overall, 73% of patients collected in June 2011 were considered correct prophylaxis with LMWH and 27% incorrect. 4) May 2012: 114 patients. 26.3% oral anticoagulation with acenocoumarol or LMWH at therapeutic doses. The prophylaxis of

VTE in 77.9% of the patients was considered correct and incorrect in the 22.1% (inappropriate dose in the 3.5%) The mean age was 76.5 ± 13 years, 53.5% were women. The average stay was 11.7 ± 9.7 days, 4.9 ± 6.7 days bedrest, 5.4 ± 8.1 days relative rest, 1 ± 3.2 days without rest. 67.5% stay more than 7 days. The average score according PRETEMED was 5.3 ± 3.2 points. 69.3% had scores greater than or equal to 4. 56.8% patients had at least 2 chronic diseases by the Spanish group of Comorbidity. 83.2% of patients took more than 4 drugs and 70.8% at least one psychoactive drug. 34.5% of patients had attended the emergency at least 2 times the previous year and 32.7% urgency. The average number of visits to the emergency room was 2.3 ± 2.6 days. The average number of hospital admissions was 1.2 ± 1.4 days.

Discussion: It reveals that thromboprophylaxis is inadequate in nearly a quarter of the patients and the inadequacy is due, in most cases to overuse. It confirms the need to develop strategies to increase the completion rate and the importance of learning. We propose an algorithm that facilitates assessment of the risk of VTE in medical patients following the recommendations of the guide PRETEMED and the ACCP.

Conclusions: VTE is a disease of high incidence, and it is essential an adequate prophylaxis. It is demonstrated the importance of medical training programs It is noteworthy that a high percentage of our patients are elderly and have multiple pathologies that hinder their clinical management.

T-64
SPLENIC PORTAL AND MESENTERIC VENOUS THROMBOSIS IN AN AREA HOSPITAL

A. Pérez Pérez[1], J. Laso Trillo[1], A. Sobrao López[1], S. Valero Cifuentes[1], E. García Villalba[1], C. López Rodríguez[2], J. Muñoz Sánchez[1], F. López Andreu[1]

[1]Department of Internal Medicine. Hospital General Universitario Reina Sofia. Murcia, Spain. [2]Department of Internal Medicine. Fundación Jimenez Díaz. Madrid, Spain.

Objectives: To present the clinical, analytical characteristics and treatment of patients diagnosed with venous thrombosis (VT) of the portal system and mesenteric vein in an internal medicine department.

Material and method: A retrospective study of a cohort of patients diagnosed with mesenteric and portal venous system thrombosis from January 2006 to December 2011 at Reina Sofia University General Hospital was performed. Only those cases whose diagnosis was confirmed by an image study were included. The data were processed using the SPSS 15.0 software.

Results: 16 patients diagnosed of splenic portal axis and mesenteric VT were admitted to our hospital between 2006 and 2011. The 68.8% were men and 31.3% women with a mean age of 68.13 ± 18 years. The average hospital stay length was 9.94 ± 5 days. The diagnosis was obtained by Doppler ultrasound in 31.3% and CT angiography in 68.8% of cases. In those patients who underwent CT angiography cavernous portal was found in 18.8%, ascites in 43.8% and splenomegaly in 43.8%. As to the extension in the portal venous system: 56.3% affected portal, 18.8% mesenteric 18.8%, 6.3% splenic portal, 6.3% mesenteric portal and 12.5% splenic portal and mesenteric. The degree of obstruction was partial in 56.3%, complete in a 6.3% and 37.5% was unspecified. Regarding to the causes: 25% showed cirrhosis, chronic liver disease 12.5%, 31.3% hepatocellular carcinoma, pancreatic carcinoma 12.5%, 6.3% other tumors (colon carcinoma, myeloproliferative syndrome etc), 12.5% pancreatitis, 6.3% spontaneous bacterial peritonitis and 6.3% biliary issues (cholangitis, etc...). The main complications presented were: upper gastrointestinal bleeding in 6.3%, hydropic decompensation in 6.3%, intestinal ischemia in 18.8%, hepatic encephalopathy in 12.5%, spontaneous bacterial peritonitis in 6.3% and biliary issues in 18.8%. The most remarkable laboratory results were a total bilirubin level of 2.53 ± 3 mg/dl, prothrombin activity 14% ± 79.69, alkaline phosphatase 137 ± 195.88 IU/L, aspartate aminotransferase 73.38 ± 68 U/L, creatinine 1.02 ± 0.2 mg/dl, albumin 3.12 ± 0.5 g/dl and hemogolbine 12.41 ± 2 g/dl. A conservative treatment was chosen in 56.3% of cases and anticoagulation was started in 43.8%. The hospital mortality was 18.8%.

Discussion: The liver receives a dual blood supply a 70-80% from the portal vein. In the adult population splenic portal axis thrombosis is related to multiple causes such as: malignant disease (liver and pancreatic carcinoma, liver metastases, myeloproliferative disorders and other tumors), inflammatory or infectious abdominal processes (pancreatitis, cholangitis), cirrhosis, splenectomy, acquired hypercoagulable states (oral contraceptive, pregnancy) or hereditary (factor V Leiden mutation, prothrombin gene mutation, antithrombin III deficiency, antiphospholipid syndrome), and trauma. Venous thrombosis can cause a partial or complete obstruction and can affect any portion of the portal venous system. The evolution may be acute or chronic, in this case the long evolution develops small vascular structures that represent collateral circulation (cavernous portal). The association of splenic portal axis and superior mesenteric vein thrombosis is rare but has a high mortality. The CT angiography is the best diagnostic tool because it allows to know the extension and commitment degree of thrombosis. The most feared complication is intestinal ischemia that appears up to 15% of cases. The treatment is early anticoagulation, surgery when necessary and thrombolysis in selected cases.

Conclusions: The outcome of the portal system thrombosis is variable and depends on the cause and time of evolution. The establishment of early anticoagulant therapy can be successful, especially if there is no established intestinal ischemia.

T-65
ASSOCIATION BETWEEN LEVELS OF HIGH-DENSITY LIPOPROTEIN CHOLESTEROL AND BIOMARKERS OF PULMONARY EMBOLISM

M. Feliu Masgoret[1], F. Marimon Cortés[1], S. Parra Pérez[1], J. Merino Ribas[2], B. Urdin Oroz[1], A. Castro Salomó[1]

[1]Department of Internal Medicine, [2]Departament of Research in Lipids and Atherosclerosis. Hospital de Sant Joan de Reus. Tarragona, Spain.

Objectives: To investigate the existence of any association between levels of High-density lipoprotein cholesterol (HDLc) and biomarkers of thrombosis as fibrinogen, D-dimer or C-reactive protein (CRP) in patients with acute pulmonary embolism (PE). To evaluate if there is any association between HDLc levels and the severity of PE and mortality.

Material and method: In this cross-sectional study we included 131 patients diagnosed with symptomatic pulmonary embolism admitted to the hospital between 2007 and 2011. The diagnostic was assessed and confirmed by computed tomography angiography (CT). The severity of PE according to their location, central (saddle or at least one main pulmonary artery) or distal (segmental or subsegmental arteries), and hemodynamic status determined by Simplified Pulmonary Embolism Severity Index (sPESI) were assessed at the recruitment. Moreover, plasma levels of D-dimer, fibrinogen, CRP and a standard lipid profile were also considered.

Results: We observed that patients with acute PE had low HDLc concentrations (36.3 ± 14.8mg/dl). No statistical differences were observed according to the HDLc with major cardiovascular risk factors such as hypertension, smoking or diabetes. HDLc was inversely associated with fibrinogen ($r = -0.219$, $p = 0.033$) and CRP ($r = -0.247$, $p = 0.017$). Assessing the severity of PE, the individuals with high sPESI (> 3) had higher CRP concentrations than individuals with low sPESI (11.1 ± 11.1 vs 4.49 ± 5.1, $p = 0.013$). On the other

hand, HDLc was not associated with the sPESI. Also, D-dimer levels were independent of HDLc concentrations and CRP (p = NS for all). Patients with acute central PE had lower, but not significantly, HDLc concentrations compared with individuals with acute distal PE (35.1 ± 12.9 vs 39.8 ± 20.6 mg/dl, p = NS). We observed that patients who died after one year of follow-up had lower HDLc concentrations than survival group (24.5 ± 7.9 vs 37.3 ± 15.4 p = 0.028).

Discussion: Venous thromboembolism is a frequent multicausal and potentially fatal disease. Clinical research in patients with acute PE has improved their clinical prognosis due to the early diagnosis and appropriate therapy. Stratifying risk management according to some clinical manifestations may decrease the burden of disease. In fact, clinical biomarkers, like troponin I or D-dimer are strongly related to worse clinical prognosis. Translational investigation focused on HDL particle has shown atheroprotective effect related to inflammation, thrombotic and oxidative stress. There is a lack of evidence regarding the HDL concentrations in the acute effect of PE patients. In this study we observed an inverse relation between HDL and inflammatory, thrombotic markers and the prognosis of PE. Furthermore, the HDL concentrations are important in the localization and severity of PE. Our results reinforce the clinical assessment of these parameters in PE patients.

Conclusions: We have observed that HDLc is associated with inflammatory and thrombotic markers, as well as with the severity and prognosis of patients with acute PE. Our results reinforce the importance of HDLc assessment in venous thromboembolism.

T-66
HYPOPLASIA OF THE VENA CAVA: A REPORT OF SEVEN CASES

F. Rodríguez Pérez-Reverte, J. Oliva Navarro, J. Martínez Bordonado, V. Rosa Salazar, M. Molina Boix

Department of Internal Medicine. Hospital Universitario Virgen de la Arrixaca. El Palmar (Murcia), Spain.

Objectives: Inferior vena cava agenesis is a rare entity wich is often found out in vein thrombosis studies. This agenesis is a congenital malformation of the venous system that takes place during de embryological development, and in 90% affects the suprarenal segment. The clinical findings consist in acute deep vein thrombosis or chronic vein failure. Other findings are abdominal collateral circulation and unspecific abdominal pain.

Material and method: We present a series of seven patients with deep vein thrombosis diagnosis, in which a secondary inferior cava vein agenesis was found.

Results: A retrospective study of seven patients. Four male and three female, with ages among 24 and 63 years old (mean 32 years old). Nine episodes of deep vein thrombosis were found with the next location: 5 ilio-femoral; 2 right femoral; 1 right ilio-femoral popliteal; and one case left femoral popliteal. The diagnoses were made by doppler ultrasonography. Cava vein agenesis was found out with an angio-CT in five patients and angio MRI. In five times a flebography were needed. Hypoplasia of the cava vein was found in infrarenal cave two times. Thrombofilia secondary studies were negative in a half of the patients.

Discussion: Hypoplasia or agenesia of inferior cava vein is a malformation that rarely can be observed in patients with vein thrombosis. In this review we can see that in young people image studies help to rule out the presence of malformations in cava vein. These findings can make a change in therapeutically approach with a long or permanent anticoagulant therapy in order to avoid new thrombotic episodes and mortality.

Conclusions: These findings can make a change in therapeutically approach with a long or permanent anticoagulant therapy in order to avoid new thrombotic episodes and mortality.

T-67
ASSESSMENT OF VENOUS THROMBOEMBOLIC DISEASE MANAGEMENT IN A SINGLE CENTER ACCORDING TO CURRENT GUIDELINES

J. Rodríguez Roca, C. Collado Pérez, A. Martín Aspas, I. Tinoco Racero

Department of Internal Medicine. Hospital Universitario Puerta del Mar. Cádiz, Spain

Objectives: The aim of this work was to identify areas for improvement in the management of first episode of venous thromboembolism disease (VTE) in internal medicine department, according to Chest 2008 guidelines.

Material and method: Prospective observational analysis of VTE cases treated in our hospital during three consecutive years 2006-2008 (222,515 inhabitants attended), managed either as outpatient or hospitalized, with no specific protocol for diagnostic and therapeutic decisions. Patients included were over 14 years old; exclusion criteria: prior history of VTE, severe sepsis, ischemic heart disease or stroke in the last month or previous anticoagulation because other indications. Cases were included from Emergency Department or hospitalized patients. Sociodemographic data, underlying disease, diagnostic procedures, treatment received and evolution (for at least 18 months or until death) were collected.

Results: Fifty-nine cases were analyzed, 27 deep vein thrombosis (DVT) and 32 pulmonary embolism (PE) with or without DVT. Mean age was 58 years (SD ±18.8), 38 women (64.4%). 76.3% of patients had previous comorbidity. Six patients (10.2%) were receiving prophylactic doses of low molecular weight heparin before inclusion in the study. In patients with high probability of VTE according to Wells scale (n = 56), D-dimer was determined in 35 patients (62.5%), but in one patient of those with low probability (n = 3) it was not determined. No patients with DVT presented respiratory failure (by pulse oximetry), but 4 were tachycardic (14.8%) with both normal plain chest radiography and electrocardiogram, but only in one patient PE study was performed (perfusion/ventilation scan), and another patient died at follow up (advanced cancer). Five patients with PE (15.6%) presented severe hypotension (Systolic blood pressure < 90 mmHg), but only 2 patients underwent echocardiography, and fibrinolysis was not performed in any patient. Hypercoagulability test was not performed in four (30.8%) of the thirteen patients with no risk factors for VTE. In 35 of the 46 patients with at least one risk factor (cancer, recent surgery, immobilization, oral contraceptives or pregnancy), hypercoagulability test was performed (76.0%). Forty six patients developed VTE during a transient risk factor, maintaining anticoagulation treatment for more than nine months in 23 (50.0%), of whom two patients (8.7%) presented gastrointestinal bleeding complications (not severe).

Conclusions: We detect areas for improvement in the diagnosis of VTE, especially in excess of D-dimer determinations and default in evaluation of PE; also in the management of severe hypotensive patients. We can optimize the application of tests for hypercoagulability and the duration of anticoagulation (maintained in excess).

T-68
THORACIC CT ANGIOGRAPHY AND CLINICALLY SUSPECTED PULMONARY EMBOLISM: ONE-YEAR REVIEW OF CLINICAL CASES

A. Calaf Viñals[1], P. Comas Casanova[1], I. Pons Martín del Campo[1], E. Sanchís Querol[2], F. Báguena Escolano[1]

[1]Department of Internal Medicine, [2]Department of Diagnostic Imaging. Hospital d'Igualada. Barcelona, Spain.

Objectives: To analyze the clinical characteristics of patients with suspected pulmony embolism (PE) who underwent multidetector CT Angiography (CTA) and to assess their diagnostic utility.

Material and method: The medical records of all clinical cases that occurred in hospital d'Igualada in 2010 were reviewed retrospectively. 160 patients, who underwent a thoracic CTA for suspected pulmonary embolism (PE) were analyzed. The evaluated parameters were: age, gender, d-dimer (high sensitivity method), Wells score (WS), final diagnosis, morbidity and follow-up beyond 3 months. The D dimer (DD) was stratified into four categories: < 500 ng/ml; between 501-1,000; between 1,001-10,000 and > 10,000. The results of the WS were grouped into three categories: low/medium/high probability. Data were analyzed using SPSS.

Results: The average age of the 160 patients studied was 74 years, 73 women and 87 men with average WS 2.62, cardiorespiratory (CR) comorbidity in 36% of the cases and malignant in 12.5% and median DD (n = 125) of 6,386 ng/ml. 38 cases were diagnosed with PE: 37 cases by CTA and 1 by angiography (24%). Other diagnoses were: 16.2% chronic respiratory disease, heart failure 12.5%, pneumonia 10%, malignancy 5.6% and miscellaneous 31.9%. CT scan provided diagnostic data in 73% of the overall series, 65% of the non-PE cases. PE group (n = 38): average age 72.3 years, 18 women (av. age 72.6) and 20 men. Average WS 4.7 (DE 1.9), low WS 10.5%, medium 73.7% and high 15.8%. Comorbidity CR 21% and 28.9% in neoplasms. DD median: 10,160 ng/ml, DD: negative 0; 500-1,000 ng/ml 0; 1,001-10,000 ng/ml 47.2% and > 10,000 ng/ml 52.8%. Predisposing factors: 11 neoplasms, 10 with sedentarism, 1 thrombophilia, 1 hemolytic a., 1 rheumatoid a. and 14 idiopathic cases. Non-PE group (n = 122): average age 74.5 years, 55 women (av. age 77.6 years) and 67 men. Average WS 2.0 (SD 2.0), low WS 56.5%, medium 41.8%, high 1.6%. CR comorbidity 40.2% and 7.4% neoplastic. DD was performed in 89 cases, median: 4,901 ng/ml, negative 3.4%, 500-1,000 ng/ml 12.3%, 1,001-10,000 ng/ml 70.8% and > 10,000 ng/ml 13.5%. During the follow-up period 2 cases of probable CT false negative were detected: a sudden death at 10 days and a documented episode of PE at 2 months.

Discussion: The prevalence of PE by CTA in our series was 23%, comparable to other series (15-35% prevalence). It was also the most frequent final diagnosis, which shows the correct clinical indication. Their high sensitivity (88%) and NPV (97.5%) confirm its role as a reference diagnostic test. On the other hand, the CTA helped to establish a diagnosis in 65% of the cases without PE. Women of the non-PE group were older (5 years) than the PE group. The factors associated with PE were malignant comorbidity and very high levels of d-dimer (> 10,000) while the predictors of non-PE were CR comorbidity, low clinical probability (EW < 2) and low DD levels (< 2xN). Using this DD value as a threshold for further study with CTA in patients with low or intermediate probability of PE could improve diagnostic accuracy.

Conclusions: 1. The prevalence of PE by CTA (23%) has been at the average reported in the literature and has been the most frequent final diagnosis. 2. The thoracic CTA has provided a high diagnostic performance: it has shown high sensitivity (88%) and NPV (97.5%) for the diagnosis of PE and has provided diagnostic data in 65% of patients without PE. 3. Neoplastic comorbidity and high levels of d-dimer (> 10,000) are factors associated with PE. 4. Cardiorespiratory comorbidity, low clinical probability (EW < 2) and low levels of d-dimer (< 2xN) are factors associated with non-PE.

T-69
CORRELATION OF THROMBOPROPHYLAXIS IN HOSPITALIZED NON-SURGICAL PATIENTS BETWEEN DIFFERENT MEDICAL SERVICES

S. Valero Cifuentes[1], J. Gómez Verdú[1], S. Galicia Puyol[2], I. Gil Rosa[2], C. Capdepón Vaillo[2], J. Bauset Navarro[2]

[1]Department of Internal Medicine, [2]Department of Emergency. University General Hospital Reina Sofia. Murcia, Spain.

Objectives: To determine whether indication of thromboprophylaxis in medical patients (admitted in both Intern Medicine Services and Emergency Department) was adequate according to clinical guideline PRETEMED 2007 and compare the indication of thromboprophylaxis between the two services.

Material and method: Prospective observational epidemiological study. In tis study, 145 patients were selected including 10% of likely missing data, all consecutively admitted from the ED for medical causes. After calculating the risk of VTE in the ED, thromboprophylactic treatment was considered and subsequently was performed follow-up of instituted therapy during hospital stay. In addition to sociodemographic variables, we collected the following variables in all patients in our sample: 1. Personal history of VTE. 2. Previous anticoagulant treatment for the same reason. 3. Assessment of VTE risk according to the clinical guideline PRETEMED 2007. 4. Presence of contraindications to antithrombotic treatment. 5. Pharmacological thromboprophylaxis indication from ED. 6. Appropriateness of thromboprophylaxis indicated by the emergency physician responsible for admission. 7. Appropriateness of thromboprophylaxis indicated.

Results: 145 patients were initially enrolled, 8 patients were missed (5.52%) due to difficulty to follow-up. The gender distribution was 76 (55.47%) males and 61 (44.52%) women, with a mean age of 65 years old. The average hospital stay of patients was 9.84 days. Only one of them had a history of previous VTE, 18 (13.14%) were anticoagulated with warfarin and previously received a prior prophylaxis with low molecular weight heparin, 14 (10.21%) cases of arrhythmias. Of 137 participants, 73 (53.3%) patients received prophylaxis for VTE indicated by physician from ED. 46 patients (31.4%) did not treat with anticoagulant prophylaxis from the Emergency Department. There were 18 patients (13.14%) previously anticoagulated, in which anticoagulation was maintained. Enoxaparin subcutaneous was the drug employed (40 mg/24 hours). It was indicated thromboprophylaxis in 85 patients (62'04%) after the admission in the Intern Medicine Service, and it wasn't indicated in 43 (31'38%) of these patients. There were 9 patients (6'57%) previously anticoagulated, in which anticoagulation was maintained. Regarding to the indications included in the thromboprophylaxis guidelines, 3 patients (2'19%) didn't receive thromboprophylaxis from ED despite fulfilling standards criteria according to PREMETED guideline. 30 patients (27'9%) received thromboprophylaxis without criteria from the guidelines. In the Intern Medicine Service, there were 11 (8.03%) patients in whom prophylaxis was not performed despite having the criteria for this recommendation according to clinical guidelines, while 43 (31.39%) patients received thromboprophylaxis without criteria that recommend it. With regard to the correlation between indication of prophylaxis from the different departments, in 24 (17.52%) patients in whom prophylactic treatment was not indicated from the ED, received prophylactic anticoagulation during their hospital stay in Intern Medicine Service. In 13 (9.49%) patients who received thromboprophylaxis from the ED, this therapy was removal when they were admitted to Intern Medicine Service.

Conclusions: Almost half of all patients who were admitted to hospitalization from ED received thromboprophylaxis. According to current clinical guidelines, only 40% really required prophylaxis. At the moment of admission to hospital wards, the percentage of patients treated with heparin prophylaxis reaches 60%, many of them after removal oral anticoagulant therapy (OAC). In both the ED and Internal Medicine Service (IMS), the percentage of patients who received prophylaxis despite not fulfilling strict criteria is greater than non-indication of this therapy when patients fulfilled criteria. We observed a tendency to excessive prescription of thromboprophylaxis by all physicians (both ED and IMS).

T-70
AUDIT OF EMERGENCY DISCHARGE REPORTS IN PATIENTS WITH LOWER-EXTREMITY DEEP VEIN THROMBOSIS. COMPARATIVE ANALYSIS BETWEEN 2010 AND 2011

P. Flors, A. Aljibe, V. Descalzo, R. González, Y. Torres, Y. Tung, R. Gil, E. Calabuig

Department of Internal Medicine. Medical Area. La Fe University and Polytechnic Hospital. Valencia, Spain.

Objectives: Evaluate the improvement in compliance with our hospital protocol about the management of patients with lower-extremity deep vein thrombosis (LE-DVT) without symptomatic pulmonary embolism (PE) before and after giving a basic education to the physicians involved in their medical care.

Material and method: 1) We listed all patients discharged with LE-DVT diagnosis from Emergency Department (ED) at La Fe University and Polytechnic Hospital in 2010 and 2011, and review all discharge summaries. 2) Inclusion criteria: LE-DVT patients without symptomatic PE diagnosed by a validated diagnostic procedure (Doppler ultrasound and/or Computed Tomography). 3) Exclusion criteria: not confirmed diagnosis of DVT or symptomatic PE. 4) ED physicians received a clinical session to remind them of the DVT protocol in December 2010. 5) A 24-item questionnaire was designed according to the parameters included in the DVT-protocol, and it was used to evaluate whether the discharge reports were filled out correctly.

Results: Compared to 2010 we found improvement ($p < 0.05$) in filling out some parameters: thromboembolic disease risk factors, weight, height, lymphadenopathies and LMWH (Low Molecular Weight Heparin) treatment at discharge (table 1). However, the majority of these parameters did not obtain a satisfactory level (> 80%). We found no statistical significance improvement difference in other parameters, such as duration of disease, previous treatment, blood pressure, heart rate, oxygen saturation, temperature, auscultation, analytical results, chest X-ray, Doppler ultrasound, LMWH first dose, bedrest, discharge destination, control by hemostasis unit and post-thrombotic syndrome prevention regimen.

Conclusions: Audit of emergency discharge reports in patients with LE-DVT allows us to find areas we should improve and prioritize them in order to design specific strategies for its management. According to our study we should give better information to discharged patients from ED, and be more accurate in data collection in clinical reports. The training strategy should be more elaborated than a brief reminder of the current hospital DVT protocol in a clinical session.

Table 1 (T-70). Comparative analysis in 2010 and 2011

Parameters	Statistical significance
DVT risk factors	p = 0.049
Weight	p = 0.035
Height	p = 0.020
Lymphadenopathies	p = 0.026
LMWH treatment at ED discharge	p = 0.042

T-71
AUDIT METHODOLOGY OF EMERGENCY DISCHARGE REPORTS IN PATIENTS WITH LOWER-EXTREMITY DEEP VEIN THROMBOSIS

A. Renau[1], P. Berrocal[1], A. Toro[1], E. Amor[1], L. Díez[1], M. Nieto[2], I. Castro[1], E. Calabuig[1]

[1]Department of Internal Medicine. [2]Department of Allergy. La Fe University and Polytechnic Hospital. Valencia, Spain.

Objectives: To develop an appropriate methodology to audit issues related to the emergency discharge report in patients with the diagnosis of lower-extremity deep vein thrombosis (LE-DVT) without symptomatic pulmonary embolism (PE), related to our hospital DVT treatment protocol.

Material and method: 1) We listed all patients discharged with LE-DVT diagnosis from Emergency Department (ED) at La Fe University and Polytechnic Hospital in 2010 and 2011, and reviewed all discharge summaries. 2) Inclusion criteria: LE-DVT patients without symptomatic PE diagnosed by a validated diagnostic procedure (Doppler ultrasound and/or Computed Tomography). 3) Exclusion criteria: no confirmed diagnosis of DVT or symptomatic PE. 4) ED physicians were trained about hospital DVT treatment protocol in December 2010. 5) A 24-items questionnaire was filled out, according to the presence or absence of the different parameters included in our hospital DVT treatment protocol. 6) Comparison of the adequacy of discharge summaries to our hospital DVT treatment protocol. 7) Check that the audit of a limited number of discharge reports is representative of the total sample. The audit was repeated with a random sample with 10% of patients (1 in 10 patients listed in chronological order) and compared to the total sample using the Z test for comparing two proportions.

Results: In 2010, were analysed 90 LE-DVT patients, of which 50% (45 patients) needed hospital admission, and the rest were treated as outpatients (Table 1). In 2011, were analysed 93 patients (64.5% outpatients). This method was validated with 2011 LE-DVT patients: random analysis of 10% of 2011 sample was representative of the total sample in all items analyzed ($p > 0.05$).

Conclusions: Basic parameters were successfully completed over 80% of LE-DVT patients. Weight, height and lymph nodes exploration were the less reflected items in ED discharge reports. Information given to ED discharged patients with LE-DVT (treatment information sheet, post-thrombotic syndrome prophylaxis recommendations, LE-DVT first days life regime...) did not obtain a satisfactory level. Random analysis of 10% of LE-DVT patients treated in 2010 and 2011 was representative of the total sample in all analysed items. No statistical significant differences were found.

Table 1 (T-71). Correctly filled out audited parameters for outpatient therapy indication

	Yes (total sample) N = 45/90 (50%)	Yes (randomsample) N = 6/10 (60%)	p-value
First dose of LMWH in ED	22 (48.9%)	3 (50%)	0.7
LMWH therapy in ED discharge report	42 (93.3%)	5 (83%)	0.9
24 hour bed-rest, followed by relative rest	10 (22.2%)	3 (50%)	0.3
Discharge destination to Internal medicine	29 (64.4%)	6 (100%)	0.2
Control by Haemostasis unit	19 (42.2%)	3 (50%)	0.9
Post-thrombotic syndrome prophylaxis advices	7 (15.6%)	1 (17%)	0.6
Handle information sheet to patients	5 (11.1%)	1 (17%)	0.8
First visit to Internal medicine in 10-days period	25 (55.6%)	4 (66.6%)	0.98

T-72
VENOUS THROMBOEMBOLIC DISEASE: RISK FACTORS

L. Novoa, J. Álvarez, P. Sánchez, A. Sanjurjo, R. Puerta, J. de la Fuente

Department of Internal Medicine. Povisa Hospital. Vigo (Pontevedra), Spain.

Objectives: Determine the incidence of risk factors involved in VTE in our population.

Material and method: Retrospective study of patients admitted to our hospital from 1 January to 31 December 2008 with the diagnosis of venous thromboembolism (VTE). We considered as risk factors: use of oral contraceptives (OC), smoking, immobilization in the previous month, surgery in the last month, neoplasia in the six months before or at the time of diagnosis, heredity or previous episodes of VTE. Are also evaluated demographic characteristics, comorbidities, location and extent of VTE.

Results: We included 165 patients (54.5% women), mean age 71 ± 14.8 years. 65.5% (56 patients) had only deep vein thrombosis (DVT) and 73.8% (109 patients) pulmonary embolism (PE) with or without DVT. 3.3% of women consumed OC; 10.9% of patients were smokers, male more often significantly, 21.8% had history of immobilization in the previous month and 10.9% underwent surgery in the last month. 19.4% had been diagnosed of neoplasia in the previous 6 months and 20.6% had at the time of diagnosis active neoplasic disease. In 20 patients (12.1%) it was identified a hereditary factor for VTE, and in this group was less frequent PE. 15.8% had a previous episode of VTE. The most frequent comorbidities were: hypertension (40%), dyslipidemia (18.8%), permanent atrial fibrillation (15.8%), more common in women significantly; chronic renal insufficiency (14.5%), DM 2 (13.3%), COPD (8.5%), more common in men significantly, heart failure (7.9%), ischemic stroke (7.3%) and MI (2.4%). The most common site of DVT was proximal venous system of lower extremities (41.2%) and 9.1% of PE were massive.

Discussion: All risk factors for venous thromboembolism evaluated in our study are recognized in the medical literature. In particular, neoplasic disease, as confirmed by our results. Immobilization is another widely recognized risk factor, especially that associated with hospitalization and surgery.

Conclusions: The risk factors most frequently associated with VTE were neoplasia at the time of diagnosis or within 6 months prior and immobilization. These findings are similar to those found in other articles in the literature.

T-73
HIGHER RISK OF THROMBOSIS FROM NON-HODGKIN LYMPHOMA CAN BE ANTICIPATED BY CLOT LYSIS INDUCTION ASSAY

K. Portillo, F. Esquivel, A. Riega, N. Ruiz, M. García-Peral, A. Ruedas, V. Gómez del Olmo, J. Murciano

Department of Internal Medicine. Hospital Universitario Ramón y Cajal. Madrid, Spain.

Objectives: Thromboembolic risk increases in cancer patients, independently of the initiation of the antitumoral treatment. Cancer environment is also highly hemorrhagic, which sometimes limits thromboprophylactic regimes. Both risks cannot be anticipated, and vary with each individual patient and the type of tumor. In order to anticipate such diagnostic parameter/s and develop a more appropriate "a la carte" pharmacological regime, Internal Medicine Unit, in the Ramon y Cajal Hospital in Madrid, initiated a collection of plasma and peripheral blood lymphocytes from recently diagnosed cancer patients who does not undergo antitumoral treatment yet. The principal aim is to define the lymphoma risk to procoagulant or antifibrinolytic effect.

Material and method: Blood from cancer patients were obtained by venipuncture between 7-11 am. The clinical laboratory measured in whole blood the levels of protein C, brain natriuretic peptide and D-dimer and the research unit isolated plasma and mix it with 1nM tPA to study its induced clot lysis effect over pure (125)iodinated fibrin clots. Healthy volunteer plasma was isolated parallely as a control group. Data were run in triplicates for each experiment and statistically analyzed with SigmaStat 3.1.

Results: Since July 2011, our unit collected 98 tumoral patients samples containing 21 non-Hodgkin lymphomas. This cancer group distributed in an age range (66.5 ± 15.8 years) similar to the total number of patients (70.3+13 years). A 62% of lymphomas were females, and 76% disseminated. D-dimer, C reactive protein and brain natriuretic peptide (BNP) showed elevated, but not conclusively enough levels that prevented the anticipation of the prothrombotic risk. Interestingly, among the lymphoma patients, development of thromboembolic disease or pulmonary embolism at the time of diagnosis occurred in a 14% of the patients (3 cases out of 21). Subsequently, during their 6 months evolution, another 2 patients developed a TEP accident. Both observations increase the thromboembolic occurrence to a significant 23%. tPA induced clot lysis assay demonstrated a significant ($p < 0.001$) impairment of the fibrinolytic percentage, both in localized (61.40 ± 17.78) or disseminated lymphomas (66.65 ± 15.92) as compared to control plasma (80.22 ± 7.96).

Conclusions: Presented data pinpoint the higher prothrombotic risk of the recently diagnosed non-Hodgkin linfomas. This critical observation becomes anticipated by the clot lysis induction assay which demonstrated equal thrombotic hazard both from localized or disseminated linfomas.

T-74
VENOUS THROMBOEMBOLIC DISEASE: CLINICAL PRESENTATION AND MEDICAL EVOLUTION

J. Álvarez, L. Novoa, A. Sanjurjo, P. Sánchez, R. Puerta, J. de la Fuente

Department of Internal Medicine. Povisa Hospital. Vigo (Pontevedra), Spain.

Objectives: Determine the long-term prognosis of patients with the diagnosis of venous thromboembolism (VTE). We also want to evaluate the presentation and clinical course, anticoagulant therapy and survival.

Material and method: Retrospective descriptive study of patients admitted to our hospital from 1 January to 31 December 2008 with the diagnosis of VTE. We consider demographic characteristics, clinical presentation, diagnosis methods including laboratory tests and imaging techniques, anticoagulant therapy at the time of diagnosis and indication for permanent anticoagulation. We analyzed the survival at 3, 6, 9 and 12 months and the prognosis at 48 months.

Results: We included 165 patients (54.5% women) with mean age 71 ± 14.8 years. 65.5% (56 patients) had only deep vein thrombosis (DVT) and 73.8% (109 patients) pulmonary (PE) with or without DVT. The most common symptom of patients with PE was dyspnea (61.4%), followed by pleuritic chest pain (23.8%), syncope (13.7%) and hemoptysis (2.6%). The most common clinical in patients with DVT was swelling (74%), pain (58.7%) and erythema (18.4%). About laboratory tests, D-dimer had a mean value of 1946.24 ± 1662.2 and was normal in 3 patients. The most commonly used imaging test in the diagnosis of PE was chest CT-angiography (59.4%), showing DVT in 27.3% of cases; Scintigraphy V/P was high probability diagnostic in 34.7% of cases. 3% of patients required admission to the ICU for

massive pulmonary embolism. In two patients, thrombolysis was performed, in one patient was placed a vena cava filter and all initially received anticoagulation therapy with LMWH and 70.9% began oral anticoagulation prior to discharge. 42.4% of patients permanently maintain oral anticoagulation, and 33.9% have known risk factors. Died during admission 12.1% of patients and survival was 87.3%, 84.2%, 80.6% and 78.2% at 3, 6, 9 and 12 months respectively. 5.6% of patients had a new thrombotic event during follow-up period and was more frequent in patients with a hereditary risk factor. At 48 months, 36.8% of patients died, more likely in the group of women (12.3% by cancer, 2.5% cardiovascular causes, 0.6% rethrombosis and 16% by other causes). Moreover, 63.2% of patients are alive at 48 months of which, 8% were diagnosed with neoplasia and 2.5% developed a new episode of VTE.

Discussion: Clinical manifestations of VTE reported in our study (dyspnea and chest pain in PE; swelling and pain in DVT) are consistent with those contained in the medical literature, no doubt. The recurrence rate and risk factors for recurrence, as the case of hereditary factors were similar to findings reported in unselected populations. Also, while VTE is a major cause of morbidity in oncological patients, cancer is a known cause of death in these patients.

Conclusions: Patients with a hereditary risk factor had more thrombotic recurrence. Survival was decreasing progressively during the first year. The most common known cause of death was the neoplasic disease.

T-76
PLASMA FROM METASTATIC, BUT NOT LOCALIZED, LUNG TUMORS INHIBITS TPA FIBRINOLYTIC CAPACITY

K. Portillo, A. Veiga, F. Esquivel, A. Riega, N. Ruiz, M. García-Peral, V. Gómez del Olmo, J. Murciano

Department of Internal Medicine. Hospital Universitario Ramón y Cajal. Madrid, Spain.

Objectives: Thromboembolic risk increases in cancer patients, independently of the initiation of the antitumoral treatment. Cancer environment is also highly hemorrhagic, which sometimes limits thromboprophylactic regimes. Both risks cannot be anticipated, and vary with each individual patient and the type of tumor. In order to anticipate such diagnostic parameter/s and develop a more appropriate "a la carte" pharmacological regime, Internal Medicine Unit, in the Ramon y Cajal Hospital in Madrid, initiated a collection of plasma and peripheral blood lymphocytes from recently diagnosed cancer patients who does not undergo antitumoral treatment yet. The principal aim is to define the lung cancer risk to procoagulant or antifibrinolytic effect.

Material and method: Blood from cancer patients were obtained by venipuncture between 7-11 am. The clinical laboratory measured in whole blood the levels of protein C, brain natriuretic peptide and D-dimer and the research unit isolated plasma and mix it with 1nm tPA to study its induced clot lysis effect over pure (125)iodinated fibrin clots. Healthy volunteer plasma was isolated parallely as a control group. Data were run in triplicates for each experiment and statistically analyzed with SigmaStat 3.1.

Results: At the present time, from the 98 cancer patients collected for our study, a group of 27 patients were diagnosed with a lung tumor. Lung patients showed an age distribution (68.5 ± 9.6 years) that does not differ from the total cancer patients diagnosed in the unit (70 ± 13 years). Majority of these lung cancers occurred in males (93%) and reached the hospital in metastasis (86%). Immunohistological classification of the lung patients felt in four different groups, a) microcytic (32%), b) epidermoid (8%), c) adenocarcinoma (52%) and d) undefined (8%). D-dimer, C reactive protein or brain natriuretic peptide do not offer a statistically significance between blood levels in metastatic or localized lung tumors. However, clot lysis assay depicted a reduction of the percentage of the external tPA lytic capacity in the presence of metastatic patient plasma (55.9% ± 14.8), but not plasma from localized ones (79.9% ± 2.9) as compared with plasma from healthy volunteers (80.7% ± 7.8). When the analysis from metastatic patients were crossed with the immunohistological tumoral group, the reduction of tPA lytic capacity was even greater in the epidermoid (21.7% ± 2.3) and microcytic (55.6% ± 12.2) patients, than in the adenocarcinoma (65.1% ± 8.6) ones.

Conclusions: Presented data demonstrate that fibrinolytic-induced analysis in the presence of plasma from lung patients could anticipate a higher prothrombotic state, assigning a clear risk to metastatic patients. Interestingly, within the metastatic lung patients, the highest risk associates to epidermoid and microcytic groups.

T-77
COLORECTAL TUMOR INCREASES PROTHROMBOTIC RISK IN NON-CANCER TREATED PATIENTS

K. Portillo, A. Ballester, F. Esquivel, A. Riega, N. Ruiz, G. Fraile, V. Gómez del Olmo, J. Murciano

Department of Internal Medicine. Hospital Universitario Ramón y Cajal. Madrid, Spain.

Objectives: Thromboembolic risk increases in cancer patients, independently of the initiation of the antitumoral treatment. Cancer environment is also highly hemorrhagic, which sometimes limits thromboprophylactic regimes. Both risks cannot be anticipated, and vary with each individual patient and the type of tumor. In order to anticipate such diagnostic parameter/s and develop a more appropriate "a la carte" pharmacological regime, Internal Medicine Unit, in the Ramon y Cajal Hospital in Madrid, initiated a collection of plasma and peripheral blood lymphocytes from recently diagnosed cancer patients who does not undergo antitumoral treatment yet. The aim is to define the colorectal cancer risk to procoagulant or antifibrinolytic effect.

Material and method: Blood from cancer patients were obtained by venipuncture between 7-11 am. The clinical laboratory measured in whole blood the levels of Protein C, Brain Natriuretic Peptide and D-dimer and the research unit isolated plasma and mix it with 1nm tPA to study its induced clot lysis effect over pure (125)iodinated fibrin clots. Healthy volunteer plasma was isolated parallely as a control group. Data were run in triplicates for each experiment and statistically analyzed with SigmaStat 3.1.

Results: At the present time, from the 98 cancer patients collected in the study, 17 patients suffered from an adenocarcinoma colorectal tumor. These patients distributed in an age range (75.52 ± 9.14 years) comparable to the cancer patients enrolled in the study (70.3+13 years). A 65% of colorectal cancers were males, and 52% arrived in metastasis. D-dimer comparison demonstrated statistically significant difference ($p = 0.029$) between localized (860 ± 462) vs metastatic patients (4592 ± 2847). However, only subtle, but not significant difference was found in terms of C-reactive protein (40 ± 38 vs 195 ± 182) or BNP (422 ± 441 vs 296 ± 375). Interestingly, external tPA plasma fibrinolysis significantly reduced its activity ($p < 0.001$), both at localized 60.33% ± 12.16 or disseminated colorectal patients 54.95 ± 18.98, as compared to healthy volunteers plasma (80.22% ± 7.96).

Conclusions: Adenocarcinoma colorectal patients present high prothrombotic risk both by means of D-dimer and clot lysis assay

determination. This risk is comparable for both localized or disseminated colorectal cancer.

T-78
INCIDENCE OF THROMBOEMBOLIC RISK IN TUMORAL PATIENTS BEFORE ANTITUMORAL TREATMENT

K. Portillo, A. Veiga, A. Ballester, A. Ruedas, G. Fraile, I. Said, J. Murciano, V. Gómez del Olmo

Department of Internal Medicine. Hospital Universitario Ramón y Cajal. Madrid, Spain.

Objectives: Thromboembolic risk increases in cancer patients, independently of the initiation of the antitumoral treatment. Cancer environment is also highly hemorrhagic, which sometimes limits thromboprophylactic regimes. Both risks cannot be anticipated, and vary with each individual patient and the type of tumor. In order to anticipate such diagnostic parameter/s and develop a more appropriate "a la carte" pharmacological regime, Internal Medicine Unit, in the Ramon y Cajal Hospital in Madrid, initiated a collection of plasma and peripheral blood lymphocytes from recently diagnosed cancer patients who does not undergo antitumoral treatment yet. This work will serve to define the cancer risk to procoagulant or antifibrinolytic effect. To elaborate a better knowledge and evolution of the tumoral patient diagnosed at this type of clinical unit.

Material and method: Blood from cancer patients were obtained by venipuncture between 7-11 am. The clinical laboratory measured the levels of Protein C, Brain Natriuretic Peptide and D-dimer in whole blood and the research unit isolated plasma and mix it with 1nm tPA to study its induced clot lysis effect over pure (125) iodinated fibrin clots. Healthy volunteer plasma was isolated parallely as a control group. Additionally, a data base was started and included all clinical and experimental observations, while it will monitored the patient evolution and the appearance of thromboembolic events during the following two years.

Results: First classification of the 98 patients showed an age range of 70 ± 13 years, which is noticeably lower than the non-tumoral patients diagnosed at the Unit (85 + 17 years). 65% of the patients were male and a great percentage of the patients arrived in metastasis (70%). Interestingly enough, 30% of the total patients arrived with a localized and potentially curable tumor situation. Patients could be classified in three major tumoral groups: 1) Lung cancer, 29 patients (27%); 2) Hemathological ones: 22 linfomas (21%), 4 Hodgkin disease (3.8%) and 1 myeloma (1%) and 3) Colorectal tumors: 18 cases (17%). Our unit also diagnosed 1 esophagus (1%), 5 stomach (4.8%), 3 pancreas (2.9%), 3 liver (2.9%), 2 biles (1.9%), 1 bladder (1%), 1 prostate (1%), 1 ovary (1%), 1 breast (1%), 3 brains (2.9%), 3 other localizations (2.9%) and 2 non-defined (1.9%) tumors. 2 other patients (1.9%) exhibited simultaneously colorectal and lung unrelated primary tumors. Thromboembolic risk at diagnosis revealed 4 cases of venous thromboembolism, VTE, and 5 pulmonary embolisms, PE, (9% of cases) representing a combined odds ratio of 28. Within the following 3 months appeared 3 newer cases from 42 patients monitored (2 VTE, 1 PE, 7%) and within 6 months, 2 more cases out of 22 (1 VTE, 1 PE, 9%). Lymphoma group was the most sensitive one with 5 thrombotic events (23%), followed by the lung 3 cases (10%) and colorectal ones (5.5%). Other thromboembolic risk parameters such as BNP, D-dimer and C Protein could not demonstrate significant differences between cancer patients and control ones.

Conclusions: Thromboembolic risk in tumoral patients increases significantly (9% at diagnosis) and remains high within the following 6 months. Lymphomas were the most thromboembolic ones with a 23% risk, followed by lung tumors (10%) and colorectal ones (5%).

T-79
A COMPARATIVE STUDY OF THE CARDIOVASCULAR RISK FACTORS IN CASES OF VENOUS THROMBOEMBOLISM AND ARTERIAL DISEASE (VENART PROGRAM)

L. Boix, A. Contra, S. Jordán, I. Cabello, X. Solanich, F. Trias, X. Pintó, A. Riera Mestre

Department of Internal Medicine. Hospital Universitario de Bellvitge. Hospitalet de Llobregat (Barcelona), Spain.

Objectives: The aim was to compare the prevalence of the cardiovascular risk factors in patients with venous thromboembolism (VTE) and those with arterial disease, all of them attended in a specific unit of Internal Medicine Department in a university hospital.

Material and method: A retrospective and comparative statistical analysis of the prevalence of cardiovascular risk factors in two different groups of patients. The first group was composed by patients who suffer from VTE during the first six months of 2011 and the second group included patients who suffer from an acute myocardial infarction (AMI) between 2003 to 2006.

Results: The first group of VTE included 65 patients, 58.5% with deep venous thrombosis and 37% wit pulmonary embolism. Mean age was 62.8 (SD 18.4) years and 58.5% were men. Mean corporal mass index was 28.7 (SD 3.6) Kg/m^2. Most patients (66%) suffer from an idiopathic VTE episode. With regard to cardiovascular risk factors, 50.7% of the patients were ex-smokers or active-smokers, 44.8% were obese, 49.2% had hypertension, 15.6% diabetes and 45.3% dislypemia. A comparative analysis of VTE patients with the group of 137 patients who had an AMI showed a significant higher percentage of women (41.5% vs 13.1%), lower percentage of tobacco use (50.7% vs 80%) and an older age (62.8 vs 57.8 years old). However, hypertension (49.2% vs 49.6%), diabetes (16.6% vs 23.4%), dyslipenia (45.3% vs 54.4%) and obesity (44.8% vs 45.3%) showed similar prevalence between 2 groups.

Discussion: The hypothesis that VTE and atherosclerosis share common risk factors is still matter of debate. VTE and cardiovascular disorders may share common risk factors and in some patients at risk for atherosclerosis, VTE might occur as the first symptomatic cardiovascular event. This association between VTE and atherothrombosis has great clinical relevance with respect to individual screening, risk factor modification, and the primary and secondary prevention of VTE.

Conclusions: Smoking, obesity, hypertension and dyslipidemia were the cardiovascular risk factors more frequently associated to VTE. Prevalence of these cardiovascular risk factors were similar in AMI patients, except for smoking. It is necessary a multidisciplinary approach to optimize detection and treatment of cardiovascular risk factors in VTE patients.

T-80
ADEQUACY OF THROMBOPROPHYLAXIS IN HOSPITALIZED MEDICAL PATIENTS ACCORDING TO CURRENT RISK SCALES

A. Franco Moreno[1], J. Bascuñana Morejón de Girón[2], P. Agudo de Blas[2], C. de Ancos Aracil[3], C. Maínez Saiz[4], A. Rodríguez Benavente[3], J. Ortiz Sánchez[1]

[1]Department of Internal Medicine. Hospital de Torrejón. Madrid, Spain. [2]Department of Internal Medicine. Hospital Infanta Leonor. Madrid, Spain. [3]Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain. [4]Department of Internal Medicine. Hospital Universitario Puerta de Hierro Majadahonda. Majadahonda (Madrid), Spain.

Objectives: To assess the thromboprophylaxis (ThP) rate and its adequacy according to different scales for venous thromboembolism risk (VTE-r) and bleeding risk (B-r) in hospitalized medical patients.

Material and method: an observational descriptive study was undertaken in 4 medical services in Madrid (HU Infanta Leonor, H. de Torrejón, HU de Fuenlabrada y HU Puerta de Hierro), which included 247 inpatients during a defined period. The individual risk to ETV was evaluated according to current scales: PRETEMED Guide (low risk: 1-3 points; moderated- high risk ≥ 4), Caprini Predictive Model (CPM) (low risk: 0-1, moderate: 2, high: 3-4 and very high: ≥ 5), and Padua Prediction Score (PS)(low: 1-3, high ≥ 4). The individual bleeding risk estimation (H-r) was evaluated by: IMPROVE-h (high risk ≥ 7), RIETE-h (low: 0, moderated: 1-4, high > 4). All inpatients without previous anticoagulation were considered subsidiary to ThP.

Results: 59.5% of patients were male, with an average age of 69.6 ± 17.4 years. At hospital admission 16.2% of patients were not subsidiary of ThP (67.5% due to previous anticoagulation, and 32.5% due to having started it in the hospital). The ThP global rate in all patients subsidiary to ThP was 36.3% (59.3%-66%). It was started at ER department in 74.24%. We found a higher ThP rate in the Internal Medicine (IM) department than in the other departments (67.9% vs 40% onco/hematology and 53.6% rest of medical departments). Patients with PtH were older (71.4 ± 17.7 vs 63.7 ± 18.4, p = 0.03) and had a higher BMI (27.3 ± 5.8 vs 25.6 ± 4.7, p = 0.03). There was a high VTE-r in 64.6% of the patients (Padua Prediction Score).Of the 3 ETV risk scales, Padua PS is the one that classifies more patients as low risk. The recommendations for ThP were as follows: Caprini 91.9% (76.4% high/very high risk), PRETEMED Guide 55.4% (moderated/high risk), and PRETEMED Guide 49.2% (high risk). ThP is adequate in 57.9% according to Padua PS and Pretemed Guide and in 67.7% according to Caprini PM, with low kappa concordance indices (< 0.2) for all of them (0.163; 0.132 y 0.152 respectively). Bleeding risk when entering the hospital was high in 14% (IMPROVE-h, initiating ThP in 44.8%, OR 0.43; 95%CI of 0.2-0.9 versus 5% with RIETE-h scale).

Discussion: The agreement degree of ThP with respect to any of the scales that were used is statistically significant, being higher in IM than in other specialties (excluding oncohematology). In 15.5% LWMH dose is considered non adequate (35% underdoses and 65% overdoses).

Conclusions: 1. About two thirds medical patients receive thromboprophylaxis. 2. Adequacy of ThP depends on current specific scores but in general it is low.3. It would be appropriate to include an automatic Warning or Check list in electronic medical history to improve the thromboprophylaxis management.

Others

V-1
UTILITY OF CINACALCET IN NON-SURGICAL PRIMARY HYPERPARATHYROIDISM

J. Marti, J. Rodríguez, A. Zurutuza, B. Lasa

Department of Internal Medicine. Hospital de Zumárraga. Zumárraga (Guipúzcoa), Spain.

Objectives: Parathyroidectomy remains the only curative approach to most primary hyperparathyroidism (PHPT), medical treatment with cinacalcet has been proven to be an alternative for patients with secondary hyperparathyroidism and parathyroid cancer. Aim. To analyze the treatment with cinacalcet, in patient with primary hyperparathyroidism not tributary of surgery.

Results: We present 4 patients 2 women and 2 man 67 ± 11.5 year-old with diagnosis of PHPT, in whom surgical procedure was rule out. Calcium levels previous treatment was 11.85 ± 0.28 mgr/dl and PTH 169 ± 42 pg/ml. Treatment with cinacalcet 30 mg. daily was started. Fifteen days after initiated treatment calcium levels were 10.6 ± 0.15 mg/dl and PTH 146 ± 12 pg/ml. Cinacalcet was increased to 30 mg bid. Two months after initiated treatment, calcemia levels were 10.1 ± 0.6 mg/dl and PTH 92.3 ± pg/m. Adverse events not observed.

Discussion: In 80% of cases, PHPT is due to a single parathyroid adenoma, for which surgery is considered the treatment of choice based on guidelines established by the National Institutes of Health Consensus Panel. However, since success rates of the operation are less than 100% and vary between centers, pharmacotherapy with agents such as cinacalcet could be an alternative in a subset of patients with persistent hypercalcemia after one or more surgical interventions. Cinacalcet is a calcimimetic agent that increases the sensitivity of the calcium-sensing receptor to activation by extracellular calcium. Serum calcium and serum phosphorus should be measured within 1 week and iPTH should be measured 1 to 4 weeks after initiation or dose adjustment. Cinacalcet is useful in the management of primary hyperparathyroidism in patients in whom parathyroidectomy is contraindicated or who have failed surgical correction of their primary hyperparathyroidism, in doses of 30-60 mg daily. Patients should be carefully monitored for the occurrence of hypocalcemia. Potential manifestations of hypocalcemia include paresthesias, myalgias, cramping, tetany, and convulsions.

Conclusions: Cinacalcet, the first available calcimimetic, increases the sensitivity of the calcium-sensing receptor (CaR) to circulating serum calcium, thereby safely reducing serum calcium and PTH concentrations in patients with mild-to-moderate PHPT, intractable disease, and also parathyroid carcinoma. Cinacalcet in a reasonable and safe alternative to treatment of PHPT not tributary of surgery.

V-2
PNEUMOMEDIASTINUM AS AN UNUSUAL CAUSE OF CHEST PAIN: REPORT OF TWO CASES

R. Qanneta[1], G. García Pardo[2], A. Sheikh Khanji[3], J. Gálvez Mora[3], C. Boqué Oliva[4]

[1]Department of Internal Medicine. Hospital Sociosanitari Francolí. Tarragona, Spain. [2]Department of Internal Medicine, [3]Emergency Medical Physicians, [4]Emergency Medical Unit Coordinator. Hospital Universitari Joan XXIII. Tarragona, Spain.

Objectives: Pneumomediastinum is an uncommon clinical entity. May complicate processes that increase intraalveolar pressure leading to alveolar rupture. The etiology is multifactorial and can be primary (spontaneous) or secondary (traumatic). We present two patients diagnosed of pneumomediastinum in the Emergency room. One of the cases was spontaneous while the other one was traumatic.

Material and method: Descriptive analysis of two cases of pneumomediatinum reviewing medical record data.

Results: 1st patient: 23 year old male patient, active smoker of cigarettes and cocaine, who consults for odynophagia, dysphagia and pain retroesternal of several days of evolution in the context of hyperemesis continuously and copiously. Physical examination revealed supraclavicular fossa subcutaneous emphysema and synchronous crepitation with the cardiac beating (sign of Hamman). Electrocardiogram registration and blood test were normal. Urine testing for cocaine was positive. Chest X ray and Scan evidence presence of air in mediastinum separating structures (pneumomediastinum). 2nd patient: 46 year old female patient who consults for cough, dyspnea and chest pain 24 hours immediately to a central

venous catheter placement for chemotherapy for hepatocelullar carcinoma with lung metastases of recent diagnosis. Physical examination showed subcutaneous emphysema in the neck, tachypnea and 88% of oxygen saturation. Electrocardiogram registration evidence sinus tachycardia. Blood test was normal. Chest Scan evidence presence of air in mediastinum separating structures (pneumomediastinum). Maintaining both patients at rest and vigilance as well as oxygen therapy and symptomatic treatment with spontaneous resolution immediatly to 5 and 7 days respectively.

Discussion: The spontaneous pneumomediastinum is an entity that was described as a clinical syndrome in 1939 by Hamman. In 1944 Macklin was described their pathophysiologic basis. Some authors have been found as causes bronchial asthma, coughing, maneuvers of Vasalva, ketoacidosis, repeated vomiting and drug use abuse such as cocaine and ecstasy (Vidal Marsal et al. Med Clín, 1984) taking into consideration the last two conditions in our 1st case. The 2nd case is clearly traumatic (iatrogenic) due to dissected mediastium secondary to a central venous catheter. The evolution of the pneumomediastinum is benign and self-limited with rare complications as seen in our two cases.

Conclusions: The pneumomediastinum is an uncommon clinical entity and has a benign course with symptomatic treatment. The differential diagnosis is extremely essential in the Emergency room.

V-4
EVOLVING PATTERNS OF THE ACTIVITY OF AN INTERNAL MEDICINE DEPARTMENT OVER A TWELVE YEAR PERIOD

J. Trindade Nave, L. Santos Pinheiro, M. Lucas, R.M.M. Victorino

Department of Internal Medicine 2. Hospital Santa Maria. Lisbon, Portugal.

Objectives: Given the clinical and institutional challenges faced by Internal Medicine (IM), it is relevant to detail its recent evolving patterns relevant to planning the future of hospital care in this area. We aim characterize here the evolution of clinical activity and patient profiles of an IM department in a University Hospital over a period of 12 years.

Material and method: We conducted a study with retrospective data collection of the admissions in an IM department between 1999 and 2010. The data source was the hospital electronic data records. The main variables recorded included: demographic patient data (gender and age), length of stay (LoS), occupancy rate (OcR), discharge destiny and deaths. Diagnosis and nosological groups were coded using the International Classification of Diseases 9th revision and recoded using the Clinical Classifications Software. For each admission the existence of chronic conditions was identified by the Chronic Condition Indicator (AHQR - EUA). Elixhauser and Charlson comorbidity indexes were calculated as surrogates of patient complexity and comorbidities.

Results: There were 42,350 admissions (females: 55.1%) with 43.4 discharged patients per bed. The mean patient age was 67.9 years, with a consistent 13.8% increase between 1999 (63.9 years) and 2010 (72.7 years), similar in both genders. The percentage of patients over 80 years doubled from 20.6% in 1999 to 39.7% in 2010. The LoS remained stable (average 8.8 days). There was a slight although significant increase in the death rate (DR) (1999:9.8%, 2010:11.6%), more prominent in patients under 65 years (1999:5.4%, 2010:8.5%). The OcR was 89%. The number of coded diagnosis per patient increased from 3.4 in 1999 to 7.0 in 2010. This tendency was also present in the number of chronic conditions that averaged 2.2 in 1999 and 4.3 in 2010. In the period considered, between 91% and 97% of patients had at least one chronic condition. Both the Charlson and Elixhauser comorbidity indexes steadily increased from 1999 (Charlson: 1.6; Elixhauser: 1.0) to 2010 (Charlson: 2.5; Elixhauser: 2.3). The global pathological profile did not vary, with predominance of respiratory and urinary infection, cerebrovascular disease and heart failure. In the age group under 65 years, there was a 70.2% increase in the relative weight of neoplasias from 1999 (20.1%) to 2010 (34.2%) compared to an increase of 40.8% in the patients over 64 years.

Discussion: The significant number of discharged patients per bed and patient ageing, with predominance of the advanced age groups, the greater clinical complexity illustrated by the increment of comorbidity indexes and number of comorbidities, most of them chronic diseases, pose a growing pressure on IM departments. Interestingly the DR upward slope was more pronounced in patients under 65 years partially explained by the major increase in the relative weight of admitted neoplastic conditions.

Conclusions: The increasing complexity and multipathology of the IM hospitalized patients brings additional pressure on its response to the healthcare needs of this population. We emphasize the primordial role of Internal Medicine as a provider of differentiated and integrated medical care to this profile of patients.

V-5
FEATURES OF PAPILLARY THYROID MICRO CARCINOMA, RETROSPECTIVE STUDY

J. Marti, A. Zurutuza, B. Lasa, M. Manrique, J. Rodríguez

Department of Internal Medicine. Hospital de Zumárraga. Zumárraga. Guipúzcoa, Spain.

Objectives: Papillary thyroid micro carcinoma (PTMC) is defined as a papillary thyroid cancer measuring 10 mm or less in greatest dimension. Increasing incidence of papillary thyroid micro carcinoma (PTMC) is due to accurate histological study of surgical specimens or to improved preoperative diagnostic techniques. Recent data reveal that in the last 25 years it has been a 2.4 fold increase in thyroid cancer, with concomitant rise in thyroid microcarcinoma cases Aim. The objective of this study was to assess the clinical presentation, tumour characteristics and follow-up.

Material and method: We analysed clinicopathologic data of incidentally papillary thyroid micro carcinoma, from 321 thyroid surgeries carry out in our hospital between 2005 and 2010.

Results: Of 321 surgeries carried out in our hospital, in 18 cases all females of 55.11 ± 11.34 year-old (range 37-79) PTMC was detected in hystopathology. FNA previous surgery was negative for papillary tumor, in 4 cases follicular cells were detected. Total thyroidectomy was carry out by multinodular goiter to all patients. PTMC size was 5.44 ± 2.66 mm (range 1-9). Multicentric 1 case, association with Hashimoto thyroiditis was detected in 6 patients, and benign follicular lesions in 4. Radioiodine therapy 1 patient. Mean of follow up 2.95 ± 1.56 years. No metastasis or relapses or death have been detected during follow up.

Discussion: PTMC are incidentally discovered in pathological examination after the surgery of benign thyroid disorders. Its prevalence is high, is a malignant thyroid tumor with potential multifocality (almost 1/3) and diameter 10 mm or less and the epidemiology is not clearly established. PTMC appears to have a benign course in the majority of patients initially treated with near-total thyroidectomy and therefore, according to the revised ATA thyroid cancer guidelines, additional radioiodine ablation is not justified. However, an aggressive subtype of PTMC seems to exist. More prospective studies or probably molecular markers are needed, in order to identify this subtype.

Conclusions: In our study PTMC appears only in women, have a benign course, radioiodine ablation is not justified.

V-6
CLINICAL CHARACTERISTICS OF PATIENTS DIAGNOSED WITH NEOPLASTIC DISEASES IN A INTERNAL MEDICINE UNIT

B. Rodríguez, J. Moreno, J. Beato, M. Moreno, F. Polo, L. Ramírez, Y. Santisteban

Department of Internal Medicine. Hospital de Hellín. Hellín. Albacete, Spain.

Objectives: The aim of this study is to analyse the clinical characteristics of patients diagnosed with neoplastic diseases in our Internal Medicine unit, and evaluate their initial management, by looking for factors which are related exclusively to palliative treatment and their hospital stay.

Material and method: A retrospective study was carried out, which gathered all cases of patients diagnosed with neoplastic diseases between January 2009 and May 31st 2011. The information collected is: patient demographics, means of hospitalisation, characteristics of neoplastic development, functional class, clinical characteristics, treatments carried out, if death occurred during hospitalisation, discharge referral, exclusive symptomatic control referral and hospital stay. We carried out a binary logistic regression analysis of the different qualitative variables with the aim of building a prediction model. This new model was created in order to try to predict the different factors which influence the decision to opt for an active treatment as opposed to an exclusively palliative one, in order to identify which patients were referred to Oncology and which factors are more prominent in a shorter hospital stay.

Results: There were 76 patients diagnosed with neoplastic disease. In just 16 of them (21%) the use of active managements was ruled out, with them being referred to the Home Care Support Team (HCST), the Palliative Medicine Unit (PMU) and the primary care doctor for symptomatic control. In the linear regression univariate analysis, the correlation between patients referred for symptomatic control (to HCST, OMU and primary care) aged over 70 ($p = 0.009$) and those with a Karnofsky Index below 60 ($p = 0.026$), turned out to be statistically significant. The use of analgesia helped towards a hospital stay of less than a week.

Discussion: Terminally ill patients mean a significant group with specific characteristics which are going to set its initial management in our Internal Medicine area. It is about relatively younger patients, with an acceptable functional class, who, mainly, are going to be referred for active treatment. From the beginning of their illness, they are going to show symptoms which must be evaluated and treated correctly, which supports the role of the internist in the medical attention to this population and forces the internist to acquire the different specific competences for the development of the necessary integrative management. Unlike this series, the most of the patients from our study was in the group between the ages of 50 and 70, and showed an acceptable functional status. Probably, that's why in the most of them, the diagnosis options were run out, being left just 4 patients (5.3%) without histological diagnosis. In just 16 of them (21%) the use of active managements was ruled out, with them being referred to the Home Care Support Team (HCST), the Palliative Medicine Unit (PMU) and the primary care doctor for symptomatic control. In our study, Karnofsky Index has shown a predictor role for an exclusive palliative treatment choice when it's below 60%, suggesting the importance of the functional assessment of patients and the necessity of reflecting and managing appropriately the functional status scales, not only in the diagnosis, but also during the development of the illness.

Conclusions: The study shows the statistic correlation among the symptomatic exclusive treatment choice and those aged over 70 and the functional class deterioration gauged by the Karnofsky Index which is below 60%. As well as the relation between the use of analgesia and a shorter hospital stay.

V-10
AGRANULOCYTOSIS BY METAMIZOLE: REVISION OF 8 CASES DESCRIBED IN A COUNTY HOSPITAL

A. Lucas Dato[1], R. Hurtado-García[1], B. López Martínez[1], C. Fernández Miñano[2], I. González-Cuello[1], A. Guillén Meseguer[1], J. Cepeda Rodrigo[1], J. Custardoy Olavarrieta[2]

[1]Department of Internal Medicine, [2]Department of Haematology. Hospital Vega Baja. Orihuela (Alicante), Spain.

Objectives: To analyze and to describe clinical and epidemiological findings of this adverse effect in a health area in southern Valencia during a period of 7 years.

Material and method: Retrospective analysis of all patients admitted with a discharge diagnosis of agranulocytosis by metamizole at the Hospital de la Vega Baja in a period between 2005 and 2012. We conducted a thorough review of medical records and the puncture and bone marrow aspirate. Neutropenia was defined as all those tested with neutrophils < 1,500 ml) with origin suspected of having been caused by metamizole. Defining itself as a serious one with neutrophils less than 500 ml/h. The hospital of the Vega Baja in Orihuela includes a reference population of about 200,000 inhabitants, with a significant foreign floating population due to tourism.

Results: For the study period, 8 cases were found, 4 males and 4 females with a mean age of 61 years old (standard deviation (22-84). Of these 4 were foreigners (50%) were all British. The most common clinical presentation was fever above 37.8 ° C in 6 of 8 patients in the 6 cases showed foci of infection: 3 respiratory infections, urinary tract infection, an abdominal, a knee replacement and myositis. The average patient stay was 8.25 days. Only one patient did not require hospitalization. All debuted with severe neutropenia but one that was moderate. All patients were treated with colony stimulating (G-CSF) except one. There was only one death during hospitalization. In all cases the adverse effect appeared in the first month of treatment.

Discussion: Metamizole is one of most popular drugs sold in Spain, is widely used as a spasmolytic analgesic with high oral bioavailability (> 90%), a suitable half-life (6-9 hours) and a comparable analgesic effect with low doses of opioids. Agranulocytosis is a potentially life-threatening multi-drug-induced. Metamizole identified as a cause of agranulocytosis, which is why we have withdrawn from different countries. Agranulocytosis appears frequently in the first two months of treatment and is worse if it affects other series. In our series one patient died (12.5%), being superior to others described in which mortality is situated in 7.7%. Regarding the treatment is amply demonstrated that the use of G-CSF with antibiotics reduces the numbers of agranulocytosis and the average hospital stay. In our series, use was 87%. Is recorded in our study that there is a strong genetic predisposition among the white population and northern Europe, as described in the literature, 50% of our sample was of British origin.

Conclusions: In our area agranulocytosis is a side effect more common among British citizens, so it is necessary to disseminate among the medical and pharmaceutical services in tourist areas the potential adverse effect of this drug and avoid use in this population.

V-11
DOES LOW CENTRAL DOPAMINERGIC ACTIVITY INFLUENCE METABOLIC PARAMETERS?

L. Brunerova[1], J. Potockova[1], J. Horacek[2], M. Andel[1]

[1]II Department of Internal Medicine. 3rd Faculty of Medicine, Charles University and Faculty Hospital Kralovske Vinohrady. Prague, Czech Republic. [2]Psychiatric Center Prague. 3rd Faculty of Medicine, Charles University. Prague, Czech Republic.

Objectives: Dopaminergic agonists have been proved to improve glycemic and lipid control in type 2 diabetic patients, which suggests that lower dopaminergic activity can be present in subjects

with risky metabolic profile. Central dopaminergic activity can be measured by apomorphin challenge test: apomorphin increases growth hormone and decreases prolactin; the levels of these hormones can be used as markers of central dopaminergic activity. The aim of our study was to evaluate the relationship between central dopaminergic aktivity, metabolic parameters and food preference in healthy men.

Material and method: We examined 42 healthy men (average age 43.5 ± 7.4 years, BMI 27.4 ± 5.7 kg/m^2), anthropometric (body mass index/BMI/, waist-hip ratio, blood pressure and body fat by bioimpedance) and metabolic (glycaemia, lipids, glycated hemoglobin) parameters were measured and HOMA index of insulin resistance was calculated at the beginning of the study. All the subjects filled in Heller´s Carbohydrate Craving Questionnaire, describing the extent of carbohydrate preference in food. Sublingual apomorphine (0.033 mg/kg with 4mg as the highest dose) was administered and prolactin and growth hormone were measured at -30,-15, 0, 15, 30, 45, 60, 75, 90, 120, 150 and 180 minutes. Areas under the curve for prolactine (AUCPRL) and growth hormone (AUCGH) were calculated using trapezoideal rule. Linear regression was used for statistical analysis.

Results: Negative correlations were observed between AUCPRL resp. AUCGH and BMI (r = -0.36, p = 0.013; resp. r = -0.56, p = 0.0001) and AUCGH and age (r = -0.53; p = 0.001). Since the majority of metabolic parameters are known to be influenced by age and BMI, we adjusted all the correlations for those two parameters. After adjustment for age and BMI we observed statistically significant negative correlations between AUCGH and HbA1c (r = -0.37, p = 0.016), AUCGH and HOMA index (r = -0.34, p = 0.025), AUCPRL and carbohydrate craving questionnaire (r = -0.345; p = 0.025), resp. AUCPRL and total cholesterol (r = -0.41, p = 0.007).

Discussion: The results of our study contribute to the increasing evidence of the links between glucose and lipid metabolism and central dopaminergic activity. Decreased dopaminergic activity seems to be connected with impaired glucose metabolism and risky lipid profile. Multiple mechanisms are discussed – i.e. dopamine can influence the food intake, regarding amount and preference of macronutrients (palatable food, carbohydrates), on the other side, insulin influences dopamine signaling in the brain (dopamine signaling is decreased in conditions of insulinopenia or insulin resistance).

Conclusions: In healthy men, lower central dopaminergic activity is connected with higher total cholesterol, glycated hemoglobin, HOMA index and increased preference of carbohydrates in food.

The study was supported by VZ MSM 0021620814.

V-13
ADMISSIONS INTO AN INTERNAL MEDICINE DEPARTMENT OF A COMMUNITY HOSPITAL: A POPULATION-BASED STUDY

J. Palomares-Rodríguez, R. Peñafiel-Burkhardt, D. Sánchez-Cano, P. Castillo-Higueras

Department of Internal Medicine. Hospital General Básico Santa Ana. Motril (Granada), Spain.

Objectives: Our aim was to analyze the characteristics of the admissions into an Internal Medicine department of a community hospital throughout a 1-year period.

Material and method: A prospective study was performed. Data was collected from the hospital application Medicx, from January 2011 through December 2011. Variables recorded were divided into demographical (age, sex and geographical origin) and clinical (diagnosis at admission according to CIE 9-MC). A descriptive assessment of data was carried out.

Results: A total of 2,015 patients were admitted into our department, whose data were available for 1,627 patients. Mean age was 68.9 ± 16 years, 67 ± 15 years for men (59.4%) and 70 ± 17 years for women (40.6%). Most patients (55%) were originals from the town where the hospital is located, whereas 40% lived in the influence area, the rest being from other areas, with a 7% of foreigners. The most frequent cause of admission was cardiovascular diseases (35%, including stroke), followed by respiratory disorders (24%) and gastrointestinal ones (17%). Individually considered, the most prevalent disorders were as follows: acute coronary syndrome (11%; 43% for non-ST elevation myocardial infarction and 29% for unstable angina), heart failure (10%), bacterial pneumonia (9%), stroke (8%), respiratory infection other than pneumonia (6%), gastrointestinal bleeding (5%) and acute pancreatitis (4%). Eighty-four per cent of patients were discharged, while 8% was transferred to another department or center. However, overall mortality was 8% (12% due to pneumonia and 10% due to heart failure).

Discussion: Our study shows a high rate of admissions for a community hospital with an official reference population of 131,251 inhabitants (as of 2010). However, being a coastal area with a mild climate, the actual population attended is even higher, with a significant foreign population. Furthermore, the patients' average age is elevated, especially for women, which is a reflection of the aging population. We found a high prevalence of cardiovascular diseases, possibly higher than in other areas. Of particular interest is the stroke rate, taking into account the unavailability of a Neurology specialist consultant in our Department, the reference centre being over 70 km away. Other prevalent disorders (cardiac, respiratory and gastrointestinal) have their correspondent specialist consultants. As for mortality, we admit it may be higher than expected, but we attribute it to the aging population and their multiple disorders, as well as a significant rate of advanced malignancies (data not shown).

Conclusions: Even though this is only a descriptive study, it may help to carefully think about the direction the future planning of our Health system should take.

V-14
MUSCULOSKELETAL TUMOR COMMITTEE, RESULTS OF OPERATION OF MULTIDISCIPLINARY TEAMS IN A SPANISH HOSPITAL HEALTH AREA

R. Hurtado García[1], P. Sánchez Gómez[2], N. Martínez Banaclocha[3], J. Ruiz Maciá[4], J. Meca[5]

[1]Department of Internal Medicine, [2]Department of Traumatology, [4]Department of Pathology, [5]Department of Radiology. Hospital Vega Baja. Orihuela (Alicante), Spain. [3]Department of Oncology. Hospital General Universitario de Elche. Elche (Alicante), Spain.

Objectives: Detection, study and programming of all patients with sarcomas Department of soft tissue and bone. Proposed therapeutic procedure, or any other attitude, in the same condition. Proposals for monitoring and control patients evaluated by the Committee. Update of diagnostic procedures and treatments to improve the quality of care and teaching and promote teaching and research activity.

Material and method: We have collected all the cases that have been rated by the committee of musculoskeletal tumors since its inception in December 2011 to March 1, 2012. We describe the clinical features, epidemiology of patients and clinical actions performed.

Results: Since its inception on December 13, 2011 Musculoskeletal Sarcomas Committee has assessed, treated and followed 20 patients in a multidisciplinary manner. Of these 10 were men and 10 women with a mean age of 52 years (25-79 years), 14 were soft tissue tumors and 6 bone tumors. Of soft tissue tumors treated 9 were malignant (64%), one child diagnosed as melanoma primary lesion in pretibial area and 8 primary soft tissue sarcomas: 4 liposarcomas of low grade, 2 high-grade pleomorphic sarcomas, 1 leiomyosarcoma and 1 spindle cell sarcoma. Within the benign soft tissue tumors pathologically suspected malignancy but further tests found in 3 cases of giant lipomas, 1 case of villonodular synovitis and ganlión

in popliteal fossa. Of the 6 tumors were benign bone 2, 2 patients with osteochondromatosis multiple and 4 malignant, 3 metastatic lesions of lung cancer in 2 cases and breast in 1 case, and a adamantimoma to warm. Soft tissue sarcomas were operated all the Traumatology Service of our center, receiving adjuvant radiotherapy 5 of the 8 primary malignant sarcomas (sarcomas of high grade and one case of low-grade liposarcoma) with a current 100% survival without local recurrence, lymph node and distant. Metastatic bone sarcomas were referred to special committee of the primary pathology and the primary cause, the adamantimoma another center was referred to the benign and were treated at our center.

Discussion: Soft tissue sarcomas are tumors of low incidence and clinical management is difficult. Usually patients are referred to reference centers for diagnosis and treatment. These focal points are usually tertiary hospitals that have all the disciplines involved in the management of soft tissue sarcomas. In our experience most of the tumors submitted for evaluation by the committee found to be soft tissue sarcomas (64%), indicating that the structure and organization of the committee is allowing the detection of cases correctly. Although our hospital is county, we found that the creation of the committee of soft tissue sarcomas is serving to unify criteria with referring patients from different specialties and streamline processes both diagnostic and treatment thereof. This shows that despite having a low incidence, soft tissue sarcomas can be handled properly and with high chances of success if a specialized multidisciplinary team proposes this.

Conclusions: The treatment of soft tissue sarcomas requires a multidisciplinary specialized committee to deal with streamlining the diagnostic process and plan the treatment strategy. We think that the successful evolution of the case will depend on decisions made on that committee.

V-15
PREVALENCE OF PERIPHERAL ARTERIAL DISEASE IN PATIENTS WITH PSEUDOXANTHOMA ELASTICUM

J. Carrillo-Linares[1], T. Moreno[1], M. Morillo[1], P. Sánchez[2], I. García-Fernández[3], D. Quaglino[4], P. Valdivieso[1]

[1]Department of Internal Medicine. Complejo Hospitalario Virgen de la Victoria. Málaga. Spain. [2]Department of Medicine and Dermatology, [3]Department of Human Physiology. University of Málaga. Málaga, Spain. [4]Department of Biomedical Sciences. University of Modena and Reggio Emilia, Italy.

Objectives: Pseudoxanthoma elasticum (PXE) is a rare disorder due to mutations in the transporter ABCC6; it is unknown which molecule is involved. Calcifications of elastic tissues, in the retina (angioid streaks and blindness), skin (yellowish plaques) and arteries (ischemic symptoms) are the main pathological features. As a consequence, peripheral arterial disease (PAD) is increased in this population. The aim of our study was to assess the prevalence of PAD in patients with PXE.

Material and method: 19 patients with clinical, pathological and/or genetic diagnosis of PXE were included. PAD was assessed by the measurement of the ankle-brachial index systolic pressures ratio (ABI) with a portable Doppler device. PAD was diagnosed if ABI was < 0.9. Clinical relevant data, vascular risk factors, intermittent claudication (IC), anthropometric data and vascular examination were registered.

Results: The mean age was 41.8 years (range 25-71), with a body mass index (BMI) of 26 kg/m^2. 69% were female and 31% were male. Treatments are shown (table 1). Hypertension was present in 36% of the patients; dyslipidemia in 21% and 1 patient (5.3%) had type 1 diabetes. 32% were smokers and 10.5% were former smokers. Among 19 patients, only 2 had an ABI below 0.9 (10.52%), both of them suffering from intermittent claudication (IC). No other patients had neither symptoms of IC nor abnormal ABI measurement.

Discussion: Only 10.52% of our patient had PAD; this is in contrast with other study who found a prevalence of 45% in a series of 53 patients (Lefhtériotis. J Vasc Surg, 2011). The reason of this discrepancy may be related to age; in our group, constituted mostly of women, the age was lower compared to another study.

Conclusions: Prevalence of PAD in our patient with PXE was lower than expected.

Table 1 (V-15). Treatments

	Antiaggregants	AntiHTA	Hypolipemics	ADO	Insulin
Yes	5%	37%	16%	-	5%
No	95%	63%	84%	100%	95%

V-16
IMPACT OF GLOMERULAR FILTRATION IN THE LONG-TERM SURVIVAL AFTER A FIRST EPISODE OF STROKE

L. Mérida, A. Blázquez, D. Urdiales, F. Poveda, T. Pérez, R. Quirós, J. García Alegría

Department of Internal Medicine. Costa del Sol Hospital. Marbella (Málaga), Spain.

Objectives: Explore the association between glomerular filtration rate (GFR) and survival after a first ischemic stroke.

Material and method: Retrospective cohort study. Follow-up: 5-10 years. Variables: demographic, laboratory, and evolution. Exclusion criteria: foreigners, prior stroke, hemorrhagic stroke. t-Student for quantitative and qualitative chi-square.

Results: We included 415 cases, being 73.5% atherothrombotic (AT) and 26% cardioembolic (CE). Analytical: GFR 81.04 ml/h (95%CI 59.6 to 108.45) (AT 82.4 ml/h, 95%CI 55.3 to 109.6 vs 77 CEml/h, 95%CI 49.2 to 104.8, p = NS). Had GFR < 60 ml/h after admission to follow up 111 patients (27.3%). The total had GFR > 60 ml/h were 27% (n = 112) (28% AT vs 24% CE 24%, p = NS) between 30-60 ml/h 24.8% (n = 101) (22 AT vs CE 31, p = NS) and less than 30 ml/h for 22% (n = 101) (2.3% AT vs CE 2.8%, p = NS). For the total sample mortality was 44.6% (42.5% AT vs 57.5% CE). Of all patients who died, 26.4% had renal failure, 39% had a clearance < 60 ml/h p ≤ 0.001). It was observed a statistically significant association between the presence of a further deterioration of renal function and a worse outcome for each 10 years of follow up (OR 11.1 95%CI 5.7 to 16, p < 0.001), while adjusting for age, association only exists in more than 80 years (47.4% vs exitus live 65.5%, p = 0.011).

Conclusions: 1. After a first stroke during follow-up the deterioration of glomerular filtration, is associated with a worse prognosis, especially in elderly. 2. The kidney disease is a manifestation of target organ damage in patients with vascular risk, which runs in a silent, requiring a global approach to patients suffering from stroke event to increase survival.

V-17
CYSTATIN C AS PROGNOSTIC BIOMARKERS IN FABRY DISEASE

M. Matia Sanz, C. Gómez del Valle, M. Bucard Bajurd, C. Josa Laorden, B. Amores Arriaga, M. Aibar Aguerri, J. Pérez Calvo, M. Torralba Cabeza

Department of Internal Medicine. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: Fabry disease (FD) is a progressive, X-linked inherited disorder of glycosphingolipid metabolism. According to published literature, there is not an accepted biomarker to assess disease progression and treatment efficacy. In our study we hypothesize that cystatin C (CsC) is potentially useful as biomarker in FD.

Material and method: We designed a prospective study based on 4 unreported patients with FD who were studied at Lozano Blesa University Hospital of Zaragoza. All FD patients were diagnosed through the identification of the mutation in the alfa-galactosidase A gene and/or showed reduced activity of alfa-galactosidase A enzyme in leukocytes and/or plasma. Cystatin C (CsC) was measured at the beginning of the study and 2 years later.

Results: Seventy-five percent of the total samples were from female patients (N = 3) and twenty-five percent were from male patients (N = 1). The mean age was 32 years, range from 11 to 43 years old. Mean duration of patient monitoring was 21 months. Three patients were asymptomatic and they were not receiving treatment. One patient presented cardiovascular involvement (severe dilated cardiomyopathy) with multiple hospital admissions due to congestive heart failure. This patient was receiving enzyme replacement therapy (ERT) with a mean duration of 3 years. For renal evaluation, the mean serum creatinine level was 0.69 mg/dl (range 0.56-0.79). Glomerular filtration rate (GFR) was calculated by MDRD formulae. Mean GFR was 119.34 ml/min. Means CsC concentration was 0.71 mg/l (range 0.53-1 mg/l) and 3 years later means CsC concentration was 0.67 mg/l (range 0.57-0.86 mg/l). In the patient was receiving ERT, CsC concentration was 1 mg/l at the beginning of the study and 0.86 mg/l 3 years later.

Discussion: Fabry disease (FD) is a lysosomal storage disorder caused by mutations in the alfa galactosidase A gene. It is characterized by the deposition of the incompletely metabolized substrate globotriaosylceramide in several cell types and multisystem involvement mediated by endothelial dysfunction. Renal failure, cardiovascular disease, and stroke are the major causes of morbidity and mortality, occurring in the fourth or fifth decade of life. Enzyme replacement therapy (ERT) is an efficient treatment in controlling symptoms and also it may reduce the severity and/or progression of disease manifestations. However, there is not a reliable and validated biochemical marker to assess disease progression and treatment response. CsC is an extracellular cysteine protease inhibitor that belongs to the cystatin superfamily. In general population, it has proven to be highly useful as a marker for early renal and cardiac damage and endothelial dysfunction. For this reason, we evaluate the usefulness of CsC as a potential biomarker in FD. In our study, we observed a correlation between CsC concentration, cardiovascular involvement and severity of the signs and symptoms. Also, during the 3 years of observation, we found a decrease of CsC concentration and a improvement of cardiac symptoms and quality of life in the patient who was receiving ERT. Therefore, the results of our study suggest tha CsC concentration is a better marker than serum creatinine in detecting visceral involvement in FD patients, specifically renal and cardiovascular involvement. Additionally, CsC may provide useful information regarding treatment efficacy and it would be a good biochemical marker of response to ERT.

Conclusions: CsC is a useful and valid biomarker that can be used to evaluate patients with FD and may also be used to monitor the subsequent effects of ERT in individual patients. In future, this findings should be further validated on others FD patient population.

V-18
SEASONAL DIFFERENCES IN MORTALITY RATES AMONG TERMINALLY ILL PATIENTS ATTENDED IN A SOUTHERN EUROPEAN HOSPITAL AT HOME UNIT

J. Galindo Ocaña[1], J. Romero Mena-Bernal[1], J. Castillo Ferrando[2], C. Aguilera González[1], M. Rincón Gómez[1], S. Sobra Calderón[1], A. Fernández López[1], J. Garrido Nieto[1]

[1]Department of Internal Medicine, [2]Department of Clinical Pharmacology. Hospital Virgen del Rocío. Sevilla, Spain.

Objectives: Excessive mortality rates during winter months have been perceived by palliative care professionals, but these phenomenons has not been documented in our area. The aim of this study was to determine any relevant clinical difference in outcomes or healthcare variables among seasons of the year.

Material and method: All patients consecutively attended by a southern European university hospital at home unit, who were terminally ill, were recruited. Inclusion period: January 2000 to May 2010. Analysed variables were the number of home visits by physician or nurse, length of stay per episode, death rate and month in which the patients were attended. Comparison of qualitative variables was done by Chi-Square and multivariate logistic regression models were performed to identify those variables independently associated to higher mortality. Quantitative variables were compared through median comparison (Mann-Whitney's U test) as all were non parametric, and they were converted to dummy variables and were included in multivariate logistic regression models.

Results: 5,442 patients in 8,427 episodes were included for analysis. 2,615 were cancer patients and they had 3,559 episodes. 374 patients died during active follow-up (4.44%). Monthly mortality rate was: January: 43/688 (6.25%); of which lung carcinoma 9/66 (13.6%), central nervous system 4/13 (30.8%), liver and bile ducts 3/22 (13.6%), cervix and endometrial tumours 2/5 (40%); February: 34/720 (4.72%); March 33/792 (4.16%); April 24/712 (3.37%); May 26/720 (3.61%); of which lung carcinoma 5/63 (7.9%), central nervous system 0/15 (0%), cervix and endometrial tumours 0/8 (0%); June 31/705(4.4%); July 28/644 (4.35%); August 21/532 (3.95%); September 29/597 (4.86%); October 39/670 (5.82%); November 33/648 (5.09%); December 33/625 (5.28%). In winter, mortality rate was 5.1% as opposed to a 4.2% in the other seasons (Fisher's unilateral exact test p = 0.042). Among cancer patients, such differences were clearly evident, with a mortality rate of 10.94% in January vs 6.9% in May (aOR 1.944; 95%CI 1.083-3.490; p value = 0.026). There were significant differences in monthly mortality rates between January-February-September-October months (circa 10%) and April-May-June months (circa 7%) in these patients (p = 0.04). However, mortality rate was very low amongst non cancer patients (mortality rate range 0.06-1.99%; p = 0.68) and low amongst cancer non terminally ill patients (mortality rate range 1.9-3.69%; p > 0.5). No differences were found in home visits either length of stay between seasons or months. Independently associated to higher mortality variables amongst terminally ill cancer patients were being submitted by Medical Oncology or Radiotherapy (aOR 7.667; p = 0.000) and being attended during January vs May (aOR 1.944; p = 0.026).

Discussion: Higher wintertime mortality rates among frail patients have been previously published and particularly affect Portugal, Spain and Ireland, and social factors have been advocated (J Epidemiol Community Health. 2003;57:784-9). Although excess winter mortality also occurs in the UK, age and not socioeconomic gradient did associate with this finding in Britain (BMJ. 2004;329:647-51). Vitamin D deficiency may be also involved (Cancer Epidemiol Biomarkers Prev. 2005;14:2303-9). A small sample size and selection bias may influence negative results amongst non cancer patients. Several subsets of cancer types showed higher differences.

Conclusions: A significant increase of mortality rate during Winter months was identified amongst terminally ill cancer patients treated in their homes. The nature of this phenomenon is yet to be determined.

V-19
ENDOSCOPIC FINDINGS IN ADULT PATIENTS WITH CELIAC DISEASE

L. González Vázquez[1], C. Casas Hernández[1], A. Fernández Villaverde[2], A. Arca Blanco[1], L. Novoa Lamazares[1], M. Rodríguez Arias[1], M. Vecoña Valiñas[1], J. de la Fuente Aguado[1]

[1]Department of Internal Medicine, [2]Department of Gastroenterology. POVISA. Vigo (Pontevedra), Spain.

Objectives: Clinical manifestations of celiac disease (CD) in adults are highly variable. It can be manifested by many nonspecific gastrointestinal symptoms that can be attributed to other common gastrointestinal diseases. Our objective is to describe macro and microscopic findings in upper endoscopies and colonoscopies performed on patients who were diagnosed with CD in adulthood. We included typical findings of CD, and other signs that are suggestive of different diseases that may justify the symptoms and can lead to misdiagnosis or delay CD diagnose.

Material and method: Observational, retrospective study designed to describe all the upper endoscopies and colonoscopies performed on patients who were diagnosed with CD in our hospital between January 1990 and December 2010. Data were collected from both macroscopic and microscopic findings.

Results: During this period a total of 103 adult patients were diagnosed of CD. All patients underwent at least 1 upper endoscopy and 15 patients also have a colonoscopy. Endoscopic findings were: changes compatible or suggestive of CD (cobblestone pattern and folds decrease) in 41 (39.8%), gastritis in 15 (14.5%) – acute in 2 and chronic in 13 -, esophagitis in 4 (3.8%), scars from old ulcer in 2 (1.9%), stomach retention in diabetic gastroparesis in 1, hiatal hernia in 1, gastric polyp in 1, and 1 esophageal papilloma. Endoscopies were informed as normal macroscopically in 53 (51.5%) patients. Microscopic findings were compatible with chronic gastritis in 21 (20.3%), one of them with intestinal metaplasia, acute gastritis in 7 (6.9%), erosive duodenitis in 3 (2.9%) and Barrett's esophagus 1. Moreover, in 12 (11.6%) patients we found the presence of Helicobacter pylori. Regarding to colonoscopy, the most frequent indication to realize it was the presence of diarrhea. It was reported as normal in 13 patients, one had colonic diverticulosis and one an adenomatous polyp with mild dysplasia.

Conclusions: Patients who are undergoing to gastroscopy for suspected CD may have another gastrointestinal diseases that occur superimposed to CD in up to 50% of cases. The most common are acute and chronic gastritis, with or without the presence of Helicobacter pylori. The macroscopic findings of injuries or diseases that can cause these symptoms should not prevent duodenal sampling to rule out CD.

V-21
WHAT PATIENTS THINK ABOUT INTERNAL MEDICINE AS A CONSULTANT ARE TREATED IN INTERNAL MEDICINE (IM) FOR THE INTERNIST AND FAMILY PHYSICIAN?

S. Romero Salado, M. Escobar Llompart, A. García Egido, O. Mera Gallardo, G. García Domínguez, V. Lechuga Flores, V. Manzano Román, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: Knowing what is IM seems to create doubts, uncertainties, about what they know or treat doctors called "internists". That is why the reason for this survey, to clarify their image our patients about what they believe is the IM.

Material and method: Based on the IM training program published by the Ministry of Health in the Official Gazette No. 33 (February 7, 2007) 10-question test designed on the concept, knowledge areas and areas of IM care. The test was proposed to 50 patients evaluated by the consulting internist at the health center of our dependent IM (well answered by the patient or primary caregiver as a second option). Form test questions: 1. What do you think is the IM? 2. What do you think is a doctor "internist"? 3. Who do you think is a doctor? 4. What do you believe the internist who knows? 5. If you suffer or suffer from various diseases, for example, diabetic, hypertensive, and have cholesterol, and suffers from the lungs because of snuff? What doctor or doctors believe you can help them most to improve their health? 6. Who do you believe that often seek medical cardiologist, pulmonologist, Digestive, Neurologist when a patient suffers from several diseases at once and want to improve your general? 7. What do you think is responsible for the internist? 8. Where do you think you can work the internist? 9. Who do you think is the doctor who can perform a comprehensive care for diseases that have or may be suffering? 10. Finally, How do you form an internist?

Results: 50 surveys were conducted: patients 44 (88%)/family 6 (12%). Gender: male 14 (28%)/female 36 (72%), mean age of 50.92 years. 38% (11) previous contact with IM, the first time 62% (31). Correct answers according questions: 1 (88%) 2 (76%) 3 (78%) 4 (92%), 5 (58%), 6 (66%), 7 (20%), 8 (70%), 9 (78%), 10 (34%).

Discussion: Regarding the concept of specialization (test 1, 3 and 10): most patients/carers recognize internal medicine and medical specialty but do not know how the internist as 66% of cases and even 20% of them believe that studying medicine and then begin work on the CS with family physician. Area of knowledge (test 2 and 4): over 76% think that the medical internist understands most medical illnesses. Care area (test 5,6,7,8 and 9): Despite the comprehensive knowledge to identify who owns the internist, the patient does not have clear air care that carries out its work, identifying the internist as a consultant to other specialties (66%) but not rely on the response capacity of the internist in traditional medical areas (as respiratory, endocrine, neurology, cardiology...). However, understand intercommunication/coordination IM/Family Physician in attendance integral similar to these specialties.

Conclusions: The patients do not really know what an internist medical. Can sense that medical work areas but confused. We must let us know and communicate the vision we have of comprehensive medical pathologies. In this way patients will have more confidence in our work.

V-22
WC, A STRONG PREDICTOR AND A CONFOUNDING FACTOR FOR OSA

E. Sánchez Ruiz-Granados[1], M. Sáez Goñi[2], P. Aguirre[1], A. Grilo Reina[2]

[1]Department of Internal Medicine. Hospital Infanta Elena. Huelva, Spain. [2]Department of Internal Medicine. Complejo Hospitalario Nuestra Señora de Valme. Sevilla, Spain.

Objectives: To identify clinical and epidemiological risk factors for OSA. To investigate if genetic heterogeneity exits between individuals at low and high risk for this factors.

Material and method: The study population comprises 387 subjects retrospectively assessed at the Internal Medicine Unit. In order to analyze the association between OSA and demographic/clinical data, we used logistic regression analysis. To select the independent determinants of OSA we used a stepwise regression model: The traits associated with $p < 0.05$ in this model were used as covariables for the genetic association study of OSA with the selected polymorphisms. We performed a genetic association analysis of 373 polymorphism (SNPs) selected through a genome wide association study for metabolic syndrome (MS) and its components. In order to test the independence of these associations with metabolic syndrome (ATP3 definition), and with waist

Table 1 (V-22)

		Controls (non abdominal obesity).		Cases (abdominal obesity).	
CHR	SNP	OR	p	OR	p
4	rs7677890	0.99	0.97	0.50	0.000758

Table 2 (V-22)

SNP	Controls (No MS) OR	p	Cases (MS) OR	p
rs2687855	1	0.98	0.43	0.0004
rs4299396	1.23	0.42	0.40	0.0005

circumference we performed a Breslow-Day test and a stratified analysis in cases and controls.

Results: Waist circumference (WC), is the strongest predictor of the occurrence of OSA in our population study (OR = 0.5, p = 1.76 E-46), MS is strongly associated with the occurrence of OSA ($p = 2.4 \times 10^{-20}$), although in the stepwise its effect is masked by the effect of WC. In the stratified analysis by the presence of abdominal obesity, the rs7677890 polymorphism (Chr 4) is not associated with OSA in the non obese population but it has a strong association with OSA in the obese population ($p = 7.6 \times 10^{-4}$, in the range determined by Bonferroni correcction) (Table 1). We have identified two SNPs with a significant effect in SM (Table 2).

Discussion: OSA and MetS share clinical determinants. In this study, we have observed that WC, the major determinant of MS, is the best predictor of OSA in our study. It is known that obesity and MS have a high frequency in OSA patients, and OSA patients have obesity and MS at a higher frequency than general population. Given this strong association, the presence of abdominal obesity and MS can be a confounding factors for the study of OSA. In our study, we have found evidence of genetic heterogeneity at three loci depending on the presence of abdominal obesity and MS.

Conclusions: WC is the strongest predictor of OSA syndrome in our study. The rs7677890 polymorphism showed association with OSA only in the abdominal obese subpopulation. Regarding the presence of MS, two SNPs (rs2687855 and rs4299396) showed evidence of association with OSA in the population with MS. The later illustrates how the presence of abdominal obesity and MS can be confounding factors for the identification of genetic factors for OSA.

V-24
FAT EMBOLISM SYNDROME AFTER BONE FRACTURE

C. Campo López, P. Flors Villaverde, J. Calabuig Alborch

Department of Internal Medicine. Hospital Universitario La Fe. Valencia, Spain.

Objectives: We describe epidemiological, clinical, diagnostic and treatment aspects of fat embolism syndrome (FES) in our hospital.

Material and method: Retrospective and descriptive study of patients diagnosed with posttraumatic FES between January 2000 and December 2011.

Results: We evaluated 19 patients, 16 men and 3 women, with an average age of 27.47 years. All had long bone fractures, multiple in 78.9% of cases. The overall incidence was 0.14%. Respiratory symptoms were the most frequent (89.5%), followed by neurological symptoms (68.4%) and petechial rash (63.2%). The average time of presentation of the syndrome after admission was 42.47 hours. All patients underwent early stabilization of the fracture, respiratory support and prevention of pulmonary embolism and gastrointestinal bleeding. Steroids were not used in any case as prophylaxis and definitive surgical treatment had an average delay of 7.35 days. Average hospital stay was 33.56 days and average mortality was 10.5%.

Discussion: Epidemiological and clinical features of FES in our institution are similar to those in previous studies, except a lower incidence. It is difficult to make comparisons in this aspect, as incidence varies greatly depending on the type of fracture considered. In our study, we account only long bone fractures (femur, tibia and humerus). In the case of the femur, and also to calculate the overall incidence, we consider hip fractures, which may imply an underestimation of incidences.

Conclusions: The epidemiological and clinical features of FES in our sample are similar to those in previous studies. The incidence and mortality continue the downward trend of recent studies. The diagnosis is clinical and, since there is no specific treatment, prevention is essential. Once it is established, it causes a delay in definitive surgical treatment and increased length of hospital stay.

V-26
THE COMPUTER BOOK OF THE INTERNAL MEDICINE RESIDENT: VALIDITY AND RELIABILITY OF A QUESTIONNAIRE FOR SELF-ASSESSMENT OF COMPETENCES IN INTERNAL MEDICINE RESIDENTS

J. Oristrell[1], A. Casanovas[1], R. Jordana[1], R. Comet[3], M. Gil[4], J. Oliva[2]

[1]Department of Internal Medicine, [4]Department of Digestive Diseases. Hospital de Sabadell. Barcelona, Spain. [3]Acute Geriatric Unit. Centre Socionanitari Albada. Sabadell (Barcelona), Spain. [2]Fundació Parc Taulí. Corporació Sanitària Parc Taulí. Sabadell (Barcelona), Spain.

Objectives: There are no simple and validated instruments for evaluating the training of internal medicine residents. Our aim was to analyze the reliability and validity of a computerized self-assessment method to quantify the acquisition of medical competences during the Internal Medicine residency program.

Material and method: All residents of our service participated in the study during a period of 28 months. Twenty-two questionnaires specific for each rotation (the computer-book of the Internal Medicine resident, CIMR) were constructed with items from three competence domains: clinical skills, communication skills and teamwork. Most items were scored on a scale of 1 to 5 (1 = min; 5 = max). Reliability was analyzed by measuring the internal consistency of items in each competence domain using Cronbach's alpha index. The validation was performed by comparing mean scores of clinical and communication skills and teamwork between senior and junior residents. Cut-off levels of competence scores were established in order to identify the strengths and weaknesses of our educational program. Finally, self-assessment evaluations were correlated with evaluations made by the medical staff.

Results: There was a high internal consistency of the items of clinical skills, communication skills and teamwork (Cronbach's alpha: 0.88, 0.75 and 0.90 respectively). We observed higher scores

of clinical skills competence in senior than in junior residents (3.6 versus 3.2; p = 0.005). Similarly, senior residents expressed higher scores of communication skills than junior residents (4.2 verses 3.9, p = 0.03). The correlation between self-assessment evaluations and medical staff evaluations was weak and did not reach statistical significance (r = 0.20; p = 0.06). CIRM questionnaires identified the strengths and weaknesses of our educational program. As strengths, our residents felt competent in the management of most prevalent medical conditions. However, low scores were obtained for funduscopic examination, placement of central lines, interpretation of chest and abdominal CT, management of vasopressors drugs, tracheal intubation and treatment of systemic autoimmune diseases.

Discussion: The monitoring of the acquisition of medical competences is especially important in the field of Internal Medicine, a specialty with a broad curriculum and a heterogeneous training between centers and countries. There are few experiences in the use of self-assessment questionnaires to identify the acquisition of medical competences during the Internal Medicine residency program. In our experience, CIMR was a reliable and valid instrument to analyze the progression in the acquisition of clinical and communication skills in a team of Internal Medicine residents. In addition, CIMR questionnaires allowed us to identify the strengths and weaknesses of our training program. The weak correlation observed between self-assessments and the evaluation made by staff physicians limits CIMR use for interindividual comparison. However, in our experience, CIRM was a potent instrument to guide resident mentoring.

Conclusions: The items of CIMR showed a high internal consistency and enabled to measure the acquisition of medical competences in a team of Internal Medicine residents. In addition, CIMR questionnaires allowed us to identify the strengths and weaknesses of our training program. This self-assessment method should be complemented with other evaluation methods in order to assess the acquisition of medical competences by an individual resident.

V-27
CHANGES IN BLOOD GLUCOSE LOWERING THERAPY IN PATIENTS WITH TYPE 2 DIABETES AFTER ADMISSION TO AN INTERNAL MEDICINE SERVICE

J. García Aparicio, J. Herrero Herrero

Department of Internal Medicine Los Montalvos. University Hospital. Salamanca, Spain.

Objectives: The main objective of this study was to compare the anti-diabetic treatment that patients with type 2 diabetes were receiving at home, before hospital admission, with the therapy administered during their hospitalization for any reason in a general internal medicine service in Spain. The secondary objectives were to analyze the feasible causes for the changes and to describe the epidemiological profile of these patients.

Material and method: The study was conducted on patients with type 2 diabetes on pharmacological anti-diabetic treatment, who were admitted at the Los Montalvos-Internal Medicine Service of the University Hospital of Salamanca (Spain) over six months. Participants were included in the study successively in order of admission. We collected patients' epidemiological data (age, sex and diagnosis) and data on their anti-diabetic treatment (pharmaceutical specialty, dosage, posology and administration device, if this was de case) that they were receiving at home (outpatient treatment) and during their hospital stay (inpatient treatment). Also, data were collected on their dietary compliance (nutritional survey), physical activity and adherence to treatment. An observational survey was conducted on the technique of applying insulin, when necessary.

Results: We studied 296 patients with diabetes, that corresponded to 37% of patients admitted to our service hospitalization wards during the indicated time period. Sixty four per cent were women, mean age: 79.3 years (SD: 7.38, range: 55-88). The most common diagnoses were hypertension (51.1%), renal failure (41.2%), heart failure (34.3%), anemia (33.4%), chronic obstructive pulmonary disease (32.3%), cognitive impairment (22.7%), ischemic heart disease (20.2%) and depressive syndrome (13.4%). Outpatient drug treatment: 140 patients (47.3%) were under insulin treatment and 186 (66.2%) were taken oral anti-diabetic agents. Forty patients (13.5%) received insulin associated with oral anti-diabetics. Patients treated with insulin used a pen device for its administration in 97.1% cases (136 patients) and 4 patients (2.8%) used the Inholet® system. The number of administrations of medication (insulin ± oral agents) was median: 2, range: 1 to 6. Outpatient non-pharmaco-logical treatment survey: 69.6% patients acknowledged do not properly observe the diet, 71.2% did not exercise regularly, 17.2% confessed to forget or not to administer some of the doses of their regular treatment (oral agents and/or insulin). In 32 patients treated with insulin (22.8%) the procedure of administration of insulin was incorrect (as judged by a nurse after observation of the patient's technique). Inpatient drug treatment: During their hospital stay, 25 patients (8.6%) did not need any anti-diabetic drug treatment, 43 (14.5%) maintained the same dose of oral anti-diabetic and/or insulin, 78 (26.3%) needed less treatment dose and 150 (50.6%) required higher doses of medication (insulin and/or oral antidiabetics).

Discussion: Treatment of diabetes is based on three pillars: diet, exercise and pharmacological treatment (insulin and/or oral anti-diabetics). It is common the failure to comply with diet, the lack of regular exercise and to make mistakes when administering insulin with the different types of devices, especially in the case of patients aged over 65. This entails that in many cases, when patients are admitted to hospital and they follow a strict dietary control and the treatment is administered correctly, needs of insulin and oral anti-diabetics decrease.

Conclusions: Although it is frequent that during hospital admission requirements of anti-diabetic medication increase (because of the effects of an acute disease, steroids use... that decompensate the glycemic profile) there is a high percentage of patients (34.9% in our study) that during hospitalization requires lower dosages of antidiabetic medication. This could be explained on the grounds that during admission dietary control is strict (but not at home), the prescribed dosage is followed correctly and administration of insulin is made by health professionals.

V-28
PRIMARY CARDIAC SARCOMA: CLINICOPATHOLOGY STUDY OF FOUR CASES

A. Alguacil Muñoz[1], V. Cano Llorente[1], P. Lima Cañadas[2], G. Muñiz Nicolás[1], J. Bayona León[1], A. Piqueras Martínez[1], F. López Almodóvar[2], M. Martín Toledano[1]

[1]Department of Internal Medicine, [2]Department of Cardiovascular Surgery. Complejo Hospitalario de Toledo. Toledo, Spain.

Objectives: Primary cardiac tumours are a rare entity with a lifetime incidence of 0.0017 to 0.02% in autopsy series. Three-quarters of these tumours are benign with near 50% being myxomas. Metastatic involvement of the heart is over 20-30 times more frequent than primary cardiac tumours. Malignant heart neoplasms can be primary in origin, they can develop from direct extension of a neighboring tumour or be the manifestation of metastasis of a distant tumour. Primary neoplasms of the heart are extremely rare and are almost exclusively sarcomas with angiosarcoma, rabdomyosarcoma and fibrosarcoma in decreasing incidence. We describe the clinicopathological findings in four cases diagnosed of sarcoma of heart.

Material and method: The surgical database from our institution was reviewed for surgical resection of cardiac tumors from May 2003 to April 2012, and the benign and metastatic tumors were excluded. The clinical records for these patients were reviewed.

Results: Case report 1. A 67-year-old woman presented with epigastric pain and weight loss. A radiological and sonographic study was undertaken. A mass of 72 × 36 × 70 mm was discovered arising from the posterolateral wall of the pericardium. Videothoracoscopy with a biopsy were performed; the mass was considered as unresectable. The pathologic examination revealed a leiomyosarcoma. The patient was treated with adjuvant chemotherapy. After 5 months, the patient presented progressive heart failure and she died. Case report 2. A 69-year-old woman presented with sudden dizziness. The echocardiogram revealed a mass of size 50 × 50 mm in left atrium implanted in the mitral valve. She underwent surgery with a preoperative diagnosis of atrial myxoma. Median sternotomy was performed and was completely resected. The pathologic examination revealed a myxofibrosarcoma. Unfortunately 9 months later, she was readmitted to the hospital and died of congestive heart failure. Case report 3. A 54-year-old woman presented with fever, dyspnea and chest pain. The chest radiograph showed cardiomegaly. A Echocardiogram revealed severe pericardial effusion. Computed tomography (CT) and magnetic resonance scans demonstrated a 100 × 100 × 110 mm heterogeneous mass arising from the posterolateral wall of the pericardium extending itself to the superior and posterior wall of the left atrium, reaching the space between the pulmonary artery and the pulmonary veins. Median sternotomy was performed which revealed a cystic mass arising from the pericardium of the anterolateral wall of the left ventricle, invading the myocardium. The mass was deemed unresectable. After confirming the diagnosis of synovial sarcoma the patient was treated with adjuvant chemotherapy and radiotherapy. The tumour was considered to be in complete remission. After 26 months, the tumour relapsed with no response to therapy and she died. Case report 4. A 76 year-old lady presented with sudden onset of intense epigastric pain, with nausea and vomiting. A CT scan was undertaken and a left atrial mass of 53 × 29 × 60 mm was discovered as well as severe caliber change in the small intestine with data of ischemia. A median laparotomy was performed and 30 cm of jejunum were resected and sent for pathological examination with confirmation of transmural ischemia with acute peritonitis. Ten days later, median sternotomy was performed, the fosa ovalis was noted to be infiltrated by hard tumour that invaded the right inferior pulmonary vein and the endocardium near the mitral annulus. The neoplasm was removed. The pathologic examination revealed a stromal sarcoma. She was treated with adjuvant chemotherapy with recurrence and death after 5 months.

Conclusions: Primary cardiac sarcomas have a heterogeneous clinical presentation and a high degree of suspicion is needed to diagnose them. Surgery remains the cornerstone of the treatment and the role for adjuvant therapy remains controversial. These tumours are associated with a reduced survival despite adequate treatment.

V-29
ADIPONECTIN LEVELS IN PATIENTS WITH NEWLY DIAGNOSED HYPERTENSION AFTER TREATMENT OF VALSARTAN AND AMLODIPIN

S. Demirkol[1], S. Balta[1], S. Ay[2], M. Karaman[2], T. Celik[1], H. Sarlak[2], S. Demirbas[2], H. Yaman[3]

[1]Department of Cardiology, [2]Department of Internal Medicine, [3]Department of Biochemistry. Gulhane Medical Faculty. Ankara, Turkey.

Objectives: Adiponectin is one of the adipocyte-derived hormones that have profound antiinflammatory and antiatherogenic properties, which is also thought to play an important role in the modulation of glucose and lipid metabolism. The aim of the present study was to investigate the effects of valsartan as an angiotensin II receptor antagonist, and amlodipine as a calcium channel blocker on the adiponectin level in patients with essential hypertension.

Material and method: Patients with a newly diagnosed essential hypertension were admitted to our internal medicine outpatient clinic. Exclusion criteria were secondary hypertension, atherosclerotic heart disease, diabetes, chronic kidney disease, thyroid dysfunction, chronic liver disease and other chronic diseases. Patients were randomized to one of the following intervention protocols: angiotensine II receptor blocker (valsartan, 80-320 mg/day) as group A or calcium channel blocker (amlodipine, 5-10 mg/day) as a group B. Serum adiponectine levels of the patient groups were measured before treatment and on the 12nd week.

Results: Study group consisted of 50 patients with a newly diagnosed essential hypertension (group A n = 28 and group B n = 22). Statistically significant difference was not detected among the groups in terms of age, sex and body mass index (BMI). (group A/B; mean age: 52.9/50.1, female: 22/13, male: 6/9, BMI: 30.3/30.4; $p > 0.05$). In the amlodipine group, there was a significant increase in the levels of adiponectin after treatment ($p < 0.05$) in comparison with valsartan.

Discussion: Dysregulated adipokine secretion contributes to the development of systemic low-grade inflammation, insulin resistance and metabolic syndrome. The coexistence of hypertension and low plasma adiponectin levels has an additive effect on the development of coronary heart disease and the associated mortality rate.

Conclusions: We found that amlodipine has increased the level of adiponectin more than valsartan. As a result, in the treatment of hypertension, prior knowledge of the levels of plasma adiponectin could be important in antihypertensive drug choice.

V-30
HEMOCHROMATOSIS (HH) FEATURES AND OUTCOMES OF C 282 Y HOMOZYGOTES (HZ) AND C 282 Y/H 63 DOUBLE HETEROZYGOTES (DHTZ)

J. Rodríguez-Chinesta, J. Martí, A. Zurutuza, B. Lasa, M. Almendral

Department of Internal Medicine. Hospital de Zumárraga. Zumárraga (Guipúzcoa), Spain.

Objectives: To analyze differences between C282Y homozygotes and heterozygotes to C282Yand H63D patients with diagnosis of HH in Internal Medicine Departament.

Material and method: Study of all patients with diagnosis of HH attended in our department during 5 years. We analyzed age, gender, family occurrence, liver test, iron levels, genetic test, radiological images, treatment and follow-up.

Results: We present 25 patients, 18 male and 7 female, (51.1 ± 14.2 years-old). HZ for C282Y were 9 patients, 8 men (49.7 ± 20.3 years-old) DHTZ for C282Y and H63D were 16 patients, 11 men (52 ± 10. years-old). Patients were identified by abnormalities on routine blood test (16 hyperferritinemia, 7 hypertransaminasemia) or by screening test after a family member was diagnosed (6 cases). None had signs or symptoms related to HH. HZ objectifies a greater increase in alkaline phosphatase. All patients present high levels of ferritin and transferrin saturation, in HZ this increase was higher than in DHTZ. These differences were not significant except for transferrin saturation ($p < 0.005$). We recorded neither alteration in carbohydrate metabolism, hematology nor in coagulation. Determination of hepatic iron stores by MRI was performed in 9 patients. They were higher in HZ than DHTZ (143.8 ± 58.7 vs 56.6 ± 35 $p < 0.02$) All patients HZ and 6 DHTZ were treated with phlebotomy (once every two weeks). Normalization of iron levels

were achieved at 30 ± 18 months in HZ and 10.8 ± 6.6 months in DHTZ.

Discussion: HH is an autosomal recessive disorder in which mutations in the HFE gene cause increased intestinal iron absorption. HH remains the most common genetic disorder in Caucasians. HH is increasingly being recognized by clinicians and it can be further defined genotypically by the family occurrence of iron overload associated with C282Y homozygosity or C282Y/H63D compound heterozygosity. The vast majority is asymptomatic, with a low incidence of cirrhosis, diabetes or skin hyperpigmentation because many patients are diagnosed when elevated serum iron or ferritin levels are detected on a routine chemistry or when screening is performed in a relative diagnosed with HH. Other studies have suggested that these patients may be at increased risk for diabetes, colorectal cancer, and hematologic malignancies, but in our study we recorded neither alteration in carbohydrate metabolism nor in hematology. Phlebotomy once every two weeks was the treatment until the iron stores were normal (serum ferritin concentration < 50 ng/ml and transferrin saturation < 50 percent).

Conclusions: HH is increasingly being recognized by clinicians. HH are identified at a younger age because of abnormalities on routine blood test or by screening after a family member was diagnosed. They did not have complications at the time of diagnosis. All patients present high levels of ferritin and saturation transferrin, in HZ this increase was higher than in DHTZ. Treatment is phlebotomy. It is done once per week until the iron index is normal. This may require 9 to 12 months and it is usually needed for a lifetime.

V-31
CASE SERIES OF AMYLOIDOSIS WITH CARDIAC INVOLVEMENT AT THE UNIVERSITY HOSPITAL MARQUÉS DE VALDECILLA (HUMV)

A. Sánchez González, F. Arnaiz de las Revillas Almajano, L. Corral Nieri, C. Salas Pelayo, M. García Hoyos, S. García Rubio, M. Valero Díaz de Lamadrid, F. Ortiz Flores

Department of Internal Medicine. Hospital Valdecilla. Santander (Cantabria), Spain.

Objectives: Study the clinical characteristics of patients diagnosed as having amyloidosis with cardiac involvement at our hospital, analysing mortality and the usefulness of diagnostic tests.

Material and method: We performed a retrospective study of 19 patients (men 58%) with biopsy-proven diagnosis of amyloidosis and heart involvement at the HUMV (Santander, Spain) from 2007 to 2012. Age, diagnostic service, form of presentation and clinical manifestations were gathered from medical records. Proteinogram results and proteins in urine of 24h (> 150 mg/24h) were also included. We recorded the presence of arrhythmias, heart blocks, low voltage complexes (< 1 mV at precordial and/or < 0.5 mV at unipolar leads) and pseudo-infarction pattern (QS at anterior leads) in the EKG. We also took down the presence of left ventricular (LV) wall or interventricular septum thickening and LV diastolic or systolic dysfunction from the transthoracic ecocardiogram (TTE). The results from the gadolinium-enhanced cardiac magnetic resonance (CMR) and cardiac catheterization were evaluated. Localization of diagnostic biopsy and amyloid type were registered (primary amyloidosis (AL), secondary amyloidosis (AA), systemic senile amyloidosis (SSA) and familial neuropathic amyloidosis (ATTRm)), as well as treatment received and mortality.

Results: The average age at diagnosis was 68 ± 13 years. The service with the highest number of cases was Cardiology (37%),followed by Nephrology (10%) and Internal Medicine (5%). Dyspnea was the most frequent form of presentation (32%),followed by general syndrome (16%) and syncope (16%).More than half of the patients (53%) presented signs of right heart failure but only 26% presented signs of left heart failure. In a third of the cases there was a monoclonal band in the proteinogram and 60% of the cases had proteinuria. The most frequent arrhythmia in the EKG was atrial fibrilation (29%), being very infrequent (5%) the conduction alterations. Half of the patients had low voltages and 35% had an anterior pseudo-infarction pattern. A TTE was performed on 12 patients, most of them with LV wall thickening (92%) or interventricular septum thickening (42%). Diastolic dysfunction was more frequent than systolic (83% and 50% respectively). A CMR was performed on 3 patients (all with biventricular subendocardial late enhancement) and a cardiac catheterization on 5 patients (60% without coronary injuries). The diagnosis of amyloidosis was made during necropsy in 8 cases (42%), all of them with cardiac infiltration of amyloid material, by endomyocardial biopsy in 5 cases (26%), by bone marrow biopsy in 4 cases (21%) and by kidney and rectal biopsy in 2 cases. The most frequent type was AL, which affected 11 patients (58%), followed by SSA on 7 patients (37%). There was only one case of TTRm amyloidosis.70% of SSA cases were diagnosed by an incidental finding in necropsy; average age at diagnosis was 81 ± 7 years. 54% of patients with AL received treatment with melphalan-dexamethasone, 18% did not receive any treatment. A heart transplantation and a renal transplantation were performed on two different cases. Mortality in our group was 84% with a survival period of 4-8 months since diagnosis.

Discussion: Regarding cardiac involvement, AL was more frequent than SSA at our hospital. Dyspnea, along with right heart failure, are the main clinical manifestations on these patients.EKG and TTE are the most useful diagnostic tests. Patients with cardiac SSA are elderly and develop few clinical manifestations. Frequently, the diagnosis of this illness is made during necropsy. Mortality in our group is very high, so we consider necessary to make an early diagnosis of this illness so that a suitable treatment can follow.

Conclusions: Cardiac involvement of amyloidosis is an illness hard to handle that requires a high clinical suspicion as well as an adequate interpretation of tests aimed at an early diagnosis and treatment.

V-32
CONCORDANCE BETWEEN 1990 AND 2010 AMERICAN COLLEGE OF RHEUMATOLOGY (ACR) CRITERIA FOR THE DIAGNOSIS OF FIBROMYALGIA IN THE USUAL CLINICAL PRACTICE

C. Sánchez Jódar[1], V. Blanes Castañer[1], E. Pappalardo Ordiñana[1], M. Esteban Giner[2], M. Nicolau Laparra[2], T. Marco Domingo[2], V. Giner Galvañ[2]

[1]Department of Health. Centro de Salud de Cocentaina. Alcoy (Alicante), Spain. [2]Department of Internal Medicine. Hospital Virgen de los Lirios. Alcoy (Alicante), Spain.

Objectives: Fibromyalgia (Fm) is diagnosed according to clinical criteria after the exclusion of other illnesses. The usual difficulty to strictly apply this criteria in the usual clinical practice has the immediate potential consequence of an over diagnosis of the entity.

Material and method: 57 patients with CIE 9 code MC 729.0 and 780.71 were found after revision of electronic database of the Centro de Salud of Cocentaina (Alicante, Spain). 46 patients were contacted by phone, 25 accepting an interview to apply ACR 1990 and 2010 criteria. No differences were detected comparing those patients interviewed (n 25) and those that refused participation (n 16).

Results: The majority (98%) of participants were middle aged (58.7 ± 10.4 yrs) women followed during 154.5 ± 469.5 months. Fm

diagnosis was confirmed by rheumatologist in 78.9% of cases. 64% and 72% had ACR 1990 and 2010 diagnosis criteria (p = 0.066) (Table 1). Patients accomplishing for 1990 criteria had a median of 14 (0-18) gathering points, a higher number than those without such dx (14.8 ± 0.7 vs 6.9 ± 1.8; p < 0.0001). This significant difference was also present comparing patients with or without 2010 dx criteria (13.8 ± 1.09 vs 7.3 ± 1.9; p = 0.005). There was not a significant difference comparing patients with 1990 (14.8 ± 2.8) and 2010 (13.8 ± 4.6) dx criteria. When 2010 criteria were considered, significant differences were detected comparing Widespread Pain Index (WPI: 2.3 ± 0.6 vs 4.7 ± 0.7, p = 0.049), and the Symptom Severity Index (SSI: 6.2 ± 0.5 vs 4.4 ± 0.4; p = 0.064) values comparing patients with or without such Fm criteria. The most frequent SSI2 manifestations were muscle pain, stiffness and muscular weakness (100% prevalence each). Other frequent manifestations were fatigue (87%), depression (75%), anxiety and insomnia (69% each). The only significant (p = 0.018) difference considering SSI2 manifestations was referred to muscular weakness (100% vs 71.4%). Altman-Blond method showed a moderate (Kappa 0.453; p = 0.021) concordance between 1990 and 2010 diagnosis criteria for Fm.

Discussion: A third of patients previously diagnosed as having Fm don't accomplish any ACR criteria. There are a moderate concordance between 1990 and 20101 ACR criteria, with 2010 version classifying more patients as having Fm. In both cases, musculoskeletal manifestations are the most frequent. In our experience application of 2010 criteria spends about 40-50 minutes/patient.

Conclusions: Over diagnose is a frequent fact in Fm. One way to correct this over diagnose is to improve the application of recognized dx criteria. It seems from a practical point of view that the application of 1990 ACR criteria is easier and more feasible to be applied in the usual clinical practice.

Table 1 (V-32). Diagnostic concordance between 1990 and 2010 criteria for the diagnose of Fm

Diagnostic criteria		ACR 2010	
		Yes	No
ACR 1990	Yes	14	2
	No	4	5

V-33
INTERDEPARTMENTAL REFERRALS MADE TO AN INTERNAL MEDICINE UNIT OF A UNIVERSITY HOSPITAL IN THE SOUTHERN SPAIN

D. Narankiewicz, S. Santamaría Fernández, M. López Carmona, V. Buonaiuto, A. Espejo Gil, R. Gómez Huelgas

Department of Internal Medicine. Hospital General. Málaga, Spain.

Objectives: To analyze the number of referrals made to Internal Medicine by Surgical and Medical Departments during the period of October to December of 2011 and to assess the comorbidity and degree of implication of these departments in the diagnostic process.

Material and method: We examined all referrals made to Internal Medicine Department of the Carlos Haya University Hospital of Malaga, an accredited centre for training resident physicians. The medical specialties covered by the hospital that function independently of the Internal Medicine department are: Allergy, Cardiology, Digestive Medicine, Endocrinology, Haematology, Nephrology, Pulmonology, Medical Oncology, Neurology, Psychiatry and Rheumatology. The surgical area is composed by Cardiovascular Surgery, General and Digestive Surgery, Neurosurgery, Plastic Surgery, Oral and Maxillofacial Surgery, Orthopaedic Surgery and Traumatology, and Othorhinolaryngology. We analyzed: department which made the referral, type of referral (normal, on day, urgent), reason of the referral, comorbidity and the PROFOUND index, degree of implication of the medical or surgical department, final diagnosis.

Results: During the study period 51 referrals were made. 66.6% of them were from Surgical Departments. Orthopaedic Surgery and Traumatology most often requested interdepartmental referral followed by General and Digestive Surgery and Cardiovascular Surgery with 17.6% (9), 13.7% (7) and 13.7% (7) respectively. The intervention of internist was requested at the same day in 68.6% (35) of cases and urgently in the 13.7% (7). The mean age of the sample was 62.8 ± 19.5 years with 54.9% of men. The most common comorbidities were hypertension (51%), diabetes mellitus (25.5%) and dyslipidemia (25.5%). The 41.2% (21) were polypathological patients and of these 13.7% (7), 17.6% (9) and 9.8% (5) had a low, intermediate and high Profound Index respectively. The most common symptoms were dyspnea 13.7% (7), followed by fever 7.8% (4) and high blood pressure. Metabolic disorders were frequent as well, representing 11.8% (6). We defined the degree of implication in the diagnostic process as low, medium or high regarding the possible diagnosis established or complementary tests required by the implicated department before the referral was made to our department. Thus, we considered "low implication" when they referred to us at the first sight, 70.6% (36), "medium" when they contact after requesting complementary tests, 21.6% (11) and "high" when the referral was made after a clear diagnosis. In our sample none of the referrals had a diagnosis.

Conclusions: Of all interdepartmental referrals made to Internal Medicine, those requested by surgical departments were the most frequent and 68.6% were requested on the day. The most common symptom referred was dyspnea. Of these referrals, 41.2% were of patients with important comorbidities and complexity and the degree of implication of the responsible physicians was low. Thus, the interdepartmental referral represents an important additional work load and dedication of the duty internist.

V-34
DESCRIPTIVE ANALYSIS OF THE CLINICAL PROFILE IN PATIENTS WITH MYOPERICARDITIS REQUIRING HOSPITALIZATION IN 2011 IN A SPECIALICED HOSPITAL OF THE SSPA

V. Manzano Román, M. Guzmán García, S. Romero Salado, V. Lechuga Flores, G. Ruiz Villena, R. Aranda Blázquez, R. Tinoco Gardón, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Puerto Real. Cádiz, Spain.

Objectives: We proceed to analyze those features presented by patients diagnosed of myopericarditis, making visible the common findings of our group of patients. It is important to know these things, since this pathology is one of the etiologies that are associated in the differential diagnosis of acute chest pain in young patients, can be offered as trascendent early signs in diseases such as those of neoplasic or autoimmune origin.

Material and method: The results were analyzed based on the characteristics of a descriptive study. We included patients admitted to our hospital which having chest pain, went to the Emergency Department of Universitary Hospital of Puerto Real during the year 2011. Variables studied: sex, age, etiology, history of heart disease, hemodynamic status and clinical outcome.

Results: Total patients: 8 patients. Average age: 33 years (41.6% below 30 years). Total: 2,041% of patients were admitted to the

Service in 2011. 8.33% history of heart disease, Etiology found in 8.3% of cases, and these viral etiologies and neoplastic causes. Evolution: no hemodynamic instability 91.67%. Average discharge: 3 days.

Discussion: This pathology has plenty different etiologic agents, more or less defined, presenting the highest prevalence the one caused by infectious agents, being the most predominant cause viral agents (including adenovirus, arboviruses, arenaviruses, Coxsackie, Epstein-Barr virus, cytomegalovirus, among others), but we must not forget those non-infectious agents (autoimmune diseases, neoplastic, metabolic, etc). This pathology is usually diagnosed relatively frequents by Emergency Services Cardiology or after the evaluation of the symptomathology and diagnostic tests such as echocardiography or ECG.

Conclusions: In conclusion, we find that myopericarditis is usually a benign pathology in the vast majority of cases, but we should not rule out the monitoring of these patients, it may be a secondary pathology subsidiary of treatment processes such as neoplasia or autoimmune diseases.

V-36
EPIDEMIOLOGICAL STUDY OF UPPER GASTROINTESTINAL BLEEDING IN THE PATIENTS ADMITTED IN THE INTERNAL MEDICINE I UNIT OF THE UNIVERSITY HOSPITAL COMPLEX OF SALAMANCA IN A PERIOD OF 2 YEARS

L. Mateos Polo, M. García García, R. Fernández Santalla, T. García Guerrero, J. Herráez García, A. Sánchez Rodríguez

Department of Internal Medicine. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca, Spain.

Objectives: Retrospective study of patients with a diagnosis at arrival was upper gastrointestinal bleeding (UGIB), who were admitted in the Internal Medicine I Unit in a period of 2 years, in order to establish their clinical and biological characteristics, age, sex, associated diseases, gastroerosive drug use, impact of the bleeding and death rate.

Material and method: We gathered the clinical records of all patients with UGIB diagnosis from January 2010 to December 2011 which included complete anamnesis, complete blood count, renal function, ions, endoscopic tests (gastroscopy, endoscopic ultrasound)diagnostic arteriography, biopsy and death. The impact of the bleeding was classified as: slight: < 15% or between 500-750 ml; moderate: 15-25% or 750-1,250 ml; severe: 25-35% or 1,250-1,750 ml; and massive: > 35% or > 1,750 ml. The statistics were made with SPSS.18 for the analysis of the descriptive frequencies, Student's t-test for independent variables and chi-squared test for dependent variables.

Results: 121 patients were analyzed, and 50 were ruled out because they did not meet the requirements. Out of the remaining 71 patients, 43.7% were women with an average age of 84 years and 56.3% were men with an average age of 78 years. 21.1% of the patients were hypertense and 19.7% were diabetic, with ischemic cardiopathy in 11.3% of the cases. With regard to the associated disease, recent abdominal surgery was found in 22.5% of the patients, ulcer in 15.5%, cancer in 14.1% and hiatus hernia in 5.6%. The most common symptoms were melena in 56.3% of the cases and coffee ground vomit in 29% of the cases. No iatrogenic medication was found in 42% of the cases. 29.6% of the patients received antiaggregants (52.4% of the women), 15% received anticoagulants (54.5% of the women) and 12.7% received NSAIDs (22.2% of the women). The difference between sexes was statistically significant. The gastroscopy was diagnostic in 89.2% of the cases. There was an endoscopic diagnosis of acute gastric mucosal lesions (AGML) in 21.2% of the cases, duodenal ulcer in 15.5% of the cases, gastric ulcer in 14% of the cases and peptic esophagitis in 11% of the cases. A biopsy was performed in 16.9% of the cases. The impact of the bleeding was slight in 62% of the cases, moderate in 32% of the cases and massive in 4.2%. No statistical comparison was made between the hemoglobin levels and the degree of the impact, except in the case of moderate bleedings. The death rate was 4.2%, with a statistically significant association with massive bleeding and male sex ($p < 0.001$).

Conclusions: Patients with UGIB admitted in the Internal Medicine I Unit are elderly men with recent previous abdominal surgery, diabetic, hypertense and with ischemic cardiopathy, who receive NSAIDs. For this reason, the diagnosis of AGML is the most common one. Melena is the most common symptom. We may highlight that the use of antiaggregants and anticoagulants is not related with the severity of the bleeding. The hemoglobin level does also not correlate with the degree of hemodynamic impact. The importance of endoscopy in the first 12 hours for diagnosis and treatment is also remarkable. Death is statistically associated to the amount of bleeding, and it does not depend on age in our series, contrary to what has been published in the literature.

V-37
ECONOMIC ANALYSIS OF A HOSPITAL AT HOME UNIT: COMPARISON WITH CONVENTIONAL HOSPITALIZATION

M. Del Río Vizoso[1], M. Bennasar Obrador[2], L. Gil Alonso[1], J. Rascón Risco[3], E. Esteban Marcos[3], L. Martín Pena[3], L. Pallarés Ferreres[3]

[1]Hospital at Home, [2]Department of Economic Management, [3]Department of Internal Medicine. Complejo Asistencial Son Dureta. Palma de Mallorca, Spain.

Objectives: The main aim of this study is to find out the efficiency of managing patients at home, with a specialized unit, versus the standard only-in-hospital attendance. Other objectives are: 1. To determine the costs associated to a Hospital at Home (HaH) unit belonging to a tertiary Spanish hospital. 2. To describe the costs of stays in three different departments and estimate them according to cost per weighted case (CPWC).

Material and method: Retrospective analysis of the direct and indirect costs associated to the attention of inpatients in three Departments at a University Hospital in Spain in 2010. We collected data regarding HaH, Neumology (NML) and Internal Medicine (IM). We selected NML and IM as they provide more than 80% of the total patients admitted to HaH. We asked economic management for the following data: description of total costs of HaH, NML and IM, costs per stay, CPWC. We asked for the coding for total admissions and mean weghted case in 2010 for those Departments.

Results: Table.

Discussion: HaH units are well-known alternatives to conventional hospitalization. Selected patients admitted to HaH remain as safe

Table (V-37)

Service	Mean weight	Cost per stay	Mean cost per discharge	CPWC	Total costs
HAD	1.46	219	2232	1529	819.390
NML	2.65	424	2550	1526	3.368.884
MI	2.13	576	7290	3433	13.544.824

as those in the hospital, with less nosocomial infections, and they class these units as top-quality health attention. A little less is known about their efficiency in terms of economic expenses compared to conventional hospitalization. Several articles conclude that costs are equal, but newer data suggesting better outcomes, not only on health but on reducing costs are being released. In these times of reducing budgets, especially in healthcare, the more efficient the more appropriate, without narrowing medical care quality. Our data shows that stay costs at HaH are lower that MI or NML ones, and it remains the same when we adjust that on mean weighted case (an internationally accepted way to measure clinical complexity). These savings come from different places: hospital maintenance, less staff (no clinical assistants or porters at home), less staff hours (HaH units are supported by emergency extrahospitalary units at night) and less staff per patients (evenings are supported by only one nurse and one on-call physician). HaH costs are bigger in terms of transportation, whether this is by rented cars, taxis or owned cars. This study has several limitations, as it is retrospective, it doesn't consider non-sanitary costs at home (electricity, food and water supply, caregiver activity...) and HaH costs often do not include those from the emergency department as NML or IM costs do.

Conclusions: 1. Our HaH unit is an efficient way of providing medical care to selected patients, as it may be cheaper than conventional care while providing high rated assistance. 2. These units could help to reduce (or not to improve) health budgets without lowering the quality ofassistance. 3. More economic studies are needed to establish HaH efficiency.

V-39
PHARMACOLOGICAL MANAGEMENT OF SPANISH PATIENTS WITH FIBROMYALGIA. PRIMARY CARE EXPERIENCE

V. Blanes Castañer[1], C. Sánchez Jódar[1], D. Stancu[3], S. Gregorio Molina[1], J. Jover Barber[1], C. Pérez Ortiz[3], Á. Collazos Stüwe[1], V. Giner Galvañ[2]

[1]Centro de Salud de Cocentaina. Cocentaina (Alicante), Spain. [3]Department of Health of Alcoy. Centro de Salud La Fábrica. Alcoy (Alicante), Spain. [2]Department of Internal Medicine. Hospital Virgen de los Lirios. Alcoy (Alicante), Spain.

Objectives: The objective of this descriptive study is to assess which drugs are usually being used for the treatment of Fm in a Spanish Primary Care Health Center.

Material and method: 57 patients with CIE 9 codes MC 729.0 and 780.71 were found after revision of electronic database of the Centro de Salud of Cocentaina (Alicante, Spain).

Results: 25 of 57 identified patients (98% women 58.7 ± 10.4 aged) diagnosed of Fm (mean follow up 154.5 ± 469.5 months) agreed to be included. A presential interview was made with 25 patients about actual medication and potential secundarisms as well as to apply ACR 1990 and 2010 diagnostic criteria. Globally high and heterogeneous drug consumption was detected, with (median and interval) 6 (1-24) daily drugs per patient. The main amount of drugs were for Fm (61% of all), with a median of 3 (1-14) and 2 (0-16) drugs per day taken for Fm and other conditions respectively. 94% of patients were on analgesics, mainly NSAIDs. 29% of patients were taking opioids, all of them minor ones. Only 42% of the patients were taking pregabalin. Although the median for the use of NSAIDS was one/day, one third of patients using NSAIDs were having more than one (Median 1, interval 0-5). At the time of the presential interview, 16% of the 25 interviewed patients described epigastralgia/pyrosis without any other apparent secondary effect. The total estimated annual global pharmacological (reference prices for each drug) cost is 7,098.36 Euros, corresponding the highest cost to ansiolitics/antidepressants (37.6%) and NSAIDs (36.5%), pregabalin (15.6%), acetaminophen alone or combined (9.6%), and tramadol (0.5%).

Discussion: Patients with Fm have an elevated consumption of drugs. The mostly used drugs are NSAIDS as well as those drugs with antidepressants/ansiolitic effects. It is noteworthy the high number of patients having more than one NSAIDS as well as the low proportion having pregabalin. Secondary effects are all gastrointestinal and attributable to the use of NSAIDs.

Conclusions: Pharmacological treatment of Fm is clearly improvable, lowering consumption of NSAIDs as well as antidepressants/ansiolitics and increasing the use of pregabalin. However the best action would be to improve the correct diagnosis of Fm.

V-40
EARLY MORTALITY IN INTERNAL MEDICINE AND PALLIATIVE CARE

C. Blas Carracedo[1], S. Plaza Canteli[1], C. Vicente Martín[1], J. Marco Martínez[2], J. Jusdado Ruiz-Capillas[1]

[1]Department of Internal Medicine. Hospital Universitario Severo Ochoa. Leganés (Madrid), Spain. [2]Department of Internal Medicine. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: To compare patients' characteristics admitted either to the Internal Medicine Department (IMD) or the Palliative Care Unit (PCU) with early mortality (defined as that occurring in the first four days after admittance).

Material and method: Retrospective and descriptive study of patients admitted to the IMD or PCU between January, 1st 2010 and December, 31st 2011 dying in the first four days of hospitalization. The variables analyzed were age, sex, main and secondary diagnosis expressed as diagnostic related group (DRG) and the 3 most frequent therapeutic or diagnostic procedures performed to the patients during the admittance period.

Results: A total of 634 deaths among 6,706 (9.45%) admittances were identified with 32.2% (n = 204) occurring in the first four days. Table 1 shows the main results for both groups.

Conclusions: 1) The global incidence of early mortality in our population was 32.2% and it was somewhat higher in PCU than in IMD patients due to the higher incidence of neoplasic disease in the former group. 2) Patients in CPU are younger and more frequently readmitted. 3) In both groups the most frequent diagnosis is pneumonia (DRG 541) although in CPU patients were younger for the same DRG. 4) The most usual procedure in CPU was IV treatment while in IMD a diagnostic test such as CT scan was the predominant one.

V-42
EVALUATION OF THE RESPONSE TO THE PRIMARY HYPERPARATHYROIDISM WITH CINACALCET TREATMENT

M. Rodríguez, M. Pérez, P. Massi, M. Pérez, J. Ramos-Clemente, F. Díaz

Department of Internal Medicine. Hospital Infanta Elena. Huelva, Spain.

Objectives: Primary hyperparathyroidism (HP) is a common endocrine disease, caused by a primary disorder of one or more parathyroid glands which is characterized by inadequate secretion of parathyroid hormone (PTH) therefore an alteration in the metabolism of calcium, the most significant hypercalcemia. Today most frequently cases have been detected of HP with calcemias bit rates (< 11.5 mg/dl) with any or none clinical symptoms. Most are women over 50 years that found in laboratory screening parameters or evaluation of individuals with low bone mass or stones. This new

Table 1 (V-40). Characteristics of CPU and IMD patients

Total	CPU		IMD		
Patients (%): 204 (32.2)	120 (58.8)		84 (41.2)		
Mean age (SD): 79.5 (15.2)	72.4 (13.3)		82.3 (13.1)		p = 0.000
Sex (%): Males (62.3)	69.2		52.4		p = 0.015

*GRD 541: simple pneumonia and other respiratory disease with mayor complication but not asthma or bronchitis. GRD 544: heart failure, cardiac arrhythmia. GRD 082: respiratory neoplasias. GRD 552: digestive tract diseases except oesophagus, gastroenteritis and uncomplicated ulcus. GRD 533: nervous system diseases except TIA seizures and cephalea with mayor complication.

scene has resulted that in some patients the conservative medical monitoring, result sufficient. In our work we will analyze the response to treatment with cinacalcet (oral calcimimetic that acts on the calcium sensing receptor, which is the principal regulator of PTH synthesis and release) in patients with HP, who have medium symptomatology.

Material and method: This is a descriptive study of patients attending at a endocrinology consult from a Comarcal Hospital, diagnosed with hyperparathyroidism, treated with cinacalcet, during the period between January 2009 to March 2012. Would be obtained medical history, physical examination, laboratory parameters (calcium, phosphorus, and PTH) and scintigraphy parathyroid, and date of initiation of treatment, dose and follow-up.

Results: We obtained three patients, all female, mean age 69 years. The present clinical symptoms were asthenia, bone pain, polydipsia, polyuria. One of them started the treatment with 60 mg/dl and the others with 30 mg/dl, not being necessary dose adjustments in the monitoring, although in one of them, the last control presented a slight increase of calcemia serum compared with the previous, but we chose to associate bisphosphonates because of the osteoporosis. The mean calcium prior to starting treatment was 11 g/dl, falling in the first control after cinacalcet to 9.32 g/dl. After an average of two years of treatment the calcium stayed around 9.42 g/dl. The mean baseline PTH was 125pg/ml, in the first test after treatment there was a marked descent 103 pg/dl, however in the last test results after 2 years of treatment, the average of PTH was around 150 pg/dl.

Discussion: In our study we analyzed the response to cinacalcet in patients in which treatment is chosen with medium intensity symptoms and normal parathyroid scintigraphy. The response of serum calcium after treatment with cinacalcet is similar to that described in previous studies, with a major decrease of 1.5 mg/dl. Perhaps PTH levels were not expected, but these results are not very valuable because the patients have not been performed laboratory parameters between 2-4 hours after taking drug, which is the maximum of blockade peak from calcium channels.

Conclusions: We concluded that cinacalcet in patients with normal parathyroid scintigraphy and medium symptomatology is a therapeutic option to keep calcium levels in normal range.

V-43
ANALYSIS OF THE FIRST 100 PATIENTS WITH ADENOPATHIES ADMITTED TO THE RAPID DIAGNOSTIC UNIT OF INTERNAL MEDICINE

K. Goenaga Pareja, J. Sánchez Navarro, J. Martín Serradilla, I. Bombín Molinero, A. Campo Núñez, R. Carbajal Martínez

Department of Internal Medicine. Complejo Asistencial de Palencia. Palencia, Spain.

Objectives: Accomplish a descriptive analysis of patients referred to the Rapid Diagnostic Unit (RDU) of Palencia Care Complex (PCC) to study their adenopathies between the years 2008 to 2012. Describe the relationship between the different features of the lymph nodes and possible tumor causes.

Material and method: Descriptive analysis from the database of the PCC RDU (a second level hospital of Castilla y León region) for the years 2008 to 2012. Analyzing the age and sex of patients, the size and location of lymphadenopathy and final diagnoses. By the Chi-square we have analyzed the possible relationship of the variables described with the existence of a neoplasm. For the statistical analysis used the SPSS 15.0 program.

Results: During this period 100 patients with lymphadenopathy were treated (5.7% of total), 54% were male, mean age ± standard deviation of 48.1 ± 21.1 years. The location of the lymphadenopathy was: 40% lateral cervical, supraclavicular 15%, 13% axillary, inguinal 10% and 22% in other locations. The size of the lymphadenopathy were less than 1 cm in 21% of cases, between 1 and 5 cm in 68% and greater than 5 cm in 11%. Finally, 39% of the patients studied were suffering a neoplasm, of which 19% were hematologic lineage, 10% derived from head and neck and the remaining 10% were of another race. (breast carcinoma, porocarcinoma and metastases of different origins). We have only demonstrated a statistically significant relationship between the existence of tumor, age and size of the lymphadenopathy, being higher the prevalence of tumors with lymph node from 1 to 5 cm and in the group of larger than 5 cm, being more prevalent in the patients between 30 and 70 years and group of people over 70 years. No significant relationship was demonstrated between the location or sex with the existence of neoplasia.

Discussion: Statistically significant relationship was found between the presence of tumor and lymph node size greater than 1

cm. We recommend a conservative approach in patients under 30 years with lymphadenopathy of less than 1 cm.

Conclusions: Thirty-nine of patients admitted with lymphadenopathy in our clinic were diagnosed with a neoplasm.

V-44
CHARACTERISTICS OF PATIENTS RECEIVING NON-INVASIVE VENTILATION OUTSIDE NON-INVASIVE VENTILATION UNIT (NIVU) IN AN AREA HOSPITAL OF MURCIA

R. Bernabeu Mora[1], A. Pinos Blanco[2], L. Strobosch Conesa[2], B. Gálvez Martínez[1], M. Martín Cascón[2], J. Sánchez Nieto[1], F. Herrero Huertas[2], M. Franco Campos[1]

[1]Department of Neumology, [2]Department of Internal Medicine. Hospital General Universitario Morales Meseguer. Murcia, Spain.

Objectives: To determine the clinical characteristics of patients receiving NIV outside NIVU beds.

Material and method: Retrospective observational study of patients ventilated outside NIVU beds during 12 months. Sampling Method: Consecutive (January-December 2011). Data Source: Records all the consultants made to the Pneumology department and NIVU, medical records and arterial blood gases.

Results: The number of patients treated with NIV in the hospital outside the NIVU was 39. Eighty-seven percent of these patients (34) were admitted to the Department of Internal Medicine (IM). Average age: 77.3 years (51-93). Men 16 (41%), Women 23 (59%). The diagnoses of the NIV indications outside the NIVU are reflected in table 1. Charlson Index: 5.9 points (0-13). Arterial blood gases: pH 7.31 (7.15 to 7.47), pCO_2 68.2 mmHg (40-112), pO_2 55.8 mmHg (40 - 81). Respiratory acidosis (pH < 7.35): 24 patients (61.5%). Intolerance to NIV was seen in 12 patients (31%). Transfer from IM to pneumology department in 4 patients (10%). The outcome was positive in 36 patients (92%) and exitus letalis in 3 (8%). Home therapy at discharge in patients who received NIV outside NIVU beds are reflected in table 2.

Discussion: 90% of ventilated patients outside of NIVU beds are admitted to the Department of Internal Medicine. COPD exacerbations and overlap syndrome (apneas-hipopneas syndrome + COPD) is the leading cause of NIV outside the pneumology department (30.7%). Heart failure (28%) and obesity-hypoventilation syndrome (23%) were the main causes for the use of NIV outside NIVU. 92% of the patients who received NIV outside NIVU evolved favorably.

Conclusions: Noninvasive ventilation (NIV) is used in either acute or chronic respiratory failure to relieve dyspnea, reduce work of breathing, correct gasometric alterations and avoid intubation. Clinical practice guidelines recommend the use of NIV in severe COPD exacerbations and cardiogenic acute pulmonary edema.

V-45
A GLANCE AT THE ADHESION ON ACTIVITIES OF SELF-CARE IN DIABETES

M. Oliveira Ferreira, L. Oliveira, N. Cardoso, J. Salomão, M. Esteves, A. Duarte

Deparment of Internal Medicine I. Centro Hospitalar do Médio Ave-Unidade de Famalicão. Famalicão, Portugal.

Objectives: Assess the diabetes self-care in a sample of individuals observed in an outpatient diabetology medical consultation.

Material and method: We applied the Summary of Diabetes Self-Care Activities scale translated and adapted to Portuguese. Sixty-six questionnaires were completed.

Results: The mean adhesion in 7 days for self-care activities were (in days): 4.97 (having a healthy diet); 4.74 (following eating plan); 3.83 (Eating 5 or more pieces of fruit or vegetable); 4.50 (eating red meat); 2.74 (bread at meals); 5.89 (mixing carbohydrates); 6.08 (2 or more cups alcoholic drink at meals); 6.47 (alcoholic intake outside meals); 5.80 (eating aliments with sugar); 5.11 (sweeten drinks with sugar); 1.6 (physical activity at least 30 min.); 1.58 (specific physical exercise sessions); 5.24 (blood sugar assessment); 5.44 (blood sugar assessment as recommended); 5.18 (examining feet); 6.29 (washing feet); 5.29 (drying between toes); 6.62 (taking medications/insulin as prescribed); 6.32 (taking indicated number of medicine/insulin units); 0.21 (smoking).

Discussion: The activity with greater mean adherence refers to pharmacologic therapy, reflecting good therapeutic compliance, which may be justified by the majority of subsequent consultations. The mean level of HbA1c of 8.3% suggests that diabetes control goes far beyond drug prescription, emphasizing the role of other activities of self-care and adoption of a healthy lifestyle. The smoking habits seem to reflect the effectiveness of quit smoking campaigns among diabetics. The lowest mean adherence was observed in the participation in practice of regular physical activity, values possibly explained by the mean age of this sample (63.3

Table 1 (V-44). Diagnostics indication of NIV outside the NIVU

HF	OHS	COPD	Overlap	OHS+HF	IPF	ALS	Pneumonia
11 (28.2%)	9 (23.1%)	7 (17.9%)	5 (12.8%)	3 (7.7%)	2 (5.1%)	1 (2.6%)	1 (2.6%)

ALS: Amyotrophic lateral sclerosis, IPF: Idiopathic pulmonary fibrosis, OHS: Obesity hypoventilation syndrome, HF: Heart failure, COPD: Chronic obstructive pulmonary disease.

Table 2 (V-44). Home therapy at discharge in patients who received NIV outside the NIVU beds

HOT	HOT + NIV	No	HOT + CPAP
19 (48.7%)	16 (41%)	3 (7.7%)	1 (2.6%)

HOT: Home oxygen therapy, CPAP: Continuous positive airway pressure, NIV: Non-invasive ventilation

Table 1 (V-45). Age, time since diagnosis and HbA1c level

	Mean	Median	Mode	Minimum	Maximum
Age (years)	63.3	64.0	60.0	23	86
Time since diagnosis (years)	17.5	15.0	15.0	1	55
HbA1c level (%)	8.3	8.3	8.3	5.3	11.4

years). Although Portugal is being included on geographic region of Mediterranean diet, the adherence concerning alimentary patterns may expose the globalization of the type of diet.

Conclusions: The observed adherence to self-care activities was very different. Some of them presented very satisfactory results (particularly intake of drugs or insulin as prescribed and smoking abstinence), while for others the adhesion values observed were very low. In the latter, it will be fundamental to develop strategies for changing habits (especially with regard to physical activity). The smoking cessation campaigns seem to have been effective in the diabetic population and should be maintained and encouraged. They may even be an example for further activities to promote self-care. It could be concluded that it is easier to adhere to the pharmacological treatment. This study highlight the need for self-care campaigns especially directed to diet and physical activity. The future may include the strengthening of patient education and its reassessment at each visit, although limited by the short time available.

V-46
ARE THERE DIFFERENCES IN PRESCRIPTION OF STATINS BY THE DIFFERENT HOSPITAL DEPARTMENTS?

M. Chimeno Viñas[1], M. Lorenxo Pando[2], M. García Castaño[3], J. Soto Delgado[1], E. Martínez Velado[1], A. de la Vega Lanciego[1], P. García Carbó[1], G. Hernández Pérez[1]

[1]Department of Internal Medicine, [3]Medical Direction. Complejo Asistencial de Zamora. Zamora, Spain. [2]Department of Pharmaceutical. Health Area Management. Zamora, Spain.

Objectives: The statins are potent inhibitors of cholesterol biosynthesis. They are widely available, inexpensive, and represent a potent therapy for treating elevated cholesterol. The objective of this study was to analyzed the statin prescription patterns in the different hospital Department in 2011.

Material and method: Observational, retrospective study. Data on statin prescriptions were retrieved from the Pharmaceutical Inspection Service of the Health Management Zamora Area. We analyzed the use of statins in the Hospital Departments that typically prescribed: Cardiology, Endocrinology, Internal Medicine, Nephrology, Neurology and Emergency Department in 2011.

Results: See Table 1.

Discussion: There are differences in the prescription of statins in analyzed Departments. Internal Medicine is the most prescriber Service.Atorvatatin is the most widely prescribed statin in all Departments except for Cardiology. Endocrinology and Nephrology have the same pattern of prescription. Cardiology opts for new statins: rosuvastatin and pitavastatin. Fluvastatin and pravastatin are rarely prescribed in all these Departments.

Conclusions: 1. There are differences in the pattern of prescribing statins according to the Department. 2. Rosuvastatin is the most prescribed in Cardiology and is second in Endocrine, Internal Medicine, Nephrology and Emergency Prescription. 3. It's amazing the prescription of pitavastatin given the short time it has been available in Spain. 4. The prescription of fluvastatin and pravastatin is low in all Department.

V-47
ACQUIRED METHEMOGLOBINEMIA. REVIEW OF CASES ADMITTED TO OUR HOSPITAL IN THE LAST TEN YEARS

R. Baeza, M. Núñez, J. Mosquera, R. Daroca, S. Morera, M. Casañas, J. Gómez, S. García

Department of Internal Medicine. Hospital San Pedro. Logroño (La Rioja), Spain.

Objectives: The purpose of this review is to determine the characteristics of hospitalized patients with acquired methemoglobinemia (MetHb) in the last 10 years.

Material and method: We reviewed the medical history of the patients who were admitted to our hospital between 2002 to 2012 and presented acquired MetHb as principal diagnosis.

Results: We found 7 cases of MetHb (described in table 1), most of all in pediatric age (71%) who had eaten mash of different vegetables and legumes, cooked 2-4 days ago, and stored in refrigerator. All of them presented acral cyanosis and, in case 4 and 5, metabolic acidosis. Case 6 is an overdosage of topical anesthetic (lidocaine and prilocaine) prior of a cosmetic procedure. The self-administered dose exceeded 450% of the maximum, which was applied to a wide body surface area. He came to emergency department with generalized cyanosis with neurological symptoms as paresthesias in arms and sleepiness. Patient number 7 is a woman with chronic renal failure on hemodialysis program who presented persistent MetHb even with treatment with methylene blue.

Discussion: Methemoglobinemia is a blood disease in which the haemoglobin iron in the ferrous state (Fe 2 +) is oxidized to the ferric (Fe 3 +). It often appears in childhood, due to poor conservation of some foods, as in our first 5 cases. There are some cases in literature related to local anesthetic, as case 6, which usually have a positive evolution. Hemodialysis-related cases are unusual.

Conclusions: Despite being a rare pathology, MetHb is a potentially fatal disease. It is recommendable to consume cooked vegetables immediately or after refrigerated or frozen. On the other hand, the incidence of MetHb is increasing because of the use of local anesthetics in cosmetics procedures. These drugs should be used with responsibility.

Table 1 (V-46). Results

	Cardiology	Endocrinology	Internal medicine	Nephrology	Neurology	Emergency
1	Rosuvastatin (45.3%)	Atorvastatin (45.3%)	Atorvastatin (39.4%)	Atorvastatin (55.6%)	Atorvastatin (69.1%)	Atorvastatin (57.5%)
2	Atorvastatin (22.9%)	Rosuvastatin (20.3%)	Rosuvastatin (26%)	Rosuvastatin (20.4%)	Simvastatin (19.2%)	Rosuvastatin (32.3)
3	Pitavastatin (4.86%)	Simvastatin (17.2%)	Simvastatin (20%)	Simvastatin (16.4%)	Rosuvastatin (11.7%)	Simvastatin (5.3%)
4	Simvastatin (10.7%)	Pitavastatin (7.8%)	Fluvastatin (9%)	Pitavastatin (5.6%)		Pitavastatin (2.7%)
5	Pravastatin (4%)	Pravastatin (7%)	Pitavastatin (3.2%)	Pravastatin (1.2%)		Fluvastatin (1.4%)
6	Fluvastatin (2%)	Fluvastatin (2.3%)	Pravastatin (2.4%)	Fluvastatin (0.8%)		Pravastatin (0.8%)
Number of prescriptions	397	128	651	250	94	230

Table 1 (V-47). Characteristics of cases of methemoglobinemia (2002-2012)

Case	Age	Underlying disease	Associated factor	Methemoglobin (%)	Treatment	Outcome
Case 1	10 months	None	Vegetables and legumes	28.6%	Methylene blue	Favorable
Case 2	7 months	None	Vegetables and legumes	Unsolicited	Methylene blue	Favorable
Case 3	11 months	Down Syndrome	Vegetables and legumes	Unsolicited	Methylene blue	Favorable
Case 4	7 months	None	Vegetables and legumes	53.7%	Methylene blue	Favorable
Case 5	5 months	None	Vegetables and legumes	23.9%	Methylene blue	Favorable
Case 6	36 years	None	Topical anesthetics	10.1%	Methylene blue	Favorable
Case 7	76 years	Chronic renal failure	Unknown	4.6%	Methylene blue	Death

V-48
DETECTING ADVERSE DRUG EVENTS AT HOSPITAL ADMISSION

O. López Berastegui[1], L. Echarri Martínez[2], F. de la Calle Prieto[1], M. Gómez Antúnez[1], T. Blanco Moya[1], J. Santos Martínez[1], E. Durán García[2], A. Muiño Míguez[1]

[1]Department of Internal Medicine 2A, [2]Department of Pharmacy. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: Knowing the incidence of adverse effects of medicines in order to identify which could be prevented and which are the most common.

Material and method: It's evaluated patients admitted in a department of Medicine along two months. It is an observational and prospective study. We included clinic data, blood test and the previous patients' treatment. Detecting adverse effects we used first of all, an algorithm called Karch Lasagna who determines the relation of cause between the adverse effect and the suspected medicine and then, the algorithm of Schumach and Thorton who asses if we were able to prevent them.

Results: We obtained 138 patients, 50 (36.3%) showed signs of alert of a possible adverse effect, with definitive relation of cause in 5.1%, probable in 14.5%, possible in another 14.5% and improbable in 2.2% These adverse effects could be prevented in a 16.7% and they were the cause of the admission in 9.5% Anticoagulants were the medicines most common implicated (15.9%), anxiolytic (4.3%), diuretics (3.6%), and ACE inhibitors (2.9%).

Discussion: An adverse drug reactions is defined as any noxious, unintended, or undesired effect of a drug that occurs at doses used in humans for prophylaxis, diagnosis, or therapy. It's the reason of a no-well-known proportion of admissions, which have been described between 1-35%. Multiple factors influence susceptibility to drug reactions and include multiple drug therapy, severity of the disease, age, and type of drug prescribed. Since the current study enrolled patients from internal medicine ward it included a high proportion of geriatric patients. The high proportion of geriatric patients in our study group may account for the relatively high incidence of adverse drug reactions related admissions. Older individuals have more illnesses and consume more drugs. These factors, in combination with the alterations in pharmacokinetics and pharmacodynamics, made this group more vulnerable to adverse drug events. Anticoagulant drugs, diuretics and ACE inhibitors were common responsible for adverse drug events. This finding is in accordance with the high prevalence of older patients with cardiovascular disease. With regard to causality, the high proportion of adverse events classified as probable or possible was not surprising since is often difficult to prove. Firstly, measurements of drug levels were not performed routinely, secondly, a re-challenge test was never performed.

Conclusions: Adverse drug reactions are common at hospital admission. It is necessary to design strategies of security to prevent adverse effects. We might know that is just a small group of medicines who produces the most of these effects; we must be done about it.

V-49
ACCURACY OF THE HOSPITAL ADMISSION MEDICATION HISTORY

F. de la Calle Prieto[1], L. Echarri Martínez[2], E. Durán García[2], O. López Berastegui[1], M. San Julián Romero[1], A. Torres do Rego[1], M. Gómez Antúnez[1], A. Muiño Míguez[1]

[1]Department of Internal Medicine 2A, [2]Department of Pharmacy. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: To determine the incidence and type of error reconciliation of medications at the beginning of hospitalization.

Material and method: The study involved consecutive patients hospitalized for a month in an Internal Medicine Unit. It's evaluated the collection of the usual treatment of the patient in the emergency department compared with collection in our Internal Medicine Unit. It's verified with medical reports and interviews the patient, family and provider. The verification is checked by a doctor and/or pharmacist. Any discrepancies not justified is considered a failure of conciliation.

Results: 138 patients were evaluated (52% men); mean age 76.6 ± 15.5. We found at least one error reconciliation due to discrepancy not justified in 64.5% of patients; the most common are the omission of a medication (47.8%), incomplete prescription (27.5%) and the difference in dose or pattern (19.6%) Medical reports are the main source of information (29%), followed by patient interview (26.1%) and the family interview (24.6%).

Discussion: The medication conciliation is the process of knowing the previously prescribed medication of the patient compared with the different phases of medical care. This is to ensure that medicines are prescribed in the dosage and the correct pattern. The World Health Organization recognizes it as a priority strategy for patient safety. Most of the conciliation errors are detected at hospital admission. An accurate medication use history is an integral part of the patient assessment on admission to the hospital. An erroneous medication use history may result in failure to detect drug related problems or lead to interrupted or inappropriate drug therapy during hospitalization. Errors medication conciliation at hospital admission are common. Some studies describe discrepancies in 70% of cases, unfortunately, most studies fail to distinguish between unintentional or erroneous medication changes an intentioned adjustments guided by the patient s clinical condition at time of admission. The data presented suggest that the processes for recording medication histories on admission to the hospital are inadequate and in need of improvement. Development of computer systems that allow transfer of medication histories and prescription information between hospitals and community pharmacies has the potential to improve this process.

Conclusions: Unintended medication discrepancies a time of hospital admission are common, and some have the potential to cause harm. Medication Reconciliation is a goal to reduce errors related to medication use and enhance patient safety. Better methods of ensuring an accurate medication history at time of hospital admission are needed to improve patient care and minimize the potential costs of preventable adverse drug events.

V-50
IMPACT OF THE IMPLEMENTATION OF A THERAPEUTIC EQUIVALENCE PROGRAM

M. San Julián Romero[1], V. Escudero Vilaplana[2], I. García López[2], E. Durán García[2], T. Blanco Moya[1], F. Cabrera Aguilar[1], M. Gómez Antúnez[1], A. Muiño Míguez[1]

[1]Department of Internal Medicine 2A, [2]Department of Pharmacy. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: Our objective is to assess the impact of the introduction of a TEP in an Internal Medicine Section in a tertiary hospital.

Material and method: Prospective, observational study of hospitalised patients from an Internal Medicine Section for two months after TEP approval. Drug groups included: proton pump inhibitors (PPI), calcium channel blockers (CCB), angiotensin II receptor blockers (ARB), angiotensin-converting enzyme (ACE) inhibitors and HMG-CoA reductase inhibitors. On admission, patient NFD and subsequent drug changes due to TEP were recorded. Economic impact was assessed, analyzing costs reduction.

Results: 117 patients (59.0% men) were included; mean age 74 years; median hospital stay 7 days. 12.8% of patients on NFD included in TEP. Drug groups were: ARB: 60.0% (valsartan: 44.4%, irbesartan: 44.4%, eprosartan: 11.2%), ACE inhibitors: 13.3% (ramipril: 50%, imidapril: 50%), HMG-CoA reductase inhibitors: 13.3% (lovastatin:100%), CCB: 6.7% (nitrendipin:100%), PPI:6.7% (esomeprazole:100%). 33.3% prescribed the equivalent dose recommended by TEP, 26.7% did not prescribe the NFD due to clinical status, 20.0% prescribed the equivalent drug with different dose to TEP and remaining 20.0% of patients brought own medication.

Discussion: A Therapeutic Equivalence Program (TEP) is a help document approved by the Pharmacy and Therapeutic Committee for prescription and dispensing of non-formulary drugs (NFD), considered therapeutic equivalents according to scientific literature. Therapeutic interchange polices and programs grant pharmacists the authority to interchange drugs without prior consent from the prescriber according to procedures outlined in a specific policy. The role of therapeutic interchange has increased substantially in recent years as a result of two primary influences: the rapid expansion in the number of drugs within the same or comparable therapeutic classes, and the need to control drug and related health care costs while promoting more rational drug therapy. The success of the therapeutic interchange program is related to the effectiveness of the pharmacy and therapeutics committee and proper educational methods to inform the professional staff. There are many studies documenting increases in therapeutic interchange policy adherence through the use of computerized physician order entry. Computerized physician order entry allows computerized warnings, dosage guidance tools, and recommendations of preferred drugs within a class.

Conclusions: An important number of patients (12.8%) take NFD, especially ARB (60%). Consequently, TEP contributes to rational use of medicines reducing dispensing time and costs.

V-51
CLINIC URGENCY PATIENTS PROFILE ASSISTED BY AN INTERNAL MEDICINE RESIDENT ON AN URGENCY OFFICE DURING LOW ASSISTANCE PERIOD ON A SPECIALIZED HOSPITAL FROM SAS

G. Ruiz Villena, R. Aranda Blázquez, S. Romero Salado, M. Guzmán García, E. Sánchez Relinque, V. Lechuga Flores, V. Manzano Román, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario Puerto Real. Cádiz, Spain.

Objectives: The aim is to describe clinic assistance patients profile assisted on an urgency office by internal medicine resident for first year (IMR) two days during low assistance period in our center at Urgency Service.

Material and method: Descriptive study which was included patients assisted on an urgency office by two IMR, two randomized days during low assistance period (last days from April) in our center. Variables studied: basic patient profile, time spent on assistance, complementary tests realized and develop.

Results: Total included 39. Age between 5 months and 89 years old. 61.54% women, 38.46% men. Average time spent on each 2 hours 56 minutes (maximum 7 h 06 min, minimum 12 min). 23 lab tests were made, 15 X-Rays, 9 EKG, one TC and one ultrasonography. Develop: discharge to primary attention 71.79%, discharge for specialist attention 20.5%, hospitalized 5.13%, reaming were discharge without continued assistance. Reaching 97.45% continued assistance.

Discussion: It is not a notice the assistance pressure on Urgency Services. It is true they are variable clinic assistance profile depending of the season, high or low assistance period. In our center during low assistance period, basic patient profile is: most women, wide age range, average time spent less than 3 hours. Main complementary tests were: lab test and X-rays being most discharge for primary assistance.

Conclusions: Global clinic internal medicine professional view makes him able to develop a good job on Urgency Service during low assistance period when are less comorbidities on patients assisted, internal medicine professional is essential.

V-52
CENTENARIANS: REASON FOR ADMISSION TO THE INTERNAL MEDICINE WARD

M. Vázquez Ronda, E. Núñez Cuerda, L. de Matías Salces, M. Vivas del Val, A. Herrero Domingo, F. Marcos Sánchez

Department of Internal Medicine. Hospital General Nuestra Señora del Prado. Talavera de la Reina (Toledo), Spain.

Objectives: This review was made in order to know the characteristics and pathologies that led to the admission to the Hospital of our centenarians.

Material and method: A review of the medical histories of the centenarians admitted to the Internal Medicine ward during the last five years was made.

Results: Ten patients were admitted to our ward, the ages varied from 100 to 103 years. Hypertension was the most frequent past medical problem. All of the patients had no neuropsychiatric deficiencies, and only two were dependant for basic activities. The main complaints were dyspnea, fever and chest pain. The most frequent diagnosis was pneumonia followed by cardiac insufficiency. Basic laboratory tests, X-Rays and ECGs were the only tests performed and only one patient needed an abdominal ultrasound. Six patients died: 2 due to a cardiogenic shock, two due to a multilobar pneumonia and one due to an intestinal obstruction.

Discussion: Living more than 100 years is an unusual event. The raise of the standard of living and the improvement of the medical services has allowed more people to live over a 100 years. The number of centenarians in the whole world is estimated to exceed 2,189,000 in 2050. In our health care setting is a large number of patients admitted to surpass the barrier of 70 and a not inconsiderable number of patients aged 95-100 years. This leads to increased health resources and therefore increase the cost. As we have seen in our work, most had a good quality of life with hypertension arterial most common comorbidity and only 20% were dependent for basic activities of daily living; reason for their longevity. Its main pathology was infectious and non-invasive methods used in diagnosis. Despite this, mortality was 60%.

Conclusions: We highlight the absence of relevant past medical history, the relatively good quality of life before admission to the Hospital and the decision to avoid aggressive therapeutic and

diagnostic measures giving priority to the patients' comfort and to the agreement of their families in the decisions taken.

V-53
EVALUATION OF THE ADMINISTRATION OF ANTI-PLATELET MEDICATION IN DIABETIC PATIENTS

K. Rousos[1], S. Patiakas[2], I. Doukopoulos[2], A. Loli[2]

[1]Health Centre of Alexandria. General Hospital of Veria, Greece. Veria, Greece. [2]Biopathological Laboratory. General Hospital of Kastoria, Greece. Kastoria, Greece.

Objectives: To be evaluated the percentage of diabetic patients of a provincial hospital who receives anti-platelet treatment, taking into mind that the main reason of morbidity and mortality to these patients is connected with the vascular complications (either microvascular or macrovascular) and, therefore, this medication has the target of both primary and secondary prevention of these complications. Moreover, it is necessary to be estimated the usefulness of generalization of the implementation of this medication.

Material and method: Overall, 347 diabetic patients (136 men and 211 women) have been researched in the regions of Central and West Macedonia, with average of age 63 ± 11.9 years and average duration of the diabetic disease 9.2 ± 4.3 years.

Results: The number of the patients who received the anti-platelet medicament was 61 patients (17.58%), 34 men (25%) and 27 women (12.8%). 48 of these patients (78.7%) had already established coronary heart disease and, for this reason, they were already treated with this medication.

Discussion: As someone can understand, the concerning low percentage anti-platelet medication in diabetic patients in these provincial regions of Greece demonstrates the lack of prevention or the delayed prevention in this particular sector.

Conclusions: It is necessary the better education of the doctors recruited in the primary prevention care who come in close contact with the patients of frontier regions in order to be obtained the better knowledge, by these patients, of the usefulness of preventive administration of anti-platelet medicaments.

V-54
RESEARCH OF ERYTHROCYTE INDEXES, HISTOGRAMMAS AND RDW IN CIRRHOTIC PATIENTS

K. Rousos[1], S. Patiakas[2], A. Loli[2], I. Doukopoulos[2], C. Charalampous[3]

[1]Health Center of Alexandria. General Hospital of Veria. Veria, Greece. [2]Biopathological Laboratory. General Hospital of Kastoria. Kastoria, Greece. [3]Clinic of Internal Medicine of Psychiatric Hospital of Thessaloniki. Thessaloniki, Greece.

Objectives: To be investigated the data of automatic analyzer of Full Blood Count in cases of cirrhotic patients and to be evaluated the prognostic value of the elements of the Full Blood Count, for example, the erythrocyte indexes, the Histogramma and the parameters of variability of the erythrocytes in the evolution and severity of the liver disease.

Material and method: Totally, 26 cases of cirrhotic patients have been investigated (18 men and 8 women), most of them, (21 out of 26), with alcoholic cause, who have been hospitalized in the Clinic of Internal Medicine of the Psychiatric Hospital of Thessaloniki, Greece. They have been treated for alcohol abuse, without any hematologic disease or active bleeding, and they have been classified into staging of Child-Pugh. The results of full blood count have been researched to all of them.

Results: The average values of the elements of Full Blood Count, in accordance with the stage of the liver disease, have been mentioned in the following panel of the table.

Discussion: It is proved that the prognostic value of RDW and histogramma is very important for the evolution of cirrhotic disease, in comparison with the, more often used, erythrocyte indexes (MCV, MCH and MCHC). Although the existence of morphologic abnormalities of the erythrocytes (acanthocytes and spur-cells) advocates for advanced cirrhosis and, even more, for cirrhosis with bad prognosis, on the other side, it is required microscopic analysis of the blood sample by the specialist.

Conclusions: Also, the existence of acanthocytes causes the modification of RDW and it is easy detectable from the simple exam of the full blood count which can be committed by a non-specialist medical doctor. It is obvious, finally, that the morphologic variability of the erythrocytes (as it is expressed by the results of FBC on the automatic analyzer) is a very useful tool in order to be evaluated the progression of the cirrhosis even by a non-hematologist. Consequently, it is necessary to be taken into mind.

V-55
CORRELATION BETWEEN PLATELET PARAMETERS, B12 AND FOLIC ACID IN PATIENTS WITH CORONARY HEART DISEASE IN THE REGION OF CENTRAL AND WESTERN MACEDONIA, GREECE

K. Rousos[1], S. Patiakas[2], E. Doumpali[3], M. Douska[3]

[1]Health Center of Alexandria. General Hospital of Veria. Veria, Greece. [2]Biopathologic Laboratory. General Hospital of Kastoria. Kastoria, Greece. [3]Biopathologic Laboratory. General Hospital of Filiates. Filiates Thesprotias, Greece.

Objectives: To be evaluated, comparatively, among patients with established coronary heart disease and the healthy population, the parameters of full blood count, B12 and folic acid.

Material and method: There were researched 144 patients (102 males and 42 females, average age 63.4 ± 7.5 years) with established coronary heart disease (previous infarctus myocardii and unstable angina pectoris), also 140 healthy individuals (102 males and 38 females, average age 64.2 ± 7.8 years), who were the control group. At all of them was counted the complete number of eosinophiles, the number of platelets (PLT), and their MPV, by the help of haematological analyzer, while, where it was intentional, it was examined both a blood tile. Moreover, there were counted in biochemical analyzer values of B12 and folic acid.

Results: Although, both the complete number of platelets and the values of B12 and folic acid, were not differed statistical significantly, between the two groups, MPV at 126 out of 144 patients with established coronary heart disease (87.5%) was > 11 fl, while at 106 (73.6%) it was appeared rate of eosinophiles < 1%.

Table (V-54)

Patients	Ht%	Hb (g/dl)	MCV (fL)	MCH (og)	MCHC (g/dl)	RDW%
Child-Pugh A (N = 8)	29.1	9.4	84	27.2	32.1	17.1
Child-Pugh B (N = 13)	32.4	10.8	98.7	31.2	33.4	18.3
Child-Pugh C (N = 5)	30.2	9.8	100.2	31.9	32.6	19.6

Discussion: It is proved that in patients with established CHD there is statistically significant increase of MPV together with decrease of the rate of eosinophiles.

V-56
INVESTIGATING THE CAUSES OF BEING EXCLUDED FROM VOLUNTARY BLOOD DONATION

K. Rousos, S. Patiakas, I. Doukopoulos, A. Loli

Biopathologic Laboratory and Blood Donation Department. General Hospital of Kastoria. Kastoria, Greece.

Objectives: Identify and study the causes of removal from the voluntary donations of which might in this region's population our responsibility, to allow for better planning in terms of attracting them to the relevant department of our hospital, especially in our time, as the needs for blood and its derivatives, are increasing (due to the development of medical science and the increase of diseases that require blood transfusions on the one hand, and accidents on the other).

Material and method: For this purpose, specially designed anonymous questionnaire are distributed to relatives of patients who were hospitalized and transfused in our hospital, when they first appeared in Our Blood Service, to learn about the need to find an equal number of donors in order to "cover" the blood units committed or used for relative. It also concerned donor candidates first or at most second time, people say that abstained from volunteering, and came to our service only when an emergency occurred in the immediate relative or a friendly environment. In this way, we collected and studied a total of 112 responses similar questionnaires, responses that were both general questions (gender, age, educational level, etc.), and in specific, relevant to all aspects of donations (information, process, previous experience, knowledge, fears, etc.). All data were analyzed statistically worked out using the program excel.

Results: Of the total of 112 candidate donors, only 23 had previously given blood (at least once) in the past, while the remaining 89 donors were candidates for the first time. These were people on adequate social and educational level (83% had received the mandatory or even the middle or higher education), while as regards gender consisted of 67 men and 45 women. Major causes involuntary blood donation in the past proved, first, the fear of potential pain or other health problems (fatigue, stress on the body, etc.) at a rate of 61%, and no fear as regards the safety of the process, a percentage 43%. Followed: a) the admission of negligence by a rate of 35% (with a significant 21% reported difficulty in relation to the time of blood sampling), b) the previous bad treatment by the staff of blood banks (16%) or even traumatic experiences in the past (11%), and finally, c) what was impressive was that a significant 38% (more about that from 1 to 3, and even an increased percentage of young people) felt that never been informed sufficiently, nor the need for blood, nor of the whole transfusion process, much less for the security measures taken. It is finally noteworthy that the above issues there were no statistically significant differences, either in relation to age, but even in relation to the educational level of respondents.

Discussion: The overall survey has proved very interesting, and considers it appropriate, (and possibly very important), to be extended even further, including an even larger field of research (ie the relevant questions), but certainly larger sample of the general population. However, although limited, shows clearly that even people with good education, in the Greek countryside, there are still unjustified fears and prejudices about important issues of the donation.

V-58
PSYCHIATRIST'S CONSULTATION TO INTERNAL MEDICINE

J. Hernández Indurain, M. González Urrutia, P. Anaut Mayo, C. Sánchez Sáez

Department of Internal Medicine. Hospital Santiago Apóstol. Vitoria-Gasteiz (Álava), Spain.

Objectives: Analyze consultation to Internal Medicine coming from Santiago Apóstol's Hospital Psychiatry Service (SAHPS).

Material and method: Between January 2011 and April 2012 we analyzed all consults received from SAHPS. The Service doesn't admit patients with acute medical pathology, poison or drug intoxication, withdrawal or injury by suicidal attempt. For confidentiality reasons we didn't take data from the psychiatric history and the exposure to neuroleptics or antidepressant drugs wasn't listed in nominal form. We took into account five characteristics: 1) Possibility to obtain a medical history based on the consultant´s opinion 2) Group's comorbidity according to Charlson's index (CI) 3) Drugs´ interactions and adverse effects 4) Consult´s reason 5) Complexity degree. We assigned low complexity (LC) to mild acute pathology, CI < 3 or analytic data without clinical implication. We considered high complexity (HC) with multimorbidity (CI > 3), need of admission at ICU or coexistence of comorbidity and electroconvulsive therapy (ECT). In all other conditions we assign medium complexity.

Results: We registered 62 consultations of SAHPS. There were 32 female and 30 male, with an average age of 48.3. Only ten patients were older than 70. Globally, the comorbidity rate was low, with an average group value of 0.85 at CI. In 31 patients there wasn't any medical history (50%). In another 18 (29%) the CI was 1. Seven patients raised an CI of 2 and the other six were affected by values of CI 3 or 4. The CI > 2 was more common in people older than 70 years (p: 0.0004). Common coexisting diseases were: arterial hypertension (13), active alcoholism (6), diabetes mellitus (4), dementia (3) and cardiovascular diseases (4). The internist considered to make a medical history to 74% of the patients, but only a third part of those older than 70 years (p: 0.0005). Common consultation reasons were alterations on analysis (15) and comorbidity control (14). Ten feverish patients showed cystitis, pneumonia and, in eight cases, banal pathology. Three patients showed drug induced secondary effects, although all the patients (60) were exposed to neuroleptics: two cases of edema related to olanzapine and only one case of Parkinsonism. None of the conditions were related with antidepressant drugs. Three patients had relevant interactions related respectively to rifampicin, clarithromycin and many drugs at a time in a case of prurigo. According definition, 47 patients showed LC cases and other 7 showed medium complexity. We estimated 7 patients with HC, which needed admission in ICU because of acute renal failure (2), large comorbidity (3) or ECT. In this group there weren't differences related to genre (p: 0.61), but it was more frequent in the oldest (p: 0.0009). Finally, we conducted intensive study in two patients suspecting undiagnosed medical pathology.

Discussion: Despite our predictions, there was a low global comorbidity index, reasonably higher in the oldest patients. We found a few drug induced side effects, perhaps due to effective intervention from the psychiatrist. Generally, we assist LC pathology, predominating known processes and anomalies in routine analysis. We frequently obtained a good medical history which as a consequence resulted in a non-complex differential diagnosis. Active alcoholism was rare, maybe biased by exceptions to admission. This group received drugs to avoid Wernicke's encephalopathy and alcohol withdrawal, cases we didn't observe. Two patients were admitted at ICU for severe dehydration and renal failure. We performed intensive study in two patients, because of a bad response to psychiatric therapy and unexplained deep vein thrombosis. Searching for medical pathology didn´t

make results.

Conclusions: We concluded that a good clinical history was obtained in a high proportion of patients in a group with low CI and LC. Searching for medical pathology didn't make results. Several effects of drugs were uncommon. In our opinion, our main intervention consisted in controling known medical pathology, making clear values to limit unnecessary studies, and pointing out the side effects and relevant interactions of medication.

V-59
MORTALITY OF CONSECUTIVE PATIENTS WITH DIABETIC KETOACIDOSIS IN THE EMERGENCY DEPARTMENT OF A TEACHING HOSPITAL

P. Guisado Vasco[1], M. Cano Megías[2], M. Carrasco de la Fuente[2], J. Corres González[1], A. Matei[2], O. González Albarrán[2]

[1]Department of Emergency, [2]Department of Endocrinology. Hospital Universitario Ramón y Cajal. Madrid. Spain.

Objectives: Background. Prevalence of diabetes mellitus (DM) would reach to 9% of population in developed countries in year 2030. Diabetic ketoacidosis (DKA) is an acute metabolic event that could be potentially life threading. Modern guidelines (American Diabetes Association - ADA) reports a mortality < 5%, but it is references to 70s-90s manuscripts of the last century. Although data are consistent with a decline in mortality due to DKA, nowadays, few are available related to this outcome. Objective: to define the mortality of DKA in a teaching hospital in modern era.

Material and method: We designed a retrospective reviewed of electronic clinical files of consecutives patients ≥ 18 years, who came to emergency department (ED) from Jan/2008 to Jun/2011. They must fulfil diagnostic criteria of DAK according to ADA. Hyperosmolar hyperglicemic state (HHS) was excluded. Severity of the episodes (mild, moderate, severe) was classified according to ADA criteria 2010.

Results: Finally, 136 of 152 patients were included in analysis, with median age 40.46 yrs (SD 18.77); female:male ratio 1.38. Mortality rate reached 1.49% (acute coronary syndrome (n = 1), bronchoaspirative pneumonia (n = 1).28-days readmission rate was 10.4% (without deaths). The median age of DM onset was 26.37 yrs. The total number of insulin units per day was 39.1 (UI of any kind). The episode of DKA supposed a diabetic debut in 16.2%. The 59.2% had known type 1 DM and 21.5% had type 2 DM. The median of the mean laboratories values were: pH 7.103, HCO3- 9.55, glucose 609.1, Na+ 131.61 (corrected, 141.78), plasma osmolality 291.54, K+ 4.72,GAP anion 24.96, ketonemia 5.17 and 93.3% had ketonuria > 80 mg/dl. The severities of DKA were mild in 11.8%, moderate in 32.4% and severe in 50% of cases; 6.9% had mixed features (hyperosmolar state, alcoholism). Alimentary or insulin dose transgression (28.3%) and infections (29.1%) were the leading causes of DKA. More than half of patients (52.2%) were admitted to intensive care (average 1.7 days), and 86% to endocrinology ward (average 9.82 days). The average of ED stay was 10.14 hours.

Discussion: We found that DKA's mortality of patients admitted to experience teaching center still remains below 5%, although most of them have severe episodes. The rate of 28-days readmission is low, not leading to new events (deaths). It was not possible to analyze factors related to mortality, because the low numbers of events. The two deaths happened in older patients, low consciousness (coma), hyperosmolar states and severe trigger (acute infarct –type 2 DM-, bronchopneumonia – diabetes onset). Better adherent to protocols and improving in outpatient management and educational programs could explain this low rate of mortality.

Conclusions: DKA has a low rate of mortality (1.49%) in teaching hospital. Older patients, who have acute and severe causes of DKA, seem to be a higher risk of death.

V-60
5-YEARS EXPERIENCE OF OUTCOME AND CLINICAL FEATURES OF CONSECUTIVE BODY PACKERS, BODY SUFFERS AND BODY PUSHERS (DRUG MULES) ADMITTED TO REFERENCE EMERGENCY DEPARTMENT

P. Guisado Vasco, M. Estévez Rueda, L. Alba Muñoz, Y. Aranda García, M. Carpena Zafrilla, A. Trueba Vicente, C. de la Casa Resino, P. Gallego Rodríguez

Department of Emergency. Hospital Universitario Ramón y Cajal. Madrid, Spain.

Objectives: packers (drug mules) are persons who smuggled illegal drugs by hand-made of industrial capsules, which are introduced inside its bodies (mostly gastrointestinal). Our center is one of the references' hospital of Barajas Airport, where more than 32 million of international passenger transit in 2011. Mortality and complication of these patients is variable, and depends of different conditions (poisoning, severe cardiovascular events, acute abdomen). Objective: to describe clinical characteristic of large series of body-packers to date.

Material and method: We designed a retrospective clinical file review of consecutive patients (body packers) from Jul/2007 to Mar/2012, who were admitted to the special observational ward of the emergency department of the reference teaching University Hospital Ramón y Cajal. Absolute diet was indicated to all cases, till December 2011, when protocol was reviewed in order to select some cases that could tolerate liquids.

Results: We finally included in our analysis 863 patients, with a mean age of 32.61 years (SD 9.45) and male:female ratio of 5 to 1. Most of patients denied any previous illegal drug consumption (67.8%) and have not got any disease (78.9%). More than a quarter came from different countries of South America. At first attention, 0.8% has poisoning symptoms (cocaine or cannabis), and 10.4% told abdominal pain. The median transported bodies reached 60.97. The medians of capsules expulsed in and out hospital were 57.72 and 6.48, respectively. The median of days transporting drug before attention was 1.38. Almost 90% were body packers (oral ingestion), 2.9% were body pushers (rectal/vaginal). Cocaine was the most frequent illegal drug smuggled (83.2%), being in smooth capsules in 16.3% of cases. 2.1% (n = 18) had serious complications (obstruction and/or surgical procedure). 1.5% (n = 13) required any emergency surgery. We recorded none deaths in the whole series. Before discharge, it was recorded a median of clear deposition of 11.73. The average of days of hospital staying was 4.14 (SD 4.72). The most frequent complications during hospitalization were non-surgical abdominal pain (4.6%), infections (phlebitis, soft part, bacteraemia) 5.1%, and abstinence syndrome (1.6%).

Discussion: Most of body packers/stuffers (98.5%) could be successfully managed with conservative measures. These low rates of events made difficult to set a statistically relationship with any given variables. Our protocol is, in general, so restricted with oral tolerance. Thus, mostly all cases are on non-oral tolerance. Recently, we have reviewed our protocol, and in some cases, a liquid diet could be well tolerance, without any increasing in surgical complications.

Conclusions: Illegal drug transporting is increasing nowadays. Most of body packers/stuffers could be successfully managed with conservative measures (absolute or liquid diet).

V-61
SHORT STAY UNIT AT INTERNAL MEDICINE: AN ALTERNATIVE IN RESPIRATORY PATHOLOGY ATTENTION

L. Ruiz Rivera, I. Aomar Millán, Á. Ceballos Torres, F. Anguita Santos, C. Fernández Roldán, P. Giner Escobar

Department of Internal Medicine. Hospital de Especialidades San Cecilio. Granada, Spain.

Objectives: This study aims at analyzing the attention given to patients with respiratory pathology in our Short Stay Unit at Internal Medicine.

Material and method: We carry out a descriptive and retrospective study on patients with respiratory pathology who were admitted in our Short-Stay Unit (SSU) at Internal Medicine at the San Cecilio University Hospital in Granada for a five-month period, from the 1st of July till the 30th of November, 2011. The SPSS v.15, with license from the University of Granada, was used for data analysis.

Results: 196 patients were treated. The average age was 66 years old, among which 56.3% were female patients and 43.7% males. The average stay duration in the hospital was 3.41 days, between 1 and 7 days. Among the 196 patients, 51 (32.27%) were treated for having respiratory pathology: 14 (27.45%) for COPD exacerbates, 16 (31.37%) for pneumonia, 12 (23.53%) non condensing respiratory tract infections, 5 (9.8%) for asthma exacerbates and 4 (7.84%) for other respiratory problems.

Discussion: Respiratory pathology is a reason for frequent admission in Internal Medicine which turns into a significant economic cost mainly owing to the duration of the stay in the hospital. Short-stay units emerge with the intention of making better the prevailing processes which specify hospitalization for attention, as is the case of the respiratory diseases. Also, they are considered a good support for the Medical Units of conventional hospitalization, offering patients, through their operating structure, less days of stay in the hospital.

Conclusions: SSU is a high-resolution and safe unit for the treatment of the most prevailing respiratory diseases allowing decreasing the average stay of our patients through their operating characteristics. It is true that our study offers the common limitations of a descriptive-retrospective analysis, with no control group, yet we consider it interesting as a starting point for future studies which assess the real impact of the SSU.

V-62
APELIN LEVELS IN PATIENTS WITH NEWLY DIAGNOSED HYPERTENSION AFTER TREATMENT OF VALSARTAN AND AMLODIPIN

S. Balta[1], M. Karaman[2], S. Demirkol[1], S. Ay[2], M. Akhan[2], S. Demirkol[1], E. Arslan[2], H. Yaman[3]

[1]Department of Cardiology, [2]Department of Internal Medicine, [3]Department of Biochemistry. Gulhane Medical Faculty. Ankara, Turkey.

Objectives: Apelin is a new member of adipose tissue-derived peptides that is produced in various parts of the body, including the endothelial cells. Apelin regulate blood pressure. Low apelin have been reported in hypertension. We aimed to investigate the effects of valsartan as an angiotensin II receptor antagonist, and amlodipine as a calcium channel blocker on the apelin level in patients with essential hypertension.

Material and method: Patients with a newly diagnosed essential hypertension were admitted to our internal medicine outpatient clinic. Exclusion criteria were hypertension, atherosclerotic heart disease, diabetes, chronic kidney disease, thyroid dysfunction, chronic liver disease and other chronic diseases. Patients were randomized to one of the following intervention protocols: angiotensine II receptor blocker (valsartan, 80-320 mg/day) as a group A or calcium channel blocker (amlodipine, 5-10 mg/day) as a group B. Serum apelin levels of the patient groups were measured before treatment and on the 12nd week.

Results: Study group consisted of 50 patients with newly diagnosed essential hypertension (group A n = 28 and group B n = 22). No statistically significant differences were determined among the groups in terms of age, sex and body mass index (group A/B; mean age: 52.9/50.1, female: 22/13, male: 6/9, BMI: 30.3/30.4; $p > 0.05$). In the amlodipine group, there was a significant increase in level of apelin after treatment ($p < 0.05$) in comparison with valsartan.

Discussion: Apelin plays a major role in the regulation of endothelial proliferation and the arterial blood pressure regulation. The coexistence of hypertension and low apelin levels have an additive effect on the development of coronary artery disease and the associated mortality rate.

Conclusions: We found that amlodipine has increased the level of adiponectin more than valsartan. As a result, in the treatment of hypertension, prior knowledge of the level of plasma apelin could be important in antihypertensive drug choice.

V-63
UPPER EXTREMITY VENOUS THROMBOSIS: REPORT OF 15 CASES IN THE AREA OF LEON

D. García Escudero, D. Dios, D. Vázquez del Campo, D. Castelar, D. Muinelo, D. Fernández

Department of Internal Medicine. Complejo Asistencial de León. León, Spain.

Objectives: To analyze the clinical characteristics and risk factors for venous thrombosis (DTV) episodes in the upper limbs in the area of León.

Material and method: We reviewed clinical reports of patients diagnosed with upper extremity venous thrombosis during the period of 2008-2011. Associated or not with central venous catheter, and excluding those associated with peripheral catheter. We analyzed epidemiological, clinical data, methods of diagnosis, risk factors and treatment.

Results: We found a total of 15 patients: 53% women and 47% men. Mean age 58.9 years (range 14-93). Four patients had central venous catheter at the site of the thrombosis. The location was distributed as follows: 2 axilosubclavia, 2 basilica, 1 axillary, 2 cafalicas, 2 jugular subclavia, 2 jugular axilosubclavia, 2 jugular, subclavian and 1 unspecified location. Located as follows: 7 lefthandthrombosis and 8 were on the right. The diagnosis was made in 86.6% of patients by Eco- Doppler. In two cases by Computed tomography angiography. Two of these patients had one kind of thrombophilia: a case of antiphospholipid syndrome and another case of V Leiden mutation. Four patients had had a previous episode of DVT. With respect to their association with tumors: 7 patients had association with malignancies, 1 lung cancer, 1 cervical neoplasm, 2 colon tumor, 1 meningioma and finally 1 patient with a hematologic neoplasm. Four of these patients had localized disease, and three advanced disease. For treatment, 60% received low molecular weight heparins, 13.3% of patients underwent fibrinolysis, 3 patients were treated with acenocoumarol and only one case was treated with aspirin. The duration of treatment was highly variable (one patient 6 months, and the other a shorter duration) and in six cases it was not specified in their medical history. Only one patient had previously received acenocumarol, four had received low molecular weight heparins. No patient had received contraception. Regarding risk factors: seven had a history of malignancy, one anatomical conflict, two thrombophilia, one was an athlete, three cases had

a history of resting or post-operatory treatment, and in the last one, the patient had an atrial fibrillation.

Discussion: Approximately 10% of all cases of venous thrombosis occur in the upper extremities, resulting in an annual incidence of 0.4-1 cases/100.000. It occurs most frequently in the subclavian and axillary veins, and secondary forms are more common than primary. The cases have become increasingly common due to increased use of central venous catheters. In addition to intravascular devices, risk factors such as vigorous exercise, cancer or thrombophilia have been described. Compared to patients with thrombosis in lower extremities, patients with thrombosis in upper extremities are usually younger and thinner, and more are diagnosed with cancer than thrombophilia. In different reviews (studies), the Doppler ultrasound demonstrated sensitivity in nearly 97% and specificity in 96%, the screening test was the most recommendable although in this review venography (phlebography) was considered to be the gold standard. Regarding treatment, it is preferable to use low molecular weight heparin, and fractional heparin in patients with renal insufficiency. Thrombolysis and intervention (balloon angioplasty, thrombectomy...) are reserved for severe cases and with low risk of bleeding.

Conclusions: 1. The location most frequently described in our case studies was the subclavian vein. 2. Half of the patients had active malignancy at the time of diagnosis.3. In 86% of cases, the diagnosis was made by Doppler-ultrasound and in 60% low molecular weight heparin was the treatment chosen.

V-65
HEMORRHAGE OF THE UPPER DIGESTIVE SYSTEM: STUDY OF TRANSFUSION NEEDS AND CORRELATION WITH THE BLOOD GROUP DURING THE LAST DECADE IN GENERAL HOSPITALS OF WEST MACEDONIA KASTORIAS AND FILIATES

S. Patiakas[1], A. Loli[1], I. Doukopoulos[1], K. Rousos[2], E. Doumpali[3], M. Douska[3]

[1]Biopathology Laboratory and Blood Donation Department. General Hospital of Kastoria. Kastoria, Greece. [2]Health Center of Alexandria and Pathological Clinic. General Hospital of Veria. Veria, Greece. [3]Biopathology Laboratory and Blood Donation Department. General Hospital of Filiates. Filiates Thesprotias, Greece.

Objectives: Identify cases of hemorrhage of upper digestive tract, to study the administered blood units, and to consider possible positive correlation between blood type, bleeding from the upper digestive and the need for transfusion.

Material and method: A total of 167 cases where found and studied of patients who were hospitalized at the General Hospital of Kastoria during the past few years, with upper gastrointestinal bleeding.

Results: Of the total 167 patients, 115 are ultimately transfused, 68.9%. Of these, 25 (21.74% share) got only one unit of blood, 37 (rate 32.17%) two units, 21 (rate 18.26%) three units, while in 32 cases of patients (percentage 27.82%) required transfusion of more than 3 units of blood. With particular regard to blood group, data of patients who bled and transfused are shown in Table number A, as you can see below.

Discussion: It turns out therefore that: 1) Bleeding in the digestive system are common causes for blood transfusion, as in the case of our hospital in 69% of patients had blood transfusion, and even the 28% required a large amount of blood (more than 3 units of blood). 2) A greater proportion of patients with bleeding of upper digestive tract (40.11%) belongs to blood group A Rhesus (+), and 3) There is a positive correlation between blood group and the taking of blood in cases of upper gastrointestinal bleeding with a clear superiority of group AB Rhesus (+), (rate 80%).

Conclusions: Finally, It should be noted that the number of patients who ultimately received only one unit of blood (25, rate 21.74%) was quite large, which of course raises questions about the need for all these cases of transfusion.

V-66
INCIDENT REPORTING AT INTERNAL MEDICINE

J. Santos Martínez[1], A. Jiménez Muñoz[2], M. Gómez Antúnez[1], A. Torres Do Rego[1], T. Blanco Moya[1], B. Pinilla Llorente[1], F. Cabrera Aguilar[1], A. Muiño Míguez[1]

[1]Department of Internal Medicine 2A, [2]Department of Preventive Medicine and Quality Management. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: This study aimed to examine the incident reported in a tertiary centre in a general internal medicine unit. Such information would help in redesigning systems and in planning and developing strategies with the goal of improving patient safety and quality care.

Material and method: In this descriptive study, we evaluated all incident reports submitted through the reporting system in the.

hospital for the 2007-2011. Gregorio Marañón University Hospital in April 2006 created the Functional Unit of Health Risk Management (UFGR). In that year it started an adverse event reporting system, with the following features: not punitive voluntary and confidential. The system was based on the training of the staff to develop the habit of notifying all incidents to be reported, with the aim of taking preventive measures in collaboration with the UFGR. The hospital intranet allows professionals the access to the electronic reporting system.

Results: A total of 167 incident reports were submitted from all hospital areas. 113 (68%) of incident reports were submitted from internal medicine. 23% are related to infrastructure, 18% with bad coordination between services and 17% with the clinical documentation. 42% occurs in the monitoring and care, 16% in medical treatment and 12% in admission. For causes, 22% are due to equipment and a 18% to the professionals. It resulted in minor incidents a 76% of the cases or death in 24%. Reports led to recommendations by the UFGDR. Proposed corrective and preventive measures in 83% of the cases were to improve communication between services and 19% by improving infrastructure and maintenance.

Discussion: Reducing mishaps from medical management is crucial to improve quality and lower costs in health care. Outcomes in complex work depend on the integration of individual, team, technical, and organisational factors. Incident reports were low compared with reported international rates. There are powerful disincentives to reporting. Management attitudes and institutional climate can greatly influence the success or failure of reporting efforts. The reporting system can complement other tools in promoting a clinical safety culture.

Conclusions: Most of the notifications were incidents. The reporting system can complement other tools in promoting a clinical safety culture.

Table (V-65)

Blood group	0 (+)	A (+)	B (+)	AB (+)	0 (-)	A (-)	B (-)	AB (-)	Total
Bled	67	51	17	10	8	9	5	0	167
Transfused	49	33	10	8	5	7	3	0	115

V-68
ADVERSE EVENTS IN AN INTERNAL MEDICINE UNIT: A PROSPECTIVE STUDY

A. Sáenz Gutiérrez, D. Bellido Pastrana, E. Marchán Carranza, J. Ros Izquierdo, C. Monroy Gómez, M. Clemente Tomé, M. Mañas García, G. Esquinas Blanco

Department of Internal Medicine. Hospital General de Ciudad Real. Ciudad Real, Spain.

Objectives: Since most studies carried out so far on adverse events (AE) are retrospective and focus on describing these events, this study aims to assess the incidence of AEs in an Internal Medicine unit, describe the profile of patients with AEs and evaluate their consequences and preventability.

Material and method: We performed a single-cohort prospective observational study using a mixed source of data, a primary (prospective) source and a secondary source (clinical record).

Results: 667 patients were analysed with an average age of 69, generating 714 admissions. The unit of analysis was hospitalization. In total, the 714 admissions generated 140 AEs linked to healthcare. 104 admissions presented AEs, with an incidence of 14.6% (104/714); 95% confidence interval [CI]: 12.06%-17.37%. The most frequent AEs were the ones related to medication (38%), followed by nosocomial infection (21%) and those related to a procedure (21%). Independent factors for AE development were: age over 65 (relative risk [RR] = 1.91, 95%CI: 1.10-3.37), coronary heart disease (RR = 2.13, 95%CI: 1.25-3.65), urinary catheter (RR = 2.29, 95%CI: 1.40-3.76) and central venous catheter (RR = 4.58, 95%CI: 11.54-13.7). The preventability rate was 37.5%.

Discussion: The incidence of AEs detected in our Internal Medicine Unit is higher than that found in other studies, although within the established limits. There are few studies with similar characteristics (prospective studies with a daily observation of a cohort of patients). Comorbidity and the error in the use of clinical guidelines and are the most relevant causative/contributory factors.

V-69
RENAL DISEASE IN SYSTEMIC AMYLOIDOSIS

O. González Casas[1], N. Robles Pérez Monteoliva[2], R. Alvarado Gutiérrez[2], S. Barroso Hernández[2], M. Arrobas Vacas[2], E. Pardo Magro[1], M. García Morales[1], M. González García[1]

[1]Department of Internal Medicine, [2]Department of Nephrology. Complejo Hospital Universitario de Badajoz. Badajoz, Spain.

Objectives: Renal disease due to amyloidosis is a rare problem with several possible causes. We evaluated the relative frequency of these causes in a group of patients studied at a Nephrology Service.

Material and method: From 1999 seventeen patients have been diagnosed of amyloidosis by renal biopsy. Mean age was 57.4 ± 14.7 years, 57% were males. All samples were studied by optical microscopy using Congo Red and Tioflavin T stains. Clinical and analytical manifestations have been retrospectively recorded.

Results: Eleven patients had secondary (AA type) amyloidosis, of them 54.5% were previously diagnosed of any rheumatoid disease (rheumatoid arthritis and ankylosing espondilitis were the most frequent, 66.6% of total), 9%% of a chronic infective one and 9% of inflammatory intestinal disease one. Six patients had primary (AL type) amyloidosis with monoclonal lambda chains by serum immunofixation electrophoresis (bone marrow was performed in four patients, three of them showed monoclonal lambda light chains expression). All patients showed macroalbuminuria (mean proteinuria 7.5 g/24h) and 13 subjects had complete nephrotic syndrome with hypercholesterolemia and hypoalbuminemia; 59% showed reduced glomerular filtration rate at beginning. Symptoms and signs were the most common were: arthralgias 47%; gastrointestinal disorders 17.6%; hypotension 17.6% and 12% wasting syndrome. Normocytic and normochromic anemia was also common (71%), 23.5% of our patients had left ventricular hypertrophy on echocardiography but hepato-esplenomegalia was absent. Nine patients (53%) goes to hemodialysis, one patient received a kidney transplant, who presented recurrence of amyloid disease and 17% was died. 50% of patients with AL were treated with bortezomib and corticossteroids and 32% with chlorambucil and corticosteroids.

Discussion: In our series the most frequent cause of AA were rheumatologic diseases and it was more common in females, according with others reported series. Secondary forms of amlyloidosis were more frequent than primary ones (65% AA vs 35% AL). The gradual aging of the population and the increasing incidence of rheumatologic diseases, mostly associated with female gender, might explain these data. Dough in the early reported series AA there was a ethiological predominance for chronic infectious disease, in the most recent ones this dominance is for rheumatologic diseases, especially rheumatoid arthritis (AR). This is likely due to the better treatment of infectious diseases and the increased life expectancy of chronic inflammatory disease patients. The average age was 57.4-14.7 years, which is higher than those reported in the literature. Analysis of the data, we conclude that renal involvement is characterized by nephrotic syndrome, proteinuria and renal failure which is consistent with the cumulate evidence. The kidney biopsy shows a high diagnostic performance, which is usually greater than 95% (100% in our analysis). The subcutaneous fat biopsy is also useful in the diagnosis of amyloidosis but in our study was performed only in one patient. The most of our patients had a poor outcome: more than half of patients needed renal replacement therapy, very similar to other published series.

Conclusions: Renal amyloidosis is an uncommon disease which should be suspected in all patients with heavy proteinuria and renal failure. Kidney biopsy is needed to know the specific kind of amyloidosis as well as the systemic origin of disease.

V-70
ACUTE INTERMITTENT PORPHYRIA: REPORT OF SIX CASES

V. Garcés Horna, B. de Escalante Yangüela, M. Rodero Roldán, M. Navarro Aguilar, M. Torres Courchoud, B. Gracia Tello, M. Sánchez Marteles, C. Fanlo Meroño

Department of Internal Medicine. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: Acute intermittent porphyria (AIP) is an autosomal dominant inborn error characterized by decreased activity of porphobilinogen deaminase (PBGD), leading to increased levels of haem precursors, namely amino levulinic acid (ALA) and porphobilinogen (PBG). It is the commonest and most severe form acute porphyria. Abdominal pain, neurological dysfunction and psychiatric disturbances form the classic triad of AIP. Here, we report 6 cases of AIP.

Material and method: This is a descriptive, observational, retrospective and transversal study in which 6 clinical histories with the AIP diagnosis from the Internal Medicine/Digestive Service from the Clinic Hospital from Zaragoza were analyzed. There were several tables for the collection of clinical, analytical, therapeutics data and the genetic study.

Results: The mean age was 36.8 years, 83.3% were aged between 30 and 40 years. 4 were women and 2 men. In 2 patients the family study of porphyria was completed, confirming the presence of 4 asymptomatic carriers. The precipitants factors were: alcohol intake (2 cases), respiratory infection (2 cases), fasting (1 case) and menstruation (1 case). The 100% of the patients presented as major symptom abdominal pain. It is worth noting the presence of

hyponatremia in most cases and the finding of syndrome of inappropriate antidiuretic diuretic hormone secretion (SIADH). All patients were treated with glucose, but only 2 needed hemine treatment. Genetic study was realized in 2 patients and the mutations found were: R26C at exon 3 y R225X at exon 12 of PBGD gene. It was recorded the emission of high coloured urine in 2 cases. Currently all patients are alive.

Discussion: These cases show similar characteristics to those described in the literature on the AIP. It's a genetic disease with a 10% penetrance and low prevalence. It results from a PBGD enzyme hipoactivity, causing an increase of the PBG and ALA, excreted by urine. There are more women and it generally appears after puberty. It can be asymptomatic or intermittent with attacks precipitated by: stress, infections, low calories diet, hormonal changes, drugs and medicines. It courses with abdominal pain (in our series 100%), neurologic manifestations (central nervous system, autonomic and peripheral) and/or psychiatrics. Some of the neurologic symptoms, the same as the dysautonomic, were found in the reported cases. The presence of hyponatremia is very common in the study, with the presence of SIADH, which is also described in AIP, but with less frequency. The demonstration of the excess of ALA and PBG in the urine is enough for the diagnosis and the treatment consists on general maintenance, carbohydrates and intravenous hemine in the severe cases.

Conclusions: AIP should be considered in patients with abdominal pain or neurological manifestations without known etiology. In spite of the characteristic reddish coloration urine, this is not always detected. -Perhaps the diagnosis delay doesn't allow early treatment with hemine in certain patients.

V-71
THE INTERNAL MEDICINE DEPARTMENT AS A HOSPITAL CONSULTANT

A. Martínez Motos, I. Mora Escudero, L. Sáez Méndez, I. Hermida Lazcano, A. Gato Díez, M. Martínez López-Tello, A. Sedano Casas, C. Olmeda Brull

Department of Internal Medicine. Hospital General de Albacete. Albacete, Spain.

Objectives: To describe the characteristics of interconsultations from medical and surgical services to Internal Medicine Department in Albacete's General Hospital during 2011.

Material and method: In this prospective study, individual data of all consecutive patients admitted to non-Internal Medicine departments in whom consultation was requested were registered from January to December 2011. Analyzed variables were: age, sex, reference department, consultation clinical problem, medical and admission diagnoses done during the admission, number of visits and reason for discharge.

Results: During the study period, a total 0f 507 consultations were included, the majority at the request of Surgical Departments (21% of General Surgery, 16.8% of Vascular Surgery, 14.2% Traumatology followed by 8% Urology). Patients mean age was 71.5 ± 15.60 years and male were 57.8%. The most common reasons for internal medicine consultation were: co-morbidity problems management (13.8), dyspnea (13%), fever (8.3%), poorly controlled arterial hypertension (6.7%) and laboratory abnormalities (6.5%). In 42% of all consultations a cardiac diagnosis was found, including arterial hypertension (12.6%), dysrhythmias (9.5%) and cardiac failure (9.7%). In 23.9% the diagnosis was an infectious disease and 20.7% was hematologic process. The mean patients follow up 13.98 ± 10.2 days. Hospital mortality was 5.1%. (26 p) and 247 patients (48.7%) were discharged from hospital. 32 patients (6.3%) were transferred to Internal Medicine hospitalization and 56 patients (11%) were followed as outpatients after discharge.

Discussion: The role of the Internal Medicine department as a hospital consultant are not well known. The fact that consultations are often performed in between the daily work schedules, the impact on the surgical and other medical patients as well as the daily workload can be underestimated. In this study, we examine the characteristics of that consultations, the patients clinical profile and their impact on the daily workload.

Conclusions: Patients who are admitted to a non-internal Medicine department and who need consultation are particularly elderly people with a high prevalence of co-morbidity diseases and high in-hospital mortality. For these reasons internal medicine consultation is an important part of the daily workload deserving a structured approach. In our hospital, from 2010 there is a team dedicated full time as consultants.

V-73
CARDIOVASCULAR ADVERSE EVENTS: 10 YEARS OF MONITORING IN A REGIONAL HOSPITAL

J. Gutiérrez Zafra[1], M. Mora Mora[2], G. Fernández Martínez[2], T. Cantal Sánchez[2], M. Romero Ferreira[1], M. Gómez Rodríguez[1], R. Gato Morais[1], J. Sampedro Villasán[1]

[1]Department of Internal Medicine, [2]Pharmacy. Hospital Comarcal San Agustín. Jaén, Spain.

Objectives: Pharmacovigilance (medical surveillance) is defined as a public health activity aimed at the identification, quantifying, evaluation and prevention of risks associated with using drugs once they are marketed. A serious adverse drug reaction (SADR): an adverse reaction that results in death, may endanger life, might require inpatient hospitalisation or prolongation of existing, might result in disability, significant or persistent incapacity, or is a congenital anomaly or defect of birth. ADRs represent 4.7% of hospital admissions and during hospitalisation 10.9% of patients experience some type of ADR. Our objective is to describe the cardiovascular adverse reactions detected by the pharmacovigilance program (medical surveillance program) at a local hospital over the past 10 years.

Material and method: A descriptive retrospective survey of all ADRs with cardiovascular events collected by the Surveillance program at our hospital over the past 10 years.

Results: During the period 2002-2011, 100 cardiovascular ADRs were reported. Of these, 92% were severe, an 8% were not. 88% required hospital admission; 4% extended hospitalisation; 8% exitus. Average age: 69.9 years old (3-91). Gender: 44.57% men, 55.42%women. Duration of adverse event: 3% not known. 97% is known: 5.46 days average (42.26% of them < 48 hours, 39.17% 2-7 days, > 7 days 18.55%). Clinical signs - drugs involved: 63% arrhythmia (93.65% bradycardia/AV block: 64.4% due to beta-blockers and/or calcium antagonists, 30.5% due to digoxin), 13% syncope (46.15% due to beta-blockers and/or calcium antagonists, 38.46% due to digoxin), 8% digitalis toxicity (all > 75 years), 6% hypotension, descompensated heart failure(DHF) 4%, 4% chest pain, palpitations 1%, 1% cardiac arrest. A 12.69% of arrhythmia required pacemaker. Outcome: 88% full recovery, 8% exitus, 2% recovery with a disability, 2% unknown. Major indications for drugs were hypertension, atrial fibrillation, heart failure, ischemic heart disease.

Discussion: In the period 2002-2011 there was an increase of cardiovascular ADR notified. These ADRs were more common in older patients where the duration and severity of adverse events are higher (polypharmacy/drug interactions). They represent a major cause of admission. Above 80% of patients' hospitalisations were shorter than 7 days, due to the reversibility of the adverse event and its severity what makes of them a priority for medical intervention.

Conclusions: The combined use of beta-blockers + calcium channel blockers (nifedipine) produce myocardial suppression increasing arrhythmogenic risk. Digoxinemia is needed periodically as digitalis toxicity is an important cause of admission which leads to extreme bradycardia. 8% of ADRs are related to the use of ophthalmic drops, so it will be necessary to be especially careful in their use in polimedicated patients to avoid drug interactions.

V-74
THE VERY ELDERLY MEDICAL PATIENT AND INTENSIVE CARE UNIT: WILL I SURVIVE?

M. Contreras, A. Gullón, R. de Miguel, D. Martín, E. Filigheddu, R. Sampedro, R. Puchades, C. Suárez

Department of Internal Medicine. Hospital Universitario La Princesa. Madrid, Spain.

Objectives: To determine basal characteristics, prognostic factors and in-hospital mortality in very elderly medical patients (≥ 80 years old) admitted to an ICU.

Material and method: We studied patients admitted to the ICU of a tertiary University Hospital in Madrid (Spain). All medical patients ≥ 80 years old admitted to ICU between January 2003 and December 2011 were retrospectively evaluated. Data obtained from medical records included: age, sex, previous medical history, clinical and laboratory data, ICU complications, treatment and in-hospital mortality. Continuous variables are presented as mean and standard deviation (SD). Student t test was used for continuous variables. Chi square test was used to compare categorical variables. Univariate analysis was performed and significant variables ($p < 0.1$) were included in logistic regression to determine independent factors for in-hospital mortality.

Results: 214 patients ≥ 80 years old were studied. Basal characteristics were: age 83 (2.9 SD), 41.5% woman. 70.5% admitted from emergency department. Past history: 23% previous respiratory disease, 21.4% coronary heart disease and 17% heart failure. Functional status: 59% without mental incapacity (Hospital Cruz Roja scale), 49% without physical dependence (Hospital Cruz Roja scale). 52.2% had no comorbidities (Charlson index) At ICU admission, APACHE II mean score was 24.5 (8.5 SD) and SAPS score was 52.7 (18.5 SD). 62.9% received mechanical ventilation and 54% inotropes or vasopressors. In-hospital mortality rate was 46%. Logistic regression analysis showed that APACHE II scoring system (OR 0.85, CI 0.79-0.92, p = < 0.001), mechanical ventilation (OR 4.2, CI 1.4-12.4 p = 0.005) and length of stay at hospital (OR 1.12, CI 1.06-1.1, p < 0.001) were independently correlated with in-hospital mortality.

Discussion: Prognostic factors for very elderly medical patients admitted to ICU are not well defined in literature and proposed prognostic models are not validated. In our study, APACHE II score, mechanical ventilation and length of stay at hospital were independent predictors for in-hospital mortality. Combination score of these simple and clinically relevant variables could predict in-hospital mortality in very elderly medical patients admitted to ICU. In-hospital mortality rate in our study is higher than other studies, probably because we didn´t include elective surgical patients and because the majority of patients were admitted from emergency department.

Conclusions: In-hospital mortality in very elderly medical patients is high. APACHE II score, mechanical ventilation and length of stay at hospital are associated independently with in-hospital mortality in this group of patients.

V-75
LIVER BIOPSY AND TRANSIENT ELASTOGRAPHY TO ASSESS LIVER FIBROSIS

E. Resino, B. Roca, M. Penades, V. Torres

Department of Medicine. Hospital General, Universitat Jaume I. Castellón, Spain.

Objectives: Liver disease is a leading cause of death in the HIV-infected population. Transient elastography (TE) is a useful method to assess liver fibrosis, but uncertainties still exist regarding the reliability of the technique. We compare the results of liver biopsy (LB) and TE in order to improve knowledge in this field.

Material and method: In the outpatients' clinic of the Infectious Disease Division of the Hospital General of Castellon, Spain, we compare the results of LB (METAVIR stages of fibrosis) and TE (Castera et al stages of fibrosis) of all patients that have both results available, with the tau of Kendall b correlation test. We carry out a logistic regression analysis to try to find factors associated with discrepancy in both results.

Results: We include 75 patients; 52 (69%) are male; mean of age is 45 ± 10 years; mean of body mass index (BMI) is 23 ± 3 kg/m^3; 32 (43%) are alcohol-abusers; 11 (15%) are hepatitis B virus infected; 61 (81%) are hepatitis C virus infected; and 4 (5%) have received treatment with interferon, with or without ribavirin, previously. The correlation between LB and TE results is poor: 0.294, although significant: p = 0.002. There is a discrepancy of at least one stage of fibrosis between LB and TE in 45 patients (60%), discrepancy of at least two stages in 19 patients (25%), and discrepancy in three stages in 9 patients (12%). We find no associations between discrepancy in LB and TE results and the following variables: age, gender, BMI, alcohol abuse, hepatitis B infection, hepatitis C infection, stage of fibrosis detected with LB, degree of inflammation-necrosis detected with LB, or time interval between LB and TE.

Conclusions: In a large percentage of patients there is a considerable discrepancy in the stage of liver fibrosis found with LB and TE.

V-76
TUMOR OF THE DIGESTIVE SYSTEM - THE PORTUGUESE REALITY

L. Meireles[1], D. Macedo[2], E. Velhinho[3], C. Chagas[3]

[1]Department of Gastroenterology, [2]Department of Oncology. Hospital Santa Maria - CHLN. Lisbon, Portugal. [3]Department of Internal Medicine. Hospital Pulido Valente - CHLN. Lisbon. Portugal.

Objectives: Tumors of the digestive system are highly prevalent in Portugal, and colorectal cancer (CRC)is the most frequent form. It represents the second leading cause of cancer and the leading cause of death from malignant disease in patients under 65 years. In this report we analyze the data from a retrospective review of tumors of the digestive system.

Material and method: We did a retrospective study over a period of 49 months, of 337 consecutive patients with cancer of the digestive tract, admitted at an Internal Medicine department. We analyzed demographic data, tumor location and their metastases, histological type, treatment and survival.

Results: We found that over the period studied, 337 hospitalized patients had cancer of the digestive tract (62% male and 38% female). Women had a mean age of 76 years (75% of women were over 71 years); men had a mean age 73 years (75% of men aged over 65 years). The diagnosis was established at the Department for 18% of the patients in the sample. About 50% of the patients were in stage IV of the TNM classification. The main organ of metastasis was the liver followed by lung. We show a statistically significant relationship between the existence of metastases and patient mortality ($p < 0.001$); 90% of cases were primarily tumors of the

digestive tract, representing 54% of CRC. In this group the location most frequently observed was the left colon and rectum, with adenocarcinoma accounting for the majority of cases.

Conclusions: Our analysis demonstrated the relevance of colorectal cancer in the nosological group, as well as a higher prevalence in the male gender. Most patients underwent palliative treatment partly due to the late diagnosis at an advanced stage of disease, but also explained by a population sample of elderly patients, with multiple co-morbidities and a greater likelihood of developing neoplastic disease.

V-77
CLINICAL FEATURES ASSOCIATED WITH HEPATIC STEATOSIS ON ABDOMINAL ULTRASOUND

C. Diaconu[1], D. Bartos[1], A. Balaceanu[2], C. Balahura[3]

[1]Department of Internal Medicine. University of Medicine and Pharmacy Carol Davila, Emergency Clinical Hospital. Bucharest, Romania. [2]Department of Internal Medicine. University of Medicine and Pharmacy Carol Davila, Emergency Clinical Hospital Ilfov. Bucharest, Romania. [3]Department of Gastroenterology. Emergency Clinical Hospital. Bucharest, Romania.

Objectives: The main causes of liver steatosis are alcoholic liver disease and nonalcoholic steatohepatitis. Although liver biopsy is the gold standard for diagnosis of non-alcoholic steatohepatitis, elevated levels of aminotransferases in abstinent individuals, without known liver disease, suggest the diagnosis in 80-90% of cases. Identification of clinical factors associated with ultrasound-diagnosed steatosis may facilitate the diagnosis in a noninvasive and cost-effective manner. The purpose of this study was to identify clinical variables associated with steatosis in individuals with high levels of aminotransferases.

Material and method: Prospective study on 61 patients admitted in Internal Medicine Clinic, with increased levels of aminotransferases and negative markers for viral hepatitis B and C, who underwent abdominal ultrasound.

Results: Of the 61 patients, 22 had hepatic steatosis on ultrasound (36.06%). Of the 22 patients, 17 were men and 5 women. Compared with patients without hepatic steatosis, those with fatty liver were older (mean age 57 years vs 51 years), had a higher body mass index (31.6 vs 28.4 Kg/m^2), a higher frequency of diabetes (19.7% vs 2.5%) and higher levels of basal glucose and tryglicerides. From patients with steatosis on ultrasound, 60% had dyslipidemia, 19.7% had diabetes, 18.4% reported alcohol abuse and 5.3% were exposed to parenteral risk. In comparison, from patients without steatosis on ultrasound, 49% had dyslipidemia, 3.6% diabetes, 32.1% reported alcohol abuse and 1.9% were exposed to parenteral risk. Total cholesterol was similar in the group with steatosis and the group without steatosis (242 vs 239 mg/dL).

Discussion: Hepatic steatosis is common in patients with elevated aminotransferases and negative viral markers. In the presence of hepatic steatosis, hyperechogenicity is observed on ultrasound examination, associated with changes of echo texture, vascular blurring and deep attenuation; this corresponds to steatotic infiltration greater than 30%.

Conclusions: History of diabetes, higher body mass index and hypertrygliceridemia can predict the presence of steatosis on ultrasound for individuals with elevated aminotransferases and negative viral markers. Although liver biopsy remains the gold standard, ultrasonography is the method of choice for initial evaluation of these patients because of low cost, safety, availability and acceptance by patients.

V-78
GASTROINTESTINAL DISEASES WITH SKIN MANIFESTATIONS - NOT AT ALL RANDOM ASSOCIATIONS

C. Diaconu[1], A. Balaceanu[2], D. Bartos[1], C. Balahura[3]

[1]Department of Internal Medicine. University of Medicine and Pharmacy Carol Davila, Emergency Clinical Hospital. Bucharest, Romania. [2]Department of Internal Medicine. University of Medicine and Pharmacy Carol Davila, Emergency Clinical Hospital Ilfov. Bucharest, Romania. [3]Department of Gastroenterology. Emergency Clinical Hospital. Bucharest, Romania.

Objectives: There are a variety of gastrointestinal diseases associated with dermatological diseases. The correct diagnosis of skin disease is very useful for internists and gastroenterologists in order to establish a complete and correct diagnosis. The study objectives were to establish the most common and important skin manifestations of gastrointestinal diseases, the evaluation of evolution and prognosis of both diseases.

Material and method: Prospective, clinical and paraclinical study of the cases with cutaneous manifestations occurring in the context of gastrointestinal diseases, admitted in the clinic for a period of 3 years. The study group consisted of 27 patients who had gastrointestinal diseases with cutaneous manifestations.

Results: We met the following combinations: 7 cases of inflammatory bowel disease (Crohn's disease and ulcerative colitis), of which 3 patients with pyoderma gangrenosum, Sweet syndrome 1 patient, 2 cases of erythema nodosum and 1 case of oral lichen planus; 3 patients with manifestations of dermatitis herpetiformis; 2 cases of Peutz-Jeghers syndrome; 8 patients with Kaposi sarcoma; 1 patient with Ehlers Danlos syndrome; 3 patients with pseudoxanthoma elasticum; 2 patients with hereditary hemorrhagic telangiectasia and 1 case with Henoch-Schonlein purpura. The distribution urban/rural of patients was 21 patients in urban and 6 in rural. The distribution by sex: 19 women and 8 men. Distribution by age groups revealed a maximum incidence of cutaneous manifestations of gastrointestinal diseases in patients aged 31-40 years (37.03%), followed by those between 41-50 years (22.22%) and patients between 21-30 years (18.51%).

Discussion: Prompt recognition of cutaneous diseases or manifestations associated with the gastrointestinal tract may alert the clinician to occult disease within the gastrointestinal tract and may lead to early therapeutic intervention, with better prognosis.

Conclusions: The most frequent association was seen between pyoderma gangrenosum and inflammatory bowel diseases, followed by erythema nodosum and equally by Sweet's syndrome and oral lichen planus. These data coincide with those of literature, with erythema nodosum and pyoderma on top of the cutaneous manifestations on inflammatory bowel diseases. We encountered 4 cases of oral Kaposi syndrome, asymptomatic. In other 4 cases were diagnosed by endoscopy specific pink lesions in the gastrointestinal tract. Only one patient presented at endoscopy nodular lesions with central ulceration. This patient developed abdominal pain and digestive bleeding. The patients with cutaneous Kaposi sarcoma and gastrointestinal symptoms should be rigorously evaluated, because most often the symptoms are attributed to other illnesses.

V-79
CLINICAL FEATURES AND RISK FACTORS IN PATIENTS WITH WERNICKE'S ENCEPHALOPATHY

A. Mateos Díaz[1], A. Prolo Acosta[1], A. Chamorro Fernández[2], I. Pastor Encinas[1], S. Gómez Lesmes[1], M. Fernández Regueras[1], M. Marcos Martín[1], J. Laso Guzmán[1]

[1]Department of Internal Medicine. Complejo Asistencial de Salamanca. Salamanca, Spain. [2]Department of Internal Medicine. Complejo Hospitalario Universitario Ourense. Ourense, Spain.

Objectives: The aim of our study is to describe the characteristics of patients with Wernicke's encephalopathy (WE) in our setting,

and to analyze the association between epidemiological, clinical and analytical variables with outcomes.

Material and method: Retrospective observational study in which patients were identified through International Classification of Diseases (ICD) codes registered by the Admission Department. Those patients with a discharge diagnosis of WE and hospitalized at the University Hospital of Salamanca between 01/01/2004 and 31/12/2010 were selected for inclusion. Diagnosis was confirmed after review of medical records and epidemiological, clinical, and therapeutic data of each patient during hospital stay were recorded and analyzed.

Results: During the study period, 26 patients with WE were included, 22 males and 4 females, with a mean age of 53.5 years (standard deviation: 10.64). Leading risk factor was alcoholism, which was present in 22 patients (84.6%). Besides, 7 patients (26.9%) had signs of malnutrition. Most frequent signs were gait disturbances (22 patients, 84.6%), and mental status changes (20 patients, 76.9%). Twenty-five patients (96.2%) had at least three of the symptoms described by Caine et al. However, only 8 patients (30.8%) had the classic triad (ocular abnormalities, mental status changes, incoordination of gait and trunk ataxia). Magnetic resonance imaging (MRI) was performed in 14 patients and imaging tests were not performed in 4 patients. The most frequent finding on neuroimaging was cortico-subcortical atrophy and typical MRI findings were only found in 4 patients. Twenty-five patients (96.15%) were treated with thiamine; 17 patients (65.4%) had partial clinical improvement at discharge and 5 patients (19.2%) were completely recovered. One patient died due to progression of underlying disease.

Discussion: WE is clearly related to alcoholism and malnutrition, as our results have corroborated. We have also shown that criteria described by Caine et al are more useful than the classic triad for clinical diagnosis, as previously suggested. Of note, although MRI is considered the most useful complementary test, only around 50% of the patients in our study underwent this test to confirm diagnosis. Patient outcomes are similar to those reported in other studies with residual deficits being common at discharge.

Conclusions: WE is a rare disease and alcoholism is the most common risk factor in our sample. Clinical criteria proposed by Caine et al are more prevalent than the classic triad. Almost all patients received thiamine and only 5 patients (19.2%) were completely recovered at discharge.

V-80
VITAMIN D DEFICIT IN ARAB WOMEN

M. Flores, A. Piqueras, J. Gonzales, C. Yera, J. Puche, J. Rodríguez, M. Martín Toledano, T. Núñez

Department of Internal Medicine. Complejo Hospitalario de Toledo. Toledo, Spain.

Objectives: Hypovitaminosis D and its consequences are a worldwide public health issue. The two main ways of vitamin D absorption are UV (sun) exposure and ingestion of nutrients rich in this vitamin. The goal of this study was to analize the levels of vitamin D in a sector of the population with some special features: Arab women.

Material and method: Retrospective review of vitamin D levels in Arab women admitted in the Short Stay Unit, Complejo Hospitalario de Toledo between February 1st, 2010 and March 30th, 2012. The items registered were: age, admitting diagnosis and vitamin D level. We defined insufficiency as levels under 20 ng/ml and deficit as levels under 10 ng/ml. After making a statistic analysis of the results we compared them with the existing literature in this subject.

Results: The final number of patients compiled was 16. All of them were Arab women with ages between 16 and 76 years old. Average 42.31 years. These are the data obtained: 18.75% had vitamin D insufficiency, 75% presented deficit and only one patient had Vitamin D levels in range of sufficiency. The admitting diagnosis was very varied. The two most common pathologies were pulmonary tuberculosis (18.75%) and bacterial respiratory infection (18.75%).

Discussion: The investigation of vitamin D has shown it´s important role not only in calcium and phosphorus metabolism but in many other fields such as the strengthening of the immune system or cancer prevention among others. Contrary to what it was believed before, nowadays it is proved that even in sunny areas deficit of vitamin D exists on those people who don't receive adequate amount of UV radiation which turns to be the majority of the population. Factors that interfere are: covered skin, sunscreen and high skin pigmentation. In addition to this, the input of precursors taken from the diet (mainly dairy products) has demonstrated to be insufficient too. Today there is consensus to recommend that Vitamin D supplementation should be provided, especially in some groups of population. In fact this is being done in the United States from several years.

Conclusions: Our study showed marked low levels of vitamin D in the cohort we studied. All of our subjects shared many characteristics. We highlight some of them: First and probably most important, their clothing is established according to the Hiyab, a dress code that requires to cover practically most part of the body wearing different garments. Another import fact is Moslem women usually are in charge of housework and children raising. These activities take most of their time and keep them home. In conclusion, most of the population living in Europe have shown to have Vitamin D deficit because of a poor IV (sun) exposure and insufficient intake of precursors in diet. In addition, there are particular groups with specific conditions that make them more given to have this deficit. Physicians should be aware of these factors in order to seek this fault.

Table 1 (V-80). Vitamin D levels

	Patients	Percentage
Deficit of vit D < 10 ng/ml	12	75%
Insufficiency of vit D 10-20 ng/ml	3	18.75%
Normal vit D > 20 ng/ml	1	6.25

V-81
EVALUATION OF HEALTH CARE PROVISION IN THE INTERNAL MEDICINE WARD

C. Silva, S. Pereira, R. Veríssimo, A. Oliveira, M. Sequeira, V. Paixão Dias

Department of Internal Medicine. Centro Hospitalar de Vila Nova de Gaia-Espinho, EPE. Vila Nova de Gaia, Portugal.

Objectives: To analyze the relation between user satisfaction and attitudes towards hospitalization.

Material and method: The study was based on a sample survey, using a structured questionnaire developed for this purpose, with the Likert attitude scale. The study sample consists in all the patients discharged from an Internal Medicine ward between the 1st and 30th of September of 2011. The questionnaire consisted in different closed response items which had an evaluation between 1 and 5 (1 for very bad and 5 for very good). The items evaluated were the health professionals, image and facilities of the department, as well as food, transport and diagnostic exams. Additionally, in an open-ended question, was asked to the user about is experience with the services provided by the health care unit. The data were then analyzed in a quantitative perspective, using the SPSS tool (Statistical Package for the Social Sciences), version 19.

Results: During the period of time covered by the study, there were 284 episodes of discharge from our department; the answers rate was 78%, where the average age of the patients was of 63 years, being 51.3% male patients. The overall average of responses was 4.2, with different values for the health professionals (4.4), facilities (4.18), food (3.9), transports and diagnostic exams (3.8 each). Regarding the users experience, they liked most the health staff (41.12%) and least the facilities (21.43%) and the food (15.71%). The users suggested improvements in the facilities.

Discussion: The health care professionals were considered the key players in the whole process of hospitalization. To achieve continuous quality improvement in health care, there should be a greater commitment in particular on the areas of supply, diagnostic tests and transports.

Conclusions: The importance of the users opinion on the evaluation of health care provision can be used as an indicator for monitoring the quality of health services.

V-82
SERUM IL-17 IN CHRONIC HCV INFECTION AND ALCOHOLISM

E. González Reimers[1], F. Santolaria Fernández[1], C. Martín González[1], I. Hernández Betancor[1], O. Pérez Hernández[1], M. Sánchez Pérez[1], M. de la Vega Prieto[2], A. Pérez Ramírez[1]

[1]Department of Internal Medicine, [2]Department of Laboratory and Biochemistry. Hospital Universitario de Canarias. San Cristóbal de La Laguna (Tenerife), Spain.

Objectives: Interleukin-17 (IL-17) is the main product of a subset of CD4+ T-lymphocytes, called Th-17 lymphocytes, a subtype of proinflammatory CD4+ lymphocytes, which differentiation is promoted by IL-6, TGF beta and IL-23, but suppressed by IL-4 and IFN-G.. IL-17 is involved in neutrophils recruitment. The aim of this study is to analyse the behaviour of IL-17 in patients affected by chronic liver disease.

Material and method: We included 21 patients affected by chronic hepatitis C (HCV), non drinkers; 6 HCV-infected drinkers; 13 non-HCV infected alcoholics and 7 controls, to which IL-17 was measured by chemiluminiscent assay (DPC, Los Angeles, CA, USA). Mean age was 49.9 ± 12 years (median =; interquartile range (IR) =). Diagnostic criteria for HCV infection were the following two: (1) presence of anti_HCV and/or HCV RNA by reverse transcriptase polymerase chain reaction (PCR), (2) Histology consistent with HCV. We also recorded total fat and lean mass, by whole body densitometry (HOLOGIC QDR-2000, Waltham, MA, USA), body mass index, subjective nutritional score.

Results: Highly significant differences were observed between patients and controls ($Z = 3.66$, $p < 0.0001$). When alcoholics, alcoholic HCV patients, non alcoholic HCV patients and controls were classified in 4 groups, differences were also highly significant differences, both ethanol ($F = 5.67$) and HCV infection ($F = 6.13$, $p < 0.025$ in both cases) playing independent roles on IL-17 (KW = 14.93; $p = 0.005$). However, we failed to find any relation with liver function and nutritional status. Among alcoholics, a significant relationship was observed between IL-17 and TNF-alpha (rho = 0.42; $p = 0.016$). Significant relationships were also observed between MDA levels and TNF-alpha, IL-8 and TGF-beta.

Conclusions: IL-17 is higher in patients than in controls, both ethanol and HCV infection play a role on this elevation, and is related to TNF alpha levels.

V-83
MORTALITY IN ALCOHOLICS

C. Martín González, E. González Reimers, C. Fernández Rodríguez, D. García Rosado, J. Jorge Hernández, J. González Pérez, F. Santolaria Fernández, R. Ros Vilamajo

Department of Internal Medicine. Hospital Universitario de Canarias. San Cristóbal de La Laguna (Tenerife), Spain.

Objectives: Alcoholism is associated to a high mortality rate. Causes of death of alcoholics may be linked to organic complications, ethanol-related immunodeficiency, continuous drinking or underlying conditions. The aim of the present study is to analyze the causes of death among a cohort of alcoholic patients, admitted to this hospital for organic complications in relation with alcohol abuse, prospectively followed up during a median of ten years.

Material and method: Mortality, causes of death, intensity of ethanol consumption, duration of consumption, concomitant use of tobacco, age, sex, and nutritional status (BMI, subjective nutritional score (SNS)), liver dysfunction (prothrombin activity, albumin, bilirubin, ascitis, encephalopathy) were assessed at admission. Patients were followed up as outpatients every six months.

Results: Ninety-two out of 226 patients died during the observation period, 77 out of 195 men and 9 out 20 woman ($\chi^2 = 0.23$). Causes of death were liver failure 40 cases, cancer 18 cases, cardiovascular disease 15 cases, respiratory disease 8 cases, pancreatitis 2 cases, upper gastrointestinal hemorrhage not related to liver cirrhosis 1 case, sepsis 10 cases (most complicating liver failure) and stroke 3 cases and 1 case, unknown cause. By Cox regression analysis, variables independently related to death were ascitis and encephalopathy, but if these two parameters were substituted by the variable "cirrhosis", age, sex and prothrombin activity were those with independent prognostic value. Patients who died by liver failure were younger (51.1 ± 9 years) than those died for other causes (59.2 ± 14, $t = 3.1$; $p = 0.003$). Those who died had been drinking for longer time than those who survived ($t = 2.28$; $p = 0.021$). There was a highly significant association between ongoing alcohol consumption and death (only 14 out of 91 remained abstinent after admission among those who died versus 58 out of 135, $\chi^2 = 18.96$ $p < 0.001$).

Conclusions: Mortality among alcoholics who experienced at least one hospital admission is very high, and death occurs at young age. About 45% died in relation with liver failure. Death is in relation with the duration of ethanol consumption and strongly influenced by ongoing drinking.

V-84
CANCER AND ALCOHOLISM

E. González Reimers, C. Martín González, C. Fernández Rodríguez, C. Jorge Ripper, R. Hernández Luis, F. Santolaria Fernández, E. Martín Ponce, R. Pelazas González

Department of Internal Medicine. Hospital Universitario de Canarias. San Cristóbal de La Laguna (Tenerife), Spain.

Objectives: Alcoholism may be viewed as a risk factor for cancer development. The aim of the present study is to analyze which variables are associated to cancer development among a cohort of alcoholic patients, admitted to this hospital for organic complications in relation with alcohol abuse, prospectively followed up during a median of ten years.

Material and method: Incidence of cancer, mortality, intensity of ethanol consumption (g/day), duration of consumption, concomitant use of tobacco, age, sex, and nutritional status (BMI, subjective nutritional score (SNS)), liver dysfunction (prothrombin activity, albumin, bilirubin, ascitis, encephalopathy) were assessed at admission. Patients were followed up as outpatients every six months for a median of ten years.

Results: Cancer was observed in 36 out of 227 patients (15.86%). The most frequent tumors were: cavum and larynx, 13 cases; liver, 5 cases; colon, 5 cases, pancreas, 4 cases; other locations, 9 cases. Eighteen patients with cancer died during the observation period compared with 75 out of 191 without cancer ($\chi^2 = 1.44$, $p > 0.1$): No associations were observed between cancer and sex ($\chi^2 = 2.05$), liver cirrhosis ($\chi^2 = 0.56$), tobacco consumption ($\chi^2 = 2.30$) virus C infection ($\chi^2 = 1.31$) or virus B infection ($\chi^2 = 0.44$). Age of those with cancer was higher (57 ± 12 years) than that of those without cancer (51 ± 11 years, $t = 2.7$; $p < 0.01$). There was a nearly significant trend to higher daily consumption of ethanol among those with cancer (232 ± 86 g) than among those without cancer (196 ± 77 g, $p = 0.07$)). There were also no differences in nutritional status at admission, but those who developed cancer showed a grater loss of lean mass at a second evaluation 6 months later ($\chi^2 = 4.26$; $p = 0.039$).

Conclusions: Cancer among alcoholics who experienced at least one hospital admission is high, leading to a mortality rate of 50% at relatively young age (57 years). A loss of lean mass is associated with cancer, although no significant differences were observed in nutritional status at baseline between those who developed cancer and those who did not.

V-85
WHAT DOES A HOSPITALIST HAVE TO OFFER TO A SURGICAL DEPARTMENT?

A. Álvarez-Arcaya[1], S. Álvarez[2], A. Alguacil[3], M. López[4], M. Fuentes[5], P. Izquierdo[6], J. Mayol[7], A. Fernández-Cruz[8]

[1]Department of Medical Clinic, [2]Subdepartment of Management, [3]Department of Quality, [4]Cost Unit, [5]Department of Research, [6]Management Director, [7]Department of Surgery, [8]Department of Internal Medicine. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: Patients admitted to hospitals are increasingly older and sicker with many comorbidities. In Canada, US and UK there are hospitalists who manage medical conditions for hospitalized surgical patients. The benefits of hospitalist model include lower cost and reduced length of stay, lower mortality and readmission rates. In Spain a few internists are shyly integrating into surgical departments in order to improve preoperative and postoperative care. In July 2010, the Hospital Medicine Unit was created at Hospital Clínico San Carlos. Its aim is to improve care delivery, inpatient management and to guarantee continuity of care through early discharge and home hospital (HH) programs.

Material and method: Patients admitted to the Department of Surgery from July 2010 to June 2011 were included. Age, diagnosis, hospitalist (internist) follow-up days, length of stay and discharge were assessed. The most frequent surgical diagnostic related groups (DRG) were compared with a control group of patients not evaluated by a hospitalist. Patient satisfaction was studied by a normalized test given by the Hospital Quality Unit.

Results: A total of 201 patients were evaluated, mean age 67.9 ± 16.6 years, 46.8% males, 53.2% females. The most frequent diagnostic groups were non-malignant biliary disease, colorectal cancer, abdominal wall hernias and other gastrointestinal cancers. In 78% of patients, postoperative complications developed: cardiovascular, infectious, kidney and pulmonary diseases. The average length of hospitalist follow-up was 4 days (RIC = 2-11). 52.2% of patients were discharged home, 34.3% transferred to HH, 6% transferred to other facility, 4.5% deaths occurred and the remaining 3% were transferred to the ICU. The cost in euros of the hospital stay of the most frequent DRGs was compared to the control group. A total of 186 patients were analyzed, mean aged 66 ± 16 years, 44.6% males, 55.6% females. These DRGs evaluated by the hospitalist represented 40% of the overall stays and 23.7% of all patients of the Department. DRG 585 included 22 patients, mean age 74.7 ± 13.8 years. DRG 148 comprised 15 patients, mean age 71.9 ± 14.2 years. DRG 556 included 10 patients, mean age 70.7 ± 18.6 years. For these DRG 760.732€ were saved thanks to reducing length of stays (777 days). Satisfaction test began in October 2011: 100% of them were satisfied or very satisfied, 78% being very satisfied with care provided by hospitalist. All patients knew they were being treated by a hospitalist together with a surgeon. Mean age 70.6 ± 9 years. Study has not finished.

Discussion: Some patients undergoing surgery pose a challenge because of their comorbidities, their age or postoperative complications, requiring assessment by an internist. Furthermore, patients transferred to HH may see a reduction in adverse effects. An internist working in the Department of Surgery full-time and the development of "hospitalist programs" represent a new organization model beneficial to the patient. In our case, the program reduced the length of stay and the costs, and increased patient satisfaction.

Conclusions: 1. Medical comanagement of surgical patients by hospitalists and surgeons shows a shorter hospital stay, earlier discharge, lower costs and increased perceived quality by patients. 2. Shorter length of stay improves perceived quality of life because of the reduction in adverse effects. 3. Early discharge shortens length of stay so the cost of a given DRG is reduced, with high perceived quality. 4. This organization model seems to be more efficient and provides increased perceived quality to patients, so it could be extended to the rest of the Spanish health care system.

V-87
DIFFERENCES BETWEEN NON-FAMILIAL AND FAMILIAL PAPILLARY THYROID CARCINOMA: CLINICAL SERIES AND REVIEW OF THE LITERATURE

E. Nadal[1], C. Fajardo[2], J. Gómez[2], M. Edo[3], M. Abdilla[1], I. Ezquerra[1], J. Esteve[1]

[1]Department of Internal Medicine, [2]Department of Endocrinology. Hospital Universitario de la Ribera. Valencia, Spain. [3]Department of Radiology. Hospital Marina Alta. Dénia (Alicante), Spain.

Objectives: The aim of this study was to analyze the characteristics of the familial papillary thyroid carcinoma (PTC) cases diagnosed in our institution and its differences with the sporadic PTC.

Material and method: 3 families diagnosed with familial PTC were reviewed. Clinical presentation, extension, evolution after the treatment and follow-up of the healthy members in the last 6 years were studied. A literature review was performed.

Results: "A" Family: A 55 year-old male was referred for thyroid nodule study. His mother and brother were diagnosed with PTC. The fine-needle aspiration biopsy (FNAB) was positive for papillary carcinoma and the thyroid was surgically excised. Lymph-node metastases were found in surgery and ablation with 131I was made in addition to levothyroxine (T4) replacement (suppressive doses). Serum thyroglobulin (Tg) concentrations after treatment were undetectable and Tg antibodies (Ab) were negative. 4 years after surgery increased levels of Tg were detected (2.82ng/ml) with negative Tg Ab. The echography (US) showed a hypoechoic nodule (size 12 × 7 mm); body CT scan and FNAB studies were compatible with a relapse. The patient was reoperated and new 131I dose was given in the following 2 months. No distant metastases were observed in CT scan afterwards but persistently high serum Tg levels (13 ng/ml) were caused by a tumor recurrence in the surgical wound. New surgery is pending. "B" and "C" Families have similar characteristics: 2 young men (25 and 34 years old) were admitted for thyroid

nodule study (diameter 15 and 18 mm respectively). Familial clinical history included grandmother PTC. FNABs cytological evaluations were benign but the presence of microcalcifications in US study and familial clinical history motivated surgical treatment. The histological thyroid evaluation confirmed PTC with lymph-node metastases. The treatment was the same as the "A" Family. A lymph-node recurrence 3 years later was detected in the B family case and a second surgery procedure was performed in addition to new 131I dose. Both patients have undetectable Tg levels with negative Tg Ab. Physical exam and US studies were performed in the family members of A, B and C families. No new cases were identified.

Discussion: Although most PTCs are sporadic, familial PTC can be identified in a low percentage of cases. According to the literature, patients with familial PTC are younger with multifocal and more aggressive tumors compared to the sporadic type. However our study shows cases with focal thyroid lesions. There are no typical manifestations. Genetic risk factors in this variety or carcinoma are not well described. Correct clinical and complementary exams with a high clinical suspicion are essential.

Conclusions: Aggressive behavior of familial papillary thyroid microcarcinoma is confirmed in our study. Familial papillary thyroid carcinoma is probably a polygenic illness. FNAB studies have false negatives and there is no available genetic test. Hence, clinical suspicion in patients with thyroid nodule and PTC in family members is essential.

V-88
UNINTENDED MEDICATION DISCREPANCIES AT THE TIME OF HOSPITAL ADMISSION

D. Salor Moral, A. González Munera, A. García-Espona, M. Ferrer Civeira, I. Muñoz, C. Pérez de Oteyza, M. Villalba, C. López González Cobos

Department of Internal Medicine, Unit "D". Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: Adverse drug events represents an emerging pathology with an important impact in terms of hospital stay, social factors and financial costs.Unintended medication discrepancies that represent errors are common at the time of hospital admission. These errors are particularly worthy of attention because they are not likely to be detected by computerized physician order entry systems.

Material and method: We prospectively studied patients reporting the use of at least 3 regular prescription medications who were admitted to general hospital. The primary outcome was unintended discrepancies (UD) between the physicians' admission medication orders and a medication history obtained through interview. We also evaluated the probability that a medication discrepancy might have caused clinical deterioration (errors). All discrepancies were reviewed with the medical team to determine if they were intentional or unintentional. All unintended discrepancies were rated for their potential to cause patient harm.

Results: Eighty patients were enrolled. The mean age of the patient was 75, and 55% were men, 55% had hypertension, 43.8% had diabetes. Seventy percent were taking ten or more drugs. Nineteen patients (23.8%) had at least one UD. Drug omission was the most frequent discrepancy, detected in 50% of cases, followed by incorrect or omitted dose (21.8%). Only 3% of errors were harmful to patients. Medications without discrepancies per patient were 3.4.

Discussion: Results supports an improvement tendency due to the introduction of a tool which improves pharmacopeia settlement by decreasing the non-justified discrepancies frequency. Increasing the sample set size would be recommended, therefore, justifying using tools which decrease the mistake rate and in consequence, the morbimortality under consensus among all involved personal in the sanitary assistance. In our study personal of the selected units greatly welcomed.

Conclusions: Medication discrepancies at the time of hospital admission are common, and some have the potential to cause harm. To improve patient safety better methods of ensuring an accurate medication history at the time of hospital admission are needed.

V-89
HELLP SYNDROME AS A WORK OF INTERNIST

M. Rey Rodríguez[1], F. Romero Candau[1], L. Chacón Villafranca[2]

[1]Department of Internal Medicine, [2]Department of Gynecology. Hospital Viamed Santa Ángela de la Cruz. Sevilla, Spain.

Objectives: HELLP syndrome is characterized by the appearance of hemolysis, elevated liver enzymes and thrombocytopenia in the third trimester of pregnancy (between weeks 28 and 36 in particular), and that is a major cause of morbidity and mortality for pregnant women and fetus. Can lead to serious complications such as DIC, abruptio placentae, pulmonary edema, stroke, heart attack, liver hemorrhage, retinal detachment... For some authors, is considered a severe form of preeclampsia. Its incidence is 1 per 1,000 pregnancies. We work in a private hospital opened in August 2010. It has 100 hospital beds, of which 50% of income corresponds with the Department of Obstetrics and Gynecology. It created the position of Intern assigned to this specialty, to anticipate problems that may arise to, as well as its treatment and outcome derived from their income. We have detected and treated specific pathology of pregnancy, uncommon in the general population, such as HELLP syndrome. Objectives: description of the clinical features of patients affected with HELLP, a rare condition, but appears more important due to population changes and habits of life we are living, such as pregnancy in women increasingly aphthous, the use of in vitro fertilization (IVF) and increase in cardiovascular risk factors.

Material and method: We have compiled all cases diagnosed and treated in our center since its opening, representing 21 months of follow-up, to describe their clinical characteristics and evolution.

Results: We collected a total of four patients affected with this picture of a 3,204 total deliveries from August 2010 to April 2012, representing an incidence of 1.2 cases per 1,000 pregnancies. The average age of affected patients was 34 years, mean BMI of 31.54. The mean gestational age at which symptoms began was at 34.5 weeks gestation. 2 of the 4 pregnancies were achieved by IVF. All cases had to be finalized as emergency cesarean section and clinical and laboratory signs normalized within two days following the birth on average. The average stay of 7.5 days was required, with an

Table 1 (V-89). Clinical features

	Age	Gestational age	BMI	Days in hospital/ICU	Twins	IVF
Case 1	35	33	28.51	10/1	No	Yes
Case 2	34	34	28.30	8/3	Yes	Yes
Case 3	36	36	40.65	5/2	No	No
Case 4	31	35	28.71	7/0	No	No

average stay in ICU of 1.5 days. Our patients required a mean of 3.25 different antihypertensive drugs to control. None of our patients suffered serious complications. After follow-up visits of patients, symptoms were fully normalized and treatment in about two weeks.

Discussion: Early diagnosis and early treatment of our patients by the internist in charge of it, perhaps it is responsible for no serious complication and favorable resolution of the cases presented. The incidence in our series is similar to that described in the literature. With population changes we are experiencing, such as maternal age increasingly advanced, obesity and the increase in the IVF and cardiovascular risk factors, we must be prepared to diagnose and treat episodes as HELLP syndrome, which may see increased frequency.

Conclusions: The early diagnosis and management of HELLP syndrome is a problem for professionals in obstetrics, mainly due to the lack of signs and symptoms, which delays the proper management of this disease. The early and continuous evaluation of our patients by the internist helps prevent serious complications and the favorable resolution of the cases presented.

V-90
EPIDEMIOLOGY OF ISRAELI TRAVELERS WITH PRE-EXISTING MEDICAL CONDITIONS TRAVELING TO TROPICAL COUNTRIES

S. Stienlauf[1], B. Streltsin[2], E. Kopel[3], G. Segal[4], E. Meltzer[1], E. Leshem[1], E. Schwartz[1]

[1]Department of Internal Medicine C, [2]The Arrow Project. Sheba Medical Center. Tel Hashomer [3]Tel Aviv District Health Office. Ministry of Health. Jerusalem, Israel. [4]Department of Internal Medicine T. Tel Aviv Sourasky Medical Center. Tel Aviv, Israel.

Objectives: Data regarding travelers with pre-existing medical conditions (TPMC) to tropical countries are limited. We sought to describe the epidemiology of those travelers vs healthy travelers to the same countries. In addition, the rates of pre-existing medical conditions among travelers to the tropics were compared to the rate in the general Israeli population.

Material and method: A retrospective cohort study of travelers attending the Sheba Medical Center Travel Clinic, a large travel clinic in Israel, was conducted, looking at data from January 2005 to December 2007. We analyzed demographics, travel destinations, travel dates and duration, as well as the medical history (pre-existing illness, chronic medications, and allergies) of the travelers. Epidemiology of chronic illnesses in Israel was extracted from the National Health Survey 2003-2004 of the Israel Center for Disease Control, Ministry of Health.

Results: A total of 20,274 travelers attended the pre-travel clinic during this 3- year period. Complete data were available for 18,666 travelers, from whom 3,407 travelers (18.3%) reported pre-existing medical conditions. The mean age (± SD) of TPMC and healthy travelers was 41.7 ± 17.9 and 29.4 ± 12.3 years, respectively, ($p < 0.001$, Student's t-test). Among TPMC, 53% were males compared with 51% of healthy travelers ($p < 0.04$, chi-square test). The average planned duration of travel for TPMC and healthy travelers was 100 ± 165 and 74 ± 130.8 days, respectively, ($p < 0.001$, multivariate linear regression adjusted for age, gender, date of departure, destination continent and purpose of journey). Common destination continents were South East Asia (61% of healthy travelers, 59% of TPMC), Latin America (30% of healthy travelers, 34% of TPMC) and Africa (13% of healthy travelers vs 10% of TPMC),($p < .0001$, chi-square test). The major groups of pre-existing medical conditions were endocrine/metabolic (42%), cardiovascular (29%) and pulmonary illnesses (17%). Less common conditions were immune deficiency (3%), neurologic (4%) and psychiatric (5%) conditions. The rates (%) of the following diagnoses among the general Israeli population and the Israeli travelers to the tropics were, respectively, hypertension 20/3.9, allergic diseases 10/0.4, heart diseases 8.7/1.2, anxiety/affective disorders 8.2/0.9, diabetes 8.1/1.3, thyroid disorders 7.3/1.8, asthma 7.2/3.0, renal disorders 6.3/0.14, chronic lung diseases 5.9/0.02, and malignancies 3.4/0.6. The difference between each pair of rates was statistically significant ($p < 0.001$, chi-square test).

Conclusions: TPMC accounted for a significant number of Israeli travelers to the tropics who presented to our clinic, approaching one fifth of our patients. TPMC were significantly older and planned to travel for shorter periods of time than healthy travelers. The rates of pre-existing medical conditions seem to be significantly lower among travelers compared to the general population. Further studies are needed to substantiate these data and examine outcomes of TPMC.

V-91
BEDSIDE ECHOGRAPHY BY HOSPITALISTS VS STANDARD ECHOGRAPHY: REMOVING ULTRASOUND WAITING LISTS

S. Pintos Martínez, N. Lozano Cortell, P. Olcina Lloret, G. Vila Castillo, S. Olivera González, P. Martín Rico

Department of Internal Medicine. Hospital de Dénia. Dénia (Alicante), Spain.

Material and method: Medical staff participated in a simple 2 months echography training program. 65 patients scheduled for standard echocardiography and 23 for standard abdominal echography as part of clinical care underwent bedside echography (BE) within 24 hours as support for the physical examination and to assess clinically important common diagnoses. Equipment used by the internist was portable devices. Both the cardiologist and the radiologist used no portable devices. Exclusion criteria were a delay of 24 hours between the scanning by the internist and the scan performed by the radiologist or cardiologist. Agreement was calculated between bedside echography and standard echography by using standard echography as the gold standard. All corresponding measurements between the portable device and the traditional machine were assessed by linear regression analysis for kappa correlation coefficient.

Results: The agreement kappa coefficient was 0.84 (95%CI 0.69-0.99) for left atrial enlargement, 0.58 (95%CI 0.24-0.91) for left ventricle enlargement, 0.62 (95%CI 0.41- 0.83) for left ventricular global function, and 0.49 (95%CI 0.23-0.75) for pericardial effusion. For the detection of hepatomegaly the kappa coefficient was 0.43 (95%CI 0.01-0.84), for detecting of liver echogenicity the kappa was 0.79 (95%CI 0.51-1.00), for the splenomegaly 1.00 (95%CI: 1.00-1.00), for gallstones also 1.00 (95%CI: 1.00-1.00), and for ascites 0.62 (95%CI 0.13-1.00).

Discussion: Small, portable, ultrasound machines have the potential to revolutionize patient care by making ultrasound available to all clinicians. Application of this new technology, however, requires skills on the part of human users. We found that with as little as two months of training, internists could use portable devices to answer simple but common and important clinical questions. To understand whether and how portable echography can be used in clinical care, however, it is critical to understand whether it can be performed by those with less experience than currently required for standard echography. A number of prior studies have investigated portable echography by physicians without formal echography training using either a 2-month training program. DeCara et al developed a significantly more intensive portable echocardiographic training program for medical residents and then compared them with experienced echocardiographers using portable echocardiography. They found that compared with experienced echocardiographers, medical residents using portable echocardiography had a slightly lower sensitivity (88% vs 80%) and specificity (98% vs 97%) for clinically

important findings and similar sensitivity (65% vs 63%) and specificity (95% vs 92%) for all findings. Our data support the idea that physicians with limited training can use a focused portable echography examination to assess important clinical items. The portable ultrasound should not be considered a replacement for standard echocardiography. In practice, patients with other suspected abnormalities, poor sound transmission, or indeterminate or abnormal findings on portable echography should be referred for standard echography or other appropriate diagnostic testing.

Conclusions: Medical house staff with limited training in echography can use bedside echography to assess clinically important common diagnoses with moderate accuracy. Integration of a portable ultrasound device with the physical examination improves the yield of information. In this study we compare also the degree of agreement on other parameters such as valvular dysfunctions, also with good results.

V-92
IMPAIRED LIVER FUNCTION TESTS IN INTERNAL MEDICINE INTENSIVE CARE UNIT: A RETROSPECTIVE ANALYSIS

M. Çakar[1], R. Öcal[2], M. Akhan[1], E. Arslan[1], B. Yildiz[1], R. Acar[1], G. Büyükturan[1], H. Sarlak[1]

[1]Department of Internal Medicine, [2]Department of Intensive Care. Gülhane Military Medical Faculty. Ankara, Turkey.

Objectives: Impaired liver function tests are often encountered in intensive care unit patients due to various reasons. Besides alanine aminotransferase (ALT) and aspartate aminotransferase (AST); alkaline phosphatase (ALP), gamma-glutamyl transpeptidase (GGT), albumin, prothrombin time and bilirubin give information about the inflammation, damage or function of liver cells or a biliary tract obstruction. We aimed to retrospectively analyse epidemiological, clinical, and laboratory data of patients admitted for various reasons at the internal medicine intensive care unit and detected to have elevated liver enzyme(s) during the admission or hospital stay.

Material and method: 138 patients having at least one elevated liver enzyme (ALT, AST, ALP, GGT) admitted at our internal medicine intensive care unit for various reasons between 01 October 2011 and 01 May 2012 were recruited in the study. Liver enzymes (ALT, AST, ALP, GGT), prothrombin time, bilirubin, lactate dehydrogenase (LDH) and albumin measurements were recorded. SPSS 15.0 was used for statistical analysis.

Results: Of the 138 cases, 70 (%50.7) were male and 68 (49.3%) were female. Mean age of the male and female patients were 60.94 ± 21.7 and 70.7 ± 16.4. Mean values of ALT, AST, ALP, GGT, total bilirubin, LDH, albumin and prothrombin time were 203 IU/ml, 362 IU/ml, 207 IU/ml, 151 IU/ml, 2.04 mg/dl, 962 IU/ml, 2.7 g/dl and 22.5 sec, respectively. As expected due to use of many pharmacological interventions, especially antibiotics, the mostly encountered cause of impaired liver function tests were hepatotoxic agents (n = 105; 76.1%). Ischemic causes due to hypotension or cardiac failure were the second most common aetiology (n = 19; 13.8%). Other rarer causes were biliary tract obstruction (n = 7; 5.1%), viral hepatitis (n = 6; 4.3%; hepatitis C in 4 and hepatitis B in 2 patients) and Wilson's disease (n = 1; 0.7%). When toxic causes were more common in males (57/105; 54%), ischemic and cholestatic causes were more common in females (11/19; 58% - 5/7; 71%, respectively). 72 cases (52.2%) died during the hospital stay. Ischemic causes were associated with significantly higher mortality rates (14 of 19 cases; 73%, $p < 0.05$). In the subgroup analysis, ischemic causes were associated with death in females more than males (10 of 11 females; 90.1%, $p < 0.01$).

Conclusions: In internal medicine intensive care departments, liver function abnormalities are common and if there is no history or clinical finding of hypotension, cardiac failure, viral hepatitis or biliary tract obstruction, the situation is generally due to toxic causes. Possible hepatotoxic agents should be firstly reviewed when hepatic function impairment occurs in an intensive care patient. Ischemic causes generally have a poor prognosis.

V-98
RETROSPECTIVE ASSESSMENT OF METASTATIC SPINAL CORD COMPRESSION (MESCC) IN PATIENTS WITH CANCER

D. Campillo[1], M. Jimeno[1], J. Marco[2], C. Vicente[1], S. Plaza[1]

[1]Department of Internal Medicine. Hospital Universitario Severo Ochoa. Leganés (Madrid), Spain. [2]Department of Internal Medicine. Complejo Universitario de San Carlos. Madrid, Spain.

Objectives: To asses MESCC frequency and epidemiology characteristics in patients with cancer admitted to our service.

Material and method: Descriptive, retrospective study conducted at the Paliative Care Unit of the Internal Medicine department of the Hospital Severo Ochoa (Madrid, Spain) from 2002 to 2011. Among a total of 1.736 patients in palliative care, 29 patients with a diagnosis of MESCC were identified. Sex, age, tumor type and stage, signs and symptoms, median time from symptoms onset to diagnosis, treatment regime, treatment response and mortality were collected.

Results: From a total of 1.736 patients in palliative care during the study period, 29 (1.7%) cases of MESCC were identified. Mean age was 65.6 years (SD 12.2). Lung cancer was the primary tumour in 13 cases (44.8%) followed by prostate (13.8%), breast (10.3%) and, colorectal cancer (10.3%). These four types comprised 79.31% of our series (n = 23). At presentation of MESCC, 58.6% of our patients had stage IV neoplasic disease being the dorsal (41.4%, n = 12) and lumbar (20.7%, n = 6) regions of the vertebral column the most frequently affected regions. Multiple site disease was present in 55.2% (n = 16) of cases. Pain was the predominant symptom (41.4%; n = 12) followed by motor dysfunction (37.9%; n = 11) and 27.6% (n = 8) showed some type of autonomic dysfunction. Autonomic symptoms were presents in 50% of patients with median survival time of less than one month. MESCC was the presenting symptom in 20.7% of our series. Mean time from beginning of symptoms to MESCC diagnosis was 34.5 days while motor function prior to diagnosis was preserved only in 10.3% (n = 3) of patients. Steroid treatment was used in 96.5% (n = 28) of patients and radiotherapy in 96.4%. Median survival after MESCC diagnosis was 82 days. 79.3% (n = 23) of patients died in less than 4 months after diagnosis of MESCC, mostly from lung cancer as a primary tumor (52.2%). For survivals longer than 4 months, the most frequent primary tumour was prostate adenocarcinoma (50%).

Discussion: Metastatic epidural spinal cord compression (MESCC) is a complication of patients with cancer. The incidence in patients with cancer is around 2-5% which is in accordance with the results of our series (1.7%). Tumour types that cause more frequently MESCC are prostate, breast and lung cancer. In our analysis we have observed similar frequency rates between breast and colorectal cancer. In accordance to the literature thoracic spine is the most frequent location and comes after lumbosacral spine. In this study only 10.3% of patients had pre-treatment preserved basal function and more than 50% had pre-treatment basal motor dysfunction a proportion which perhaps could explain why only 6.9% benefited of steroid or radiotherapy treatments. Median survival time for patients with MESCC is 3-6 months (82 days in our series). Autonomic dysfunction could be a predictor of mortality as they were present in 50% of patients with a median survival time of less than one month.

Conclusions: MESCC is an indicator of poor prognosis in patients with cancer. The most common neoplasia behind it is lung cancer and thoracic spine is the most frequently location affected. The first line of treatment for most patient are either corticosteroids or

radiotherapy for patients who have radiosensitive tumours or are ambulatory when they begin treatment. Well established prognosis items are pre-treatment basal motor function, speed of symptom onset, functional outcome after therapy and according to our results, the presence of autonomic symptoms.

V-99
NEUROLOGIC MANIFESTATIONS OF HEART DISEASES IN YOUNG ADULTS THREE CASE REPORTS AND LITERATURE REVIEW

Z. Vesza, K. Camões Da Luz, T. García Serrano, A. Cachado

Department of Medicine 4. Hospital de Santa Marta, CHLC. Lisboa, Portugal.

Objectives: We report three cases of acute stroke in young adults as the first clinical manifestation of heart disease. The purpose of this presentation is to review the possible causes of cardioembolic stroke as well as other ischemic stroke causes in young patients.

Material and method: We present the three case reports of young adults between the ages of 21 and 25 with no other conventional vascular risk factors (hypertension, diabetes, dyslipidemia) or drug abuse. Echocardiography, computer tomography scanning and magnetic resonance imaging were performed, which allowed a definite diagnosis.

Results: The first patient had a history of Ostium primum atrial septal defect and a mitral mechanical heart valve, and an intracardiac thrombus was found as the source of embolism. In the second patient, an intracardiac mass was found in the apex of the left ventricle, while in the third patient an acute bacterial endocarditis with septic embolization was diagnosed.

Discussion: Etiology of cerebrovascular events in the young must be thoroughly investigated so as to guide prevention and treatment, as the differential diagnosis for possible etiologies is broader than that for older patients. Evaluating the source of cardiac embolism is one of the most frequent reasons for cardiac consultation.

Conclusions: Stroke in young adults is more common than expected and cardioembolism is a major cause. We present the diagnostic approach to young patients (up to 45 years of age) with stroke as it differs from the standard approach for older adults.

V-100
CORRELATION BETWEEN EPISTAXIS SEVERITY SCORE WITH COMPUTED TOMOGRAPHY FINDINGS AND OTHER CLINICAL MANIFESTATIONS IN HEREDITARY HEMORRHAGIC TELANGIECTASIA

C. Royo[1], L. Boix[1], C. Sancho[2], E. Alba Rey[2], C. Capdevila Aguilera[1], F. Cruellas[3], A. Riera-Mestre[1], R. Pujol[1]

[1]Department of Internal Medicine, [2]Department of Angioradiology, [3]Department of Otorhinolaryngology. Hospital Universitari de Bellvitge. L'Hospitalet de Llobregat (Barcelona), Spain.

Objectives: To identify the correlation between epistaxis severity score (ESS) and findings in thoracoabdominal computed tomography (CT) or with clinical severity in hereditary hemorrhagic telangiectasia (HHT).

Material and method: Descriptive study of a prospective series of patients with HHT attended at a Functional Unit of HHT in a tertiary university hospital. We included patients with thoracoabdominal CT and determination of ESS. The study period was 3 years (2009-2011). The data analysis was performed using SPSS 15.0.

Results: The study included 27 patients. The average age was 51.2 (24-79; SD 16) years and 18 (66.7%) patients were male. All patients had definitive HHT (Curaçao criteria 3 or more), except one patient who had a probable HHT. Also, all patients had a family history and presented epistaxis as first clinical manifestation, with a daily or weekly frequency in 70.4% of the cases. Mean hemoglobin, leukocytes and platelets levels were 123 (75-167; SD 23.4) g/L, 5692.59 (3,000-14,300; SD 2,509.81)/mm^3 and 246,407.41 (135,000-340,000; SD 60,499.4)/mm^3, respectively. 44'4% of the patients had anemia, being with ferrotherapy 66.7%, requiring a blood transfusion 37% and needing invasive therapeutic measures (embolization, surgery or electrocution) 29.6% of them. 40.7% of patients required emergency attention. 74.1% had visceral involvement in CT angiography: liver in 12 (44.4%) patients, lung in 5 (18.5%), liver and lung in 2 (7.4%), and pancreas in one (3.7%) patient. The average ESS was 4.34 (0.51 to 10, SD 2.29), classified as moderate-severe (4 or more points) in 40.7% of patients. Correlation between visceral involvement and patients with moderate-severe ESS (4 or more points) or mild ESS (less than 4 points) (75% vs 72.7%) has not been detected. Patients with ESS moderate- severe (4 or more points) had statistically significant, more frequently heart disease (45% vs 6.2%) anemia (72.7% vs 25%), ferrotherapy (90.9% vs 50%) blood transfusion (63.63% vs 18.75%), invasive therapeutic measures (78.9% vs 12.5%), emergency room visits (81.8% vs 12.5%), older age of onset (22.9 vs 13.2), lower hemoglobin levels (108.64 vs 133.31) and leukocytes (4081.82 vs 6800).

Discussion: ESS correlates not only with severity of epistaxis but also with consequences, but its correlation with visceral involvement in CT has not been detected. This data assesses the heterogeneous vascular involvement in patients with HHT and supports the need for thoracoabdominal CT as a screening in these patients independently of his ESS.

Conclusions: Vascular pathological findings in systematic thoracoabdominal CT are frequent in HHT. Patients with ESS moderate to severe (4 or more points) had more frequently heart disease, anemia, ferrotherapy, blood transfusions, invasive therapeutic techniques, emergency room attention, older age of onset, lower hemoglobin and leukocytes levels. We have not found significant correlation between ESS and CT pathological vascular findings.

V-102
DOES THE INTEGRATION OF THE ACUTE AND COMMUNITY TRUSTS INCREASE THE EFFECTIVENESS OF EARLY SUPPORTED DISCHARGE OF STROKE PATIENTS?

A. Gutiérrez Larrainzar, K. Kee, E. Lawrence, S. Mahmood

Department of Stroke Unit. Croydon University Hospital. London, United Kingdom.

Objectives: Studies have shown significant benefits of early supported discharge (ESD) of stroke patients from hospital. Nationally many hospital and community trusts have integrated to facilitate the smooth transfer of patients to their home. The aim of the study was to show whether there has been a reduction in length of stay of ESD stroke patients after integration of the hospital and community trusts in Croydon.

Material and method: After integration of the hospital and community trusts, the community stroke teams were co-located with the Croydon stroke unit (SU) (July 2011). Patient data were retrospectively reviewed for all patients admitted to the stroke unit six months before and after the reorganisation of the stroke pathway.

Results: From January to July 2011, 157 patients were discharged from the SU. The average age was 74 years for patients from Croydon (48.55% female). The median length of stay was 14.5 days for Croydon. Of the 143 patients that were discharged after integration of the stroke pathway the average age was 74.5 years (58.74% female). The median length of stay was 12 days.

V-103
GENERAL CHARACTERISTICS OF A INTERNAL MEDICINE SHORT STAY UNIT IN A THIRD LEVEL HOSPITAL

I. Aomar Millán, Á. Ceballos Torres, L. Ruiz Rivera, F. Anguita Santos, S. Moya Roldán, P. Giner Escobar

Department of Internal Medicine. Hospital de Especialidades San Cecilio. Granada, Spain.

Objectives: To analyze the demographic characteristics, personal medical history, comorbidity, diagnosis, average stay and diagnosis complexity in a short stay unit depending on Internal Medicine in a third level hospital.

Material and method: Descriptive study of the patients in our Internal Medicine Short Stay Unit (UCEMI), from the 1st July to the 30th November 2011. At the Unit we have 8 beds, 2 consultants and 1 resident. The data were extracted from the UCEMI database, and analyzed with the statistical program SPSS V19.0.

Results: We analyzed 196 patients, which represent the 23% of all the patients staying at the Internal Medicine Unit. The average age was 65.97 years old, 56% of which were men and 44% women. 180 patients (93%) were admitted from the emergency unit, 4 from clinic, and 8 from the surgery waiting list. The average stay was 3.41 days, and when the patients were discharged, most of them (83%) went home, other were transferred to a different unit, and there was only one exitus occurred. The main diagnosis for the patients who went home after being discharged were respiratory pathology (32%), cardiovascular pathology (24%), nephro-urological pathology (21%) and digestive pathology (11.39%). The most frequent personal medical history were arterial hypertension (55%), structural heart disease (41.8%), diabetes mellitus (38%), COPD (27.2%), chronic kidney disease (25.3%) and atrial fibrillation (19.6%). 21.5% of the patients showed advanced cognitive deterioration, and 54.5% showed 3 or more secondary diagnosis.

Discussion: UCEMIs are an alternative to normal hospitalization, and they are effective improving the clinical practice and management parameters, without damaging the quality of the practice. Their objective is to support the normal hospitalization, so there should be a joint collaboration in making protocols of action, admission criteria and/or patients flow. In our study, many patients showed very complex chronic diseases or comorbidity, having success in many of the cases, without damaging either the average stay or the quality of the practice. This study shows the typical limitations of a descriptive and retrospective analysis. Even so, the average stay, comorbidities and the characteristics of the patients are very similar to those published in other studies.

V-104
NUTRITIONAL PARAMETERS ASSESSMENT IN A POPULATION WITH CHRONIC LIVER DISEASE

G. López Larramona, A. Lucendo Villarin, M. Angueira Lapeña, S. González Castillo, M. Casero Cano, J. Rodríguez Delgado

Department of Internal Medicine and Gastroenterology. Hospital General de Tomelloso. Ciudad Real, Spain.

Objectives: The aim of this study was to assess nutritional profile disorders in a group of patients with chronic liver disease (CLD), and its relationship with the coexistence of liver cirrhosis (LC) and hepatitis C virus (HCV) infection.

Material and method: A total of 108 patients, 61 (56.5%) males with a mean age of 56.2 + 13.2 years, were enrolled. 26 (24.1%) patients had liver cirrhosis and 27 (25%) had chronic HCV infection. The following data were collected: time from diagnosis of CLD, anthropometric data (body mass index, BMI) and analytical profile including haemoglobin, haematocrit, calcium, phosphor, prothrombin index, albumin, prealbumin and lymphocytes count (absolute level and perceptual value). Statistical analysis was performed with PASW 18 (SPSS Inc).

Results: The prevalence of nutritional profile disorders was higher among cirrhotic patients. Significant lower mean levels of hemoglobin in respect to non-cirrhotic group were detected (13.3 g/dL vs 14.6 g/dL, p 0.001), as well as for hematocrit (38.5% vs 42.5%, $p < 0.001$), prothrombin index (71.0% vs 104.2%, $p < 0.001$), seric albumin (3.7 g/dL vs 4.5 g/dL, $p < 0.001$), seric prealbumin (13.5 mg/dL vs 24.1 mg/dL, $p < 0.001$), absolute lymphocytes level ($1.720 \times 10^3/\mu L$ vs $2.361 \times 10^3/\mu L$, $p = 0.001$) and calcemia (9.0 mg/dL vs 9.3 mg/dL, $p = 0.001$). Patients with HCV infection had a longer time of disease from diagnosis and significant lower levels of seric albumin, prealbumin, total cholesterol, absolute level of lymphocytes and calcemia. The differences noted were sustained when patients with LC were stratified according to the coexistence of HCV infection.

Discussion: Our study shows a characteristic nutritional profile in individuals with LC, with lower levels of hemoglobin, hematocrit, albumin, prealbumin, lymphoytes count and prothrombin index. Such alterations were not conditionated by HCV infection in this population and may reflect an impaired liver function as well as an inadequate energy and nutritional intake. Their presence should alert internists about malnutrition as a complication in the clinical course of CLD.

Conclusions: Low nutritional parameters are present in patients with LC. The effectiveness of nutritional counselling and nutritional intervention in this group should be further evaluated.

V-105
THE EVALUATION OF INDICES RESULTING FROM HOSPITALIZATION IN A DEPARTMENT OF INTERNAL MEDICINE

F. Rodrigues, N. Vieira, M. Grade, P. Magalhães, C. Santos, L. Arez

Department of Internal Medicine. Centro Hospitalar do Barlavento Algarvio. Portimão, Portugal.

Objectives: The Charlson comorbidity index age adjusted (CCIaa) is frequently used like a measure of patient comorbidity. We describe in our study a validation of relationship between different comorbidites showed by patients admitted in an internal medicine department, using ICCaj scale, and mortality, duration of hospitalization and hospital re-admission rates.

Material and method: Observational, retrospective cross-cut analytical study, including all patients admitted in the Internal Medicine Department during five years (since 1/7/2005 to 30/6/2010). We calculated the CCIaa for each patient and the indices that showed the result of the admission (duration of hospitalization, hospital mortality, re-admission after 7 days and mortality index 30 days after discharge from hospital).

Results: We included 11211 patients, with median CCIaa 4.3 (± 2.5). The CCIaa was higher in patients who died during hospitalization (5.9 vs 4.0;$p < 0.001$), in readmitted patients after seven days (5.0 vs 4.0; $p < 0.001$), and in patients who died after 30 days after discharge (5.8 vs 4.0;$p < 0.001$). Time of hospitalization was proportional to CCIaa index (9.1 ± 11.5 days in patients with CCIaa < 2 vs 13.7 ± 13.5 days in patients with CCIaa > 7; $p < 0.001$). The different indices analyzed were directly proportional to stratified CCIaa index. In V stratified group the mortality index was 24.8%, the readmission rates was 9.0% and the mortality after 30 days of discharge was 7.4%.

Conclusions: The CCIaa index reflects the co-morbidity of our patients showing that it´s an important predictive index of duration and mortality during hospitalization, readmission rates after 7 days and mortality after 30 days after discharge. Patient´s

classification in an Internal Medicine Department with CCIaa index is an important predictor of result of hospitalized patients, that's why the authors suggest his utilization to show the admission complexity.

V-106
HOW TO REDUCE READMISSION IN COPD? GROUP FOLLOW UP VS CONTROL – 2011

X. Kortajarena, A. Berroeta, U. Errasti, M. del Hierro, M. Balenciaga, A. Aldalur, A. Larrañaga, B. Román

Department of Internal Medicine Dr. G. Zubillaga. Hospital Universitario Donostia UPV/EHU. Guipúzcoa, Spain.

Objectives: To compare Readmission rates of discharged COPD patients (Group Follow up) from the Hospital, followed monthly telephonically by Hospitalists for 6 months and another Group of patients (Group Control) not being followed by hospitalists. We expect to reduce readmissions due to better pharmacological compliance and non-pharmacological measures and higher quality of care provided after better co-management monthly.

Material and method: In 2011, we asked our Medical Record Department to provide us all the 227 COPD patients discharged from July until December 2010. Randomly, 117 of them were followed telephonically monthly during 6 months (Group Follow up), the other 110 patients were Group Control. Each patient was followed by the same Internist. In the Group Follow up, 27 were excluded (9 died prior to inclusion, 9 were not available in the provided phone, 4 refused, 3 were non COPD, 2 repeated); thus, we surveyed 90 patients. In the Group Control, 10 were excluded for similar reasons. 100 were followed at the end of the 6 month period; they were not followed monthly.

Results: The patients characteristics are shown in another Poster and were similar in both Groups. Below we express the admissions the 6 months before the study and the following 6 months either with Follow up telephonically or not.

Discussion: After Hospital discharge of COPD patients, the transitional care and continuity of care recommends periodic follow up either by primary physicians or/and co-managed by Hospitalist. The better quality provided and patient well being should follow less readmissions for COPD reagudizations.

Conclusions: The monthly telephonic follow up after COPD discharge did not reduce readmissions (p = 0.8) the following 6 months compared with the ones not being followed. There is always a reduction after discharge comparing with the 6 months before de study.

V-107
ANALYSIS OF A SEQUENCE OF CASES OF ACE INHIBITORS-ASSOCIATED ANGIOEDEMA

S. García Guerreros, R. Daroca, J. Peña, E. Ruiz de la Cuesta, J. Mosquera, E. Mozos

Department of Internal Medicine. Hospital San Pedro. Logroño. La Rioja, Spain.

Objectives: To analyze the characteristics of patients diagnosed with ACE inhibitors-associated angioedema.

Material and method: Descriptive retrospective study. Patients diagnosed in 2010 with ACE inhibitors-associated angioedema in our hospital. Inclusion criteria: ACE inhibitor take previous to the episode, absence of family history of angioedema, concordant complement levels.

Results: Described in table 1.

Discussion: ACE inhibitors-associated angioedema has an incidence of 0.1-1%. It is due to a decrease in bradykinin metabolism by ACE. It is more frequent with the first doses. As in our case sequence, it shows orofacial location and episodes are rarely severe. It is more common in African Americans, over the age of 65 years, surgery, or trauma prior to head or neck, kidney disease and allergy.

Conclusions: 1 Angioedema is a rare adverse effect of ACE inhibitors. 2. Attacks usually show facial location. 3. Airway

Table (V-106)

	Admission previous 6 months	Readmission next 6 months
Group Follow up 90 patients	131 admissions	58 admissions – 11 deaths (55% reduction)*
Group Control 100 patients	121 admissions	52 admissions – 8 deaths (57% reduction)*

*p = 0.8

V-108
EFFECTS OF SELENIUM SUPPLEMENTATION ON ETHANOL-INDUCED LIVER CHANGES IN A MURINE MODEL

M. Monedero Prieto, J. González Pérez, J. Medina García, E. González Reimers, F. de Armas González, J. López Prieto, E. Rodríguez Rodríguez, I. Hernández Betancor

Department of Internal Medicine. Hospital Universitario de Canarias. San Cristóbal de La Laguna (Tenerife), Spain.

Objectives: Some observations suggest that oxidative damage play a major role in alcohol-mediated liver alterations. Selenium, a potent antioxidant, is decreased in alcoholics The aim of this work is to analyse if the supplementation with selenium may alter liver changes observed in a murine model fed ethanol and/or a 2% protein-containing diet, following the Lieber-DeCarli design.

Material and method: Adult male Sprague–Dawley rats were divided into 8 groups, which received the Lieber-DeCarli isocaloric diets: a control diet; a 36% ethanol-containing diet, a 2% protein-containing diet; and a 2% protein and 36% ethanol-containing diet; other similar four groups to which selenomethionine (1 mg/kg body weight) was added. After sacrifice (5 weeks later), the following histological parameters (proportion of liver fat, fibrosis, nuclear area and hepatocyte area of at least 20 pericentral and 20 periportal cells) were histomorphometrically assessed; liver and serum selenium were determined by atomic absorption spectrophotometry. Serum albumin, ASAT, ALAT, and liver glutathione peroxidase (GSH) activity and malondialdehyde (MDA) content were also deter-mined.

Results: Liver fat accumulation was significantly reduced in the selenium-treated animals ($p = 0.012$), which also showed significantly increased GSH activity ($p < 0.001$), and a nearly significant trend to decreased MDA levels ($p = 0.056$). Hepatocyte ballooning was also reduced in the selenium-treated animals ($p = 0.006$). Significant relationships were observed between liver selenium levels and GSH activity (Rho = 0.33; $p = 0.01$), and negative ones with hepatocyte ballooning (Rho = -0.27), liver MDA (Rho = -0.29 and weight loss during the experiment (Rho = -0.38, $p < 0.05$ in all cases). No effect was observed on liver fibrosis.

Discussion: Some observations suggest that oxidative damage play a major role in alcohol-mediated liver alterations. Selenium, a potent antioxidant, is decreased in alcoholics. GSH activity is strongly dependent on Se. In our study, GSH activity showed a positive relationship with liver selenium levels, leading to decreased peroxidation and hepatocyte damage, but had no effect on liver fibrosis.

Conclusions: Our results support the existence of a beneficial effect of selenium supplementation on ethanol and/or protein-deficiency induced liver steatosis, lipid peroxidation and antioxidant status, but not on liver fibrosis.

V-109
HEREDITARY HEMOCHROMATOSIS: A SERIES OF 59 CASES

D. Cuervo Blanco[1], E. Fonseca Aizpuru[1], E. López Fernández[2], E. Rodríguez Avila[1], R. Fernández-Madera[1], J. Nuño Mateo[1], C. Blanco Cristóbal[3], J. Morís de la Tassa[1]

[1]Department of Internal Medicine, [2]Department of Gastroenterology, [3]Department of Biochemistry. Hospital de Cabueñes. Gijón (Asturias), Spain.

Objectives: Analyze clinical features and iron metabolism and overload in a sample of patients diagnosed of hereditary hemocromatosis (HH) in our hospital between January 2001 and December 2010.

Material and method: We conducted a descriptive a retrospective study of a simple of patients diagnosed of hereditary hemocromatosis (HH) in our hospital Hospital de Cabueñes (with a population of 300,000 inhabitants). When a mutation of the gen HFE was positive, the patient showed iron overload with high levels of ferritin or high transferrin saturation index and/or liver biopsy with typical changes the diagnosis of HH was done. We studied demographics, clinical, biochemical data and clinical course. Statistical Package for the Social Sciences (SPSS) was used for the analysis. Differences were significant when p value was < 0.05.

Results: Fifty nine were diagnosed with these criteria. Forty five were males (76.3%) and 14 m (23.7%) females. The mean age was 54 ± 16 years without significant differences. Homozygous C282Y mutation was the most frequent -49 (83.1%), followed by homozygous H63D in 2 (3.4%) and heterozygous C282Y-H63D in 8 (13.6%) patients. Concerning clinical data is remarkable that 16 patients (27%) complained arthralgias, 10 (17%) cardiomyopathies, 9 (15.5%) fatigue, 9 (15.5%) diabetes, 7 (11.9%) liver disease, and 4 (6.8%) hyperpigmentation. Twenty eight were asymptomatic. Ferritine levels were increased in 45 patients (76%), mean value 1207 ± 1,296 ng/ml. El transferrin saturation index was increased in 96.6% (57) patients, mean value 99 ± 34%. A story of alcohol abuse was collected only in 28 (47.5%) patients. Ethanol consumption was mild en 8 (28.6%), moderate in 16 (57.1%), and 4 (14.3%) patients referred high alcohol intake. Hepatitis virus serology was done in 42 (71%) patients. In 35 (83%) was negative and the others showed HCV chronic infection 2 (4.8%), HBV chronic infection 1 (2.4%) and 4 (9.5%) had HBV immunity. We investigated the relation among demographics, genotype, alcohol consumption, HCV & HBV infection and the level of iron overload, by using ferritine levels (high or normal) and transferrin saturation index (high or normal), and its values. It is remarkable the association between high ferritine levels (> 350 ng/mL) and male gender. Transferrin saturation index wasn´t significantly associated. Concerning ferritine levels we found a significant association with age -older than 45 years ($p = 0.027$), with genotype homozygous C282Y mutation ($p = 0.036$) and males ($p = 0.036$). When analyzing transferrin saturation index levels, we found a significant association with genotype homozygous C282Y mutation ($p < 0.001$) and alcohol consumption ($p = 0.029$).

Discussion: Clinical features, demographics and genotypes are similar to those previously published. We observed more asymptomatic patients due to the inclusion, in this study, of patients recruited through familiar screening of index cases diagnosed of hemocromatosis. Hereditary hemocromatosis is linked with high levels of genetic transmission, but associated with low levels of fenotipic expression. For an accurate and early diagnosis high level of suspicion is needed. Poblational screening is not recommended. Alteration of iron metabolism indexes (ferritin and transferrin saturation index) in males older than 45 years, associated with alcohol consumption are good markers of disease, and can help in the diagnosis of this entity.

Conclusions: 1. Our data is similar to previous published investigations.2. Accurate and quick diagnosis of this entity requires high level of suspicion, and males older than 45 years and with alcohol consumption should be immediately tested for iron overload.

V-110
MICRO ARN POLYMORPHISMS AND ALCOHOLISM

I. Novo Veleiro[1], M. Marcos Martín[1], S. Gómez Lesmes[1], C. Cieza Borrella[2], I. Pastor Encinas[1], R. González Sarmiento[3], J. Laso Guzmán[1]

[1]Department of Internal Medicine. Hospital Universitario de Salamanca. Instituto de Investigación Biomédica de Salamanca (IBSAL). Salamanca, Spain. [2]Department of Medicine Molecular. Department of Medicine. Universidad de Salamanca. Salamanca, Spain. [3]Institut of Molecular and Cellular Biology of the Cáncer (IBMCC). Universidad de Salamanca – CSIC. Salamanca, Spain.

Objectives: The aim of our study was to evaluate the prevalence of two micro-RNA polymorphisms (hsa-mir-196a2 and hsa-mir-146a) in a cohort of alcoholic patients to analyze their association with alcohol dependence and alcoholic liver disease.

Material and method: We conducted a case-control study including 308 alcoholic patients and 157 abstinent controls. Alcohol dependence DSM-IV criteria were applied to classify alcoholic patients as dependent or abusers. Diagnosis of alcoholic cirrhosis was made by hepatic biopsy or clinical criteria. DNA extraction was performed from a peripheral blood sample, by obtaining mononuclear cells and subsequent DNA purification and quantification. Allelic discrimination was performed by real-time PCR using TaqMan® SNP genotyping assays. Analyzed polymorphisms were: hsa-mir-146a C > G rs2910164 polymorphism and hsa-mir-196a2 C > T rs11614913 polymorphism. The relationship between each polymorphism and the presence of alcohol dependence or alcoholic cirrhosis was analyzed by the chi-square test, using Fisher's exact test when expected frequency was less than 5. SPSS statistical program version 18 was used. This work was supported by Grants GRS531/A/10 from Castilla-León Regional Government and PI10/01692 from Spanish Ministry of Science and Innovation and European Regional Development Fund "Una manera de hacer Europa".

Results: All alcoholic and non-alcoholic patients were male and mean age was 44.81 (SD = 11.54) years. Among alcoholics, 60% met alcohol dependence criteria and 33% of them had alcoholic liver cirrhosis. Genotype frequencies of mir-196a2 polymorphism were as follows: CC: 39.3%, CT: 49.6%, TT: 16.0% for alcoholics and: CC: 36.2%, CT: 52.6%, TT: 11.2% for controls (p = 0.190). No statistically significant differences were found when comparing cirrhotic patients (CC: 43.0%, CT + TT: 57.0%) with non-cirrhotic patients (CC: 37.0%, CT + TT: 63.0%) (p = 0.319) or when comparing alcohol dependent patients (CC: 50.0%, CT+TT: 50.0%) with alcohol abusers (CC: 34.0%, CT+TT: 66.0%) (p = 0.108). Genotype frequencies of mir-146a polymorphism were: GG: 51.5%, CG: 40.7%, CC: 7.8% for alcoholics and GG: 64.0%, CG: 29.0%, CC: 7.9% for controls (p = 0.024), and an association between the presence of allele C and alcoholism was found in our study (alcoholics: 48.5%, controls: 36%, p = 0.023). We did not found any statistically significant difference when comparing cirrhotic (GG: 55%, CG + CC: 45%) and non-cirrhotic patients (GG: 48.5%, CG + CC: 51.5%) (p = 0.511) or when comparing alcohol dependent patients (GG: 54.5%, CG + CC: 45.5%) with alcohol abusers (GG: 48.5%, CG+CC: 51.5%) (p = 0.460).

Discussion: hs-mir-146a and hs-mir-196a2 polymorphism have been associated with different diseases, such as gastrointestinal cancer. The expression of these micro-RNAs regulates NFKB-mediated inflammatory response pathways activation and its association with liver fibrosis among alcoholic patients has been previously suggested. Mir-146a expression is also associated with inflammatory response in glial brain cells of alcoholic patients.

Conclusions: Our study demonstrates for the first time an association between mir-146a rs2910164 polymorphism and alcoholism. Further studies are necessary to apply these findings in the early diagnosis and individualized treatment of these patients.

V-113
OXYGEN THERAPY: AN UNDERVALUED PRESCRIPTION

M. Sousa, I. Fontoura, J. Lemos, A. Vaz, B. Rodrigues, F. Girão

Department of Internal Medicine 1. Centro Hospitalar Tondela-Viseu. Viseu, Portugal.

Objectives: Oxygen (O_2) is essential for the treatment of hypoxemic respiratory failure and is often used in medical wards. However, several studies have shown that the procedure is not always followed correctly and thoroughly, and the potential risks are underestimated. The main objective of this prospective study was to evaluate oxygen therapy procedures in an Internal Medicine Service, to identify the main errors and to plan strategies to solve them.

Material and method: The audit was carried out between February 21 and June 6, 2012, with checks performed on one randomly chosen day each week. All patients admitted to the Internal Medicine Ward 1 with oxygen therapy prescription or under administration of oxygen were included and data collected regarding the initial assessment, prescription, monitoring and administration of oxygen. The procedures were compared to criteria established by the British Thoracic Society in "BTS guideline for emergency oxygen use in adult patients".

Results: 257 episodes of oxygen therapy were audited. It was medically prescribed in 95% of cases, but only 68% were initially assessed for their oxygen saturation (FiO_2) by pulse oximetry or blood gases sample. The most common type of prescription was by fixed dose (53%), but none defined all the required parameters. The most frequently missing information was that relating to the duration of therapy (97%) and the delivery system (59%). All patients were monitored and in 60% of the cases this corresponded to what had been prescribed. Only 60% of patients were administered oxygen with a fixed-dose prescription; the flow rates and delivery systems were different from those that had been prescribed in 51% and 34% of cases, respectively. Of the 114 patients with prescriptions by oxygen target saturation, 89% presented values in the defined range. In the 14 patients without a medical prescription for oxygen therapy, the main reasons to explain this was that it was been given according to verbal instructions by the doctor (36%) and on the initiative of the nursing staff due to low SPO_2 (36%). In 28% of cases there was no reason given.

Discussion: The results show that the procedures for oxygen therapy continue to present serious omissions. The main problems were incomplete fixed dose prescriptions and the administration of flow rates which were different from those prescribed. Prescriptions for oxygen target saturation, defined by BTS as the most appropriate, remain below 50%, although the results presented here are better than those of recently published studies.

Conclusions: The need to evaluate and improve the quality of oxygen therapy is emphasized.

V-115
SPLENECTOMY IN UNCOMMON MEDICAL DISORDERS

M. Hernández Meneses[1], A. Conde Martel[1], J. Marchena Gómez[2], J. Casimiro Pérez[2], R. Gianchandany[2], M. Serrano Fuentes[1], A. Martín Plata[1]

[1]Department of Internal Medicine, [2]Department of General Surgery. Hospital Universitario de Gran Canaria Dr. Negrín. Las Palmas de Gran Canaria, Spain.

Objectives: Non-traumatic, non-hematologic disorders are infrequent indications for splenectomy that are usually grouped in a long list of very rare medical conditions. The purpose of this study was to analyze these uncommon non-surgical disorders in which a splenectomy was indicated.

Material and method: A series of 152 non-traumatic splenectomies performed between 1996 and 2010 in a tertiary care center was retrospectively studied. Hematologic diseases, benign and malign neoplasms, and portal hypertension disorders, were excluded. The remaining 12 patients were analyzed. Clinical data, indication for splenectomy, histological findings, morbidity and mortality from this sample were recorded.

Results: Out of the 12 patients, 9 were male and 3 were female, with mean age of 44.3 years (SD ± 20.3). The indications for surgery were fever of unknown origen and/or splenomegaly and/or hypersplenism (9 cases), spontaneous splenic rupture (2 cases), and peritonitis (1 case). The spleen was enlarged in 6 patients (50%) and 9 patients (75%) were diagnosed of hyperesplenism. A infectious disease was diagnosed in 6 patients: splenic abscess due to Salmonella (1 case), unspecific splenic abscess (1 case), Leishmaniasis (1 case), Chronic granulomatous disease (1 case), Mycotic splenic artery aneurysm (1 case), and splenic atypical mycobacterial disease (1 case). Another 6 patients were included in a miscelaneous group: amyloidosis (1 case), non-specific lymphoid hyperplasia (3 cases), disseminated lupus erythematosus (1 case), and Wegener's granulomatosis (1 case). The mean size of the removed specimen was 16.2 cm (SD ± 5.7), and the mean weight 573.8 g (SD ± 573.9). The overall postoperative complications rate was 50% (6 patients). One patient required an invasive procedure, and 2 patients required reoperation. The operative mortality was 8% (1 patient diagnosed of amyloidosis). All the remaining patients were discharged from hospital in good conditions.

Discussion: Only a few studies have evaluated the findings after a splenectomy by medical conditions excluding hematologic disorders. In fact, splenectomy may be indicated in a wide range of infrequent medical disorders, that should be taken into account and it may be the only method to achieve a diagnosis in a patient with fever of unknown origin. In some occasions spontaneous splenic rupture may be the first manifestation of the subjacent disease.

Conclusions: A wide range of diagnosis can be performed by splenectomy. In spite of a relatively high morbidity of the procedure in this subgroup of patients, the results in the survivors are excellent.

V-116
MINORITARY DISEASE UNIT IN THE SETTING OF PRIVATE HOSPITAL: FIRST YEARS OF EXPERIENCE

X. Herranz Pérez, S. Martín Fuste, L. Sánchez Sitjes, R. Serrano Morales, M. García Cors

Department of Internal Medicine. Hospital General de Catalunya. Sant Cugat del Vallés (Barcelona), Spain.

Objectives: Report the experience of a minoritary disease unit in the setting of a private hospital.

Material and method: Review of clinical records of patients where minoritary disease unit has intervened in any aspect.

Results: Since specific unit for management of minoritary diseases has been created: 1. Ehrlich reactive and Hoch test have been established for acute porphiric crisis screening. 2. Urine porphirine determination has been standardized. 3. Plasma amonium levels has been introduced and standarized in emergency laboratory determinations. 4. Plasma amonium measurement has been introduced in the methabolic coma of uncertain origin protocol in ICU. 5. A screening protocol for lysosomal disease in newborns has been started in cooperation with pediatry department. 6. In patients affected of hypertrophic myocardiopathy of unknown origin, early stroke o haemathologic alteracions, has been standarizaed screening for Fabry disease. 7. These changes in protocols and working strategies have lead to diagnosis of an ornitine-transcarbamilase defficiency, 2 cases of acute porphyria. 8. Five cases of mastocytosis had been molecular diagnosis. 9. Two families with Birt-Hogg-Dubbe syndrome have been identified.

Discussion: There have been twelve sessions with other clinical services by increasing awareness of rare diseases. We have worked on networking with other centers for metabolic and genetic. We created node knowledge of rare diseases in an environment that previously did not exist.

Conclusions: The knowledge of rare diseases early diagnosis increases. The existence of reference units in rare diseases is also needed in private centers.

V-117
SCREENING OF CELIAC DISEASE IN AN INTERNAL MEDICINE DEPARTMENT

I. Torres Courchoud[1], M. Sánchez Marteles[1], M. Rodero Roldán[1], A. Gascón Martín[1], M. Aibar Arregui[1], L. Royo Trallero[1], P. Lasierra Díaz[2], F. Ruiz Laiglesia[1]

[1]Department of Internal Medicine, [2]Department of Clinical Immunology. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: To assess the main consultation reasons before starting a Celiac Disease(CD)screening in Internal Medicine (IM). To analyze the CD diagnosis process carried out in Internal Medicine.

Material and method: We performed a retrospective study of patients who have been determined HLA and/or Antitransglutaminase IgA, Antireticulin Ig A, Antigliadin IgA and IgG, Antiendomysium IgA, for CD screening in IM Department of "Lozano Blesa" HCU (Zaragoza), during 2011.We looked trough laboratory and clinical data of these patients. We excluded patients who had been previously diagnosed with CD.

Results: The total patients were 160. 97 were women (60.62%) and 63 men (39.37%). The oldest was 91 and the youngest 16, and a mean age of 55,122 patients (76.25%) were older than 40. Serology was requested to 145 patients (90.62%); 47 of them lacked the IgA antitransglutaminase determination. HLA was studied in 74 patients (46.25%) and was the only study in 15 patients (9.37%). 52 patients (32.5%) underwent gastroscopy and duodenal biopsy.26 patients met CD diagnosis criteria by Marsh classification. Only two, were serologically positive.

Discussion: Diagnosis of CD are increasing in adulthood. Our study is consistent with this hypothesis, as the suspicion of CD diagnosis in our department is high in adults older than 50 years. In this group, atypical forms are common, as it was in these 26 patients, with compatible biopsy to CD according to Marsh classification. Screening CD, includes an initial serologic testing, followed by duodenal biopsy confirmation. In our patients, serology testing was carried out in 90.62%, and biopsy confirmation in 32.5%. HLA determination is useful in patients with negative serology and high clinical suspicion, due to its high negative predictive value for diagnosing CD. In our study we determined HLA to 74 patients (46.25%), and this data was probably somewhat elevated.

Conclusions: 1. Consultation reasons which developed starting CD screening in our IM department are varied, being iron-deficiency anemia the predominant, and later, other atypical manifestations as vitamin B12 deficiency and hypertransaminasemia. 2. The mean age of patients studied and diagnosed is 55 years, most of them as paucisymptomatic or latent CD, which is a late diagnosis of this disease.

V-119
EARLY DETECTION PROGRAM OF PATIENTS WITH HIGH-RISK IN CONVENTIONAL HOSPITALIZATION AREA WITH THE AID OF A COMPUTER SYSTEM

L. Cabeza Osorio[1], A. Abella Álvarez[2], J. Sicilia Urbán[1], E. Lozano Rincón[1], M. Díaz Blázquez[2], I. Torrejón Pérez[2], D. García Lorenzo[1], V. Enciso Calderón[2]

[1]Department of Internal Medicine, [2]Department of Intensive Care. Hospital Universitario del Henares. Coslada. Madrid, Spain.

Objectives: To describe a program of early detection and intervention of patients at high risk with the help of a owner computer application, in cooperation with the intensive care department within the project "ICU without walls".

Material and method: We design a descriptive study between July 2011 to April 2012. On business days, daily computer generated reports were produced of certain analytical data from the laboratory studies which have been altered according to predefined values. This data was requested by the hospital from the previous 24 hours. These analytical parameters are those considered "relevant" for the early detection of diseases in which intervention time is critical, such as sepsis, acute coronary syndrome and respiratory distress (Troponin I > 0.3 µg/L, pH < 7.30, pCO_2 > 60 mmHg, platelet count < 100,000/µL, lactate > 3 mmol/l). Subsequently, the partners of internal medicine and intensive care review the medical records of patients detected by the software who selected those considered at probable high risk on clinical records. However, it should be in accordance with the physician in charge of the patient who decides which one of these "interventions" is appropriate: confirmation of clinical stability, close monitoring in the next hours, therapy adjustment, diagnostic approach, early admission to ICU, or limitation the life-sustaining treatment (LLST).

Results: During the study period, the software detected 1081 analytical alterations, corresponding to 872 patients. After reviewing the medical records, 210 cases were selected and were joined by 33 patients detected by clinical data. 113 (46.5%) were females with a mean age of 66.4 years (range 15 to 92) with an average SOFA 3.3. The majority of the patients were in the emergency room (61.3%) followed by conventional hospitalization in 89 patients (36.6%). The analytical data altered was: pCO_2 in 60 cases, with a mean value 69.3 (range 60 to 105), pH in 38 cases, with mean value 7.25 (range 7.08 to 7.29), platelets in 49 cases with mean value 62,000 (3,000-99,000); troponin I in 39 cases, with mean value 1.8 (range 0.34 to 12.2), and lactate in 57 cases with mean value 4.8 (range 1.4 to 12) The most frequent pathology found was: respiratory failure in 79 patients (32.5%), followed by sepsis in 68 patients (28%), cardiological in 25 patients (10.3%), abdominal in 25 patients (10.3%), neurological in 21 patients (8.7%), hematological in 12 patients (4.9%), renal in 11 patients (4.5%), metabolic in 1 patient (0.4%) and shock in 1 patient (0.4%). The "intervention" was: to confirm clinical stability in 152 cases, medical follow-up during an on call doctor in 42 cases, modification of treatment in 28 cases, diagnostic approach in 54 cases, early admission to the ICU in 12 cases, and LLST decision in 60 patients. 19 patients died (7.8%) but more than half (12 to 63.1%) had previously agreed LLST.

Discussion: Early identification and treatment of patients at high risk is of great importance in diseases such as sepsis, coronary disease or respiratory failure. This task is not always easy and it is important to use all resources available to us. There are advantages associated with electronic medical records and the development of specific software to detect high risk markers, in conjunction with the close collaboration between services. In our case it would be desirable to have sufficient infrastructure to extend the work described to all days of week.

Conclusions: Close collaboration between intensive care and internal medicine in a program as described can contribute to improving healthcare quality during hospitalization. This reduces morbidity and mortality, through better management of healthcare resources.

V-120
DOES THE EDUCATIONAL LEVEL INFLUENCE THE PATIENTS SATISFACTION?

C. Silva, A. Neto, A. Barbosa, A. Oliveira, M. Sequeira, V. Paixão Dias

Department of Internal Medicine. Centro Hospitalar de Vila Nova de Gaia/Espinho, EPE. Vila Nova de Gaia, Portugal.

Objectives: To determine if the educational level is most likely to influence satisfaction with care in Internal Medicine hospitalizations.

Material and method: The study was based on a sample survey, using a structured questionnaire developed for this purpose, with the Likert attitude scale. The study sample consists of all the patients discharged from an Internal Medicine ward between 1st and 30th September 2011. The different closed response items had a evaluation between 1 and 5 (1 for very bad and 5 for very good). The educational level was stratified based in schooling: basic (until 9th grade), secondary (until 12nd grade) and higher (university degree). The items evaluated were the health professionals, the image and facilities of the department, as well as food, transports and diagnostic exams. The data were analyzed in a quantitative perspective, using the SPSS (Statistical Package for the Social Sciences), version 19.

Results: During the period of time covered by the study, there were 284 episodes of discharge from our department; the answer rate was 78% and the average age was 63 years, with 51.3% of male patients. The users with the basic educational level answered in average above 4 for all the items giving higher scores to the majority of items, comparing with the other groups. There were statistical differences regarding the evaluation of transports ($p = 0.045$), food ($p = 0.001$) and security staff ($p = 0.003$), being the lower scores given by the users with higher schooling.

Discussion: Several aspects are described as being most likely to influence satisfaction with health care provision, and the educational level seems to be one of them. The evidence suggests that users with lower educational levels presents more satisfaction with health care.

Conclusions: The educational level may influence the users satisfaction regarding health care provision and their opinion can be used as an indicator for monitoring the quality of health services.

V-121
CHARACTERISTICS OF CELIAC DISEASE IN AN INTERNAL MEDICINE DEPARTMENT

I. Torres Courchoud[1], M. Sánchez Marteles[1], M. Rodero Roldán[1], A. Gascón Martín[1], M. Serrano Herrero[1], M. Búcar Barjud[1], P. Lasierra Díaz[2], F. Ruiz Laiglesia[1]

[1]Department of Internal Medicine, [2]Department of Clinical Immunology. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: To evaluate the clinical, immunological and histologic diagnosis process of Celiac Disease (CD) in an Internal Medicine (IM) department.

Material and method: We performed a descriptive study based on patients who met histologic diagnostic criteria of CD in the duodenal biopsy according to Marsh classification. The data were obtained through the review of serologic tests (antigliadin,

antiendomysium, antireticulin and antitransglutaminase) and/or genetic study (HLA) forCD screening, requested from the IM Department of "Lozano Blesa" Hospital (Zaragoza) during 2011.We obtained 160 patients considered suspected cases. We excluded patients who had been diagnosed as CD, previously to this period. Duodenal biopsy results, were classified according to Marsh classification, choosing the higher degree.

Results: The total patients diagnosed with CD was 26. 15 were women (57.69%) and 9 men (34.61%). The youngest was 18 and the oldest 83, with a mean age of 50.5 years. Half of patients (13) were under 50. The main consulting reason was extraintestinal (anemia) and the second one was intestinal (diarrhea). Serologic testing was requested in all patients; 2 of them (7.69%) had autoantibodies high titers. HLA was determined in 23 patients (88.46%):18 were HLA DQ2 and/or DQ 8. These 26 patients had histologic criteria of CD according to Marsh classification. 24 patients (92.30%) fulfilled criteria of pauci-symptomatic or silent forms. Gluten-free diet (GFD) was prescribed to 21 patients and after 6 months follow-up, 17 showed clinical improvement and 15 analytical improvement.

Discussion: CD is in frequently diagnosed in adulthood in these days, as in our study, in which 26 adult patients (50% older than 50) present diagnostic criteria for CD according to the latest protocols. The proven histological intestinal lesion remains the gold standard for diagnosing CD, although classically Marsh grade I was considered a latent form and not associated with symptoms or complications. However, recent evidences show that this form can present them with the same frequency as the atrophy villous forms. Pauci-symptomatic and Latent CD forms are defined as seronegative forms with atypical symptoms with villous atrophy or mild enteropathy respectively. In our study, 92.30% of the patients fulfilled criteria of pauci-symptomatic CD, who probably would not have been diagnosed decades ago. Currently diagnosis of these CD forms have risen. That is consistent with data obtained in our study. According to literature DQ2/DQ8 HLA is associated with CD in 95% of cases and it is possible to discard it, if we have another HLA, because of its high negative predictive value. 6 of 26 patients (23.07%) presented different HLA DQ 2 nor DQ8, which supports the hypothesis that some of these patients labeled as CD, are not a really gluten-sensitive enteropathy, but other enteropathy, or maybe we are in the way of accurate knowledge of the pathophysiology of this entity.

Conclusions: 1. Half of patients, with histologic criteria of CD in duodenal biopsy, are over 50 years 2. 92.30% are pauci-symptomatic or latent CD forms 3. An important percentage of patients in our study have HLA unrelated to CD.

V-122
PATIENT COMPARATIVE STUDY ADMITTED ON CRITICAL CARE UNIT (CCU) REFERRED FROM MEDICAL AREA (MA) RELATED TO PATIENTS REFERRED FROM SURGERY AREA (SA) ON AS SPECIALIZED HOSPITAL FROM SAS

V. Lechuga Flores, G. García Domínguez, O. Mera Gallardo, V. Manzano Román, R. Aranda Blázquez, G. Ruiz Villena, M. Guzmán García, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Puerto Real (Cádiz), Spain.

Objectives: Identify patients clinical profile referred from MA admitted on CCU difference with SA referred patients during 9 months between 2011-2012.

Material and method: We included patients admitted on CCU during that period and referred from MA/QA. Variables studied: age, sex, reason for admission, hospital stay time, cardiovascular risk factors (CVRF), associated pathology, deaths as well as diagnosis discharge and destiny service. We used χ^2 test by SPSS statistical program to analyze results, and design a descriptive chart study.

Results: 105 patients (330 admitted on ICU). The 74.3% referred from MA, average age of 62, men 75.6%. Average hospitalization time was 3.9 days proceeding from Cardiology (C) and Internal Medicine (IM)16.7%, transfer from another CCU 19.2%, Interhospital transfer 10.3%, Neumology (NM) and Digestive (D) 9%, Nephrology (NF) 7.7%. Admission Diagnosis was Acute Coronary Syndrome (ACS) 32.1%; Respiratory failure (RF) 9% followed by PTCA, stroke, surgery complication, severe acute pancreatitis all 5.1% and 3.1% serious NAC among other. CCU average time stay 6.7 days, 32.1% died. 21.8% were smokers, 6.4% out-smokers. Drinkers 21.8% and out drinkers 3.8%. Suffered DM 38.5%, HBP28.2% and DLPM 24.4%. 47.4% were sufferingfrom Myocardial Ischemia (MI), chronic obstructive pulmonary disease (COPD) 44.9%, Heart Failure 23.1%, CRI 12.8%. Obesity 11.5%. Most prevalent Discharge diagnosis was MI 32%, Stroke 9%; PTCA complicated 7.7%, Respiratory Failure 7.7%, severe pneumonia 5.1%, Anoxic encephalopathy, severe acute pancreatitis, and Urinary sepsis and Hypovolemic shock by HDB 3.8%. Target services were C 29.1%, IM 16.4%, transfer to other ICU 23.7%, transfer Hospital and NM 5.5%, D, Neurology and Hematology 3.6%.22.9% (24) were from QA, with an average age of 63 men 74.1%. Time hospitalization average on floor of 7.81 days, being original service Surgery (S) 63% followed by Urology (UR) on 14.8%, Gynecology (GI) 11.1%, otorhinolaryngology (ORL) 7.4% and Traumatology (TR) 3.7%. The reason for admission on CCU was on 48.1% a complicated surgery, sepsis 18.5%, RI 14.8%, MI7.4%. Average time spent on ICU 5.89 days with 14.8% mortality. 25.9% of sample smoke or did smoke before. Drinkers 14.8% and out-drinkers 7.4%. DM 33.3%, 14% DLPM and HBP 22.2%. Obesity 11.1%, COPD 37%, MI 33.3%, 25.9% suffered from oncologic pathology and heart failure 22.2%. Diagnosis discharge was surgery complication on 37% followed by abdominal sepsis, resulting 14.8% and 7.4% severe pneumonia, among others. Most prevalent service discharge was S 60.9%, IM 13% GI 8.7% followed by C, ORL, TR, and UR in a 4.3%.

Discussion: Patients from MA have a longer stay on CCU, higher probability of death (χ^2). Usually men, 62 years old, most from S, C, and IM, due secundary surgical complications, MI and severe respiratory failure. Return to MA although they come from QA 13% based on need for holistic care of these patients.

Conclusions: It is increasing the necessity to perform a comprehensive patient assessment on base to complications and pluripathology appearance. This comorbidity is disbalanced which, at time, makes necessary a treatment on ICU. Internal medicine professional based on his global view is able to deal clinical management and prevention of complications appeared on these patients.

V-123
ACUTE POISONING BY PARAQUAT. A 30-YEAR MULTICENTER STUDY

F. Laynez Bretones[1], G. López Lloret[1], S. Domingo Roa[1], P. Sánchez López[1], A. García Peña[1], C. Maldonado Úbeda[1], C. Lozano Padilla[2], F. Díez García[1]

[1]Department of Internal Medicine. Complejo Hospitalario Torrecárdenas. Almería, Spain. [2]Department of Clinical Management Bajo Andarax. Distrito Sanitario Almería. Almería, Spain.

Objectives: To describe our series of patients poisoned by paraquat that have been treated at the hospitals of the province of Almería in the last 30 years.

Material and method: A retrospective study developed between 1982 and 2011 in the three public hospitals of the province of Almeria: Torrecárdenas (Almería), Poniente (El Ejido) and La Inmaculada (Huércal-Overa). We included all patients treated at

the 3 hospitals for acute poisoning by paraquat. The diagnosis was made by the contact proved with the toxic and the presence of symptoms and signs attributable to it.

Results: During the 30-year study, 47 patients were admitted to our hospitals for acute poisoning by paraquat. 68% of those poisoned was males. The middle ages were 37.2 years. The route of entry of the toxin was digestive in all the cases. The poisoning was voluntary in 42 patients (89%); of these patients, 62% had a psychiatric history. The most frequent symptoms were: abdominal pain (95%), vomiting (94%), sore throat (78%) and dyspnea (63%). The most frequent complications were: respiratory failure (96%), renal failure (70%) and liver failure (57%). 42 patients died (89%). The most common cause of the death was the multiorganic failure (73%). The average time being the ingestion of toxic and the death was 42 hours. 5 survivors patients developed pulmonary fibrosis.

Discussion: Paraquat is an herbicide that has been used often in agricultural areas, particularly in the cultures under plastic of Almeria (Spain). Due to its high toxicity to humans, the commercialization of paraquat was prohibited inside the area of the European Union in July, 2007. The route of entry of paraquat in humans is the digestive tract, and symptoms of poisoning are located preferably in this area. The intoxication with high doses of toxic causes death within hours. Poisoning with less toxic lead the patient to respiratory failure and multiple organ dysfunction and subsequently death. The mortality of paraqat poisoning over 90% in all series.

Conclusions: 1) We present the largest case series of acute poisoning by paraquat in Europe. 2) The poisoning was digestive in all cases, and with suicide attempt in 89%. 3) The mortality of the series was 89%, being the most frequent common cause of death the multiorganic failure. 4) The 5 surviving patients developed pulmonary fibrosis.

V-124
A COMPARISON OF MISCONDUCT POLICIES AT TOP-RANKED PEER-REVIEWED BIOMEDICAL JOURNALS

C. Hernández, J. Pericás, P. Doti, X. Bosch

Department of Internal Medicine. Hospital Clínic of Barcelona. University of Barcelona. Barcelona, Spain.

Objectives: We determined the research misconduct (MSC) policies among top-ranked biomedical journals from different disciplines.

Material and method: We selected 399 peer-reviewed journals of biomedicine and life science specialties from 27 categories and included the 15 top-rated journals of each category rated by the 2010 Impact Factor (IF) published by the Institute for Scientific Information Journal Citation Reports. No title overlapped between categories. We only included original research-publishing journals. Two different authors independently reviewed each journal website to find out any relevant information to MSC including definitions, procedures for responding (PR) to MSC allegations and the use of antiplagiarism software (APS). We also analyzed whether journals belonged to any Editorial Association (EA) with MSC guidelines (e.g., COPE), professional associations and publishers. Data were analyzed using the SAS 9.1 statistical system.

Results: 69.9% of journals mentioned the term 'misconduct' in their website and 35.1% provided a definition of MSC. Specific definitions of MSC types included falsification (F) (28.3%), fabrication (FB) (26.1%), plagiarism (P) (56.1%), duplication (D) (60.7%), and image manipulation (IM) (38.6%). 44.9% journals had PR and 28.1% claimed to use APS. 59.9% of all journals belonged to any EA, with 68.9% of European journals belonging to any EA vs 53.2% of US journals ($p = 0.004$). Considering the EA separately, these differences were only significant for COPE ($p < 0.001$). When comparing journals belonging or not to some EA, we found significant differences with regard to mention and definition of MSC, F, FB, P, D as well as PR, IM and APS ($p < 0.05$ in all). When considering the EA separately, the differences were significant for ICMJE, COPE and ORI, except for APS, where differences were significant for COPE only ($p = 0.007$). When comparing US vs European journals, there were no significant differences regarding any of the variables analyzed except for APS, which was more commonly used by European journals ($p = 0.014$). For IM, 38.6% of journals considered it as MSC. 71.4% of journals with an IM policy vs 52.9% without it belonged to some EA ($p < 0.001$), with significant differences for ICMJE, COPE and ORI. The most represented publisher among the journals analyzed was Elsevier (22.6% of all journals). 67.5% clinical vs 45.7% basic journals belonged to some EA ($p < 0.001$), with significant differences for ICMJE ($p < 0.001$). 51.6% basic vs 37.4% clinical journals had PR ($p = 0.018$), with significant differences for retraction ($p = 0.008$) but not for expression of concern ($p = 0.816$). Also, 41.9% basic vs 30.9% clinical journals included IM as a MSC policy but differences were not significant ($p = 0.058$).

Discussion: A high proportion of the analyzed journals included some reference to MSC but only 35.1% of journals provided a detailed definition, with 28.3% and 26.1% including F and FB definitions in their websites, respectively. This finding contrasts with the relatively high proportion of journals having PR (almost a half of them). Although we found differences in the way journals adhere to the EA recommendations depending on the category, region, publisher, contents (basic vs clinical) or belonging or not to an EA, we did not find differences regarding the IF. Moreover, complying with single EA principles does not ensure that all recommendations to avoid MSC are accomplished.

Conclusions: MSC policies among peer-reviewed journals vary widely. The fact of belonging or not to an EA is the most relevant factor accounting for the existence of MSC policies. The finding that only about 35% journals define MSC and 45% have PR means that a big effort remains to be done to ameliorate MSC policies and their application by most biomedical journals.

V-125
PREVALENCE OF ATRIAL FIBRILLATION IN GENERAL POPULATION AND AMONGST 2011 HOSPITAL ADMISSIONS IN THE AREA OF MARINA ALTA

P. Martín Rico, A. Valdivia Pérez, N. Lozano Cortell, A. Calcedo Ascoz

Hospital Marina Salud Denia. Denia (Alicante), Spain.

Objectives: Description of the prevalence of atrial fibrillation (AF) in the community of our Health Area of 170,000 inhabitants. Analysis of the prevalence of AF as Principal or secondary diagnosis in all 2011 medical admissions and comparative analysis of age, comorbidities, mortality and lenght of stay.

Material and method: Data for diagnosis of AF in the community was extracted from the Primary Care Electronic Medical Record (EMR) in our area. For admissions the data base was the Minimum Basic Data Set (MBDS) using ICD-9-CM code for atrial fibrillation to identify it as principal or secondary diagnosis both in absolute figures and percentages. They were compared for sex, age, morbidity, mortality and length-of-stay.

Results: Our Health Area attends 171,348 citizens. The diagnosis of AF is registered in the EMR in 2,173 (1.27%). In 2011 there were 4,033 medical admissions in our Hospital. 15.8% (639) of patients admitted had AF, 103 (2.6%) as principal diagnosis and 536 (13.3%) as a comorbidity Median age for all admissions was 71 (IQR 59-80). Patients with AF were older than those without it (78, IQR 72-83) (Mann-Whitney, $p < 0.001$). 41.84% were women. There was no significant difference in proportions of AF for gender (chi square,

p = 0.196). Death occurred in 7.47% of the analyzed admissions. FA as a comorbidity was more frequent in admissions resulting in death than in the rest (18.3% vs 12.9%) (chi square, p = 0.008). The median length-of-stay for those without AF as a comorbidity was 5 days (IQR 3-8) while in those with AF it was longer, 6 days (IQR 3-9.5) (Mann-Whitney, p < 0.001). The main principal diagnoses associated to AF as a comorbidity were: heart failure (15.5%), occlusion of cerebral arteries (10.1%) and ischemic cardiopathy (9.0%; for acute myocardial infarction: 3.7%). The relative risk for admission in the population with AF was 11.9 (95%CI: 10.9-13.1) when compared to the population without AF comorbidity.

Conclusions: 1. AF prevalence in our Area is slightly superior to that estimated in the Spanish general population (0.4-1%), perhaps due to our greater population over 65 years of age. 2. We can identify its association with aging and the great number of admissions in which AF is present either as the principal cause or as a comorbidity and how AF accompanies a longer length-of-stay and a higher mortality. 3. We can consider AF as a high risk marker for hospital admission and therefore insist in the assessment of its correct management and consider its inclusion as a criterion in our program for chronic patient management.

V-126
USE OF A MARKER OF LIPID PEROXIDATION IN BONE-MUSCULAR DISEASE

J. de la Higuera[1], A. Ramos[2], M. Gómez[2], V. Díaz[2], M. Salinas[2], D. García-Machuca[2], T. Nestares[3], M. López-Frías[3]

[1]Department of Internal Medicine. Hospital Clinico San Cecilio. Granada, Spain. [2]Department of Physiology. Instituto de Nutrición (INYTA). Granada, Spain. [3]Department of Physiology. Universidad de Granada. Granada, Spain.

Objectives: The aim of the study was determining the lipidic peroxidation in patients diagnosed bone-muscular pathology.

Material and method: A total of 77 subjects were recruited for the study. A group (n = 55) consisted of outpatients with bone-muscular pathology diagnosed by functional and clinical variables in a Rehabilitation Clinic. This was compared with a control group (n = 22) consisted of healthy subjects. Blood was drawn to obtain plasma and its lipid peroxide content was determined as thiobarbituric acid-reactive substances (TBARS) (Orrenius et al, 1977). Plasma protein content was measured according to Lowry (1951) using bovine serum albumin as standard. Student's t test for independent samples was used to determine significant differences between groups, using the SPSS software version 19.0.

Results: There was a significantly greater lipid peroxidation (p = 0.000) in the subjects with bone-muscular pathology regarding with healthy subjects.

Discussion: Results suggest that the free radical process of lipid peroxidation could be involved in the pathogenesis of bone-muscular disease. In fact this pathology is commonly associated with inflammation, a process which rise free radicals levels promoting lipid peroxidation (Rosanna and Salvatore, 2012) Moreover oxidized lipids induce cytokines expression (Berliner et al., 1995; Van Lenten et al., 2001) which, together other factors, might inhibit osteoblastic differentiation and increase osteoclastic activity. At this way it produces bone loss which usually worse with the disease (Frye et al, 1992; Parhami et al, 1997; Manolagas et al, 2000).

Conclusions: Our results indicate a possible greater oxidative stress associated with the bone-muscular disease which could indicate acute inflammatory activity.

V-127
AUTHORSHIP CRITERIA, CONFLICTS OF INTEREST DISCLOSURES AND GHOSTWRITING IN PEER-REVIEWED BIOMEDICAL JOURNALS: CURRENT SITUATION

J. Pericás, C. Hernández, P. Doti, X. Bosch

Department of Internal Medicine. Hospital Clínic of Barcelona. University of Barcelona. Barcelona, Spain.

Objectives: We investigated how top-ranked peer-reviewed biomedical journals handle authorship criteria (ASC), conflicts of interest disclosures (CoI-DS) of authors and editors and ghostwriting (GW).

Material and method: We performed a detailed study of websites of the 15 top-ranked journals according to the 2010 Impact Factor (IF) published by the Institute for Scientific Information Journal Citation Reports of 27 different categories in biomedicine and life sciences. No title overlapped between categories. Journals publishing reviews only were excluded. 399 journals were chosen to evaluate their fulfillment of the requirements established by ICMJE for ASC, COPE for CoI-DS (financial, non-financial and editors' disclosures) and ORI for GW. Other data such as publisher, type of contents (clinical vs basic), belonging to an Editorial Association (EA) (ICMJE, COPE, ORI, CSE, WAME and others) and editorial office region were also collected. Since Elsevier was the most represented publisher among the journals reviewed (22.6%), we compared Elsevier journals with the rest of publishers. Each journal was independently reviewed by two authors using a standardized data-collection form. Data was statistically analyzed with SAS 9.1 statistical system.

Results: 78.9% journals mentioned ASC in their website, with significant differences regarding the IF (6.857 for those mentioning ASC vs 5.219 for those not mentioning ASC; p = 0.015). However, only 51.9% journals required the three established ICMJE ASC. 239 (59.9%) journals belonged to any EA; among them, 64% included the three ICMJE ASC, while only 33.5% of those not belonging to an EA did so (p < 0.001). The same was true when considering separately the EA for ICMJE (p < 0.001), COPE (p < 0.001), ORI (p = 0.018) and WAME (p < 0.001), but not for CSE and other associations. When comparing US-published journals vs those published in Europe, no differences were found (p = 1.01). ASC were more frequently mentioned in Elsevier journals than in the rest of publishers (90.0% vs 75.7%; p < 0.03), but no differences were found when considering the three ICMJE ASC (p = 0.375). 67.5% of clinical vs 40.6% of basic journals belonging to any EA required the three ICMJE ASC (p < 0.001). 91.2% journals mentioned CoI-DS, but only 38.8% included editors' disclosures. Differences were found between journals belonging and not belonging to an EA for financial, non-financial and editors' CoI-DS (p < 0.001 in the three cases) and significant differences remained when considering EA separately for ICMJE, COPE and ORI (p < 0.001 in all). No differences were found between journals published in Europe and US. Elsevier journals included more commonly financial (p = 0.038), non-financial (p = 0.040) and editors CoI-DS (p = 0.001) than the rest. Likewise, clinical journals included more commonly financial (p = 0.010), non-financial (p < 0.001) and editors CoI- DS than basic ones (p = 0.036).

Discussion: Only 16.8% and 9.5% journals mentioned and defined GW, respectively. Just 4% of journals had methods to detect it, and 5.8% had specific procedures to deal with it. Eight (29.63%) categories of the 27 did not even have a single journal defining GW. Journals with procedures for responding to GW more commonly belonged to ICMJE (p < 0.001), COPE (< 0.001), and CSE (p = 0.003). Likewise, journals whose ethical guidelines were provided by the publisher had more commonly procedures for responding than those whose publisher did not have guidelines (p = 0.001).

Conclusions: Top-ranked biomedical journals fail to achieve the desirable degree of recommendations provided by main EA with regard to ASC, CoI-DS and GW.

V-128
ASSOCIATION OF ATRIAL FIBRILLATION WITH ADMISSIONS DUE TO ISCHAEMIC CEREBROVASCULAR DISEASE AND HEART FAILURE IN 2011 IN THE AREA OF MARINA ALTA

A. Valdivia Pérez, N. Lozano Cortell, P. Olcina Lloret, P. Martín Rico

Hospital Marina Salud. Denia (Alicante), Spain.

Objectives: Description of admissions due to ischaemic stroke or Heart failure associated to atrial fibrillation (AF) in our health area in 2011.

Material and method: For admissions the data base source was the Minimum Basic Data Set (MBDS). We used a predefined set of codes (ICD-9-CM) to identify both admissions for ischaemic stroke (433-434-435) and heart failure (428) and then we identified the presence of AF as a comorbidity expressing its frequency both in absolute figures and percentages.

Results: From all medical admissions in study the absolute counts (percentage) proportions were as follows: Cerebral arteries occlusion (434): 206 (5.15%). Precerebral arteries occlusion or stenosis (433): 55 (1.37%). Transient ischaemic attack (435): 48 (1.20%). Heart failure (428): 215 (5.37%). AF as a comorbidity was much more common in patients with ischaemic stroke codified as cerebral arteries occlusion (26.21%) than in the rest of admissions for other causes (12.62%): OR 2.46 (95%CI 1.78-3.40). This strong association was not seen for transient ischaemic attack (OR 1.11; 95%CI 0.50-2.49) or precerebral arteries occlusion or stenosis (OR 0.79; 95%CI 0.34-1.86). AF was also much more common in patients with heart failure (38.60%) than in the admissions due to other causes (11.88%): OR 4.66 (3.48-6.24). Once we adjusted the associations by age, gender and Charlson comorbidity index, we confirmed an independent relation between admissions due to cerebral arteries occlusion and AF as comorbidity (OR 2.42; 95%CI 1.72-3.40) as well as for admissions due to heart failure and AF (OR 4.07; 95%CI 3.00-5.52).

Conclusions: 1. There is a strong association between cerebral arteries occlusion as cause of admission and AF comorbidity. We failed to find such an association for transient ischaemic attack or precerebral occlusion. We consider necessary to audit the medical records for a deeper study of this strokes and review the adequacy of the anticoagulant therapy 2. There was also a strong association between heart failure admission and AF. 3. Both associations were quite similar after adjustment by age, gender and comorbidity score.

V-129
RISK OF MALNUTRITION RELATED TO OTHER COMORBIDITIES IN PATIENTS WITH HIP FRACTURE

R. Arnáez[1], E. Huarte[1], M. González[1], M. Ruiz-Castellano[1], M. Acha[1], T. Martínez[2], B. Lacruz[1], E. Bidegain[1]

[1]Department of Internal Medicine B, [2]Department of Traumatology. Complejo Hospitalario de Navarra. Pamplona. Navarra, Spain.

Objectives: Hip fracture is a prevalent cause of hospitalization on elderly patients that usually is associated to other comorbidities. Malnutrition in older adults with hip fracture is associated with increased complications, mortality, disability and dependence on others. The aim of the current study was to examine the relationship between the risk of malnutrition in our population of elderly patients with hip fracture and age, cognitive and functional status, comorbidity and long term mortality.

Material and method: 225 patients with hip fracture that were admitted in Traumatology Department from de 1st of March 2010 to the 28th February 2011 were studied retrospectively. They were evaluated daily by Internal Medicine Department. The mean stay was 13.11 days (± 3.8 SD), mean age was 83.4 years (± 9.3 SD), Charlson score was 2.02 (± 1.6 SD) and the mean of medicaments patients took was 4.20 ± 1.467 SD. We calculated the risk of malnutrition using the parameters of the CONUT® program (albumine, lymphocytes and cholesterol), classifying them in no risk (0-1 points), low (2-4), moderate (5-8) and high risk (9-12).

Results: 169 patients (75.11%) were at risk of malnutrition. Those patients were older, had higher Charlson and ASA score and lower Barthel score. They had more decompensations of their chronic diseases, more transfusions, confusional states and the mean of exitus within 12 months was higher. Demographic, clinical, functional and outcomes of different groups are detailed in Table 1.

Discussion: Aging is associated with physical, mental, social and environmental changes which may contribute to the risk of malnutrition. The worldwide increase in hip fractures among the elderly poses a major challenge to the health care system and society. The importance of early detection of the risk of malnutrition and aggressive intervention are very important, because treatment of malnutrition has been shown to improve hospitalization outcomes surgical elderly patients, with decreased mortality, morbidity and length of hospital stay.

Conclusions: In our sample the prevalence of patients at risk of malnutrition is higher. Elderly patients admitted with hip fracture and high or moderate risk of malnutrition had more nosocomial

Table 1 (V-128)

Description	Code	Total Cases	Cases with AF comorbidity (%)	OR
Cerebral arteries occlusion	434	206 (5.15)	54 (26.21)	2.46; 95%CI 1.78-3.40
Precerebral arterial occlusion or stenosis	433	55 (1.37)	6 (10.91)	0.79; 95%CI 0.34-1.86
Transient Ischaemic attack	435	48 (1.20)	7 (14.58)	1.11; 95%CI 0.50-2.49
Heart failure	428	215 (5.37)	83 (38.60)	4.66; 95%CI 3.48-6.24

Table 1 (V-129) Malnutrition and other risk factors

	No risk (n: 56)	Low risk (n: 108)	Moderate and high risk (n: 61)
Age	80.7 (± 11.2)	83.9 (± 8.74)	85.9 (± 7.72)
Charlson	1.78 (± 2.08)	1.93 (± 1.03)	2.34 (± 1.41)
Barthel	81.96 (± 21.37)	67.57 (± 29.30)	62.94 (± 24.40)
ASA	2.83 (± 0.62)	3.17 (± 0.57)	3.30 (± 0.53)
Exitus in 12 months	8 (14.28%)	25 (23.14%)	19 (31.14%)
Decompensation of associated comorbidities	23 (41.07%)	60 (55.5%)	35 (57.37%)

infection, confusional states, transfusions, decompensation of its associated comorbidities and deceased after twelve months. Patients with low cognitive and functional status assessed by Charlson, Barthel and ASA indices are in worse nutritional conditions.

V-130
AGING POPULATION AND DEMAND FOR HOSPITAL ADMISSIONS ACCORDING TO AGE IN A DEPARTMENT OF INTERNAL MEDICINE, GENERAL HOSPITAL

L. Hernanz, A. Gutiérrez, A. Beltrán, S. Rizzo, L. Briongos, L. Abad, L. Inglada, J. Crespo

Department of Internal Medicine. Hospital Universitario Río Hortega. Valladolid, Spain.

Objectives: To assess the demand for hospital admission and therefore part of health care consumption in the population over age.

Material and method: We divided the total number of patients analyzed (hospital admissions during the years 2009, 2010 and 2011) in two groups: older and younger than 65 years, analyzing numbers, percentage, average age, average stay and GRD weight. Want to know if the age of 65 years is still valid to study the medical use in the elderly. Thus the results have been compared with those obtained studying the sick in 3 groups: under 65 years, patients aged 65-79 and finally those aged > 80 years.

Results: Of all hospital admissions analyzed (n = 9241) in 2009-2011 at the Department of Internal Medicine HURH, 1650 (18.03%) had < 65 years and their mean age was 52.75 ± 16.32. The % of patients over 65 years was 82.15 (n = 7591) with a mean age of 80.25 ± 10.35. The ratio > 65/< 65 years was 4.60. When analyzing the data that measure the health consumer, such as average stay and GRD weight after hospital discharge, it is found that both the average stay and the average weight of the DRGs are higher with significant differences in patients older ($p < 0.001$). By grouping patients according to age in three strata, we found that patients between 65 and 79 years represented 39.6% of revenue over 65 years (n = 2,930) with a mean age of 72.55 ± 7.82). Patients aged over 80 years represent 61.4% of patients over 65 years (n = 4,661) with a mean age of 85.39 ± 5.31. The average stay of two groups of patients aged more high (between 65-79 years vs > 80) was similar in both age groups (10.15 days and 10.45 days), being the average weight of the DRGs of patients older than 80 years slightly higher in the older group (1.82 vs 1.78).

Conclusions: In relation to hospital admissions, the population over age 65 consume more health resources than the population under 65 years. From the data obtained from the population over 65 years, no difference between the two groups of older populations, presented consumption rates in health related hospital admissions in relation to average stay and DRG weight therefore appears in the group of studied patients age 65 years continues to be valid to study the impact of aging on health care consumption.

V-131
EPIDEMIOLOGICAL CHANGES OF COPD PATIENTS ADMITTED TO A TERTIARY HOSPITAL OVER LAST TEN YEARS

F. Arnaiz de las Revillas Almajano, E. Cobo García, M. García Hoyos, M. Lisa Gracia, A. Sánchez González, S. García Rubio, F. López Gutiérrez, C. Gutiérrez del Río

Department of Internal Medicine. Hospital Valdecilla. Santander. Cantabria, Spain.

Objectives: To study the characteristics in COPD patients admitted to Internal Medicine and to compare epidemiologic and clinic changes between two samples separated each other with a gap of ten years.

Material and method: We performed a retrospective descriptive study with COPD patients admitted to an Internal Medicine department in a tertiary care hospital from 1st January to 31st December of years 2000 and 2010. We used two randomized samples with one hundred patients each. We included COPD patients 18 years old or more admitted for acute exacerbation. In this study we evaluated the epidemiologic characteristic of the patients, for which we made a protocol. We used SPSS program to data analysis.

Results: The mean age was 78.49 years old in sample of year 2000 and 79.79 in 2010 (p 0.23). Regarding gender distribution, the percentage of men was 77% in 2000 and 73% in 2010 (p 0.29). The income had an average stay of 10.98 in 2000 and 13.48 in 2010 (p 0.12). The average of previous income in the last year, was 1.12 and 0.98 respectively, of which, 9% and 11% was ICU admissions. In both years approximately 30% have two or more exacerbations. The 96% of patients had comorbidities in 2000 compared with 99% in 2010, which have following distribution respectively: hypertension 50%-61% (p 0.056), diabetes mellitus 23%–43% (p 0.01), dyslipidemia 15%-22% (p 0.16), renal dysfunction 36%-29%, acute myocardial infarction 17%-41% (p 0.3), atrial fibrillation 37%-35%, heart failure 38-23%, Cor pulmonale 20%-25%, depression 7%-9%, obesity 4%-25% (p 0.02), malnutrition 29%-23% (p 0.05), cerebrovascular disease 17%-24% (p 0.7), cognitive impairment 14%-10%, peripheral vascular disease 14%-23% (p 0.17), osteoporosis 4%-13% (p 0.02), hepatopathy 7%-4%, gastro esophageal reflux 9%-13% and peptic ulcer 22%-15%. In 2000, 25% of patients were smokers and 39% was former smokers. In 2010, 19% was smokers and 34% was ex-smokers. The phenotypes were 30% of exacerbators in 2000 compared with 26% in 2010 (p 0.4). The emphysematous phenotype had a frequency of 2% in 2000 and 14% in 2010 (p 0.009). The overlap phenotype was 3% in 2000 and 7% in 2010 (p 0.41).

Discussion: It´s important to remember that this is a retrospective study and some data have been lost, which can influence in the results. The mean age was slightly higher in 2010 as expected by population aging. The frequency of women is higher in 2010; it is probably due to the increase of the smoking women. Among the comorbidities, in both years we observed high prevalence of vascular disease, it is related with the disease itself and cigarettes consumed, which could be a confusion factor. It's important remarking the high percentage of diabetic and obese people in 2010 with statistically significant difference, and that could be secondary to changing lifestyle. In 2010, there were less number of patients with malnutrition, although emphysematous phenotype is increased. Also is remarkable high prevalence of osteoporosis probably because in last years, it became more important, and now it is more studied. In this study the phenotypes were suggested with clinical and radiologic data, because in 2000 the phenotypes were not protocoled. However we observed that the most patients were exacerbator.

Conclusions: Epidemiological data of COPD have been changing over the years. It may be due to lifestyles changes. This change can lead a different therapeutic attitude, which should include the treatment of the comorbidities. We considered that patients with COPD require a multidisciplinary approach, attending to the comorbidities and side effects of treatment.

V-132
PROFITABILITY OF CAPSULE ENDOSCOPY IN THE ETIOLOGICAL DIAGNOSIS OF IRON DEFICIENCY ANEMIA IN THE CAPSULE ENDOSCOPY UNIT OF UNIVERSITY HOSPITAL COMPLEX OF BADAJOZ IN A PERIOD OF TWO YEARS

T. García Guerrero[1], S. Argenta Fernández[2], G. Rodríguez Caraballo[1], E. García Martos[1], P. Sánchez Risco[1], A. Guiberteau Sánchez[1], M. García García[2], C. Jiménez Jaén[1]

[1]Department of Gastroenterology. Complejo Hospital Universitario de Badajoz. Badajoz, Spain. [2]Department of Internal Medicine. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca, Spain.

Objectives: Retrospective study of the levels of hemoglobin and the findings of capsule endoscopy in patients with iron deficiency anemia resistant to oral iron therapy in the last 2 years (March 2010-February 2012) in the Capsule Endoscopy Unit of University Hospital Complex of Badajoz.

Material and method: The Capsule Endoscopy Unit services the whole province of Badajoz. We reviewed the clinical records of all the patients who underwent a capsule endoscopy, and we selected those that included a complete exploration (clear view of the intestine, with a view of the cecum), iron deficiency anemia with Hb levels < 12 mg/dl, ruled-out celiac disease and complete colonoscopy and gastroscopy without lesions that show potential risk of bleeding. The patients were grouped into "mild anemia", when Hb > 10 or "severe anemia" when Hb ≥ 10. Also, the findings of the capsule endoscopy were classified as "no findings", "lesions with low risk of bleeding", "lesions with medium risk of bleeding", "lesions with high risk of bleeding", "lesion with signs of bleeding" and "other lesions". Cases of angiectasis were included in the previous groups according to their number, size and aspect. The statistics were made with SPSS.18 for the analysis, Student's t-test for independent variables and chi-squared test for dependent variables.

Results: Out of the 124 cases analyzed, 71 met the requirements and were selected. In this group, 57.7% were men with an average age of 67.92 years and 42.3 were women with an average age of 62.43 years (total average: 65.6 years). 43.7% of the patients presented "severe anemia", and no significant differences were found regarding sex (p = 0.91). 27.1% were receiving non-steroidal anti-inflammatory drugs (NSAIDs) and 22.9% used anticoagulants. We found 21.1% of normal capsule endoscopies (93.3% in mild anemia), 15.5% of the patients showed lesions with low risk of bleeding (81% in mild anemia), 14.1% showed lesions with medium risk of bleeding (70% in mild anemia), 9.9% showed lesions with high risk of bleeding (100% in severe anemia), 25.4% showed lesions with signs of bleeding (77.8% in severe anemia) and 14.1% showed other non-bleeding lesions as the only finding (100% in mild anemia). Significant differences were found regarding the distribution of the severity of anemia in the different groups (p < 0.001). NSAIDs and anticoagulant use showed no significant differences. The most common lesion with risk of bleeding in the 4 groups was angiectasis, in 91.5% of the cases, and the rest were ulcerated lesions (5.6%) and erosions (2.8%). Statistically significant differences between sexes were only found in the group of lesions with high risk of bleeding.

Discussion: According to our results, it seems reasonable to assume that the capsule endoscopy is more profitable in patients with low Hb levels, both in the diagnosis and in the planning of possible therapies, such as enteroscopy or thalidomide (which is a promising and less invasive alternative, especially in pluripathological patients). The long-term clinical impact of lesions with low-medium risk of bleeding still needs to be analyzed, as well as the possibility that other chronic pathologies may contribute to maintain or aggravate the anemia.

Conclusions: Patients who underwent a capsule endoscopy in our center usually present lesions with risk of bleeding, and a significant percentage shows lesions with signs of bleeding without influence of NSAIDs or anticoagulants. Most of the lesions with high risk of bleeding and signs of bleeding are found in patients with the lowest levels of Hb, while capsule endoscopies without findings are those of patients whose Hb levels are close to normal.

V-133
ADULT HOSPITAL ADMISSION IN SPAIN: A COMPARATIVE ANALYSIS OF IMMIGRANT AND SPANISH CITIZENS

H. Galvis Cárdenas[1], H. Pinargote Celorio[1], A. Zurita[1], J. Mateo[1], J. Ramos[1], B. Valero[1], J. Sastre[1], F. Nieto[2]

[1]Department of Internal Medicine, [2]Admission Unit. Hospital General Universitario de Alicante. Alicante, Spain.

Objectives: The number of immigrants in Spain in the last decade has increased dramatically. At this point there are few studies that have evaluated the impact of this migratory phenomenon on the hospitalization. The purpose of this study was to investigate differences in hospitalization between immigrants and the resident population during the year 2011 in of a public hospital in the city of Alicante (Spain).

Material and method: Cross-sectional study of 27,956 hospitalization episodes by patients > 14 years attending during the year 2011 in a public teaching hospital. Hospital admissions of immigrants were compared to those of Spanish-born population. The study was based on the hospital discharge data collected by the Hospital General Universitario de Alicante Information System.

Results: From 27,957 hospitalization episodes, the country of born was available in 27,737 visits. From 27,737 episodes, 3.027 (19.9%) were immigrant. The main country was Morocco (17.7%) follow by Colombia (8.4%) and Ecuador (8.3%) and United Kingdom (7.7%). The median of age was less in immigrant (42 [RIC: 32-60]) than autochthonous (62 [42-75] (p < 0.001). The overall percentage of hospitalization in the group aged over 65 years was 19.9% in immigrant and 45.0% in autochthonous (p < 0.001). The sex female was higher in immigrant (60.8%) than autochthonous (51%) (p < 0.001). The admission in obstetric service, gynecology service and neurosurgery service was more common in immigrant (24.6%, 3.8% and 3.1%) than autochthonous (10.6%; 2.4% and 2.4%) (p < 0.01). However, the admission in unit of short stay, pneumology, cardiology, and traumatology was less common in immigrant (4.5%, 3.9%, 3.6%, and 3.3%) than in Spanish-born population (6.6%, 6.0%, 5.7% and 4.1%) (p < 0.01). Hospitalization discharges for some specific main group of diagnosis: "pregnancy, childbirth and puerperium", "female genitourinary system", and "blood and blood-forming organs" were higher for immigrants than for residents (24.7% vs 10.6%; 3.5 vs 2.2% and 2.9% vs 1.8%; p < 0.01). And hospitalization discharge for "circulatory system", "respiratory system" and "musculoskeletal system" and connective tissue" as main group of diagnosis were less for immigrant than for autochthonous (10.6% vs 16.7%, 6.8% vs 10.8, 6.7% vs 8.4%; p < 0.01). The mortality of admission rate was less in immigrant (1.9%) than Spaniards (3.9%) (p < 0.001). The median days of admission were less in immigrant (2.24 [RIC: 1.5-4.5]) than autochthonous (3.0 [RIC:1.5-6.0]).

Discussion: Deliveries and gynecological problems for females were identified as critical areas for migrants' health, in which public health interventions may be promoted.

Conclusions: As the presence of foreigners becomes an established phenomenon, it is important to evaluate their epidemiological profile for hospitalization, develop instruments to monitor and fulfill their specific health needs and plan health services for a multi-ethnic population.

V-134
ELEVATION OF CARBOHYDRATE ANTIGEN 15.3 (CA 15.3) IN PATIENTS WITH VITAMIN B12 DEFICIENCY

C. Muñoz[1], E. Marchán[1], M. Mañas[1], J. Castro[1], G. Esquinas[1], L. Sáenz[2], I. Clemente[1], A. Sáenz[1]

[1]Department of Internal Medicine, [2]Department of Clinical Analysis. Hospital General de Ciudad Real. Ciudad Real, Spain.

Objectives: To describe the epidemiological characteristics of patients with vitamin B12 deficiency and elevated plasma tumor marker CA 15.3.

Material and method: We reviewed the medical records of patients who presented in their blood tests elevated levels of CA 15.3 and deficiency of vitamin B12 in 2011 in Internal Medicine, Hospital General Universitario de Ciudad Real. We collected the following variables: sex, age, diagnosis, hemoglobin (Hb), mean corpuscular volume (MCV), lactate dehydrogenase (LDH) levels of B12 and CA 15.3 plasma, if gastroscopy and mammography had been performed, and the treatment received. All analytical values were determined before and after treatment.

Results: 6 patients, who were included in the checked blood tests, had a high value of CA 15.3 and a decrease of vitamin B12. The age range was between 47 and 81. Of these patients, 5 were women. Three were diagnosed with pernicious anemia, and 3 with megaloblastic anemia. At diagnosis the analytical values collected were, vitamin B12 (68-135 pg/ml), Hb (7.5 to 12.4 g/dl), MCV (93.5 to 146 fl), LDH (256-4,822 U/ml). The tumor marker CA 15.3 was between 54.1 and 161 U/ml (reference values in our laboratory < 32 U/ml). Two female patients underwent mammography during the study of anemia, the results were negative for malignancy. All patients were treated with vitamin B12, 5 of them intramuscularly and 1 oral. After treatment the levels of B12 and tumor marker were normalized.

Discussion: The CA 15.3 is a glycoprotein commonly used in the diagnosis and monitoring of breast cancer. It can also be found elevated in other tumors (ovarian, lung, pancreas and liver) and non-oncological diseases such as chronic liver disease, sarcoidosis, tuberculosis, lupus erythematosus or thyroid dysfunction. After reviewing the available literature on the subject, we found very few studies on the association between the elevation of CA 15.3 and B12 deficiency. This tumor marker recognizes epitopes of MUC1 glicoprotein. This glycoprotein is not only expressed in tumor cells but also in hematopoietic cells. Some authors suggest that the elevation of the marker in patients with B12 deficiency may be associated with apoptosis of erythroblasts due to ineffective erythropoiesis in these patients. Our results are similar to those referenced in other studies. The patients had no underlying tumor pathology, and after correction of B12 levels tumor marker values were normalized.

Conclusions: The increase of CA 15.3 can be seen in patients with B12 deficiency. This is not related to the presence of underlying malignancy. Altered laboratory values are normalized after correcting the vitamin deficiency.

V-135
STUDY OF CLINICAL ASPECTS AND CRITERIONS OF AN AGGRESSIVE BEHAVIOUR IN GASTROINTESTINAL STROMAL TUMOURS IN OUR AREA

A. Merlo Serrano[1], A. Bejarano García[2], I. Cobos López[3], A. Maraver García[2], A. Talavera Fabuel[2]

[1]Department of Internal Medicine, [2]Specialist in Gastroenterology. Hospital Infanta Elena. Huelva, Spain. [3]Translation and interpretation. Universidad de Córdoba. Córdoba, Spain.

Objectives: To analyse the appearance of this kind of tumours, the factors related to their aggressive behaviour and the role that the complementary tests play in its diagnosis. Gastrointestinal stromal tumours (GISTs) are the most common mesenchymal neoplasms of the gastrointestinal tract although they constitute only 0.1-3% of gastrointestinal tumours. The interest in these tumours has been increased recently due to its malignancy and different risk and prognosis factors.

Material and method: A retrospective observational study. The pathology reports of GIST within the last five years in the hospitals Juan Ramón Jiménez and Infanta Elena were reviewed. Clinical aspects, endoscopies, histology and immunohistochemical expression were reviewed.-Statistical study through the program SPSS 20.0 for Windows.

Results: A total of 28 GIST were reviewed. Two of them were excluded because the medical histories of the patients were not completed. Therefore 26 records were reviewed (11 females, 15 males; average age 60.8 years). The most common site of location was the stomach (50%; 13 patients) The most common symptom was high digestive bleeding (50%; 13/26). The bleeding was located in the stomach in 80% of patients in this group. The complementary test which helped the most for the diagnosis was the CT scan which was used in 18 patients with an objective result. The second method with the highest effectiveness in diagnosis was the endoscopy of the GI tract which helped to diagnose 92% of patients (12/13). In all the cases it showed a high submucosal lesion with a smooth surface, which sometimes showed ulcers and erosions. We report here 1/12 cases of GISTs that was diagnosed by endoscopic biopsy (8.33%). In the rest of the study surgery was necessary to get a definitive histologic diagnosis. 87% of tumours express CD 117, 76.8% CD 34 and only a 29% express S100. Regarding the aggressive behaviour in the neoplasm, it showed a higher risk when they were located out of the stomach with a OR 3.5; 95%CI (1.085-11.29) without any differences between genre or age groups younger or older than 65 years.

Conclusions: The GISTs occurred in patients with a median age of 60 years without genre discrimination. High digestive bleeding is the most common symptom. The most common site of location is the stomach, in which there is a less aggressive behaviour. The endoscopy is a valid tool in its study mainly in those cases which have high bleeding. Nevertheless the endoscopic biopsy does not get material enough for its definitive diagnosis. We have not found any differences related to its aggressive behaviour with regards to gender or age.

V-137
IN-HOSPITAL MORTALITY IN AN INTERNAL MEDICINE DEPARTMENT OF A TERTIARY UNIVERSITY HOSPITAL

E. Muro Fernández de Pinedo, A. Morales Cartagena, B. de Miguel Campo, F. Alonso Navas, J. Vila Santos, J. Aranda Arcas, A. Torralba Morón, J. Guerra Vales

Department of Internal Medicine. Hospital Universitario 12 de Octubre. Madrid, Spain.

Objectives: Previous studies have mentioned the importance of mortality as an indicator of clinical activity. The aim of this study was to analyse in-hospital mortality and associated clinical and epidemiological factors of the patients admitted to the Internal Medicine (IM) department during a one year period, in a tertiary Universitary Hospital.

Material and method: We carried out a retrospective analysis of the admissions registered in IM in our hospital during 2011 using the minimum basic set of data (in Spanish: "Conjunto Mínimo Básico de Datos": CMBD) database. We collected information about clinical characteristics of the patients, diagnostic information and global mortality and compared these results, establishing two different

Table 1 (V-137). Demographic characteristics of patients admitted in Internal Medicine

	Total	Death	Alive	Statistical significance
Sex% male	52.9	54.6	52.7	0.227
Average age (years)	74.7	81.6	73.9	< 0.001
Emergency admitted (%)	95.8	98	95.5	0.003
Number of diagnosis	9.3	9.6	9.3	0.01
Average weight of DRG	2.1	3	2.1	< 0.001
Average stay (days)	13.4	13.01	13.4	< 0.001

groups depending on whether death occurred during the hospital stay or not. We compared age, sex, Charlson index, condition prior admission (emergency department, scheduled admission, etc), number of diagnosis, and Diagnosis Related Group (DRG). We used the SPSS tool for the analysis of the results (chi squared and t-Student for independent samples test). We assumed statistical significance for $p < 0.05$.

Results: There were 5,559 patients admitted to the IM department of the Hospital 12 Octubre in Madrid in the year 2011, of which 47.05% were women, with mean age of 74.7 years old (SD 14.6). The mean weight of DRG was 2.1 (SD 2.5), and the mean stay 13.3 days (SD 11). The average number of final diagnosis in the discharge reports were 9.3. 95.8% of patients were admitted through the emergency department (ED). The overall mortality of the sample was 9.2% (509 patients). Within the group of deceased, 45.4% were women and the mean age was 81.6 years old. There was an average of 13 days stay with a mean weight of DRG of 3. 98% of the patients were admitted through the ED and the average number of final diagnosis in the discharge reports was 9.6. Comparing the characteristics of the two subgroups of patients (deceased and alive) mortality was significantly associated with the type of admission (through the ER or scheduled), mean age, mean stay and mean weigh of DRG (table 1). Among the 509 deceased, 21.6% were ≥ 90 years old. This age group showed association with a greater mortality ($p < 0.0001$). The most prevalent DRGs were: "Simple pneumonia and other respiratory disorders" 726 patients (13.1%), "Heart failure (HF) and arrhythmia" 461 patients (8.6%), and "HF and shock", 365 patients (6.5%). The DRGs that show higher mortality were "HF and arrhythmia" (11.3%), "stroke" (14.8%), "other CNS disorders" (34%), "septicemia" (33.7%), and "hepatobiliary and pancreatic disorders" (17.2%).

Conclusions: Patients admitted to the Internal Medicine department have a high overall mortality. This could probably be explained by the patients' characteristics: elderly patients, with multiple comorbidities and who are frequently admitted through the emergency department in a worse clinical situation than other admission regimes.

V-138
CLINICAL CHARACTERISTICS OF A FAMILY AFFECTED VON HIPPEL-LINDAU IN SEGOVIA

S. Martín Rodríguez, J. Moreno Palomares, B. García López, M. Carralón González, B. Quevedo Bautista, P. Velasco Martínez

Department of Internal Medicine. Hospital General de Segovia. Segovia, Spain.

Objectives: Von Hippel-Lindau's disease (VHLD) is an infrequent and genetic pathology, so it is habitual to find the cases grouped in families. The inheritance is autosomal dominant and is characterized for abnormal angiogenesis and later, the appearance of diverse tumors affecting diverse organs, already be benign or malignant, in early ages. Our aim is to study the affected persons of EVHL in the province of Segovia.

Material and method: There were checked the clinical histories of the patients diagnosed of EVHL and confirmed by genetic study, finally 2 cases being included.

Results: We found only one family affected of VHLD in the province of Segovia, with two sympathetic brothers. Inside the family an uncle (renal and retinal disease), three cousins (cerebellum, retinal and spine disease) and a sister (optical nerve affection) suffer the disease. Our patients were diagnosed from his infancy and being demonstrated in the genetic study a great delection of the gene VHL. The 28-year-old brothers have retinal angiomas in the right eye, which has been treated with laser and supports normal visual. The small one of the brothers, 24-year-old of age, presents also retinal angiomas, that produces amaurosis of the right eye. But in addition he has a pancreatic cyst of stable size in 1.2 cm. And hemangioblastomas of small size (5 mm) in fundamental cone and spinal marrow to level of C5. In the last clinical control it is observed a mass in the left testicle of 1 cm of size, not painful and mobile, hanging of completing study to reject epididymis cistoadenoma.

Discussion: VHLD is a infrequent pathology that is related to the mutation in the suppressing VHL oncogene, located in the short arm of the chromosome 3 (3p25-26). This mutation is present in one of every 36000 births and is inherited from form autosomal dominant by complete penetration but variable expressiveness. The initial manifestations of the disease can be given to any age, but it is more frequent that it happens concerning 26 years. The clinical manifestations come determined by the appearance of diverse tumors, both benign and malignant, there are described hemangioblastomas in nervous central system, retinian angiomas, carcinomas of renal cells, hemangiomas and adenomas of kidney, multicentral cysts of clear cells, feocromocitomas, adenomas and tumors neuroendocrinos of the pancreas and papillary cistoadenomas of the epididymis and broad ligament. The affectation more frequent is the renal one, specially the carcinoma of clear cells in up to 75% of the cases, and in 10% they are present at the diagnosis. For this motive and for the possibility of developing new tumors, there is obligatory the periodic vigilance of these patients of for life. For the diagnosis the genetic study is necessary, and it has to be suspected in those patients that presents various typical tumors or a tumor and the familiar precedent. In our concrete case, the patients with VHLD are young patients and retinal angiomas, coming even to the total blindness. None of them suffers renal affectation, and his principal reason of alarm is the appearance of affectation of nervous central system. None of two patients has just now active treatment and periodic controls are kept.

Conclusions: It is necessary to suspect this pathology when there are VHLD's familiar precedents or there takes place clinical typical affectation. The survival and the quality of life of the patients with VHLD has improved in the last years and owes to the precocious diagnosis of small and asymptomatic tumors, as well as the specify and aggressive treatment of other complications like renal insufficiency.

V-139
PULMONARY DISEASES: EXPERIENCE OF AN INTERNAL MEDICINE DEPARTMENT OF A PRIMARY NON UNIVERSITY HOSPITAL

A. Monteiro, F. Lourenço, A. Rodrigues, A. Panarra, N. Riso, M. Vaz Riscado

Department of Internal Medicine 2. Hospital Curry Cabral. Lisbon, Portugal.

Objectives: Pulmonary diseases are responsible for a significant percentage of admissions and deaths in an internal medicine department particularly in those hospitals who lack a pneumology department. The objective of this work was to characterize the patients with pulmonary diseases admitted in the nurseries of an internal medicine department during the year 2011.

Material and method: Observational retrospective study of patients admitted to a internal medicine nursery and having pulmonary diseases as first diagnosis. The items evaluated were age, gender, nº of days of hospital stay, the prevalence of various nosological entities, namely the airways diseases, pneumonias, other infectious diseases, lung cancer, pleural and interstitial diseases and pulmonary thromboembolism among others, and the outcome.

Results: During the study period there were 1,510 admissions, including 187 reinternments and corresponding to 1,349 patients. The lung pathology was responsible for 32.6% of admissions compared with 12.8% of cardiology, 12.9% nephrology, 11.4% of gastroenterological and neurological 14.3%. With regard to patients with lung pathology a total of 431 patients with pulmonary diseases as first diagnosis were admitted. There were 61 reinternments, thus totalising 492 admissions. The mean age was 76 years, the male gender accounting for 59.35%. The average nº of hospital stay was 11.04 days which was identical when compared to the total number of stay of patients in the department and a mortality of 15.77% which was slightly higher when compared to the average of the department (11.93%). The community acquired pneumonias topped the list with 61.8% of admissions and mortality of 19.4%, followed by airways diseases with 26.2% and a mortality of 2.3%. The lung cancer with 1.8% of admission rate had a 22.2% of mortality.

Discussion: Internal medicine is, in its composition, a subset of other specialties; however the prevalence of admission is not homogeneous. In this study, and in various others papers published, it is quite clear that the respiratory diseases are more prevalent when compared to other organs or systems pathologies. This evidence has to be taken to consideration in the structural organization of the departments as well as in the training programmes of residents of internal medicine.

Conclusions: In 2011 about a third of patients admitted in this internal medicine nursery had a pulmonary disease as its first diagnosis and a mortality rate superior to the average of the department. The community acquired pneumonia had a higher rate of admissions with roughly 20% of deaths. Although the percentage of airways diseases was quite high the mortality was low. The opposite was verified regarding the lung cancer with a low rate of admissions but a high mortality. These numbers are highly suggestive of importance of pulmonary pathology in internal medicine departments in hospital who lack a pulmonology department and should be considered in the residency training programs.

V-140
CLINICAL PRESENTATION AND RISK FACTORS OF HEPATOCELLULAR CARCINOMA IN SAUDI ARABIA; SINGLE CENTER EXPERIENCE

H. Kuriry, A. Aljumah, F. Sanai, A. Al Khathaami, M. Al Ghobain

Department of Internal Medicine. King Abdulaziz Medical City. Riyadh, Saudi Arabia.

Objectives: To identify pattern of presentation of hepatocellular carcinoma at King Abdullaziz Medical City in Riyadh (KAMC-Riyadh). To identify the most frequent underlying liver disease among these cases. To determine the demographic and clinical presentation differences of hepatocellular carcinoma. To estimate the prevalence of viral and non viral cause of liver disease among hepatocellular carcinoma cases.

Material and method: Study Area/Setting: This study conducted in King abdullaziz Medical city (KAMC-Riyadh) data collected from charts of hepatocellular carcinoma cases diagnosed between January 2009 and September 2011). Inclusion criteria: 1. All adult patients above 18 years including male and females diagnosed to have hepatocellular carcinoma based on the Saudi gastroenterology association guidelines. 2. Diagnostic criteria of HCC according to Saudi gastroenterology association guidelines as following (one criteria enough to diagnose HCC): Pathological diagnosis of HCC, or Cirrhotic liver, with lesion larger than 1 cm in diameter and one imaging modality (dynamic CT-scan or MR) confirms early arterial enhancement and venous washout of the lesion.

Results: Total of 226 charts were included. The median age at detection of HCC was 65.5 years, with male predominant (71%). Viral hepatitis was most common cause of underlying chronic liver disease particularly hepatitis C virus (HCV) infection (48.7%) and hepatitis B virus (HBV) infection (25.2%). Forty-eight percent of hepatocellular carcinoma were asymptomatic. Both abdominal pain and abdominal distension were present in 52%, 27% of the patients respectively. At the time of diagnosis, 37.1% had three lesions or more (multi-nodular tumours). Most of our patients presented with CHILD score of A (63.3% of case). Relation between symptoms at time of presentation and liver enzymes abnormalities, tumor size, vascular invasion and portal vein thrombosis was statistically significant (p value < .05).

Discussion: Viral hepatitis is the most common underlying etiology around one-third of cases present with advance disease symptomatic cases usually tend to have advanced disease. Diagnosis is usually made during routine screening.

Conclusions: We need to intense HCC screening in chronic liver disease to discover the disease in early stage and also increase awareness between physician and patient about HCC.

V-141
PROJECT TUTOR'S COMPETENCE MAP

I. González Anglada, C. Garmendia, M. Velasco, H. Martín, L. Moreno, G. Cacho, A. González-Spinola, C. Arnaiz

Department of Internal Medicine and Teaching Unit. University Hospital Foundation. Alcorcón. Madrid, Spain.

Objectives: The resident's tutor has a key role in the organization and working of MIR program, although he does not receive vocational guidance and teacher training. To define the skills profile of the resident's tutor is important to developing the attributes (knowledge, skills and attitudes) that allow them to improve performance of the role as tutor. Objective: To improve and promote the teaching-learning process of residents, we are focusing on competencies and developing the profile of the "ideal tutor".

Material and method: The project develops skills of the tutors in 4 phases: 1. An anonymous survey was sent to senior residents (20

residents) gathering information about the tutor. The questionnaire contains 15 questions relating to the tutor in 4 blocks of content: teaching attitudes, professional attitudes, tutor's attitude toward resident. 2. All the tutors of the center identify the core competencies of the tutor by open discussion in a meeting. 3. The list of tutor's competencies and definition is developed through teamwork formed by 6 tutors over 10 meetings. Each of the competencies is defined and graduate with levels of increasing competence. 4. The list of skills is validated by all tutor. 5. Competence profile of resident tutor: A questionnaire was sent to all tutors to graduate (1-4) the level of each of the competencies in the effective tutor.

Results: The competency profile is organized into three dimensions: professional and global dimension, the individual dimension and the relational or social dimension. It was graduated minimum, adequate, prominent and outstanding. To dominate a certain level means dominating the previous levels. After the surveys of residents, the meeting of the tutors and work in the group of tutors, 10 core competencies for tutors were selected and identified: A. Professional skills: A.1. Focus on quality, A.2. Professional ethics, A.3. Teaching ability and motivation, A4. Planning and organization, A.5. Goal-oriented. B. Personal skills: B.1. Emotional management, B.2. Initiative, B.3 Flexibility and management of change. C. Skills relational C.1. Internal Communication,C2. Development of teamwork. After the surveys the map of competencies of efficient tutors was: Professional ethics (4), Teaching ability and motivation (4), Encouraging Teamwork (4), Internal communication (3), Adaptation Flexibility (3), Achievement orientation (3), Planning and organization (3), Initiative (3), Quality orientation (3).

Discussion: The profile of tutor competence constitutes a decalogue of competence that are identified by easily observable and measurable behaviors. The most important skills that define an effective tutor is professional ethics, teaching ability and motivation, emotional management and promotion of team work. Less important are internal communication, flexibility, goal-orientation, planning, initiative and quality orientation. This will determine the best tutor practices for resident's training and serve as targets for tutors.

Table 1 (V-141)

Competence	Mean	SD	Final level
Professional ethics	3.75	0.55	4
Teaching ability and motivation	3.70	0.47	4
Emotional management	3.50	0.51	4
Encouraging teamwork	3.50	0.61	4
Internal communication	3.45	0.6	3
Adaptation flexibility	3.30	0.57	3

V-142
LACTIC ACIDOSIS SECONDARY TO TREATMENT WITH BIGUANIDES: SITUATION IN THE HEALTH AREA OF ZAMORA

P. García Carbó[1], M. Chimeno Viñas[1], E. Martínez Velado[1], P. Sánchez Junquera[1], A. de la Vega Lanciego[1], J. Soto Delgado[1], M. Mateos Andrés[1], T. Garrote Sastre[2]

[1]Department of Internal Medicine, [2]Admission Service. Complejo Asistencial de Zamora. Zamora, Spain.

Objectives: Biguanides are drugs used for the treatment of diabetes mellitus. In Spain metformin is the only biguanide marketed. Lactic acidosis is the principal adverse effect that can occur generally develop in association to an overdose or the presence of certain concurrent factors: kidney failure, heart failure, liver failure, tisular hypoxia, sepsis or infectious process, alcoholism, concurrent making drugs, iodinated contrast using. We won't to know the cases of lactic acidosis secondary to treatment with metformin in our Complex Care.

Material and method: Retrospective, observational study of patients admitted in CAZA (Complejo Asistencial of Zamora) with the diagnosis of lactic acidosis secondary to treatment with metformin during the last six years. We reviewed the medical records and analyzed the following: age, sex, previous pathologies, previous treatment, days of admission, medical service of admission, gasometric data, final diagnosis and treatment to discharge.

Results: We found a total of nine cases, 4 men and 5 women, with a range of age from 45 to 86 years and average of 71 years. They were admitted Internal Medicine (4 patients), Nephrology (3 cases), Endocrinology (2 cases). Two cases of admitted in Nephrology were evaluated for Endocrinology too. The length of the stay was from 3 to 39 days with a mean length of stay of 14 days. Twenty two percent of patients had cardiovascular risk factor, 22% had previous cardiac pathology, 33% had both of them, 11% had other factors and 11% had only antecedent of treatment with metformin. Fifty five percent of cases had only treatment with metformin; 45% have metformin and other oral antidiabetic. The cause of admission was in 4 cases kidney failure, in 3 cases infectious process, 1 case with heart failure and a patient with inadequate dose of metformin. Two cases had the antecedent of iodinated contrast using. The average gasometric data was: pH 7.17, pCO_2 39, HCO_3^- 17 and lactic acid 9.83. Metformin was suspended in all the cases. In 4 patients was changed for other oral antidiabetic. In 4 patients insulin was the final treatment. A case didn't require hypoglycaemic treatment.

Discussion: The lactic acidosis was the principal adverse effect of treatment with metformin. In our revision the incidence is low. The main admission service was Internal Medicine with a mean length of stay of 14 days. In only one case they were not others concurrent factors. The principal cause of admission was renal failure followed by infectious processes. In tow cases there was the antecedent of iodinated contrast using. The blood gases were variables. Metformin was suspended in all the cases, with different treatments at discharge.

Conclusions: 1. The incidence of lactic acidosis in our revision was low. 2. Internal medicine admitted the greater number of cases.3. Renal failure was the principal concurrent factor. 4. The iodinated contrast use was an important concurrent factor. 5. The metformin was suspended in all the cases.

V-143
DECISION TO RESUSCITATE: WHAT IF THE HEALTHCARE WORKER WAS THE PATIENT?

R. Ferreira, E. Meira, R. Pina, F. Santos, J. Nascimento Costa

Department of Internal Medicine. Centro Hospitalar e Universário de Coimbra. Coimbra, Portugal.

Objectives: The decision to start cardiopulmonary resuscitation (CPR) maneuvers raises quite often difficult ethical questions to healthcare workers. What are the key points that change the decision whether to star or not CPR? This study is aimed at knowing what the Portuguese healthcare workers (doctors and nurses) would like to be done if they were the ones suffering cardiopulmonary arrest, in different clinical scenarios. It is also intended to evaluate if there would be differences between doctors and nurses in these decisions.

Material and method: A questionnaire directed at Portuguese doctors and nurses (available in Portuguese at: https://docs.google.com/spreadsheet/viewform?pli = 1&formkey =

dHRmc0tSNFJjbmt4amY4NkRlaDFkM0E6MAγid = 0) was created, including scenarios of cardiopulmonary arrest in patients with different clinical conditions (elderly patients, cancer, comma, dementia). It was made available at several online forums of doctors and nurses and its divulgation was asked. The participation was voluntary and anonymous. Results were gathered automatically at a web based spreadsheet and later analysed with SPSS version 19.0.

Results: A total of 477 healthcare workers answered (322 doctors and 155 nurses), with an average age of 30.8 years old. Translation of the questions made and answers whether to start or not CPR in different clinical scenarios (dementia, cancer, coma, elderly age with good and bad physical condition) are displayed questions 1 to 6. Questions 8 and 9 show the reflection previously made and personal preferences in a scenario were the professional becomes unable to decide.

Discussion: In several questions the answers seem to be quite consensual as far as starting CPR or not is concerned (even between doctors and nurses). The vast majority (but surprisingly not all) would like a resuscitation attempt to be made if the arrest happened with the present health condition. Clinical condition seems to be more important than age when deciding to resuscitate. In the scenarios with the same age (90 years), the answers change drastically from yes to no when the health status is changed from good to bad. Some heterogeneity exists among decisions in other conditions, especially in cancer, where doctors are much more prone to want manoeuvres to be started. Nurses are more likely to have participated in CPR manoeuvres and more likely to have previously thought on these questions.

Conclusions: Although preferences are quite homogeneous in some scenarios, some would choose differently, even when facing irreversible conditions. What to do when personal preferences and medical logic collide? Ethics in end of life situations and critically ill patients is a very difficult issue and is far from consensual. Therefore, knowing what population and professionals think and would prefer to be done to them as patients is crucial to improve our (hard) clinical decisions.

V-144
PULMONARY FUNCTION IS IMPROVED SIGNIFICANTLY 5 YEARS AFTER BARIATRIC SURGERY

S. Hewitt[1], S. Humerfelt[2], T. Søvik[1], H. Risstad[1], H. Aftab[1], J. Kristinsson[3], C. Schou[3], T. Mala[3]

[1]Department of Morbid Obesity and Bariatric Surgery, [2]Department of Pulmonary Medicine, [3]Department of Gastrointestinal Surgery. Oslo University Hospital. Oslo, Norway.

Objectives: Obesity is associated with reduced pulmonary function. Bariatric surgery provides sustained weight loss and may improve pulmonary function. The aim of this study was to evaluate pulmonary function before and 5 years after surgery for morbid obesity.

Material and method: Bariatric surgery has been performed at Oslo University Hospital Aker since 2004. Patient data included anthropometric and spirometric data at baseline and at 5 years follow-up. Only one physician performed the 5 year follow-up consultations. Continuous data are reported as mean ± standard deviation (SD). Informed and written patient consent for use of data were retrieved. In total, 113 patients with BMI 47 ± 6 kg/m^2 and age 40 ± 9 years at time of surgery were included. 80 (71%) were women. 101 (89%) had gastric bypass, 10 (9%) duodenal switch and 2 sleeve gastrectomy. Spirometric data included forced expiratory volume in one second (FEV1), forced vital capacity (FVC), FEV1/FVC ratio and peak expiratory flow (PEF). Information of asthma and obstructive sleep apnea (OSA) were reviewed at baseline and at follow-up.

Results: Weight declined from 140 ± 25 kg at baseline to 100 ± 24 kg after 5 years ($p < 0.001$) and BMI from 47 ± 6 kg/m^2 to 34 ± 6 kg/m^2 ($p < 0.001$). FEV1 increased from 3.10 ± 0.93 liter (L) to 3.25 ± 0.76 L ($p < 0.001$) and FVC from 3.91 ± 0.90 L to 4.16 ± 0.94 L ($p < 0.001$). FEV1/FVC ratio was reduced and PEF was increased, the latter changes were small but statistically significant. Improvements in FEV1 and FVC correlated significantly with weight loss. At baseline, asthma was reported in 27 and OSA in 25 patients. After 5 years this was reduced to 14 and 5, respectively.

Discussion: Weight loss in this study compares to results of other long term studies after bariatric surgery. The improvements in pulmonary function correspond to the findings in short term studies. Also in this long term study, the improvements in FEV1 and FVC were substantial. The main improvements seem to be a relief in pulmonary restriction.

Conclusions: Bariatric surgery provides considerable weight loss and improvements in pulmonary function, and also in asthma and OSA 5 years after surgery.

V-145
HYPERCALCEMIA: THE REALITY OF AN INTERNAL MEDICINE DEPARTMENT

C. Cunha[2], T. Fonseca[1], J. Silva[3], A. Silva[1], M. Moreira[1], L. Andrade[1], V. Paixão Dias[1]

[1]Department of Internal Medicine, [2]Department of Nephrology, [3]Department of Gastroenterology. Centro Hospitalar de Vila Nova de Gaia/Espinho. Vila Nova de Gaia, Portugal.

Objectives: Hypercalcemia is a relatively common clinical problem with a wide range of possible etiologies. However, hyperparathyroidism and malignancies account for greater than 90% of all cases. The degree of hypercalcemia and hypercalcemic symptoms can be useful in diagnosis. Patients with hypercalcemia of malignancy usually have higher calcium concentrations and are more symptomatic than individuals with primary hyperparathyroidism. Briefly, treatment should be started with hydration in all cases, and calcitonin and bisphosphonates are usually necessary in severe cases. Loop diuretics may be necessary in patients with renal or cardiac failure and glucocorticoids are effective in hypercalcemia due to chronic granulomatous diseases or lymphoma. The purpose of this study is to review the characteristics and management of patients hospitalized in an Internal Medicine Department with a diagnosis of hypercalcemia.

Material and method: A descriptive and retrospective study performed in an Internal Medicine Department. All patients admitted between January 2004 and March 2012 with primary or secondary diagnosis of hypercalcemia were included. Patients whose clinical process was unavailable were excluded.

Results: This study identified 29 patients with primary and secondary diagnosis of hypercalcemia; 4 were excluded. Of the 25 patients included 68% were females and the average age was 71 years. Hypercalcemia was the cause of admission in one third of the cases and they were hospitalized on average for 14.5 days. The serum calcium levels at the time of diagnosis ranged between 9.8 and 16.5 g/dl. The causes of hypercalcemia were solid tumors (7 cases), hematological malignancies (10 cases), primary hyperparathyroidism (5 cases), sarcoidosis (1 case) and two cases of unknown etiology. There was a higher prevalence of malignancy in severe hypercalcemia. Impaired renal function occurred in 44% of patients but no relation was found with the degree of hypercalcemia. Fluid therapy was a frequent treatment applied (72%).

Bisphosphonates (pamidronate or zoledronic acid) were used in only 24% of cases and calcitonin in only one patient. Most patients were normocalcemic at discharge.

Discussion: Primary hyperparathyroidism and malignancies were the most common causes of hypercalcemia, with a higher prevalence of malignancies in severe hypercalcemia, which is consistent with bibliography. In this study, no association was found between the degree of hypercalcemia and acute kidney injury, perhaps a consequence of the small study sample. Hydration is essential in the treatment of hypercalcemia and was performed in most cases. Pamidronate and zoledronic acid were the bisphosphonates used and are the most suitable according to literature. However, the administration of calcitonin and bisphosphonates in these patients was expected to be higher.

Conclusions: Primary hyperparathyroidism and malignancies were the most common causes of hypercalcemia in our study, as expected. As regards treatment, fluid therapy was frequently applied, but only a small proportion of patients received calcitonin and bisphosphonates.

V-146
THE EFFECT OF HOT OR COLD APPLICATION IN THE PATIENTS WITH KNEE OSTEOARTHRITIS

C. Inan[1], E. Kiyak[2]

[1]Nursing. Ordu University. Ordu, Turkey. [2]Nursing. Ataturk University. Erzurum, Turkey.

Objectives: This study was carried on the patients with knee osteoarthritis with the aim of evaluating the effect of hot and cold applications.

Material and method: The study, carried out experimentally, was realized on the patients with knee osteoarthritis who come to Physical Treatment and Rehabilitation Out-patient Clinic of Ordu State Hospital between the dates of February-October 2011. 25 of 79 patients participating in the study were divided into hot group, and 29 of the patients for cold group, and 25 of the patients were divided into control group randomly. Hot application was applied to the hot group for 15 minutes per day and for the five days throughout a month, and cold application was applied to the cold group for 15 minutes per day and for the five day throughout a month, and any application wasn't applied to the control group. In the collection of the study data, questionnaire form, WOMAC Osteoarthritis Index, VAS pain scale and medicine assessment form were used. In the assessment of the data, Chi-square, One-way Anova and Duncan tests were used. The research was funded Ataturk University (BAP -2011/63).

Results: It was found out that there was no significant distinction between pre-test pain, stiffness and physical functional score of averages of the patients in the group of hot, cold and control ($p > 0.05$). But there was a significant distinction between post-test pain, stiffness and physical function score averages of the patients in the group of hot, cold and control group ($p < 0.05$). It was detected that this distinction between post-test pain, stiffness and physical function score averages resulted from hot-control group and cold-control group, but there was no significant distinction between hot and cold groups ($p > 0.05$, Duncan), throughout a month application process. It was also defected that there was no significant distinction between the use of medicine averages of hot, cold and control groups ($p > 0.05$).

Conclusions: In the conclusion of this study, it was found out that in the patients with knee osteoarthritis, the application of hot and cold provided significant recoveries in pain, stiffness and physical functions.

V-147
ACUTE HYPERGLICEMIA AND SEPSIS IN AN INTERMEDIATE CARE UNIT

L. Fernandes[1], C. Conceição[1], F. Aguiar[1], T. Pereira[1], A. Mansinho[1], S. Mateus[1], V. Batalha[2], L. Campos[1]

[1]Department of Internal Medicine IV, [2]Department of Intermediate Care. S. Francisco Xavier Hospital, Western Lisbon Hospital Center. Lisbon, Portugal.

Objectives: Clinical and demographic description of inpatients of an Intermediate Care Unit (UCINT) who had sepsis criteria, as well as prevalence study of acute hyperglycemia (AH) in this group of patients.

Material and method: Retrospective and observational study based on UCINT´s data base (453 patients), from 2008 to 2011. Selection of patients with sepsis criteria (n = 151). Comparison of demographic characteristics, severity scores, clinical presentation, morbidity and mortality during internment in the group of patient who presented AH at admission (n = 31) and the control group (normal glycemia) (n = 120).

Results: Demographic characteristics were similar in both groups. The main infection focuses were respiratory and urologic. Amongst the 31 patients with AH (20.5%), the average glycaemia values were 358 mg/dL (minimum 201 mg/dL; maximum 752 mg/dL). In this group, 17 (54.8%) were diabetics, against 29 (34.1%) diabetics in the control group. The group with AH presented more co-morbility at admission, with an average Charlson Comorbility Score of 6.04 vs 4.40, and a higher average of Simplified Acute Physiology score, 31.0 vs 28.4. The AH group presented lower average internment days (8 days vs 10 days) but higher mortality rates (9.8% vs no deaths in the control group).

Discussion: Acute hyperglycemia occurs frequently in critical patients. Its physiopathology is complex and some authors have described an association with an increase in morbidity and mortality amongst seriously ill patients. In this study we found more co-morbidities and a higher severity scores at admission in the group of patients with AH, as well as a higher mortality rate.

Conclusions: Though we have found a statistical trend in our results, we consider that being a small dimensioned sample and a retrospective study, more studies are needed to clarify this trend.

V-148
MAGNETIC RESONANCE ENTEROGRAPHY (MRE) FOR THE MANAGEMENT OF CROHN'S DISEASE

J. Mendoza[1], R. Lana[2], F. Matute[3], N. López-Palacios[1]

[1]Department of Gastroenterology, [2]Department of Internal Medicine, [3]Department of X-ray Diagnosis. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: To describe the experience a tertiary care centre during the first year of use of magnetic resonance enterography (MRE) for the management of Crohn's disease (CD): indications, results and influence of the technique in clinical decision making.

Material and method: Retrospective descriptive study in which patients who underwent MRE were included consecutively. Epidemiological and clinical data were collected from the patients, as well as the indication for the study and how it influenced clinical decision making in the 10 days following the radiological study.

Results: 150 MREs were performed. The indications were: presence of clinical symptoms of partial bowel obstruction in 53 patients (35%), monitoring of medical treatment in 34 (23%), suspected CD in 24 (16%), completion of study due to incomplete ileocolonoscopy in 16 (11%), extension study of the small intestine in 15 (10%) and suspected complicated CD in 8 patients (5%). The MRE was the reason for a change in treatment in 83 (55.3%) patients.

16 (10.7%) patients with immunosuppressants, 41 (27.3%) patients were started on or had a change in their anti-TNF, 15 (10%) patients were ordered surgery and in 3 (2%) patients the MRE led to a change from combined therapy to monotherapy.

Conclusions: The use of MRE in clinical practice had a relevant impact on decision making in more than half of patients, especially with regards to decisions related to the use of biological therapies and the indication for surgery.

V-149
RAPID DIAGNOSIS AND CARDIOVASCULAR RISK IN OUTPATIENT SETTING

A. Berroeta, M. Vaquero, A. Fuertes, U. Errasti, X. Kortajarena, M. Elola, N. Pérez, M. Ibarguren

Department of Internal Medicine -A. Pierola. Hospital Universitario Donostia EHU/UPV. Guipúzcoa, Spain.

Objectives: We aimed to assess the differences in basal characteristics and medical conditions of patients who are attended in Rapid Diagnosis & Cardiovascular Risk Consultation in hospital by Young Internists, in order to improve patients management.

Material and method: We searched in our Consultation´s database the registration number of patients attended between June-2010 and January-2012 in weekly Young Internists Quick Diagnosis Consultation. We extracted dates from medical records about age, sex, morbidity assessed by Charlson Score, patients origin, presenting complaints, certain diagnosis and the follow up after discharge.

Results: In period between June -2010 and January-2012, 120 patients were attended in our consultation. 63% were men and 37% were women. The mean age was 65 years and the mean comorbidity assessed by Charlson score was 1.52. The mean of visits which were required to complete the diagnostic and therapeutic process was 3 visits.30.77% patients were referred from primary care physician, 32.48% from emergency department, 27.35% from specialties and 9.4% from Vascular Surgery. After complete evaluation, 66.32% were remitted to primary care physician, 4.08% to Surgical specialties and 29.59% to Medical Specialties. Most frequent presenting complaints and diagnosis are shown in the tables below.

Conclusions: Rapid Diagnosis Consultation may be a good tool to avoid unnecessary admissions, providing a quick way to manage patients. The 11% of patients come to our consultation are referred from Vascular Surgery to evaluate cardiovascular risk factors in a global way. Thus, we can provide a complete treatment of hypertension, diabetes, hypercolesterolemia... avoiding the cost of too many specialties.

V-150
THE ROLE OF FECAL CALPROTECTIN IN CLINICAL PRACTICE

F. Marc[1], C. Moldovan[1], D. Farcas[2]

[1]Department of Internal Medicine. Municipal Hospital. Oradea, Romania. [2]Faculty of Medicine and Pharmacy. Oradea, Romania.

Objectives: Calprotectin is a polypeptide derived form neutrophils; fecal calprotectin can be considered as a direct measure of intestinal inflammation; it may be used to differentiate among patients with abdominal symptoms those who require invasive investigations. In our study we wanted to evaluate the practical utility of this marker for patients admitted in an Internal medicine Department.

Material and method: We have performed a prospective study on 60 consecutive patients admitted in the Internal Medicine Department of Municipal Hospital in Oradea during 2011 who presented with: diffuse abdominal pain, bloating, diarrhoea, constipation or alternation between diarrhoea/constipation. In these patients we measured fecal calprotectin (normal values ≤ 40 µg/g; 40-60 µg/g inconclusive, > 60 µg/g = positive) and we also performed colonoscopy. Colonoscopy was mandatory in patients with weight loss, familial history for cancer, positive Hemocult test.

Results: The patients evaluated had the following diagnosis: 30% irritable bowel syndrome (IBS), 28% diverticulosis, 20% polyps, 14% inflammatory bowel diseases (IBD), 8% colorectal cancer. In patients with normal colonoscopy, the values of fecal calprotectin were < 40 µg/g in 97% of cases and the diagnosis was IBS. In patients with organic lesions the values of calprotectin were > 60 µg/g in 92% of cases. Values above 100µg/g have been found in IBD and cancers. There was also a correlation with age: in younger patients the prevalence of IBS and IBD was higher, in older patients we found diverticulosis, polyps and colorectal cancer more prevalent.

Conclusions: Fecal calprotectin is a useful marker for screening, being able to differentiate IBS from organic lesions. There is a good concordance between the values of calprotectin and the results of colonoscopy; in patients with normal values of fecal calprotectin, colonoscopy is not required. In those with increased values of fecal calprotectin colonoscopy becomes necessary (compulsory). The cost of calprotectin is half of the colonoscopy price.

Table 1 (V-149). Presenting complaints

Presenting complaints	Percentage	Presenting complaints	Percentage
Constitutional symptoms	8.47%	Cardiovascular risk	11.01%
Adenopathies	6.78%	Syncope	6.78%
Digestive disorders	12.71%	Anemia study	9.32%
Dyspnea	9.32%	Miscelaneous	29.66%
Arrhythmia	8.47%		

Table 2 (V-149). Certain diagnosis

Certain diagnosis	Percentage	Certain diagnosis	Percentage
Neoplasia	9.64%	Cardiovascular risk factors	12.28%
Heart failure	4.38%	Infectious diseases	10.52%
Arrhythmia	11.4%	Autoimmune disease	3.5%
Pulmonary disorders	7.01%	Miscelaneous	29.82%
Digestive disorders	16.66%		

V-151
IS THE ULTRASOUND A USEFUL TOOL DURING CARRYING OUT OF PROCEDURES IN AN INTERNAL MEDICINE SERVICE?

E. Amao, F. Michel, S. Somovilla, C. Quintero, E. Val

Department of Internal Medicine. Virgen de la Luz Hospital. Cuenca, Spain.

Objectives: Ultrasound use has grown considerably becoming a standard of care in a variety of procedures in some specialties so the aim of this study was to describe the initial use of ultrasound during carrying out of procedures by internal medicine physician in the internal medicine service of Virgen de la Luz Hospital.

Material and method: During April 2012, ultrasound assisted procedures were performed by an internal medicine physician in patients admitted to internal medicine wards. Patients gave their written informed consent. The procedures were thoracocentesis, paracentesis and central vein catheter placement. A M5 colour Doppler Ultrasound with static technique was employed. Physicians had been trained to use ultrasound by clinical ultrasonography group of SEMI.

Results: Ultrasound assisted procedures were performed in 6 male patients of internal medicine wards. The mean age was 75, 6 years old. There were five thoracocentesis (83.3%) and one (17.7%) ascites puncture. There was not central catheter placement. Fluid was successfully obtained in the first attempt in all occasions without complications. The majority of pleural effusions were exudate (66.6%).

Discussion: Internal medicine physician perform bedside invasive procedure such as thoracocentesis, paracentesis and central venous catheter placement in many teaching hospital in Spain. Data suggests that ultrasound assisted during this procedure can decrease complications, reduce costs, improve procedure related outcome and enhance patient safety. Our study though performed in a small number of patients in consistent with previous data. The societies of American emergency physicians, Echocardiography and Cardiovascular anesthesiologists have developed some criteria to assist practitioner performing emergency ultrasound study and ultrasound guided vascular cannulation. There are not currently recommendations in Spain about ultrasound assisted procedures. In this study we followed the American emergency physicians' guidelines. Although we had a small number of patients and there was not a control group, these findings suggest that implementation of ultrasound assisted procedures in our Internal Medicine Department could improve clinical outcome, because we obtained fluid from pleural effusions and ascites in the first attempt. Besides patients' safety and less costs can be also achieved.

Conclusions: Ultrasound appear to be a useful tool for interventions performed bedside by internist so it is imperative that future internal medicine physician have solid foundation in ultrasonography and is trained to take advantage of this powerful tool.

V-152
USE OF THE BLATCHFORD SCORE IN UPPER GASTROINTESTINAL BLEEDING IN THE EMERGENCY DEPARTMENT

G. Patrón Román[1], A. Gálvez Miras[1], B. Hernández Sierra[2], L. Moreno Fernández[2], J. Vega Sáez[1], F. Díez[2], A. Hernández[1]

[1]Department of Gastroenterology, [2]Department of Internal Medicine. Complejo Hospitalario Torrecárdenas. Almería, Spain.

Objectives: To determine the usefulness of the Blatchford score in non-varicose upper gastrointestinal bleeding as a predictor of emergency clinical and/or endoscopic intervention in our population.

Material and method: Observational study that included 127 cases of upper gastrointestinal bleeding confirmed by endoscopy as high-risk according to the Blatchford score applied retrospectively. The study setting was the emergency department at Hospital Torrecardenas Almería, Spain, between January 2009 and December 2010. The data were obtained from the DIRAYA computer system. Subjects were classified quantitatively into 2 high-risk subgroups according to the Blatchford score, group I less than 10 points and group II greater than or equal to 10 points, which was correlated with the need for emergency versus early clinical and endoscopic intervention.

Results: In our study, 63.8% (81 cases) were men and 36.2% (46 cases) were women. The most frequent endoscopic lesion for both subgroups is the type IIC based on the Forrest classification. Therefore, only 32.3% of cases required endoscopic sclerotherapy. There were no statistically significant differences between endoscopic or surgical treatment in the high-risk subgroups. 63% of cases received a blood transfusion due to acute anemia. This correlated significantly with a higher Blatchford score.

Discussion: A high-risk Blatchford score is not useful in predicting the need for urgent versus early endoscopic intervention in non-varicose upper gastrointestinal bleeding. The most frequent lesion in patients with a high-risk Blatchford score is Forrest IIC, with no significant difference in the high-risk subgroups.

Conclusions: The need for blood transfusion is directly proportional to the high-risk Blatchford score. Validation studies are needed for risk-stratification scales in order to understand their use and improve their utility in healthcare services.

V-153
CHARACTERISTICS OF HOSPITAL READMISSIONS IN ONE YEAR PERIOD IN AN INTERNAL MEDICINE WARD

S. Barbero Alonso[1], M. Fernández Blest[1], I. Díaz del Río[1], F. Pedro de Lelis[1], V. Granell[2]

[1]Department of Internal Medicine, [2]Department of Nutrition. Hospital General Universitario de Valencia. Valencia, Spain.

Objectives: Described patient characteristics, nutritional status, length of stay, diagnosis in first admission and source of the patients

Table 1 (V-151)

Age	Sex	Pathology	Procedure	Liquid characteristic	Complication
55	Male	Ascitis	Paracentesis	Transudate	No
88	Male	Pleural effusion	Thoracocentesis	Exudate	No
89	Male	Pleural effusion	Thoracocentesis	Exudate	No
75	Male	Pleural effusion	Thoracocentesis	Exudate	No
61	Male	Pleural effusion	Thoracocentesis	Exudate	No
86	Male	Pleural effusion	Thoracocentesis	Transudate	No

that have at least one readmission during this period compared with the patients that were not readmitted.

Material and method: A retrospective, descriptive study of hospital readmissions that occurred over a one year period from January to December 2011 in an internal medicine ward of the General University Hospital in Valencia City.

Results: This study included 869 discharges between January 1st and December 31st 2011, in a total of 824 patients. We analyzed results dividing them into two groups; 204 were readmissions (23%) and 665 (77%) were admitted only once. there were no differences in patient sex among the two groups. The median age in these two groups groups was 84 years. In the group of patients who were not readmitted, the main diagnosis was pneumonia (10.5%) followed by urinary tract infections (UTIs) (7.4%) and among the group of readmitted patients, the principal diagnosis was pneumonia (12.6%) followed by congestive heart failure (CHF) (11.9%) with p 0.028. For the patients who were only admitted once, the average length of stay in their first hospitalization was 8.5 days compared to 9.88 days among patients readmitted (p 0.03). For the readmission group, 22% of the patients were discharged on Thursday and 27% on Friday compared with 16% on Thursday and 20% on Friday in the non readmitted group (p 0.01). The nutritional status in the non readmitted group were 61% malnourished and among them, 18% had protein malnutrition, 16% caloric malnutrition and 26% mixed malnutrition; in contrast, in the readmitted group 61% were malnourished; among them, 21% had protein malnutrition, 17% caloric malnutrition and 22% mixed malnutrition. 19% of the patients who came from nursing homes were malnourished (p 0.013). Amongst the patients who were readmitted within the first 30 days after index discharge, 37% of them were malnourished versus 28% of patient who were readmitted after 30 days (p 0.022). Patients in the readmitted group who had more days of hospitalization in their first admission were the ones who had more chance of being discharged in their second admission with the help of the home hospitalization unit. The source of admission had an implication on the duration of hospitalization, the patients transferred from other wards had more days of hospitalization with a mean of 33.33 days versus those who came from their home, 9.42 and those who came from nursing homes, 9.46 (p 0.001).

Discussion: A quarter of the patients seen in one year were readmissions with no statistical differences between men and women. The main diagnoses were pneumonias followed by CHF in the readmission group, so the patient that has one of those as initial diagnosis, has more chance of being readmitted compared to the patients that have a different initial diagnosis. Another possible predictor of rehospitalization is the duration of the index hospital stay, if a patient is first admitted for a longer period, it is more likely that he will be readmitted. Also, we found a difference in the day of the first discharge, because if this occurs on Thursday or Friday, there is more chance the patient will be readmitted. We found two characteristics in the patients who were readmitted; firstly, patients coming from a nursing home were more malnourished and secondly, that there is a link between the nutritional status and the likelihood of being readmitted within the first 30 days after their index discharge.

Conclusions: We found no difference in the nutritional status amongst patients admitted once and the patients who were readmitted more than once, we cannot however assure that this could be used as a predictor for patient readmission, more studies would be necessary in order to establish a relationship between the nutritional status and the possibility of readmission. Also, we are not so far from having a scale that will predict the possibility of a patient being readmitted in the future.

V-154
CLINICAL PROFILE OF PATIENTS ASSISTED BY THE INTERNAL MEDICINE RESIDENT DURING SHIFTS IN A SPECIALITIES HOSPITAL OF THE SAS

G. García Domínguez, O. Mera Gallardo, S. Romero Salado, G. Ruiz Villena, R. Aranda Blázquez, V. Lechuga Flores, V. Manzano Román, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: Clinical and epidemiological analysis of the beeps received in the blepper of the internal medicine resident during shifts in a specialities teaching hospital.

Material and method: Analysis of 200 calls received in different shifts of the internal medicine residents from a database including: time of day, speciality, reason for calling, age and sex of patients, diagnosis at admission and whether it was necessary or not treatment adjustment.

Results: From the 200 beeps analysed, the majority of them (37%) were from the period of time ranging from 12 pm to 18 pm, followed by the one from 18 to 22 pm (34%), 8 am-12 pm (15%) and 22 pm-8 am (14%). The most demanding service was Internal Medicine (46%), followed by Cardiology (12%), other surgical areas (9.7%), specially for case conferences (26.7%), Pneumology 88.7%), Oncology (6.3%), Gastroenterology (5.8%), Neurology (4.8%) and Infectious Diseases (3%). The most frequent cause for it were admissions (32.2%) and case conferences and complementary test results (26.7%). Glycemia disorders (7.2%), dyspnea (6.3%), deceases (4.6%) and agitation (4.6%) were less frequent. The age of our patients mainly ranged 60-80 years-old (48.2%), followed by the 40-60 stage (21.7%) and those older than 80 years-old (20.5%). They were male (60.6%) predominantly. The most common reason of admission were infections of different etiologies (29%) and heart failure (17.4%), followed by COPD exacerbations (14.3%), neoplasias (10.3%) and myocardial ischemia (14.3%). The majority of them needed treatment adjustment.

Discussion: Most beeps received by the internal medicine resident are for admissions of patients and case conferences and complementary test results. Beeps are usually in the afternoon-evening and the patients are mainly males, ranging from 60 to 80 years-old, with any kind of infection, heart failure or COPD exacerbation.

Conclusions: Although mostly claimed for admissions of its speciality, the internal medicine resident deals with clinical and therapeutic difficulties of patients and pathologies of all medical specialities, allowed by its overall view of medicine.

V-155
A DESCRIPTIVE STUDY OF THE RARE DISEASES UNIT IN THE INTERNAL MEDICINE DEPARTMENT OF UNIVERSITY GENERAL HOSPITAL OF ALICANTE (HGUA): THE EXPERIENCE OF FOUR YEARS

D. Jover, S. Olmos, A. Zurita, J. Cama, J. Mateo, H. Pinargote, D. Galvis, R. Sánchez

Department of Internal Medicine. University General Hospital of Alicante. Alicante, Spain.

Objectives: The Internal Medicine Service of HGUA, in response to society's demand, initiated in November 2008 the creation of a reference unit for the management of rare diseases. Since its creation, a progressive increase in the number of consultations has been observed. The aim of this study is to analyze the activity of the Rare Diseases Unit in our Department of Internal Medicine since its opening in November 2008 to May 2012.

Material and method: Descriptive study of patients treated in the Rare Diseases Unit of the Internal Medicine Service of HGUA since November 2008 to May 2012. The medical records of all patients seen were reviewed and clinical variables were collected. This information was introduced in a database. The analysis of this database has been carried out through the program SPSS.

Results: During the period from November to May 2012, a total number of 165 patients were treated, out of which 69 were male (41.8%) and 96 (58.2) were female, with an average age of 45.3 years. The age at diagnosis of the diseases in a range of 1-69 years old. Patients were referred mainly from the Internal Medicine Service (25%) and from The Spanish Federation of Rare Diseases FEDER (9.7%). Patients were also referred from Primary Care department (6.1%) and other services such as Rheumatology (5.5%), Otorhinolaryngology (4.8%), Neurology (4.2%), Digestology (4.2%) among others. 81 different diagnosis were collected, being the main reason for consulting the study towards the discard of Marfan's syndrome (11.5%). The most frequent diagnosis is Marfan's syndrome (9%), followed by Ehlers-Danlos disease (5.5%), Von Recklinghausen disease (4.2%), marfanoid habitus (3.6%), acute intermittent porphyria (3.6%) and ectopia lentis (3%). 48.5% of the diseases are congenital and 27.9% are acquired. A genetic study was conducted to 91 patients (55.2%). The patients were referred to other specialists, being the most consulted services: Ophthalmology (16.74%), Cardiology (16.25%), Digestology (10.83%), Neurology (8.8%) and Rheumatology (6.8%).

Discussion: The increase of the diagnosis of rare diseases is based on the best knowledge and medical consensus on the disease which also contributes to an increase of its prevalence diagnosis. The Internal Medicine Service meets the requirements for the assistance to patients with a diagnosis of rare diseases. The growing demand in this consults has been exponential in the last two years, becoming the reference unit in our province. The study has allowed us to know the needs of our unit and therefore to carry out a more suitable planning of the health care of a unit in continuous growth.

Conclusions: The Internal Medicine service has proved to meet the necessary requirements for the management of these pathologies and the Rare Disease Unit has become a reference unit. In our Rare Disease Unit the most frequently managed pathology is Marfan's syndrome. Patients are referred from different services for a multidisciplinary management. The implementation of diagnosis protocols and treatment for some diseases has allowed a better and more responsive health care of rare diseases. It would be necessary to create protocols for each of the rare diseases.

V-156
HEDEDITARY HEMACHROMATOSIS. A VERY FREQUENT DISEASE DIAGNOSED IN THE HEALTH CENTRE AREA IN THE NORTH JAÉN

J. Gutiérrez Zafra, M. Romero Ferreira, J. Sampedro Villasán, M. Gómez Rodríguez, R. Gato Morais, D. Rosado Álvarez

Department of Internal Medicine. Hospital Comarcal San Agustín. Jaén, Spain.

Objectives: The hemachromatosis belongs to a group of diseases characterized by the overload of iron in our body. It can have acquired or hereditary forms (mutations CD82YD, H63D). This last one is especially prevalent in our health centres area of the north of Jaen. In this study we describe our experience as well as the factors which determine its evolutionary development.

Material and method: Descriptive and retrospective epidemiology study of the patients who present some genetic mutation of the hemachromatosis in an outpatient consultation of Internal Medicine.

Results: The total number of identified patients is 19. The average age is about 48 years (between 19-70). Sex: 79% men, 21% women. In the 47.4% of the patients diagnosed there are family inherited factors of hemachromatosis, in 52.6% these are unknown. The most common mutation is H63D which is found in 100% of the patients (73.68% are heterozygotes, 21.05% are homocygotes, one only patient is double heterozygote for the mutation of the gene H63D and C282Y). Among the concomitant pathologies which have been found in 57.9% of the patients, the most frequent are hypertension (36.8%), dyslipemia (21%), diabetes (only one patient). Toxic habits; 26.31% are smokers and heavy drinkers (all of them men). All the diagnosed patients are refered to the Primary Care Emergency Service by an increase of the ferritin in the anlytic control (42.1%), familiar study (42.1%), others by an increase of the elevated liver enzymes (17.78%). Only one of the patients presents symptomath¡ology in the form of osteoarticular symptoms, the rest of them are asymptomatic. There is any patient who shows in the monitoring process degeneration in cirrhosis or hepatocellular carcinoma. The 26.31% presents fatty liver which coincides with those patients who have an increase of the elevated live enzymes. The average of the monitoring process is 4.6 years. In the therapeutic:31.57% of the patients do not need phlebotomies during the follow-up process, 31.57% need less than 5 phlebotomies, 15.78% between 5-10 and 21.05% more than 10.

Discussion: The periodicity of the phlebotomies is higher in the homozygote carrier or double heterozygote in the disease diagnosis, men and the existence of a severe ingestion of alcoholic beverages (the alcohol increases the absorption of iron in our body). There are any cases of hepatic cirrhosis or hepatocellular carcinoma due to the short follow-up period since the disease was diagnosed. These will probably develop as time goes by, above all in those patients with concomitant pathologies and or persistence of toxic habits.

Conclusions: All the patients have been diagnosed in our consultations in the last 5 years. The regularity of the phlebotomies decreases with the age, feminine sex and healthy lifestyle. The heterozygote carrier H63D needs some sporadic phlebotomies except in heavy drinkers. The healthy heterozygotes H63D diagnosed with familiar study only need half-yearly or yearly medical tests. The homozygote's carriers H63D and the double heterozygote C282Y-H63D need phlebotomies more frequently, they have a check-up every 3 months. The heterozygotes H63D alcohol drinkers need phlebotomies and checkups as regularly as the other previously mentioned. Further complications have not been detected as the case of cirrhosis or hepatocellular carcinoma because of the short/narrow monitoring of our patients in the Outpatient Services Center.

V-157
A STANDARDISED MORTALITY REVIEW OF PATIENTS DYING OF ACUTE KIDNEY INJURY AT SHERWOOD FORREST HOSPITALS TRUST IN 2011

F. Choudhary, S. Stinchcombe

Department of Patient Safety. Sherwood Forrest Hospitals Trust. Mansfield, Nottinghamshire, United Kingdom.

Objectives: To standardise the process of mortality review. To identify any evidence of suboptimal care in the management of patients who had died having presented with acute kidney injury (AKI). To initiate change in practice based on the findings of the mortality review. To devise methods or systems that could prevent avoidable death in this patient category. To improve patient safety in patients being admitted to this trust with acute kidney injury.

Material and method: A case note review of patients with acute and unspecified renal failure was triggered following analysis of the hospital standardised mortality review (HSMR). We used the IHI Global Trigger Tool grid (UK version) to identify any triggers of

patient harm in the selected group of patients and then categorised these triggers into the level of harm sustained as a result. Care was compared to optimal care as outlined in the hospital policy for management of AKI. We also used a series of "deep dive questions" extracted from the NHS institute for Innovation and Improvement to assess and identify failure of care at the trust. These were then categorised into the following: Was death avoidable? Was there harm before admission?; Failure to plan/follow protocol: Failure to rescue or Failure to communicate.

Results: We analysed 34 sets of case notes and identified 15 deaths which were possibly avoidable if optimal care had been given. Of these 15 deaths, the following categories of harm were identified. Harm before admission due to delayed recognition of AKI was evident in 3 (20%) patients. A failure to follow hospital protocol on management of AKI was a significantly contributing factor in 8 (53%) patients. Failure to plan was evident in 12 patients ie; 80% of avoidable deaths. This was either a failure to follow protocol on the management of AKI, failure to plan management of coexistent cardiac failure or failure of general nursing care. Failure to rescue was identified in 2 (13%) patients, due to failure to act on deteriorating vital signs. A failure to communicate was identified in 1 case (7%). The Trigger Tool for was used and identified patient harm triggers in 12 of the 15 possibly avoidable deaths. These ranged from 1 to 6 triggers per patient. However, these were not felt to correlate with the degree of harm to the patient.

Discussion: The results show a failure in all 4 categories that were highlighted. The majority being a failure to follow the hospital policy. To combat this, we have initiated a computer alert system for patients who develop AKI and we are currently putting together an education pack for junior doctors on AKI. We want to relaunch and republicise the hospital policy and communicate this to the primary care doctors. We will also be reviewing discharge documentation to allow clearer instructions on further management to the primary care physicians. We will also take steps to improve general care and prevent dehydration in inpatients.

Conclusions: A standardised mortality review of patients can lead to identification of patient safety issues which can then allow new systems to be put into place to avoid such errors. We would suggest that individual hospitals incorporate standardised mortality review into their routine audit practice.

V-158
CLINICAL FEATURES, DIAGNOSTIC PROCEDURES AND TREATMENT ON PATIENTS WITH CAROTID GLOMUS TUMOR ON A THIRD LEVEL HOSPITAL OF CASTILLA LA MANCHA

R. Cordero Bernabé[1], I. García del Valle[1], Á. Martínez Monsalve[2], I. Hermida Lazcano[1], E. Sánchez Muñoz[4], A. Fernández Sáez[3]

[1]Department of Internal Medicine, [2]Department of Angiology and Vascular Surgery, [3]Department of Family and Community Medicine. Hospital General de Albacete. Albacete, Spain. [4]Department of Orthopaedics and Traumatology. Complejo Hospitalario de Toledo. Toledo, Spain.

Objectives: Analize clinical features, diagnosis procedures, treatment and postoperative sequels of the population with carotid glomus tumor on a third level hospital of Castilla-La Mancha.

Material and method: We made a retrospective descriptive study on the patients diagnosed of carotid glomus tumor in the General Universitary Hospital of Albacete between 1995 and 2012. We analyzed: sociodemographic variables, clinical findings at the moment of diagnosis, complementary test used, treatment and postoperative follow up of the patients.

Results: A total of 23 patients were included in the study, 16 men (69.5%) and 7 women (30.5%). Average age was 57 years [IR: 47-65.5]. Four patients presented bilateral tumor (17.4%), with a total of 27 tumors included in the study. Sixteen patients (69.56%) showed neck mass, most of them pulsatile at the moment of diagnosis. One patient (4.34%) showed dysphagia when was diagnosed. In four patients (17.4%) the diagnosis was a casual finding, two patients (8.7%) were diagnosed after an ischemic stroke, dysphagia was the first clinical finding on one patient (4.34%). Patients were diagnosed by their clinical findings and eco-doppler in seventeen cases (74%). Cervical CT was the key for diagnosis in six patients (26%). In all patients we realized a body CT to look for extended disease. Catecolamin-production test was realized on twelve patients (52.17%) to identify active paragangliomas. In twenty four patients (88.8%) was performed surgical treatment. In asymptomatic patients (11.2%) we performed conservative treatment. We realized embolization before surgery on ten out of the twenty four patients that observed surgical treatment. Arteriography before surgical procedure was realized on twenty patients (74%). The twenty seven cases were divided according Shamblin classification: ten patients (37%) as type I, eleven patients (44%) as type II, and six patients (22%) as type III. Postsurgical complications: Nervis vagus lesion was found in four patients after surgery, nervis hypoglossus lesion was found in seven patients after surgery, cerebral stroke in one patient, clinical paresthesias in one patient, scar pain in one patient and one patient needed additional surgical procedure due to postsurgical bleeding. Postsurgical follow up: three patients (13%) need no additional tests, eco-doppler was realized in fourteen patients (60.86%), in four patients (17.4%) was realized CT and in two patients (8.7%) was realized CT and eco-doppler. In the pathology were found: twenty paragangliomas (83.2%), two glomus tumors (8.4%), one fibrohisticioma (4.2%) and one hemangioma (4.2%). No family-associated disease was found in our group of study.

Conclusions: Carotid glomus tumors show low incidence in population. The main clinical finding is laterocervical tumor on the neck, usually pulsatile. Carotid glomus tumors are diagnosed by their clinical findings and using complementary tests, cervical eco-doppler in most cases. A body CT should be realized in every patient with carotid glomus tumor to valuate metastasis. Urine levels of catecolamine should be tested as part of the usual valuation after diagnosis to identify functional paragangliomas. Postsurgical follow up must check the presence of clinical symptoms after surgery and additional eco-doppler should be realized when those symptoms appear.

V-159
FOUR REASONS WHY THE MORTALITY RATE IS GROWING IN MEDICAL WARDS

L. Andrade Maia, Â. Coelho, M. Ferreira, L. Oliveira, N. Cardoso, M. Aguiar, P. Neves, A. Duarte

Department of Internal Medicine. Centro Hospitalar do Médio Ave - Famalicão. Vila Nova de Famalicão, Portugal.

Objectives: Describe and characterize the deceased population between the years of 2008-2009 and 2010-2011. Understand the progressive and growing mortality rates in medical wards.

Material and method: In order to characterize this population, we conducted a four year retrospective analysis and review of the deceased patients' medical records in our medical ward between January 2008 and December 2011. For each patient we registered the patient's age, gender, dependence degree, main and associated diagnosis as well as cause of death, inpatient length of stay, death predictability and origin of the incoming patients.

Results: A total of 1018 mortality records were reviewed, corresponding to an overall mortality rate, in the four year period, of 14.22%. Comparing the years of 2008 and 2009 with 2010 and 2011, we found and increase in the mortality rate from 13.97% to 15.80%. The mean age of the deceased patients increased from

77 (2008-2009) to 79 years old (2010-2011) (p = 0.015). With regard to the dependence degree, we obtained a statistically significant result (p = 0.0005) when analyzing the amount of patients with need of special nurse care, which has been growing in the last four years. Although the complexity rate of all the inpatient, evaluated based on Diagnostic Related Groups classification, has remained roughly the same during the last four years, the opposite occurred among the deceased ones, in whom we found a rising tendency when comparing the first two years with the last two of the study period. When analyzing the origin of the incoming patients prior to being hospitalized, we found that in the last two years of the study the proportion of patients previously institutionalized in long term medical care facilities quadrupled. We also registered an increase in the death predictability, which grew from 27.0% (2008-2009) to 40.0% (2010-2011).

Discussion: The data analysis allowed us to note that we are basing our judgment in mortality rates that are not comparable because they relate to different populations, at least in what concerns to age distribution, dependence degree, complexity rate and patients' origin. Regarding the age distribution between all the inpatients and the deceased ones, we confirmed what we already knew about how our population is ageing, but also found out that the ones who are dying are increasingly becoming even older. If we adjust our mortality rate, standardizing by age, we reach lower values even without taking into account all the other studied and non-studied variables. The complexity of this trend makes it very difficult to appreciate, understand and turn in to countable facts all the variables that are involved. Besides, there are dynamic cultural differences between populations that also have the potential to shape this problem.

Conclusions: World population is changing. The inpatient population is changing. The deceased population is changing in so many directions and so quickly that it is becoming a challenge keeping up with all these changes in order to understand them and to adapt our standard of care. With the purpose of better characterizing and explaining this recent and global increase in mortality rate in medical wards, several studies are already in progress, including one in our hospital, so that we can better understand and accompany this phenomenon.

V-160
QUALITY OF LIFE ANALYSIS ACCORDING TO EDUCATIONAL LEVEL OF CARERS IN A PALLIATIVE CARE PROGRAMME IN THE AREA OF PUERTO REAL UNIVERSITARY HOSPITAL

G. García Domínguez, M. de la Hoz Adame, A. González Quiñones, O. Mera Gallardo, V. Manzano Román, V. Lechuga Flores, R. Tinoco Gardón, S. Romero Salado

Department of Internal Medicine. Hospital Universitario Puerto Real. Puerto Real (Cádiz), Spain.

Objectives: Introduction: Terminally ill patients tend to be seen at home, by Palliative Care programs. In them their family play a basic role. Carers of terminally ill patients deal with lots of responsibility, which can reduce physical and mental health of the person in charge and affect its quality of life. Objectives: Evaluate quality of life of carers of terminally ill patients included in palliative care program of our center, related to educational level.

Material and method: Descriptive transverse study with a two months inclusion period. Participants: patients included in the palliative care program and assisted by the unit in the first two months of 2012. A questionnaire of quality of life (including degree of satisfaction with information, training on cares, emotional support, symptoms of tiredness, stress, anxiety, disappointment, anorexia, social relations) was passed on carers. For the analysis we used χ^2 test of the SPSS statistical program. Correlations between variables of the carer (educational level) were performed with every dimension of the questionnaire "quality of life of the carer".

Results: Educational level high/low: tiredness 42.9%/57.1%, fear 35%/65%, sorrow 31.8%/68.2%, anxiety 30.4%/69.6%, loss of hope 33.3%/66.7%, disappointment 30.4%/69.6%, rest disorders 37.5%/62.5%, couple problems 31.2%/68.8%, distraction 34.5%/65.5%, stress 38.9%/61.1%.

Discussion: Taking care of a terminally ill patient clearly influences quality of life and welfare of the carer. Carers with low educational level show higher affectation of their quality of life.

Conclusions: It is necessary a full assessment of the family that takes care and accompany a patient in a palliative care program to try to prevent the arousal of a pathological decrease of quality of life.

V-161
CHANGES IN MANAGEMENT OF COPD PATIENTS ADMITTED TO A TERTIARY HOSPITAL OVER THE LAST TEN YEARS

M. García Hoyos, M. Lisa Gracia, F. Arnaiz de las Revillas Almajano, E. Cobo García, S. Neila Calvo, P. Garmilla Ezquerra, M. Aller Fernández, C. Gutiérrez del Río

Department of Internal Medicine. Hospital Valdecilla. Santander (Cantabria), Spain.

Objectives: To evaluate differences in management and specific diagnostic procedures in COPD patients admitted to an Internal Medicine department between two samples separated each other with a gap of ten years.

Material and method: We performed a retrospective descriptive study with COPD patients admitted to an Internal Medicine department in a tertiary care hospital from 1st January to 31st December of years 2000 and 2010. We used two randomized samples with one hundred patients each. We included COPD patients 18 years old or more admitted for acute exacerbation. In this study we evaluated the diagnostic and therapeutic characteristic of the patients, for which we made a protocol. We used SPSS program to data analysis.

Results: The mean age was 78.49 years-old in sample of year 2000 and 79.79 in that of 2010. Regarding gender, percentage of men was 77% vs 73%. 19% of patients were on domiciliary oxygen therapy in 2000 and 25% in 2010 (p 0.25). Arterial blood gas analysis were performance in 93% vs 72% (p 0.001). We observed a PaCO2 greater than 45 mmHg in the 52% and 30% of each sample. 73% vs 84% had undergone pulmonary function tests (PFT). Among corticosteroid-dependent patients, 25OHD were not obtained in 85% and 90% of the patients for each sample, and no densitometry was performed in any of them. Furthermore, none of the patients was given oral D vitamin, calcium or treatment with bisphosphonates in the year 2000, and only 1% of patients of 2010 received treatment with Vitamin D supplements. Parenteral corticosteroid treatment was given to 50% of patients in both groups. We observed a greater dose in the year 2000 sample (up to 140mg). In both samples doses of corticosteroids were in accordance with severity of COPD. On other hand, concomitant use of parenteral and nebulized glucocorticoids was found in 69% vs 29% (p 0.001). 92% vs 91% of patients received antibiotics, although only 63% and 69% respectively met the Anthonisen criteria. The most used antibiotic was amoxicillin-clavulanate (58% vs 35%). Use of broad-spectrum antibiotics, such as piperacilin-tazobactam, increase from 2% to 13% in both samples. Low molecular weight heparins were used in 19% and 50% of patients with associated comorbidity, respectively (p 0.01). Among patients who received parenteral corticosteroids, proton pump inhibitors were given in 34% and 66% of each group (p 0.01).

Discussion: The patients who had oxygen at home increased in 2010. In this study we observed that gas analysis was performance in most our patients in 2000, while it decreased in 2010, which lead to detect less number of CO_2 retainers and this made more difficult the treatment of exacerbations. 27% of patients in year 2000 and 16% in 2010 were diagnosed of COPD with clinic criteria, although the diagnostic require a spirometry. It's known that in corticosteroid-dependent patient, osteoporosis study should be performance; in our patients we observed that this practice is insufficient and we should promote it. Actually it is not defended combined use of systemic and nebulized corticoid, in our sample this practice is decreased in more than 50%. We use antibiotics in almost all the patients, although in much case doesn´t exit clinic criteria of infection. The antibiotics more used are similar than recommendations of guidelines. The use of broad-spectrum antibiotics had increased in last years. According to the publications, patients with comorbidities who income for a COPD exacerbations have to received antithrombotic prophylaxis; that is increasing in our patients, although actually only 50% of patients received it. The use of inhibitors de proton pumps is higher now than in 2000.

Conclusions: COPD treatment and diagnosis have changed in the last years. Pulmonary disease must be treated but also comorbidities. In our study, we observed that those changes are increasing although there are some aspects that we should improve.

V-163
RETROSPECTIVE STUDY TADE IN HOME HOSPITALIZATION UNIT AT UNIVERSITY HOSPITAL NUESTRA SEÑORA DE LA CANDELARIA DE TENERIFE

D. Gudiño, E. Rubio Roldán, S. Vicente Rodrigues, C. Girola, P. Laynez Cerdeña

Department of Internal Medicine. Complejo Hospital Universitario Nuestra Señora de Candelaria. Santa Cruz de Tenerife, Spain.

Objectives: Home intravenous antibiotic treatment (TADE) is the treatment of infectious disease in the patient's home and is also accompanied by set of care activities, health and social taking place at home. Its design is comprehensive and the secret of its functioning is based on the proper development and exquisite coordination of health care resources that flow into it.

Material and method: A descriptive retrospective review of the database of the treatments administered in the period May 2010 to February 2012. We analyzed age, sex, length of stay, the treated pathologies, common microorganisms.

Results: We analyzed a total of 180 medical records, the average age 59.8 years, the average stay of patients was 15.01 days, of which 58.49% were men, and women 41.5%. The most common pathologies were intra-abdominal infections (18.64%), urinary tract infections (16.9%) followed by the NAC (15.25%), febrile neutropenia (6.7%), other causes (42.51%). As for the most common microbial isolates are methicillin resistant Staphylococcus aureus at (MRSA) 15%, Pseudomonas aeruginosa 12.5%, 12.5% coagulase-negative staphylococci, E. 10% ESBL coli, E. coli 7.5%, Enterococcus faecalis 7.5%, Klebsiella neunoniae 7.5%, other 22.5%. They avoided a total of 2,702 days of income.

Conclusions: When the antibiotic should be used at the extra hospital should be considered primarily the bacterial spectrum and method of administration/dosage, being always preferred, according to the antibiogram, that make it easier to administer. Arguably, any infection is treatable in a program TADE. The complexity and severity of patients seen are increasing. There is also a general tendency to limit hospital stays because of its cost and the risks inherent to hospitalization.

V-164
RESULTS OF THE RAPID DIAGNOSTIC CONSULTATION IN THE HOSPITAL OF ZAMORA

P. Sánchez Junquera[1], G. Hernández Pérez[1], A. de la Vega Lanciego[1], J. Soto Delgado[1], E. Martínez Velado[1], M. Mateos Andrés[1], M. Chimeno Viñas[1], T. Garrote Sastre[2]

[1]Department of Internal Medicine, [2]Admission Service. Complejo Asistencial de Zamora. Zamora, Spain.

Objectives: To assess the patients seen in the Rapid Diagnostic Consultation (RDC) to improve its performing.

Material and method: Retrospective study performed from February 1st 2011 to April 31st 2012 to analyze the patients seen in the RDC. The data source used was the archive of clinical records of our hospital. The analyzed data were: time elapsed from the application day to the day of the appointment; number of consecutive consultations until diagnosis; requested tests (blood tests, CT scans, endoscopies, serologies, others...); time passed until the performance of imaging tests and endoscopies; number of patients that required a biopsy; time gone by until anatomo-pathologic diagnosis; reached diagnosis; time elapsed until diagnosis (that is, until the case is presented in the Tumour Committee when the diagnosis is a neoplasm).

Results: Eighty nine patients were analyzed, 48 females (53.9%) and 41 males (46.1%) with an age range from 16 to 100 years (average 61.1). Appointments were given in 1 to 14 days (average 7.5) and the number of consecutive consultations varied from 0 to 4 (average 1.4). Blood tests were performed in 85 patients (95.6%) and any kind of imaging technique in 59 (66.9%). Thoracoabdominal CT scan was requested in 39 cases (43.8%) with a mean appointment time (MAT) of 8.9 days. Other imaging procedures in figures are: 9 abdominal ultrasound (US) (MAT 8.4), 2 thyroid US (MAT 9.5), 2 thoracic angioscan (urgent appointment), 1 arterial Doppler US, 1 mammography, 4 MRI (MAT 11.5), 1 cervical spine CT scan and 1 cranial CT scan. Thirteen gastroscopies have been performed (MAT 7.9), 9 colonoscopies (MAT 14.1) and 7 upper and lower gastrointestinal endoscopies (MAT 9.2). Five CT-guided biopsies were carried out (MAT 9.6) and 2 EUS-guided ones (1 from the respiratory tract and 1 from the esophagus). The average time until anatomo-pathologic results were given was 6.9 days. A total of 26 biopsies were performed. In relation to the treated pathologies assembled into groups we found: 19 oncological processes (19%), 17 non-oncological GI processes (19%), 16 infectious processes (17.9%), 8 traumatological processes (9%), 7 systemic diseases (7.8%), 7 thromboembolic diseases (7.8%), 5 psychiatric disorders (5.6%), 3 surgical processes (3.4%), 4 dermatologic processes (4.5%), 2 processes related to side effects of drugs (2.4%), 2 cardiopathies (2.4%) and 8 cases with no relevant pathology (9%). The average time to diagnosis was 15.9 days.

Discussion: The RDC takes place once a week. There is a doctor and a nurse as human resources with the possibility of attending 3 new patients each day. The possibilities of improvement are in the number of the seen patients and the MAT until the consultations and the complementary tests, especially CT scans and colonoscopies.

Conclusions: With the results of this study we have decided to change the RDC to a Unit of Rapid Diagnosis increasing the human resources to a full-time doctor and nurse and a part-time doctor. This way it will be possible to see three times the number of patients currently attended which will reduce the MAT. We have also improved the MAT for CT scan and colonoscopy.

V-165
CARDIAC AUTONOMIC NEUROPATHY IN PATIENTS WITH PRIMARY HYPERTENSION

S. Ay[1], F. Bulucu[1], S. Balta[2], T. Celik[2], U. Yolcu[3], M. Karaman[1], E. Arslan[1], K. Saglam[1]

[1]Department of Internal Medicine, [2]Department of Cardiology, [3]Department of Ophthalmology. Gulhane Military Medical Faculty. Ankara, Turkey.

Objectives: Cardiac autonomic dysfunction is one of the important factors implicated in the pathogenesis of primary hypertension. Heart rate variability measurement has been used widely to determine the cardiac autonomic dysfunction. In the present study, it was aimed to establish the heart rate variability in primary hypertensive patients. It was also investigated its relationships with end organ damages due to hypertension and cardiovascular risk factors.

Material and method: Ninety adult patients with primary hypertension and 28 healthy controls were included into the study. Heart rates and heart rate variability parameters (rMSSD: square root of the mean squared differences between successive normal-to-normal (NN) intervals; SDNN: Standard deviation of all NN intervals; SDNN index: mean of the standard deviations of all 5-min NN intervals of the entire recording; SDANN: standard deviation of the averages of NN intervals in all 5-min periods of the entire recording; Percentage of differences between successive RR intervals that are greater than 50 msec) were measured by monitoring with 24 hour holter electrocardiographic records in both the patients and the controls. Retinopathy, microalbuminuria and left ventricle hypertrophy were established in the patients.

Results: As expected, primary hypertensive patients (144 ± 14/89 ± 10 mmHg) had statistically significant blood pressure values than those of the controls (106 ± 10/65 ± 8 mmHg) ($p < 0.001$). When the patients were divided into the two subgroups as being newly diagnosed (n = 45) and previously diagnosed (n = 45), the subgroups were significantly different from each other for their blood pressure levels (149 ± 14 systolic, 93 ± 9 mmHg diastolic in newly diagnosed patients vs 138 ± 13 systolic, 86 ± 10 mmHg diastolic in previously diagnosed patients, $p < 0.001$ for systolic and $p = 0.001$ for diastolic blood pressure). Minimum heart rates of the all patients (46 ± 10 per minute) were significantly higher than those of the controls (40 ± 13 per minute) ($p = 0.017$), while heart rate variability parameters showed significantly lower values in the primary hypertensive patients compared those of the controls (Table 1). The subgroups showed no difference from each other with respect to their demographic, clinic features and studied laboratory results including heart rate variability parameters. The heart rate variability parameters showed no significant correlations with retinopathy, left ventricle hypertrophy and cardiovascular risk factors. However, microalbuminuria had a significant positive correlation with one of the heart rate variability parameters (SDNN; $r = 0.243$, $p = 0.027$).

Discussion: The fact that the lower heart rate variability parameters in the primary hypertensive patients than those of the controls suggests the presence of a cardiac autonomic dysfunction in these patients. However, such a difference was not observed between the newly and previously diagnosed patients indicating that the heart rate variability seems not to be influenced by antihypertensive treatment. Furthermore, except microalbuminuria, hypertensive end organ damages are not related to the heart rate variability.

Conclusions: Finally, the data from the present study suggest that the cardiac autonomic dysfunction may precede the primary hypertension.

V-166
THERAPY WITH EXENATIDE IN PATIENTS WITH TYPE2 DIABETES MELLITUS AND OBESITY

C. Moldovan, F. Marc, D. Farcas

Department of Medicine. University of Oradea. Oradea, Romania.

Objectives: Exenatide (Byetta) is a GLP-1 receptor agonist which increases Insulin secretion from pancreatic β-cells in a glucose-dependent manner; decreases the glucagon secretion, which determines the decrease of liver glucose production and slows the gastric emptying. Aim: to evaluate the efficacy and safety of therapy with Exenatide in patients with type2 diabetes mellitus poorly controlled with oral therapy (metformin ± sulphonylurea).

Material and method: 30 patients (25 females and 5 males), aged between 48-65 years, obese, with type2 DM, with a poor control with metformin ± sulphonylurea, received an additional therapy with exenatide, 5 µg BID 30 days and then 10 µg BID. We evaluated at the beginning and at 6 months of therapy: FPG, PPG, HbA1c, BMI, side effects.

Results: after six months of therapy with exenatide 10 µg BID, HbA1c decreased with 0.9% (from 8.3 ± 0.5% to 7.4 ± 0.4%); FPG decreased from 192 ± 11.2 mg/dl to 168 ± 10.5 mg/dl; PPG decreased from 205 ± 10.2 mg/dl to 172 ± 8.5 mg/dl; average weight loss that we achieved was 2.4 kg. Side effects: 5 patients had mild hypoglycemia, rapidly solved with oral glucose intake, 12 patients presented at least 1 episode of nausea, mild to moderate that disappeared during therapy.

Conclusions: Exenatide (Byetta) improves glycemic control through decreasing postprandial and fasting glucose levels, in obese patients with type 2 diabetes mellitus and promotes weight loss, being well tolerated.

V-167
INTUSSUSCEPTION: NOT ONLY IN CHILDREN

A. Sáenz Gutiérrez[1], C. Lozano Cejudo[2], M. Rozas Rodríguez[3], E. Marchán Carranza[1], M. Mañas García[1], C. Muñoz Hornero[1]

[1]Department of Internal Medicine, [3]Department of Radiology. Hospital General de Ciudad Real. Ciudad Real, Spain. [2]Department of Radiology. Hospital Santa Bárbara. Puertollano (Ciudad Real), Spain.

Objectives: To review patients with intussusception during the last two years, hospitalized in a 3rd level hospital.

Material and method: To describe those patients with the diagnosis of intussusception, on admission in the Internal Medicine Department, General University Hospital of Ciudad Real, during two years. We analyze epidemiological and clinical features.

Results: We included 8 adult patients with a mean age of 56.8 years. Female-male ratio was 1:1. The main clinical features of the study are shown in the table 1. Surgery was the elected treatment in 7 cases (87%). In one case, the intussusception was an incidental finding, and no therapy was required due to its autolimited course.

Discussion: Intussusception is the invagination of a bowel loop, called intussusceptum, into the lumen of the adjacent segment, called intussuscipiens, as a result of peristalsis. This condition is frequent in children. Approximately 5% of all intussusceptions occur in adults and 70-90% of the cases have a demonstrable cause (most frequently malignancies). The routine use of CT for abdominal imaging has increased the detection of transient intussusceptions with no underlying cause. Clinically, intussusception has five modalities: acute (abdominal pain associated or not with an intestinal obstructive syndrome), chronic, persistent, recurrent and transient. In the chronic course abdominal pain, vomiting and nausea are the major symptoms. Computed tomography scan (CT)

Table 1 (V-167)

Patient nº	Sex	Age	Personal history	Main symptom	CT/ECO report
1	Male	32	Traffic accident	Shock	Transiente ileo-ileal intussusception
2	Female	19	Anorexia nervosa	Suboclusive clinic	Jejunum-ileal intussusception related to anorexia nervosa
3	Male	40	Peutz-Jeguers syndrome	None	Polypoid mass that triggers the invagination
4	Female	87	None	Bowell obstruction	Intussusception caused by an adenocarcinoma
5	Male	75	None	Pain and constipation	Ileo-ileal intussusception caused by a adenomatous polyp
6	Male	51	None	Melenas	Ileo-ileal intussusception caused by a adenomatous polyp
7	Female	78	None	Pain and microcytic anemia	Colo-colic intussusception caused by an adenocarcinoma
8	Female	73	None	Intestinal bleeding	Colo-colic intussusception caused by a pedunculated polypoid mass

is the imaging modality of choice. The treatment consists on surgery (resection of the affected area), although conservative therapy is chosen in some cases (intussusception without a lead point).

Conclusions: Intussusception in adults is not common. It is most frequently associated with malignancies, but because of the increased use of abdominal CT, incidental intussusception with a transient course is more common. Surgery is the therapy of choice, although in cases of transient intussusception is not necessary.

V-168
THE VALIDITY AND RELIABILITY STUDY OF CHRONIC OBSTRUCTIVE PULMONARY DISEASE AND ASTHMA SLEEP IMPACT SCALE IN THE PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE

E. Ayhan[1], E. Kiyak[2]

[1]Nursing. Erzurum Military Hospital. Erzurum, Turkey. [2]Nursing. Atatürk University. Erzurum, Turkey.

Objectives: Chronic Obstructive Pulmonary Disease and Asthma Sleep Impact Scale is a specific scale determining sleep disorders seen in the patients with chronic obstructive pulmonary disease and asthma. This study was carried out with the aim of testing the reliability and validity of this scale in the patients with chronic obstructive pulmonary disease.

Material and method: The study was carried methodologically on 97 patients with chronic obstructive pulmonary disease applying for Chest Diseases outpatient of Atatürk University Hospital in Erzurum. Questionnaire, St. George's Respiratory Questionnaire, Pittsburg Sleep Quality Index, Chronic Obstructive Pulmonary Disease and Asthma Sleep Impact Scale and pulmonary function tests were used in the collection of the data. Cronbach Alpha Co-efficiency, Sampling Proficiency Analysis and Sphericity analysis of Barlett's Test, Scree Plot Graphics, Komolgorov-Smirnov Test, Factor Analysis, Correlation Analysis and t test were used in the analysis of the data.

Results: It was found out that the distributions of the scale scores were normal, and that Cronbach co-efficiency in reliability analysis was found 0.87. In the article total score analysis, it was found out that each item of the test is in accordance with total test ($r > 0.20$, $p < 0.01$). The single factorial structure of the scale was detected with factor analysis. The range of the scale was found 26. It was also detected that there was correlation between Chronic Obstructive Pulmonary Disease and Asthma Sleep Impact Scale, St George's Respiratory Questionnaire and its subdimensions, and Pittsburg Sleep Quality Index and its subdimensions (except for using sleep medicines) in true way and there was correlation reversely between pulmonary function tests measurements (except for FEV1/FVC). It was found out that the correlation between pre-test of the scale and post-tests measurement results was strong ($r = 0.978$, $p < 0.001$).

Conclusions: In conclusion, it was determined that Chronic Obstructive Pulmonary Disease and Asthma Sleep Impact Scale was a valid and reliable measurement tool in the patients with chronic obstructive pulmonary disease.

V-169
THE PREVALENCE & AWARENESS OF HYPOGLYCEMIC UNAWARENESS AMONG ADULT PATIENTS WITH SIGNIFICANT INSULIN DEFICIENCY IN CENTRAL SAUDI ARABIA

K. Alshammari[1], M. Alshammari[2], M. Daker[4], Y. Alsaleh[4], A. Alkhathaami[5], M. Alghobain[6], W. Altamimi[3]

[1]Department of Internal Medicine, [2]Department of Emergency Medicine, [3]Department of Anatomic Pathology. [4]Department of Endocrinology, [5]Department of Neurology, [6]Department of Pulmonology, King Abdulaziz Medical city/National Guard Hospital. Riyadh city, Saudi Arabia.

Objectives: To determine the prevalence of hypoglycemic unawareness in patients with Diabetes who are using insulin.

Material and method: A cross-sectional study was conducted where all eligible patients with Diabetes (who are on insulin) during the month of October of 2011 who attended the Endocrinology clinic were interviewed by a physician using a standardized questionnaire. Patients who have come through to the Emergency Department with a severe hypoglycemic reaction who are known to have Diabetes (and are on insulin) were also interviewed, as well as patients who have taken their insulin prescription from the Internal Medicine clinic - those were phone interviewed. Questions - adapted from a previous study - ranged from basic demographics to insulin regimes plus history of severe hypoglycemic reactions. These questions were aimed at determining the presence or absence of hypoglycemic unawareness. A total of 333 subjects were included in the study.

Results: The prevalence of hypoglycemic unawareness in this interviewed group of patients was found to be 48.9% (p value > 0.05). Interestingly, 69% of patients with end stage renal disease who are on dialysis have hypoglycemic unawareness (p value > 0.05). We have found that 35% of patients with HbA1c of less than 7% had a threshold for hypoglycemic symptoms at 45 mg/dL or less

(this was statistically significant - p 0.022), compared to 28%, and 19.8% for HbA1c values of 7-8% and above 8% respectively. We have also found that 12.5% of patients who are on insulin pump have no feelings of hypoglycemic symptoms whatsoever compared to 5%, and 1.3% in those on aspart & glargine and BID mixed 70/30 Regular/NPH Insulin respectively (significant p value of 0.001).

Conclusions: The calculated prevalence was higher than what previous studies have mentioned – although the result was not statistically significant. This indicates that the phenomenon (of hypoglycemic unawareness) is much commoner than what we may have thought. Identifying, and screening for this phenomenon is crucial to prevent severe and potential life threatening complications in our patient population.

V-170
TRANSFORMED DIFFUSE LARGE B-CELL LYMPHOMA IN A COHORT OF 219 PATIENTS

J. Alonso Alonso, G. Barreiro García, A. Cánovas Fernández

Department of Internal Medicine. Hospital Universitario de Cruces UPV/EHU. Barakaldo. Vizcaya, Spain.

Objectives: To assess the frequency of transformation to aggressive lymphoma in an unselected population with low-grade B-cell lymphoma, analyse prognostic variables related to transformation and the response of transformed lymphomas to salvage chemotherapy.

Material and method: Prospective observational study of the cohort of patients with lymphoma diagnosed in our unit (January-1986 to December-2007). Diagnosis of transformed lymphoma was based on pathologic examination of new lymph node biopsy revealing diffuse large B-cell lymphoma in patients with previously known low-grade lymphoma. Variables with potential prognostic implications for the likelihood of transformation and the response to salvage chemotherapy were analysed. Statistical methods: chi^2, Student t test, log-rank test, tables of Kaplan-Meier and Cox multivariate binary logistic and proportional hazard regression.

Results: 219 patients, 109 male and 110 female, with a median age of 64 years (21-88), were studied. Lymphoma subtypes at baseline were: 45 B-chronic lymphocytic leukemia/small lymphocytic lymphoma (BCLL/SLL); 35 lymphoplasmacytic lymphoma (LPCL); 24 marginal zone lymphomas (MZL) and 115 follicular lymphomas (FL). Transformation to DLBCL was ascertained in 22 patients (10%): 8 (36.4% of the processed) from BCLL/SLL; 3 (13.6%) from LPCL; 2 (9%) from MZL and 9 (41%) from FL. The median age of patients with transformed lymphoma was 64 years (43-85). The probability of transformation at 10 years of low grade lymphoma diagnosis was 22% in BCLL/SLL and 16% in the other subtypes (p = 0.05 by log-rank test). No significant prognostic value was found in the variables studied: age, sex, clinical stage, prior treatment with fludarabine (54 patients) or rituximab (79 patients). The median survival probability of the entire cohort was 6.6 years for BCLL/SLL, 7.5 years for LPCL and has not been reached at ten years in FL(median duration of observation:6 years). Complete remission of transformed lymphoma was reached in 13/21 (62%) with salvage chemotherapy, but median time to failure was 5.5 months and median survival 1.2 years. No significant association was found between lymphoma subtype at baseline and the response rate, duration of response or survival.

Discussion: B-BCLL/SLL has been classically associated with transformation to DLBCL (Richter syndrome). The published rate of transformation ranges from 10 to 22% at five years. However, this transformation may also occur in other subtypes of B-cell lymphoma and there are few references about its frequency and clinical outcome. The lower rate in our cohort of patients with BCLL/SLL explain the numerical dominance regarding transformation of the other subtypes set. By contrast there were no differences regarding the response to salvage chemotherapy and survival.

Conclusions: In this cohort of unselected patients with B-cell lymphoma, we have found an increased likelihood of transformation in the BCLL/SLL over the other subtypes of low grade lymphoma, in agreement with previous references. However, a high proportion of transformed lymphoma patients (nearly two thirds) were originally low grade lymphoma subtypes different from BCLL/SLL. The transformation to DLBCL implies poor response to salvage chemotherapy and short survival regardless of the original lymphoma subtype.

V-172
MORBIDITY AND MORTALITY IN PATIENTS ADMITTED WITH EXACERBATION OF COPD. A 12-MONTH FOLLOW-UP

N. Galofré, L. San Vicente, S. Fernández, J. Oriol, J. Torres, A. Serrado, E. Gálvez, L. Ortega

Department of Internal Medicine. Hospital Municipal. Badalona. Barcelona, Spain.

Objectives: To analize the most important factors on morbi-mortality in patients admitted consecutively due to exacerbation of COPD. To valore the impact in a 12-month follow-up.

Material and method: An observational study conducted between June 2009 and June 2010. Information collected included epidemiological and clinical characteristics, NT-ProBPN levels, cardiologic basic study, lung volumes and sputum culture. Length of stay, mortality and readmission were also collected.

Results: Were included 103 patients (95% men). Mean age was 71.83 (9.3). The GOLD stage III was in 41.3% of patients and 41% in GOLD stage IV. Eighteen patients had ph < 7.35. The sputum were collected in 73 cases and the bacterial species commonly isolated were Haemophillus influenzae in 19.2% and Pseudomona in 12.3%. NT-ProBNP was > 2000 in 16 cases. The length of stay was 5.74(3.4) and the in-hospital mortality rate was 2.9%. Heart failure was present in 15.5% of patients. At 12-month follow-up mortality rate was 16.35% and the readmission rate was 67.34% (32.7% early readmission). BODE index (> 5), ph < 7.35, FEV1, isolation of Pseudomona were the significant factors to readmission. The mortality was higher in patients with cardiopathy, GOLD stage IV and ph < 7.35.

Conclusions: 1. The most important factors with impact on morbi-mortality were: FEV1, ph < 7.35, BODE index, isolation of pseudomona and presence of cardiopathy. 2. The mortality rate was lower (16.35%) to the detriment of higher readmission rate (67.34%).

V-173
ANALYSES OF EARLY METABOLIC CHANGES IN OBESE PATIENTS AFTER BARIATRIC SURGERY

J. Torres Triana[1], L. Hernández[2], L. Manzanedo Bueno[1], O. Rozo[2], L. Ortega[2], R. Macías Casanova[1], A. Sánchez[2], M. Marcos[1]

[1]Department of Internal Medicine, [2]Department of Surgery. Hospital Clínico Universitario de Salamanca. Salamanca, Spain.

Objectives: The aim of this study is to evaluate the clinical characteristics and the short-term results of bariatric surgery for the treatment of morbid obesity.

Material and method: Retrospective review of a prospectively maintained database of obese adult patients (at least 18 years of age) with body mass index (BMI) greater than 35 kg/m^2 who underwent elective bariatric surgery from October 2010 to November 2011 in the University Clinical Hospital of Salamanca.

Clinical review was performed before surgery and all patients were reassessed at 3 months after surgery, the anthropometric data and blood samples were collected at baseline (preoperatively) and 3 months after surgery.

Results: A total of 17 patients were included in the present study, 12 were female and 5 were male. The mean patient age (standard deviation) was 45 (12.5) years, mean preoperative BMI, weight, fasting glucose, cholesterol and triglycerides levels, was 49 ± 6.3 kg/m^2, 132.16 ± 13 Kg/m^2, 111.5 ± 47 mg/dL, 199.86 ± 38.6 mg/dL y 135.7 ± 57.3 mg/dL respectively. At 3 months, mean BMI was 9.93 kg/m^2 and weight loss was 26.6 ± 6.6 Kg. Fasting glucose was reduced by 26.3% and triglycerides levels by 20.7%. The rest of the characteristics of the patients are shown in table 1.

Discussion: Obesity is a worldwide public health problem due to increasing prevalence and associated co-morbidities. Bariatric surgery is the most effective treatment for reducing weight among morbidly obese patients. Recent studies have even shown remission rates of type 2 diabetes mellitus in severely obese patients up to 75% at 3 years. The results of our study are similar to the results described in the literature, which is a clear association of bariatric surgery with improved glycemic profile, as well as a decrease in triglyceride levels.

Conclusions: Bariatric surgery is an effective treatment for weight reduction in morbidly obese patients, achieving a weight loss of around 20% in the first three months, while promoting an improvement in the metabolic profile with reduction in fasting glucose and triglyceride levels. Further efforts are needed to confirm the long-term metabolic benefits of bariatric surgery.

Table 1 (V-173). Characteristics of the patients at baseline

Characteristics	Nº of patients (%) (N = 17)
Obesity onset	.
Age 10-19 years	4 (11)
Age 20-30 years	8 (47)
Hypertension	8 (47)
Dyslipidemia	3 (17.6)
Cardiovascular disease	0
Diabetes mellitus	4 (23.5)
Smoker	8 (47)
Obstructive sleep apnea	9 (53)
Hepatic steatosis	6 (35.3)

V-174
INTERCONSULTATION CASES TARGET TO INTERNAL MEDICINE (IM) FROM OTORINOLARYNGOLOGY SERVICE (OS) ANALYSIS

G. Ruiz Villena, M. Escobar Llompart, R. Aranda Blázquez, M. Guzmán García, E. Sánchez Relinque, V. Manzano Román, V. Lechuga Flores, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: Analyze and identify characteristics of cases target to IM from OS during six months, and their main reason for consultation.

Material and method: Review of interconsultation register from IM Clinic Management Unit during six months of 2011. Descriptive retrospective study, there were reviewed inter consultation cases from patients hospitalized in OS. Studied variables: number of inter consultations, patient basic profile, nature and reason for consultation.

Results: There were analyzed 16 interconsultation cases. Age between 18 and 75 (men 11, women 5). Nature ordinary 14 (87.5%), urgent 2 (12.5%). Reason for consultation: therapeutic tackle ACVE assessment, sepsis, low conscious level and HTN 2 (12.5%) respectively. Miscellany: edema, hyperglycemia, EAP and discomfort 1 (6.25%) respectively.

Discussion: Inter consultation cases target to IM from OS are the second more frequent after General Surgery in our center. Their nature used to be ordinary. Age between 18 and 75. Most men (considered smoking). Wide kind of reasons for consultation, but associated to high comorbidity patients.

Conclusions: Clinic management carried by IM professional makes him able to make preventive and therapeutic assessment from patients on post-surgery period. Actually it is increasing the number of patients with comorbidities having a surgery, and the indication for surgery is based on life quality and not on patient's age, as it was before, where the internal medicine professional is essential to manage this kind of patient profile.

V-175
RESULTS OF THE ACTIVITY IN A SHORT STAY EMERGENCY UNIT DURING A HIGH ATTENDANCE PERIOD

I. Martínez Egea[1], P. Baños Piñero[1], M. Arenas Miras[1], S. Moreno Suárez[2], A. Mora González[2], J. Roca Guiseris[2]

[1]Department of Internal Medicine, [2]Department of Emergency. Complejo Hospitalario Virgen de las Nieves. Granada, Spain.

Objectives: This study describes the health-care activities in a Short Stay Medical Unit (SSMU) of the Hospital Universitario Virgen de las Nieves, which is a tertiary care centre providing health-care services to the northern area of Granada.

Material and method: A study of a series of cases including all patients admitted to the SSMU (which is equipped with 15 beds) has been carried out during a period of high hospital attendance, from January to March 2012. A descriptive analysis of the patients admitted was performed based on the following parameters: age, sex, comorbidity (i.e. coexistence of two or more chronic diseases that involve the occurrence of exacerbations and interrelated diseases), primary diagnosis, readmission within a month after discharge, and discharge destination. The statistical analysis software SPSS 15.0 was used to perform the analysis.

Results: 139 patients with a mean age of 71.43 (SD 17.91) were included in the study. Out of these, 73 were men (52.5%) and 66 were women (47.5%). There were 90 cases of comorbidity (64.7%). The average length of stay in days was 2.46 (SD 1.09). The most frequent main diagnoses were respiratory infections including community acquired pneumonia (30.21%), decompensated heart failure (24.46%) and the worsening of chronic obstructive pulmonary disease (COPD) (14.4%). 73.4% of the patients under study (102) were discharged home for outpatient follow-up. The rest were transferred to other services (mainly Internal Medicine and Pulmonology) due to the absence of improvement of the condition leading to their admission, or to the presence of a new diagnosis. The readmission rate within a month after hospital discharge was 11 patients (7.9%).

Discussion: Over the past few years, the SSMU has acted as an alternative to conventional hospitalization, with good results in different series, lowering the income rate on other services. The highest percentage of transfers to other services if compared to other series could be related to the comorbidity of patients. It is therefore important to establish admission criteria for the selection of patients to enhance the profitability and dynamics of the unit.

Conclusions: The SSMU is an effective and efficient alternative to conventional hospitalization. Its implementation on a continuous basis throughout the year, rather than during periods of high attendance only, should therefore be considered.

V-176
DIFFERENCES BETWEEN CANCER PATIENTS DIED IN HOSPITAL OR AT HOME

M. Ruz Zafra[1], A. Albarracín Arraigosa[1], M. Barón Ramos[1], A. Ruz Montes[2], M. García González[2], A. Ruiz Cantero[1]

[1]Department of Internal Medicine. Hospital de la Serranía. Ronda. Málaga, Spain. [2]Department of Palliative Care. Área Sanitaria Serranía. Ronda. Málaga, Spain.

Objectives: The aim of this study is to describe the profile of cancer patients dying at home or in hospital and determine the most relevant differences between groups.

Material and method: This is a descriptive and retrospective study. We selected cancer patients died in the Internal Medicine department of the hospital of La Serrania from November 2009 until January 2011, and the patients died at home from June 2011 until January 2012. The variables analyzed were sex, age, diagnosis, treatment received, time since last chemotherapy, followed up by the support team of palliative care and cause of the death. Quantitative variables were summarized using mean and standard deviation and categorical variables as frequencies and percentages. We considered statistically significant when the p value was less than 0.05.

Results: We included a total of 124 patients, of whom 48 (38.7% had died at home and 76 (61.3% in hospital). Those died in the hospital were aged 68 ± 13.25 years, 68.4% were male, the most common tumors were lung (25%), digestive (23.7%), colon (14.5%) and other (36.9%). A 34.2% died were diagnosed in the same income who died. 38.2% received chemotherapy, 37.9% received chemotherapy in the month prior to death. Only 17.1% was assessed by the Palliative Care Unit, and 72.4% died of tumor progression. The deaths at home were aged 71.5 ± 13.44 years, 50% were male, the most common tumors were lung (31.3), digestive (27.1%),gynecological (14.6%) and others (27.2%). A 54.2% received chemotherapy, 50% received chemotherapy in the month prior to death. 100% was assessed by the Palliative Care Unit, and 100% died of tumor progression. When comparing both groups, we observed that died in the hospital had not been followed up by the Palliative Unit and that chemotherapy died at home in the last month by 50%, being statistically significant (p = 0.0001 p = 0.004 respectively).

Discussion: With the results, we observed that patients who die in hospital are younger and are in charge of Oncology, while those who die are somewhat higher hospital and are under the care of the Palliative Care Unit. Both groups are in a high percentage in the month prior to death, which runs counter to the growing interest in the care and palliation of cancer patients.

Conclusions: A high percentage of patients with advanced cancer receiving chemotherapy in the month before his death and usually die at home. Patients who die in our service do not usually have ambulatory monitoring by the Palliative Care Unit.

V-177
OUT-OF-HOSPITAL CARDIOPULMONARY ARREST: A MEDICAL EMERGENCY TEAM EXPERIENCE

M. Miranda[1], A. Dagge[2], P. Campos[2], J. Vieira[3], P. Amaro[2]

[1]Department of Internal Medicine [2]Department of Intensive Care, [3]Department of Emergency. Centro Hospitalar de Entre o Douro e Vouga. Santa Maria da Feira, Portugal.

Objectives: This study aimed to describe the out-of-hospital cardiopulmonary arrests (CPA) occurring in a Medical Emergency Team (MET) coverage area.

Material and method: Retrospective study of all CPA in an out-of-hospital environment on a two year period (between 1 January 2010 and 31 December 2011) and in which the National Medical Emergency Service (112) and our MET were activated. Data were collected from the MET clinical records concerning the time between collapse/distress call and beginning of advanced life support (ALS) maneuvers, time to recovery of spontaneous circulation (ROSC), CPA cause, comorbidities and outcome.

Results: Over a coverage area of 895 square kilometers with 339,725 inhabitants, there were a total of 3,239 MET activations, 647 (19.9%) of which were CPA, corresponding to an annual incidence of 95.1 cases per 100 000. The average time between MET activation and arrival on scene was 11.4 minutes [SD 5.2]. In 34.0% (n = 220) of the patients was attempted resuscitation with ALS. In those whom ALS maneuvers were initiated, the mean age was of 63.6 years [SD 17.7] and 52.2% were male. The first identifiable rhythm was asystole/pulseless electrical activity in 76.3% of cases and ROSC occurred in 39 cases. The average ALS time until ROSC was of 12.9 minutes [SD 2.9]. Only three patients were discharged from the hospital and all survived after 6 months.

Discussion: Of those patients which suffered an out-of-hospital CPA, only a third was considered for ALS. ROSC occurred in a small fraction of cases. The data presented are similar to those described in literature.

Conclusions: CPA approach remains a challenge and its good outcome depends not only on a fast recognition of the severity of the situation but also on an adequate response from the MET.

V-178
KNOWLEDGE AND PRACTICE OF INSULIN THERAPY ADJUSTMENT OF INPATIENTS BY MEDICAL RESIDENTS AT VARIOUS LEVELS OF TRAINING AT DIFFERENT TRAINING INSTITUTIONS OF RIYADH

E. Al-Solamy[1], I. Hassan[2], M. Al-Ghobain[3], A. Al-Khathami[4]

[1]Department of Internal Medicine R2, [2]Department of Internal Medicine, [3]Department of Pulmonology, [4]Department of Neurology. King Abdul-Aziz Medical City. Riyadh, Saudi Arabia.

Objectives: To evaluate medical resident's knowledge about the prevalence of diabetes mellitus in their own patients, the targets blood sugar in different clinical states e.g. with infection, stroke, and acute coronary syndrome etc, the thresholds when residents should start patients with diabetes on intravenous insulin, the resident's knowledge of target HbA1c and recommended HbA1c follow-up intervals and to assess their perceived potential methods of intervention to improve inpatient hyperglycemia care.

Material and method: The study was conducted as a cross-sectional design through self-administered questionnaires distributed to internal medicine resident physicians at various levels of training at different hospitals in Riyadh.

Results: Total number of medical residents involved in the study is 198 residents from 7 training hospitals in Riyadh. Male gender comprised 69.8%. R1 residents comprised 40.2%, R2 21.7%, R3 and R4 19.1% of participants each. The commonest estimate of in-patient diabetes prevalence was between 40-60% (35.5% of respondents). Percentage of residents who quoted the wrong recommended glucose range for patients with acute infection, acute stroke, acute coronary syndrome, perioperative patients, medical ward patients, and critical patients in medical or surgical intensive care units ranged between 36-52 percent of respondents. Confidence (total familiarity) in the management of hyperglycemia, hypoglycemia, and use of subcutaneous or intravenous insulin orders ranged between 41-62 percent of respondents. Confidence in managing diabetic ketoacidosis was quoted by 52.4% of residents. 24.9% of residents quoted the wrong hemoglobin A1C target level and 21.7% the wrong interval for repeat testing. Full awareness of recommended interventions to improve glycemic control in the hospital setting was noted in 18.5% of respondents.

Conclusions: Theoretical and practical knowledge for the care of patients with diabetes is suboptimal in this cohort of medical

residents. These may result in poor patient care with its antecedent effects on morbidity, mortality and cost.

V-180
HEMATHOMAS OF THE ABDOMINAL WALL (HAW) IN AN INTERNAL MEDICINE WARD

M. Durán Castellón, C. Jorge Ripper, C. Fernández Rodríguez, R. Ros Vilamajó, J. Viña Rodríguez, J. Armas González, E. Rodríguez Rodríguez, E. González Reimers

Department of Internal Medicine. Consorcio Sanitario de Tenerife. San Cristóbal de La Laguna (Tenerife), Spain.

Objectives: Hemathoma of the abdominal wall is an infrequent clinical entity. It is usually associated with patients undergoing anticoagulant therapy. The objective of this study is to describe patients diagnosed with hemathoma of the abdominal wall in our service.

Material and method: A retrospective analysis of patients diagnosed with hemathomas of the abdominal wall over the past 1 year in the internal medicine ward in our center. We review the etiology, precipitating factors, diagnosis, treatment and evolution of this clinical entity.

Results: A total of 16 patients (62% women) with mean age of 77 (SD ± 6.15) years were included in the study. In 56% of the cases the HAW was the cause of hospitalization. Therapy with oral anticoagulant was documented in 43.8% of patients, with any type of LWMH in 50% (in prophylactic or anticoagulant regimen) and with antiaggregant therapy in 37.5% of them. Chronic renal insufficiency was documented in 37.5% of cases. In the group receiving oral anticoagulants (OA), 85% had INR greater than 4. Paroxysmal cough appeared in 31.3% of cases. The most common presentation was abdominal pain and palpable mass. In 62% of patients the hemoglobine fell more than 2 points and a transfusion of more than 2 hemathies units was needed in 60% of these patients. A total of 37.5% of patients needed a transfusion. Ultrasonography was the image test performed more frequently (68%). The most common location was the anterior rectum muscle in 68.8% of patiens. Treatment was conservative in all of the cases. The average stay was 25, 63 (SD ± 13.69) days. Two patients died because other causes than the HAW.

Discussion: All patients were receiving some antiaggregant or anticoagulant therapy at the time of diagnosis, and 85% of the oral anticoagulant receivers had a high INR. Almost 40% of the patients needed a transfusion.

Conclusions: We observed a high incidence of HAW between our inpatient. HAW appears in older people with excessive anticoagulation therapy and with high transfusionals needs. We must be aware of the correct anticoagulation indication and the adequate dosis and monitoring in this older population.

V-181
FEATURES, RESOURCES USED AND ATTITUDE TO TAKE IN PATIENTS DISCHARGED FROM HOSPITAL EMERGENCY SERVICE IN ZAMORA

E. Martínez Velado[1], N. Cruz Guerra[2], V. López Mouriño[3], M. Chimeno Viñas[1], L. Arribas Pérez[1], P. Sánchez Junquera[1], A. de la Vega Lanciego[1], F. Martín Cordero[1]

[1]Department of Internal Medicine, [2]Department of Urology. Complejo Asistencial de Zamora. Zamora, Spain. [3]Department of Internal Medicine. Hospital Comarcal de Monforte. Monforte de Lemos (Lugo), Spain.

Objectives: To describe sociological features, diagnostic resources used and therapies prescribed to patients attended at Hospital Emergency Service in Zamora.

Material and method: Retrospective, observational and descriptive assessment of 100 randomized patients attended at Hospital Emergency Service in Zamora and later discharged, on date 28 May 2012. The following variables were assessed: gender, age, place of living, previous evaluation by community health workers, period of symptom evolution, complementary diagnostic imaging and blood tests, chief complaint, assessment by other Medical Specialties, prescribed therapies and destination after discharge.

Results: Women (58%), and patients in their seventies (17 individuals) were those who predominantly needed attention. 54% from rural origin. 66% of individuals attended visited the Emergency Service without previous assessment by community health workers. Symptoms which caused our patients' visits had an evolution time over seven days in 19% of cases. 50 patients needed no blood test, while 68% of people attended required diagnostic imaging (Computerized Axial Tomography, plain X-ray and/or ultrasonography). Pain turned out to be the chief complaint which caused highest number of attentions (58%), in 55% of patients assessed pain relievers were prescribed at discharge, mainly acetaminophen. 19% of cases needed no new additional drugs. During their stay at Emergency Service 44 patients were evaluated by different specialties, mainly Internal Medicine (31% of total assessments), and 71% were referred to their Primary Care doctor.

Discussion: Since Spain´s Health Care System is an universal one, offering sanitary attention at different service levels, with almost immediately access to all them, in recent years a mostly unjustified, significant rise is found regarding visits at Hospital Emergency Services as first care level, thus leading to overloading in addition to a trend towards so-called "Defensive Medicine", that make professionals opt for urgent diagnostic tests which become not necessary if proper observation and follow-up were implemented at other levels.

Conclusions: Patients visit Emergency Service as first health care level in a significant proportion. Periods of symptom evolution over 24 hours constitute a great amount of cases. Pain was often a chief complaint, and pain-scale first-step relievers were those drugs mostly used. Internal Medicine was the Specialty with highest number of pre-discharge assessments performed in our Institution.

V-182
FEATURES OF ONCOLOGICAL PATIENTS ADMITTED AT INTERNAL MEDICINE

E. Martínez Velado[1], N. Cruz Guerra[2], M. Chimeno Viñas[1], P. Sánchez Junquera[1], A. de la Vega Lanciego[1], V. López Mouriño[3], P. García Carbo[1], G. Hernández Pérez[1]

[1]Department of Internal Medicine, [2]Department of Urology. Complejo Asistencial de Zamora. Zamora, Spain. [3]Department of Internal Medicine. Hospital Comarcal de Monforte. Monforte de Lemos (Lugo), Spain.

Objectives: Description of features showed by oncological patients admitted at Internal Medicine Department of Zamora's Virgen de La Concha Hospital.

Material and method: Descriptive, observational and retrospective assessment of 100 randomized patients with known diagnosis of tumoral condition and on follow-up by other Specialties, who were admitted at Internal Medicine Department of Zamora's Virgen de La Concha Hospital during year 2011. The following parameters were assessed: gender, age, tumoral condition cause of follow-up by other Medical Specialties, past therapy undergone and current one, time from last dose administered, diagnosis at discharge from our Department, Specialty referred to for follow-up, and length of hospital stay.

Results: From 100 patients assessed, 53% were males, global mean age was 70.3 years. Breast-origin neoplasms were those most frequently admitted (25%), and neutropenic fever was predominant diagnosis (26%). 83% of patients had chemotherapy during any stage

of their condition and 51% had been received antineoplastic drugs during last 21 days before admission. 67 patients were referred to Medical Oncology Department at discharge and mean length of hospital stay was 9.4 days.

Discussion: In recent years a significant rise of neoplastic conditions has been observed, and thanks to different available therapies an increment of life expectancy has been achieved for those patients. Therapies used often result aggressive, thus leading to not infrequent rate of complications, in some cases deadly events. On the other hand, in spite of treatment effectiveness, sometimes the neoplasm continues its growth, leading to other clinical features.

Conclusions: Our series shows high mean age of patients. Neutropenic fever was the most frequent complication linked to chemotherapy. Most patients were on active oncological treatment. Breast cancer was the most frequent neoplasm. Medical Oncology as main referral Service at discharge.

V-183
DOLICHOESCTASIA VERTEBRO-BASILAR: THREE FORMS OF PRESENTATION

M. Carbo, F. Oblitas, D. Armengol, J. Tort, A. Colome, E. García

Department of Internal Medicine. Hospital General Penitenciari. Terrassa (Barcelona), Spain.

Objectives: We describe three clinical forms of presentation of vertebrobasilar doliechoectasias, from three cases in a community hospital.

Material and method: -Review of three case reports, with the diagnosis of vertebrobasilar doliectasias in admitted patients in Internal Medicine at Terrassa's Hospital, from october/2009 to novembre/2011. -Review of the literature.

Results: Two of them were female. Aged between 74-79 years. The predisposing factors were: age, hypertension (diastolic pressure) and dyslipidemia. The diagnosis was made by neurological clinical and angio-MRI.-In two of the three patients the clinical presentation was the result of compressing structures of the central nervous system: fifth cranial nerve (neuralgia) and central vertigo syndrome. In one patient the presentation was transitory ischemic stroke. Two patients also showed of the dilatation thoracic aorta aneurysmal, without symptoms. Two of the three patients were sudden death of unknown cause.-Finally one of the patients showed aneurysmal basilar thrombosis and dissection.

Conclusions: Although the literature indicates that most of the vertebro basilar dolichoectasias also asymptomatic and are described as radiological finding, we present three symptomatic cases. The clinical presentation are the following location ischemic, compressive syndromes and intracranialhemorrhage. In our patients exist an association between the presence of hypertension, vertebro basilar dolichoectasias and aneurysmal dilatation in different vascular territories. In the literature there is no consensus on therapeutic options. The symptomatic dolichoectasias have a high mortality.

V-184
SKELETAL DISEASE EVALUATION IN PATIENTS WITH GAUCHER DISEASE

E. Trigo Esteban, P. Demelo Rodríguez, B. Andrés del Olmo, J. García Castaño, C. Gilsanz Fernández

Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: Our objective is to quantify skeletal disease in patients diagnosed with Gaucher disease and evaluate medium-term progression.

Material and method: This is an observational and descriptive study to analyze skeletal disease in three patients with Gaucher Disease (GD) with imaging tests mainly: magnetic resonance imaging (MRI), Dual-Energy X-ray Absorptiometry (DEXA), and X-ray. Clinical manifestations, biochemical and metabolic biomarkers were also used.

Results: Three patients with GD are being followed in our Internal Medicine Department during the last seven years. Two of them (Patient 1 and 2) are receiving treatment with enzyme replacement therapy (ERT). Besides, two of them (patient 1 and 3) present severe skeletal disease and needed hip replacement with prosthesis. Patient 1 is a 49 years old male. Since 2008, he is receiving ERT and he was diagnosed with severe skeletal disease that needed replacement of his right hip with a prosthesis. He has being monitored with DEXA and MRI annually. DEXA results reveal progressive bone density loss on lumbar spine and femoral neck (T-score -2.6 in 2009, -2.9 in 2010 and -3.1 in 2011) with definite diagnosis of osteoporosis. MRI shows a bone marrow without infiltration and minimal hipointensity T2 signal at L2. MRI did not show changes in the last 3 years. In this patient we meassured also chitotriosidase activity, marker of alternative type of macrophage activation overeexpressed by the Gaucher cells. Its activity has gradually decreased after ERT with initial level of 12.000 nol/mlxh to almost undetectable levels after three years of treatment. Patient 2 is a 47 years old female. She is receiving ERT since year 2010 and she has never shown skeletal manifestations. Radiology evaluation revealed osteopenia of the lumbar spine. Patient 3. 73 years old male. He is not receiving any treatment nowadays. He presents skeletal disease with bone marrow affectation at the last MRI and osteopenia at femoral neck (T-score -2.4) and lumbar spine (T-score -1.6).

Discussion: Gaucher disease is an inborn error of metabolism that affects the recycling of cellular glycolipids because an autosomal recessive disorder due to mutations in the glucocerebrosidase (GBA) gene located on chromosome 1q21. GD results from deficiency of this lysosomal enzyme GBA and leads to accumulation of glucocerebroside and other glycolipids within the lysosomes of macrophages. Classically, GD has been classified in three sub-types (1, 2 and 3). Type 1, which is the nonneuronopatic form is the most common in adults. Clinical manifestations result from accumulation of the lipid-laden macrophages in the tissues: spleen, liver, bone marrow, bone, etc. Skeletal disease is characterized by diffuse bone pain, sometimes painful crises that often results in osteonecrosis, osteolytic lesions, pathologic fractures and other manifestations associated with low bone mineral density. The basic goals of treatment are elimination or improvement of symptoms, prevention of irreversible damage, and improvement in the overall health and quality of life. In skeletal disease, ERT may slow or prevent progression of skeletal complications (osteonecrosis, osteosclerosis, fractures). The objective in adults is to increase trabecular bone density in 3-5 years. In this study, we can appreciate a significant improvement of bone pain and bone crisis in the first two years treatment with stabilization of skeletal disease at the radiologic following.

Conclusions: 1. Evolution of skeletal disease is not predictable in GD patients, even in comparison with other GD patients. 2. Skeletal disease quantified by radiologic tests, biomarkers and genetic studies is not totally concordant with the clinical manifestations bone-related. 3. Skeletal disease evolution after ERT needs to use several markers and studies (clinical, radiology, biomarkers, quality of life) for a correct assessment of patients.

V-185
LEUKOCYTE POPULATIONS AND LYMPHOCYTE SUBPOPULATIONS IN BRONCHOALVEOLAR LAVAGE FLUID OF PATIENTS WITH LUNG TRANSPLANTATION

S. de la Fuente, M. Citores, J. Vargas, P. Tutor, A. Castañeda, A. Callejas

Department of Internal Medicine. Hospital Universitario Puerta de Hierro. Majadahonda (Madrid), Spain.

Objectives: The characterization of leukocyte populations and lymphocyte immunophenotype in bronchoalveolar lavage fluid, have been postulated as a potential tool in the diagnosis and monitoring of chronic rejection in patients with lung transplantation. The aim of this study is to analyze changes in the bronchoalveolar lavage cellularity in different clinical settings in patients with lung transplantation.

Material and method: We included 105 bronchoalveolar lavage fluid samples of 13 patients transplanted between 2000 and 2007 at Hospital Universitario Puerta de Hierro. We reviewed the clinical history and collected, on the date of each sample, the indication of the study, the microbiological and histological results, BAL leukocyte counts and the definitive diagnosis. The cellular content of the BAL fluid was incubated with a combination of fluorochrome-labeled monoclonal antibodies directed against surface antigens, and the different leukocyte and lymphocyte subpopulations were analyzed by flow cytometry. Statistical analysis was performed using the Student's t to compare the means of quantitative variables for independent samples. We used SPSS 15.0 and were considered significant probability value less than 0.05.

Results: The main indication for the study of leukocyte populations in the BAL fluid was the fall in pulmonary flow. Thirty-seven BAL fluids from 8 patients were collected at the time of chronic rejection. Patients with bronchiolitis obliterans (BOS) showed an increased percentage of neutrophils (p = 0.01) along with a decreased percentage of CD4+ T lymphocytes (p = 0.02) when compared with patients without chronic rejection (21.5 ± 24.1 vs 10.8+/-10.8 and 27.1 ± 19.6 vs 35.6 ± 17.8 respectively). An inverted CD4/CD8 ratio was found in patients with CMV infection (n = 20), while it is normal in patients without this diagnosis (0.76 ± 0.86 and 1.4 ± 1.97; p = 0.02). Although the mean percentage of NK cells was higher in patients with CMV infection (13.01 ± 11.9%) than in uninfected patients (8.61/-7.42%), the difference did not reach statistical significance. NK cells tended also to be decreased in the BAL fluid (p = 0.08) of patients with acute rejection (n = 28), diagnosed by transbronchial biopsy.

Discussion: Although it is accepted that BOS has an immune basis, this condition occurs in the presence of aggressive immunosuppression regimens, and responds poorly to the intensification of it. Innate immunity has attracted particular attention in this regard, since their mechanisms are independent of T responses. Thus, the focus is on two major components of natural immunity: neutrophils and NK cells, based on different observational studies in which have been identified on the site of injury. At this regard we have found a higher percentage of neutrophils in BOS. NK cell counts were also increased in patients experiencing chronic rejection and CMV infection, although the differences did not reach statistical significance accordingly to other findings described in the literature. In the other hand, a significant decrease in the percentage of CD4+ T lymphocytes in patients with chronic rejection and CMV infection was found, probably reflecting immune system activation in lung tissue of these patients.

Conclusions: The analysis of percentage counts of leucocyte populations in the BAL fluid from patients with lung transplantation could be considered an accessory tool in the diagnosis of chronic rejection and CMV infection.

V-186
RENAL IMPAIRMENT DOES NOT AFFECT THE GLYCAEMIC EFFICACY OR SAFETY OF LIRAGLUTIDE TREATMENT IN PATIENTS WITH TYPE 2 DIABETES

J. Gómez Cerezo[1], S. Gough[2], B. Feldt-Rasmussen[3], J. Davidson[4], S. Furber[5], M. Donsmark[5], D. Scott[6]

[1]Department of Internal Medicine, Hospital Infanta Sofía. Madrid, Spain. [2]OCDEM. University of Oxford. Oxford, United Kingdom. [3]Rigshospitalet. University of Copenhagen. Copenhagen, Denmark. [4]Department of Internal Medicine. UT Southwestern Medical School. Dallas, Texas, United States of America. [5]Medical Affairs. Novo Nordisk A/S. Søborg, Denmark. [6]Department of Nephrology. Clinical Research Development Associates LLC. Springfield Gardens, New York, United States of America.

Objectives: To investigate the effect of renal impairment (RI) on the efficacy and safety of liraglutide in patients with T2D.

Material and method: Data from 0–26 wks were collected from 7 clinical trials in the liraglutide development programme and used for a meta-analysis. Patients were classified into categories of renal function/impairment (normal [> 90], mild [< 90] or moderate [< 60 mL/min]) using the Cockcroft-Gault formula to estimate serum creatinine clearance [eCrCl]. Changes in A1c, serum creatinine (Cr) and rates of hypoglycaemia in each eCrCl category during treatment with liraglutide (1.2 and 1.8 mg) and placebo were analysed using ANCOVA, with trial treatment (± metformin), and interaction between treatment (placebo, 1.2 and 1.8 mg liraglutide) and baseline eCrCl as fixed effects. Baseline A1c or Cr were used as covariates in the analysis of A1c and Cr changes respectively.

Results: Over 26 wks, patients receiving either dose of liraglutide had greater A1c reductions than those receiving placebo (Table 1). No significant differences in A1c reduction were observed between any of the renal function categories. Overall, changes in Cr were small (-4.82 to 6.08 µmol/L), however, Cr significantly improved in patients with moderate RI receiving 1.8 mg liraglutide (treatment difference vs placebo -10.90 µmol/L, p < 0.001). In patients with moderate RI at baseline improvements in renal function (mild after 26 wks) were seen in all treatment groups (liraglutide 1.2 mg: 16%; 1.8 mg: 38%; placebo: 18%). The rate of major hypoglycaemia was low in this study (0 to 0.25%) and the rate of minor hypoglycaemic episodes, in each treatment group, were lower in patients with RI compared with those having normal renal function.

Discussion: In T2D patients with concomitant mild to moderate RI, glycaemic efficacy of liraglutide is similar to those with normal renal function, even in those with the greatest RI at baseline. The fact that liraglutide is completely degraded in vivo and is not excreted via the kidneys could explain this finding. However further studies are needed to fully characterize the efficacy and safety profile of liraglutide in patients with RI.

Table 1 (V-186). A1c changes in patients with normal or impaired renal function treated with liraglutide (1.2 and 1.8 mg) or placebo

Mean A1c reduction% (SE)	Normal renal function	Mild RI	Moderate RI
Liraglutide 1.2 mg (N = 1117)	N = 770 –1.07 (0.04)	N = 222 -1.14 (0.07)	N = 35 -1.18 (0.17)
Liraglutide 1.8 mg (N = 1583)	N = 1095 –1.20 (0.03)	N = 327 -1.16 (0.05)	N = 40 -1.28 (0.16)
Placebo (N = 524)	N = 396 -0.05 (0.05)	N = 88 -0.20 (0.11)	N = 14 -0.01 (0.26)

Conclusions: Liraglutide use in patients with RI is not associated with an increased risk of hypoglycaemia and appears to be an effective and well-tolerated antidiabetic treatment for patients with T2D and mild/moderate RI.

V-187
EFFICACY OF BASAL-BOLUS REGIMEN VS SLIDING SCALE BASIS IN INPATIENTS WITH HYPERGLYCEMIA AT THE HOSPITAL SANTIAGO APOSTLE DE MIRANDA DE EBRO AND FOLLOW-UP AFTER DISCHARGE (INDIGO STUDY)

M. Sánchez Nanclares, S. Blanco Guzmán, P. del Val Torrecilla, A. Herrán Bergado, L. Jiménez Rojo, S. González Barahona

Department of Internal Medicine. Hospital Santiago Apóstol. Miranda de Ebro (Burgos), Spain.

Objectives: To determine if the Basal-Bolus regimen achieves a better or equal glycemic control rather than the sliding scale basis in patients with hyperglycemia hospitalized by any reason.

Material and method: Epidemiological, retrospective, unicenter, observational study at the Internal Medicine Department in inpatients at the Hospital Apóstol Santiago de Miranda de Ebro (Burgos), conducted within the usual clinical practice conditions. (approved by the IEC of Burgos Ref CEIC 986). Data from 174 patients with hyperglycemia defined as glycaemia over 180 mg/dl at hospital admission or diabetic type 2 patient hospitalized by any reason and also requiring insulin treatment to achieves the proper control were included. 39 patients (22.4 %) were on sliding scale basis while 135 (77.6 %) were on basal-bolus regimen.

Results: The mean age of the patients included was 72.0 years. A significant reduction on the glycemia during hospitalization as primary objective study was achieved within the basal-bolus group from 164.3 to 131.2 mg/dl ($p < 0.001$) while not within the sliding scale group (from 137.4 to 130.9 mg/dl, $p = 0.530$). There were not significant differences between both groups for the glycemia value. Significant differences were not observed neither in number of days until glycemic control achieved 4.7 vs 5.2 days ($p = 0.190$) nor in the number of hospitalization days. Regarding the number of hypoglycaemias this could not be evaluated as these were not properly collected within the sliding scale group because of the retrospective design. A reduction on HbA1c after 4 months from the discharge from the HbA1c at admission was observed within the basal-bolus group from 8.0 % to 7.3 % ($p < 0.005$). This reduction was not significant within the sliding scale group 6.6 % to 6.5 % $p = 0.348$. There were significant differences between both groups regarding the value of HbA1c that may be led by the basal–bolus regimen use in those patients with a worse basal situation.

Conclusions: The results obtained in the study reveals that the use of the Basal-Bolus regimen for the treatment of the hyperglycemia in inpatients is a suitable option that obtains a significant decrease in the values of basal glycemia during the hopitalization. A trend to use this regimen of treatment in patients who did present a worse glycemic control at admission time was observed as they had got a worse glycemia and HbA1c values that indicates inadequate control during the last 3 months. Finally we noted that after at least 4 months from the discharge there was a significant improvement in the values of HbA1c within the group of patients treated with Basal-Bolus regimen during hospitalization.

V-188
BURNOUT SYNDROME IN RESIDENT MEDICAL DOCTORS IN GRANADA: TWELVE YEARS LATER, WE ARE STILL THE SAME

M. Ruiz-Ruigómez, C. Fernández-Roldán, I. Villanueva Saucedo, I. Aomar Millán, A. Martín Pérez, J. Badiola González, M. Moreno Higueras, M. García Morales

Department of Internal Medicine. Hospital de Especialidades San Cecilio. Granada, Spain.

Objectives: Compare the percentage of residents in Granada with burnout syndrome in two samples one in 1997 and the second in 2010.

Material and method: We used data collected from May to June 1997 and 2010 from San Cecilio and Virgen de las Nieves Hospitals concerning medical residents working in these two centres. Participants were invited to answer questionnaires by email or by personal interview. We proposed them to take two tests; Maslach Burnout Inventory scale (MBI) and a second one that had been specifically designed for this purpose and that tried to analyze demographic data, related with the resident specialty and their specific activities due with it, including questions that could be related with items of burnout syndrome. MBI questioner asses three of the dimensions of burnout syndrome; emotional exhaustion (EE), depersonalisation (DP), personal accomplishment (PA). EF measures emotional overload feelings. DP measures absence of feelings, impersonal reactions with patients and PF measures competitive attitude and assess achievement of goals. Presence of burnout it's considered when EF ≥ 19 and DP ≥ 6, with low punctuation in PF. High level of wear it's considered when EF ≥ 27, and DP ≥ 10. For the statistic analysis we used PASW Statistics 17.

Results: A total of 61 medical interin residents answered both questionnaires (33% men y 66% women), for 2010 results and 45 of 1997 results (44% men and 55% women). Mean age was 28 years in both groups. 82% respondents in both periods presented moderated to high punctuations for EE and/or DP. We found high burnout levels in 54% of the participants analyzed in 2010 and 62% in 1997 sample. There was no statistic difference found for these results ($p = 0.5$). No differences found either for sex distribution. From those residents that presented burnout syndrome 35% had stable partnership in 1997 and 70% in 2010, ($p = 0.002$). We would like to underline the high punctuation in EE that presented women in 2010 sample when compared with the ones obtained for men ($p = 0.040$). For those with children punctuation in DP were lower in this sample ($p = 0.039$). These differences were not founded in 1997 sample.

Conclusions: Medical residents that are affected by burnout syndrome in Granada had suffered no change in the last twelve years. According with our data more than half of the participants present high wear level.

V-189
APPROPRIATENESS OF HOSPITAL STAYS IN AN INTERNAL MEDICINE SECTION

A. Jurado Porcel, R. Martínez Fernández, J. Ampuero Ampuero, R. Ruiz Ortega, P. Durán García, J. Polonio Bellido, F. Gómez Delgado, M. Montero Pérez-Barquero

Department of Internal Medicine. Hospital Universitario Reina Sofía. Córdoba, Spain.

Objectives: To determine the number of inappropriate stays generated by patients admitted through an internal medicine section over a 1-year period and to identify the causes of those stays.

Material and method: A representative sample of hospital stays corresponding to patients admitted by the internal medicine section

at Hospital Reina Sofia, Cordoba, Spain, in 2011 was analyzed using the Appropriateness Evaluation Protocol (AEP). These were achieved at 5 check points during this year. The review was conducted by 2 nurses who belong to the internal medicine section and a stay was considered to be appropriate when there was at least one criteria positive of AEP.

Results: The sample included 146 patients, 51.2% of whom were women with an average age of 83.5 (DS 8) years. Of the 1035 stays analyzed, 1000 (96.6%) were judged to be appropriate and 35 to be (3.39%) inappropriate. The most common reason for inappropriate stays was a delay in receiving the results of laboratory tests (48.57%), non-working days (28.54%), delays in performing diagnostic tests (11.45%) and others reasons for inappropriate stays (11.44%). The main justification for appropriate stays was the need for parenteral treatment (100%).

Discussion: The rate of inappropriate stays was low, in spite of the fact that the group studied was elderly patients. The main causes for inappropriate stays were delays in receiving and performing diagnostic tests. We were surprised because social causes were very low for inappropriate stays.

Conclusions: The rate of inappropriate stays was low in comparison with other studies. The majority of inappropriate stays were attributed to delays in performing diagnostic tests and receiving results.

V-190
IN HOSPITAL MORTALITY RETROSPECTIVE ASSESSMENT IN A GENERAL HOSPITAL

A. Ródenas, X. Martret, G. Donaire, E. Rovira, X. Pena, C. Paytubí, V. Díaz, E. Bragulat

Department of Internal Medicine and Emergency. Parc Sanitari Sant Joan de Déu. Barcelona, Spain.

Objectives: To analyze the epidemiological characteristics the exitus of our center in a certain period of time.

Material and method: Retrospective study of 151 patients in which age, gender and cause of deaths are assessed. The study included patients who died in our hospital between 1/1/11 and 15/9/11. These patients had admitted in the short stay unit and internal medicine wards.

Results: The following results were obtained: 54.6% were male. Mean age at death was 82.71 yr-old. Table 1 shows the age distribution of patients. The main causes of death are: respiratory (failure, infectious, aspiration pneumonia), cardiac (acute or chronic heart failure, acute pulmonary edema, acute coronary syndrome), oncological, neurological (stroke, neurodegenerative disease), urinary tract infections and liver failure. In the analyzed period, 2,280 discharges were made. 6.62% of patients died in that period.

Discussion: As in other series reviewed, in our hospital there is a male predominance death rate, with a greater life expectancy in women compared to men. There is no significant difference in the cause of death. Being hospital mortality one of the main clinical quality indicators, this can be used as tool for hospital planning and management. Therefore, it has been used in several studies to assess this and to be able to compare global and adjusted mortality and to develop means to allow direct hospital comparison (benchmarking) Clinical history auditing is basic to identify deficiencies in hospital care. This can allow to identify failing points and to create the means to avoid them. Post mortem studies can offer the possibility of clinical development, but there is a gradual reduction in the number of studies carrier out.

Conclusions: 1. Life expectancy is longer in women 2. Causes of death in our series are similar to those reviewed series 3. The need of a systematic review of discharge summaries and continuous auditing can help to identify failing points and to develop means of correction 4. Post mortem studies can be a useful tool to help with clinical development and to improve the quality of patient care in hospitals.

Table 1 (V-190). % age distribution

< 65 yr-old	6 patients (3.9%)
66-75 yr-old	18 patients (11.9%)
76-85 yr-old	65 patients (43.04%)
86-100 yr-old	60 patients (39.7%)
> 101 yr-old	2 patients (1.32%)

V-191
BURNOUT SYNDROME PREVALENCE IN INTERNAL MEDICINE RESIDENTS OF A REGIONAL HOSPITAL

M. Pérez Ramos, G. Granados Reyes, F. Díaz Narváez, M. Rodríguez Amigo, M. Pérez Tristancho, B. Merelo Ruiz

Department of Internal Medicine. Hospital Infanta Elena. Huelva, Spain.

Objectives: Burnout syndrome is an inappropriate response to chronic job stress markedly affecting those groups whose scope of work involves the public from steadily. Defined by Maslach and Jackson in 1981. It is characterized by a high level of emotional exhaustion, depersonalization and personal accomplishment. The aim of this study is to assess the degree of burnout among internal medicine residents in a district hospital.

Material and method: This is a cross sectional study. This will include all residents of Internal Medicine county hospital Infanta Elena de Huelva, with two residents per year, therefore a total sample of 10 residents. To all of them will be given the Maslach Burnout Inventory (MBI), consisting of 22 items, each of which is titrated with a Likert scale (the degree of agreement or disagreement with a statement of 0-6 points. Nine items respond to emotional exhaustion, depersonalization and five to eight to personal accomplishment (Annex I).

Results: Were included in the study a total of nine residents, one did not deliver the survey. Burnout is established there when you get a high score on the scales of emotional exhaustion and/or depersonalization, excluding the scale of personal fulfillment as an area greatly influenced by events outside the workplace. Met Burnout defining 7 (7 of 9) residents, ie 77.77% of the total. The staff depletion was observed in 5 residents, 55.55% of the total. Depersonalization was observed in 4 residents, 44.44% of the total. Personal fulfillment is not reflected because it is considered as a criterion Burnout.

Discussion: According to the definition, we observed Burnout syndrome in 77.77% of respondents to the MBI. Existence of burnout among residents was associated only to the total number of guards (5 or more). Residents have been the subject of several studies as a group are considered vulnerable to this syndrome. The causes that can lead to it are many highlighting the difficulties of reconciling work and personal life, lack of supervision in practice and increased external factors that put pressure on the professionals. The consequences are varied. The results of our study are similar to studies in university hospitals where more than two thirds of residents have Burnout criteria evaluated by MBI, which is only associated to the fact guards make more than 4 month. Therapeutic measures include identification of individual risk factors and specific treatment in the affected cases and corrective action on the external factors considered at risk.

Conclusions: Overall residents are satisfied with their career training and Burnout has fought with measures affecting the educational system and the organizational system of care.

V-192
NUTRITIONAL STATE OF PATIENTS WITH HIP FRACTURE IN SON ESPASES UNIVERSITY HOSPITAL

I. Gonzalez Sayago[1], M. Colomar Ferrer[2], M. Martín Fajardo[1], E. García Almodovar[1], M. Femenias Sureda[1], J. Urgeles Planellas[2], J. Forteza-Rey Borralleras[1], G. Frontera Juan[3]

[1]Department of Internal Medicine, [2]Department of Endocrinology and Nutrition, [3]Department of Pharmacy. Hospital Son Espases. Palma de Mallorca, Spain.

Objectives: 1. To evaluate biochemical nutritional parameters in patients admitted for hip fractures in our center between January and November of 2011 2. To see whether there exists any relationship between these nutritional parameters and the appearance of infections or pressure scores (PS).

Material and method: Retrospective study using clinical history review of patients admitted for hip fractures between January and November of 2011. Nutritional risk evaluation assessed using CONUT tool, pre-albumin and zinc. Descriptive analysis using the mean and median according to the distribution, and percentages for qualitative variables.

Results: We collected a total of 221 patients with 67.8% women. The median of age was 78 years old for males and 83 years old for females. 81% came from their homes, 11.3% came from a residence or social services center. The Barthel index was 100 points in 46.2% and < 20 in 4.3%. 47% of patients had a Charlson index of 3 or more. 95% of the patients were polypharmacy patients. Biochemical nutritional evaluation was carried out in 75.1% (n = 166) of the patients. The nutritional parameters are shown in Table 1, the relationship of these parameters and infection/PS is described in Table 2.

Conclusions: Patients of which had a biochemical nutritional evaluation 63% had low risk of malnutrition, 35.5% hadmoderate risk of malnutrition and 3% had high risk of malnutrition. No difference between the nutritional parameter study and the appearance of infection or DU in patients with hip fractures.

V-193
APPLICATION OF "STROKE CODE" AND STROKE UNIT OPERATION ONE YEAR OF EXPERIENCE IN SANTA BARBARA HOSPITAL

M. León Téllez[1], J. Barraza Vengoechea[1], J. Gutiérrez Salcedo[1], D. Sagarra Mur[2], P. Sánchez Oliva[1], M. Carrera Izquierdo[1], O. Terry López[1], D. López Delgado[1]

[1]Department of Internal Medicine, [2]Department of Neurology. Hospital Santa Bárbara. Soria, Spain.

Objectives: Spreading the activity that has developed the Stroke Unit of the Neurology Department belonging to the Internal Medicine Service in the first year of operation, taking into account that patients are treated and classified initially by Internist physicians in the Emergency Room.

Material and method: A retrospective observational study in which medical charts of all patients who required medical assistance for ischemic stroke in the period between late 2010 and late 2011 that included criteria for activating the stroke code protocol. We collected all the data about: the onset of symptoms; stroke code

Table 1 (V-192). Biochemical nutritional parameters

	Male	Female
Albumina (g/dl)	34.6	33.7
Total cholesterol (mg/dl)	144.1	165.0
Lymphocytes	1280	1450
CONUT	4	4
Prealbumina (g/dl)	15.1	15.2
Zn (mg/dl)	58.5	60.2

Table 2 (V-192). Relationship of biochemical nutritional parameters and infection/PS

	Infection	No infection	PS	No PS
Albumina (g/dl)	34.5	33.7	34.5	33.8
Total cholesterol (mg/dl)	157.5	155.8	157.5	155.8
Lymphocytes	1450	1350	1450	1350
CONUT	3	4	3	4
Prealbumina (g/dl)	15.6	15.1	15.6	15.1
Zn (mg/dl)	63.23	58.2	63.23	58.2

Table 1 (V-193)

Patient number	Sex	Age	Cardioembolism or Aterothrombotic	Window time minutes	NIHSS admission	NIHSS after 24 hours	Ischaemic area
1	M	51	A	220	14	6	Deep left MCA
2	F	69	A	150	17	16	Right MCA
3	M	53	A	135	13	11	Deep right MCA
4	F	55	A	210	14	2	Left MCA
5	M	69	C	150	18	16	Right MCA
6	M	62	C	90	14	5	Deep left MCA
7	M	79	A	180	16	8	Left MCA
8	M	63	A	220	14	10	Right MCA
9	F	86	A	140	15	8	Left MCA

activation and arrival time of patients; signs objectified by the Internal physician; score on the NIHSS scale on arrival; final diagnosis; and inclusion or exclusion criteria for fibrinolysis; time and doses of fibrinolytic agents.

Results: In total 10 patients met criteria for fibrinolysis which represent 4% of the Stroke Code activation, a total of 120 activations of it, and knowing that patients who came with suspect clinic of ischemic stroke were 228.

Discussion: The implementation of the Stroke Code has been shown to increase the number of patients treated with thrombolysis and improve the functional prognosis of patients with acute ischemic stroke, in our experience we need to evaluate the prognosis and final clinic situation of our patients and to compare it with the results before implementation.

Conclusions: Despite our limited experience the success of the fribrinolysis is comparable to reference units with more skilled physician in that procedure. Our population has the same incidence of ischemic events who receive fibrinolytic therapy.

V-194
HOSPITAL DETOXIFICATION UNIT IN A INTERNAL MEDICINE SERVICE. TWENTY MONTHS OF EXPERIENCE

I. Marañón Zabalza, M. Tejero Delgado, M. Martínez López, D. Galiana Martín, D. Cuervo Blanco, G. López Colina, L. Montes Gil, J. Moris de la Tassa

Department of Internal Medicine. Hospital de Cabueñes. Gijón. Asturias, Spain.

Objectives: There is little information available regarding the drug detoxification in a general hospital. The aim of this study was describe the characteristics of the patients admitted to the Hospital Detoxification Unit (HDU) along twenty months.

Material and method: Prospective study of patients admitted between September 2010 and April 2012. Medical records were reviewed. SPSS program was used to perform the statistical procedure.

Results: One hundred and sixty one patients were proposed for admission to the HDU by their mental health services, 35 patients rejected their admission to hospital. Personal o family problems and the arduousness for their location were the main reasons that made it impossible. Those who were admitted, 76% were males with a mean age of 43.76 years (27-68) without significant differences between sexes. 92.9% were from Spain, 3.9% (3 patients) from Eastern Europe and 3.1% (4 patients) from South America. Alcohol was the principal drug to detoxify (71 patients), and 30 patients had to be detoxified from two or more drugs. The average length of hospital stay was 8.44 days to alcohol, 9 days to decrease methadone dose, and 11.25 for those admitted for methadone withdrawal. Fifteen patients (12%) applied for voluntary discharge. Sixty four patients (50.8%) had used intravenous drugs sometime, 48 (38.1%) never used illicit drugs and 14 (11.1%) had used drugs through other routes, only two had phlebitis when admitted. Six patients had to be readmitted, in one case to treat another different drug. Hepatitis B virus infection was diagnosed in 12 patients (9.6%), 22 (17.6%) were immune for VHB, and 56 (44.8%) had C hepatitis infection. Twenty four out of 85 patients had been in prison, 2 of whom were women. Thirty eight patients had a steady job (37% women and 29% males), while 29% males and 24% females were pensioners. Sixty per cent of females and 30% of males lived with partner.

Discussion: The mean age is similar in both sexes, and the main drug to detoxify was alcohol. Intravenously use is steadily decreasing, and also its complications. So the demand nowadays is for decrease or withdrawal of oral opioids. Males show a higher criminal activity, and a lower economic and social stability than females. When comparing the actual with previous figures we observed that the incidence of hepatitis virus B and virus C infection, and stay in prison are lower than twenty years ago, but also there is an increase foreign patients.

Conclusions: The characteristics of the patients admitted in HDU have changed in the last ten years. Nowadays, the number of patients who have a stable situation with family support has increased and the use of intravenous drug has decreased. This is responsible, to our best knowledge, of their better social integration social and self-care. All this facts can help to provide better assessment, monitoring and treatment of these patients.

V-195
INTRACARDIAC MASSES - PROBLEMS OF DIFFERENTIAL DIAGNOSIS

D. Bartos[1], C. Diaconu[1], E. Badila[1], F. Mehic[2], S. Frunza[2]

[1]Department of Internal Medicine. University of Medicine and Pharmacy Carol Davila, Emergency Clinical Hospital. Bucharest, Romania. [2]Department of Internal Medicine. Emergency Clinical Hospital. Bucharest, Romania.

Objectives: To present a series of clinical cases with intraatrial masses that raised issues of differential diagnosis.

Material and method: We present 4 cases with intraatrial masses, extensively investigated by transthoracic and transesophageal echocardiography, venous and arterial Doppler ultrasound, thoracic CT scan, MRI, angiography. All patients were finally referred to cardiac surgery.

Results: Case 1. 53 year-old male, hypertensive, without history of peripheral artery disease, presented with sudden onset of pain in the legs. Right calf was increased in volume, endured, with sharp pain when walking and functional impotence. Lab tests: hepatic cytolysis, rhabdomyolysis, acute renal insufficiency. Venous Doppler ultrasound of pelvic limbs and muscular ultrasound were normal. Arterial Doppler ultrasound: 80% stenosis of right common femoral artery. MRI of right calf: rhabdomyolysis, probably due to ischemia. Arteriography: bilateral occlusion of external iliac arteries, occlusion of right tibio-peroneal trunk. Transthoracic echocardiography revealed a left intraatrial mass, 22/14 mm, highly mobile, attached to the interatrial septum, atypical for myxoma, due to excessive mobility and extensions. The patient was referred to surgery, with final diagnosis of atrial myxoma and peripheral embolism. Case 2. A 69-year-old female, with severe mitral stenosis and atrial fibrillation, anticoagulated with acenocumarol, with INR in therapeutic range, presented with 2 weeks history of dyspnea, fatigue and dysfagia. Thoracic CT scan raised the suspicion of mediastinal tumor with left atrium invasion. Transthoracic echocardiography: mitral disease (severe stenosis and mild regurgitation), severe pulmonary hypertension, left atrium very dilated. Transesophageal echocardiography revealed left intraatrial massive thrombosis, which was not visualized at transthoracic echo and was mistaken for mediastinal tumor at CT scan. The patient was referred to cardiac surgery, where left atrium thrombectomy and mitral valve replacement were performed. Case 3. 66 year-old female, hospitalized in the surgery clinic for abdominal pain, with diagnosis of poliserositis and suspicion of ovarian tumor. Internal medicine consult: congestive heart failure, ascites, right pleuresy. Transthoracic echocardiography revealed a left intraatrial mass, hyperechoic, 62/25 mm, mobile, attached by a stalk to interatrial septum, severe pulmonary hypertension. The patient was referred to cardiac surgery, with successful tumor excision. Postoperatively the diagnosis was myxoma. Case 4. 55 year-old female, without prior pathological history, asymptomatic. At a routine check up, including transthoracic echocardiography, a right intraatrial tumor, 44/38 mm, attached to superior and lateral wall, was identified. Thoracic CT scan and MRI confirmed the tumor. After surgery, the

diagnosis was myxoma. Particularities of the case: incidental finding of myxoma in an asymptomatic patient, atypical location on lateral wall of right atrium.

Discussion: Transthoracic and transesophageal echocardiography are the methods of choice for the diagnosis of intraatrial masses. The differentiation between myxomas and thrombi is sometimes difficult, but is critical for making the right therapeutic decision.

Conclusions: Atrial myxomas are benign neoplasms that arise from the interatrial septum and extend into the left or right atrium. Usually they are associated with atypical symptoms and only a small percentage remain completely asymptomatic. Clinical manifestations are in close relation to the location site and produced by mechanical interference with cardiac function or by intracardiac obstruction. Embolization of systemic or pulmonary circulation is a frequent phenomenon.

V-196
CLINICAL SIGNIFICANCE OF THE EXTREME ELEVATION OF THE ERYTHROCYTE SEDIMENTATION RATE: A RETROSPECTIVE ANALYSIS

B. Yildiz[1], R. Öcal[1], M. Çakar[1], E. Arslan[1], R. Acar[1], G. Büyükturan[1], B. Basgöz[1], E. Sertoglu[2]

[1]Department of Internal Medicine, [2]Department of Clinical Chemistry. Gülhane Military Medical Faculty. Ankara, Turkey.

Objectives: The ESR, defined as the rate (mm/hour) at which erythrocytes settle when placed in a vertical tube suspended in plasma, reflects a variety of factors, notably the plasma concentration of fibrinogen. The ESR is one of the tests used to evaluate the acute phase response. The ESR is a simple and inexpensive test of chronic inflammatory activity, whose usefulness is becoming limited as a result of low sensitivity and specificity and emergence of new methods of evaluating the inflammatory condition. The ESR is frequently ordered in clinical medicine. In our study, we aimed to investigate the diseases which elevate erythrocyte sedimentation rate upper than 100 mm/h.

Material and method: In this study we retrospectively examined the medical records of patients who were hospitalized in our Internal Medicine Department between January-December 2011. From the medical records of the total 389 patients admitted in this period, 89 patients having an erythrocyte sedimentation rate (ESR) 100 mm/h and over were selected and recruited in the study.

Results: 45 cases were male (M) (50.6%), and 44 were female (F) (49.4%). Mean age was 65.47 ± 14.8, mean ESR was 114.61 ± 13.9 mm/h (M: 114.02 ± 14.23 mm/h, F: 115.2 ± 13.7 mm/h). There were 47 patients having an ESR between 100-110 mm/h, 18 patients between 111-120 mm/h, 13 patients between 121-130 mm/h, 6 patients between 131-140 mm/h, 2 patients between 141-150 mm/h and a total of 2 patients between 151-160 mm/h. The distribution of the disease groups was as follows: haematologic and oncological diseases (39.3%), infectious diseases (27%), rheumatic diseases (13.5%), nephrological diseases (6.7%), gastroenterologic diseases (6.7%), endocrinological disorders (4.5%), cardiac diseases (1.1%). Lung cancer was the most common (17.1%) malign disorder among the study population. In one patient, no cause could be found as the etiology. The highest value of erythrocyte sedimentation rate detected was 159 mm/h in two patients. One of the patients had sepsis, other one was diagnosed with acute myeloid leukemia. A value of ESR as 140 mm/h was detected in a patient with urinary tract infection. It is the cause of high ESR values in 11.1% of cases and it was worth to pay attention that urinary tract infection elevated the ESR higher than 100 mm/h as a single cause.

Conclusions: As a result, hematological and oncological disorders, especially lung cancers; and among the rarer causes, urinary tract infections should be considered in the differential diagnosis of ESR values higher than 100 mm/h.

V-197
SALIVA - AS BIOLOGICAL SPECIMEN AND DIAGNOSIS TOOL

O. Burta[1], F. Marc[1], C. Moldovan[1], O. Burta[2]

[1]Department of Internal Medicine. Clinical Municipal Hospital. Oradea, Romania. [2]Department of Immunology. Faculty of Medicine and Pharmacy. Oradea, Romania.

Objectives: Saliva is a dynamic and complex fluid, reflecting the life style and being fingerprinted by different diseases. Our study is focused on 3 approaches of saliva: in vivo, in vitro and in silico, regarding specific chemical and biological features, related to two pathological conditions: diabetes mellitus associated with parodontal disease and dental cavities pathology.

Material and method: Being an on-going study, so far were assessed 50 saliva samples. Respecting the well-defined admitting criteria (gender, age, pathology) we divided the subjects into 3 groups, as follows: control (10), multiple dental cavities (20) and diabetic parodontal pathology (20). According to "individual file" were specified: general data, heredo-collateral/personal history, life style, risk behaviours, previous medical treatment, and dental evaluation. Each biological sample was obtained in similar conditions (non-stimulated saliva) in an intimate environment, with record of required time for 5 ml of saliva collection. The saliva variables followed by us were complex: macroscopic evaluation (color, consistency, pus, blood), presence/concentration of certain parameters: erytrocytes, leucocytes, glucose, proteins, bilirubine, pH, density, ketone bodies, nitrites - strip maneuvre), saliva smears (MB and NBT), spectrophotometric analysis (Trace Lab 150 and Thermoscientific AA Spectrometer ICE 3300 for metal ions: Cd, Ni, Lead, salivary amylase activity), immunologic assay: sIgA titers, and microbiological aspects (blood-agar, Levin, Drigalski and Sabouraud medium). For in silico approach was designed a personalized soft, consisting in all displayed parameters and individual data.

Results: Regarding saliva variables, we noticed a longer period of time necessary to collect the biological sample in both pathological conditions (up to 40 minutes in parodontal disease) with afferent higher consistency; in parodontal patients: 10% presented traced of pus, 30% blood traces, 50% possessed an acidic pH, 10% positive for nitrates, and 40% developed frequent Candida albicans colonies, an increased concentrations of leucocytes, and inflammatory reaction (NBT smear). Salivary amylase activity was increased in both pathologic conditions, with statistical significance ($p < 0.001$) in parodontal group, compared to control samples. Considering metallic ions concentrations, in parodontal group we noticed 2 isolated cases of increase in Cadmium level, interpretated as a professional exposure (according to personal history).

Discussion: The 3 assessed groups of saliva samples, allowed us to evaluate the presence and types of cellular components, the physical-chemical properties and the immunological features of the individuals, in correlation with health/different pathologic conditions. There was a significant statistic correlation between studied pathological conditions and oral impaired immune status. The local inflammatory reaction was predominant in parodontopathy related with diabetes mellitus, associated with Candida albicans. The salivary amylase activity followed the same trend as inflammatory reaction. Regarding the metallic ions, were noticed no correlation with studied pathology. Both dental cavities and parodontopathy induced by diabetes mellitus, are consequences of a multifactorial process, which depends on the interaction between host (genetics, oral microbiocenosis) and risk behaviours, such as: diet, smoking, incomplete dental hygiene.

Conclusions: Saliva collection is a non-invasive, stress-free procedure, easy to be used as diagnosis tool. Based on these, preventive/corrective/curative therapeutic schemes could be developed, with essential support of a personalized soft. The potential use of metallic ions in saliva, might be used to identify risk areas of pollution/professional exposure. The enlargement of

parameters panel, with ATP-ase, lysosyme and other inorganic substances is an aim for our future studies.

V-198
ORTHOPEDIC CONSULTATION TO AN INTERNAL MEDICINE DEPARTMENT

Í. Marañón, D. Galiana, A. García, A. García, N. Solís, D. Cuervo, J. Noval, J. Morís

Department of Internal Medicine. Hospital de Cabueñes. Gijón (Asturias), Spain.

Objectives: Assess frequency and motives of consultations (Cs) from Orthopedical Surgery Department (OS) to our Internal Medicine Department (IM), analyze their main features, identify patients on risk of medical complications and provide plans and guides for better outcomes.

Material and method: Descriptive, retrospective study by data gathering from archives of the Cabueñes Hospital, collecting consultations from OS to IM on 2011. Data analysis and previous bibliography review.

Results: Our IM Department receives 400 consultations each year, a third part of them from OS. This is 4.6% of all admissions to OS. Most of them were urgent, and urgent admitted patients were more prone to need a consultation. Patients were 56% women, age 81.6 (higher on women, reaching 83.75 in front of 78.98 years old on men). They were comorbid patients, with an average age-adjusted Charslon index of 5.83. Cardiorrespiratory ailments (chronic heart failure and ischemia, COPD), ischemic brain disease, DM and dementia were the most prevalent disease Polimedication was the rule. Hip fracture was the main cause of admission (56.7%), and dyspnoea the main motive of consultation. Analytic abnormalities and low consciousness were also important. We also found that delay to ask for consultations was 1.32 days after cause appeared, and another 0.17 days to answer for the request: 86.5% were answered the same day. Repetition of consultations happened in 21 out of 128 cases, 13 of them for the same motive. IM consultant performed analysis (71%) and other tests, and in 88% treatment was switched. Hospitalary stay lengthens 9.5 days and one third of diagnosis were of decompensations of chronic ailments. Renal failure/dehydration, respiratory troubles and heart insufficiency were the most common diagnosis. Further evolution was good in 71 out of 104 patients, and we had 24 deaths. Discharge note had references to our work in 65 cases. We made a subanalysis of hip fracture patients, finding they were older, most of them women and stayed longer at hospital. Mortality was very high: 27.12%, without any single death on hip fracture patients without consultation. We also studied the cases of death: many were hip fractures (22.22%), being urgent admissions 92.59% of deads. Patients who died were older but not statistical significance was found. There was a good correlation to ASA, Charlson and age-adjusted Charlson scores, with significant statistical differences. Among the causes of dead, renal failure, respiratory infection and failure and heart ischemia and insufficiency were the most important.

Discussion: Consultations from OS are in the average previously found (4 to 5% of admissions), and they relate to comorbid, old and complex patients with medical issues that worsen prognosis and are often decompensated by acute insult (trauma and surgery). Consultations were answered on time and changes in treatment were the rule. Internists were deep involved in patient care in most cases, with a follow-up rate of 71.70%, when other studies showed this rate was between 30 and 70%. New working methods for high risk patients (i.e. hiper fracture) are warranted.

Conclusions: Consultations are made nowadays on request in our setting, and there are signs showing this system is not as useful as it should. Worse outcomes, higher costs and less satisfaction is perhaps a consequence of a system needing to be improved. Better communication between staff, clinical guides about the most prevalent pathologies (starting with hip fracture) and specifically training for OS and MI residents are warranted. An internist on full-time basis at the OS department is an already tried idea in many hospitals, and also a plan to make a medical visit to every high-risk patient admitted. The good correlation with comorbidity indexes could be helpful for patient stratification, and it came already to an amelioration program within IM and OS.

V-199
THE PREVALENCE OF OBESITY IN PATIENTS ADMITTED TO INTERNAL MEDICINE CLINIC: A RETROSPECTIVE STUDY

E. Arslan, B. Yildiz, A. Kilinç, S. Demirbas, S. Sayin, M. Çakar, R. Acar, K. Saglam

Department of Internal Medicine. Gülhane Military Medical Faculty. Ankara, Turkey.

Objectives: Obesity, a chronic disease that has an increasing prevalence in adults, adolescents, and children, is now considered to be a global epidemic. In most populations, the prevalence of overweight and obesity has increased over the past 20 years. In the United States, the lifetime risk of becoming overweight or obese is approximately 50 and 25 percent, respectively. Healthcare expenditures are significantly higher for overweight and obese individuals. In this study, we investigated the clinical characteristics and the distribution of obesity in patients hospitalized for various reasons in our internal medicine department in the last 1 year period.

Material and method: We retrospectively analyzed the files of all patients hospitalized in our internal medicine clinic between June 2011 and December 2011 in this study. 92 (35.4%) patients with a BMI of 30 and above from a total of 267 patients were selected and recruited in the study.

Results: 48 cases were male (M) (52.2%), 44 were female (F) (47.8%). The mean age, mean weight, mean height and the average BMI of the patients were 55.6 years, 93.7 kg, 1.62 m, 34.9 kg/m^2 respectively. According to BMI, patients were classified as 60 cases between 25-29 (22.4%), 53 cases between 30-34 (19.8%), 29 cases between 35-39 (10.9%), and 10 cases over 40 (3.7%). The highest value of BMI was 54 kg/m^2. When the distribution of disease groups was examined, diabetes mellitus and/or hypertension were present in 64 patients (69.5%), malignancy in 10 patients (10.8%), allergic and immunological diseases in 3 patients (3.2%), infectious diseases in 3 patients (3.2%), cardiovascular disease in 2 patients (2.1%), hematologic diseases in 2 patients (2.1%) and chest diseases in 2 patients (2.1%); miscellaneous various diseases were detected in 7 patients.

Conclusions: We here found that morbid obese population had greater hospitalisation ratios than the frequency observed in the general population. Morbid obesity, often with accompanying diabetes mellitus and hypertension, is important because it creates a predisposition to hospitalizations.

V-200
NURSES AND DOCTORS HAVE A DIFFERENT VIEW OF VALUE RISK OF ADVERSE EVENTS WITH INTRAVENOUS CATHETERS

P. Rodríguez-Torres[1], M. Marín-Cabañas[2], J. Moreno Machuca[3], M. Carrión Camacho[3], L. López-Rodríguez[3], M. González Mendes[3], J. Quijano Campos[3], I. Marín León[1]

[1]Department of Internal Medicine, [3]AETSA Group of therapy IV. Hospital Virgen del Rocío. Sevilla, Spain. [2]Department of Neurology. Complejo Hospitalario Nuestra Señora de Valme. Sevilla, Spain.

Objectives: The concern about the safety of care is increasing, and an intervention planning now requires more than ever consider

the risks involved, both to inform patients as to the decision-making action to perform. During the process of elaboration of a Clinical Guideline about IV therapy by the GRADE method, is required explanation of the significance that the authors give to potential adverse events due to the intervention. This is particularly important to inform patients about potential adverse events and get their collaboration. However there are few studies on how these professionals perceive the risk of their interventions.

Material and method: The 17 authors of the guide, voted independently on a scale from 1 to 9 the clinical relevance that they thought 21 potential adverse events resulting from the channeling of a central venous line could have. The analysis of results is collected by the profession of the authors, nurses versus doctors, with the median of the votes of each professional group and overall for all authors.

Results: Table 1 shows that both groups voted 11 adverse events very differently, 7 of which were consider more relevant for doctors (exitus, secondary complications to surgery, greater laceration, catheter sepsis, lost track, broken cannula and local irritation) and 4 of them were considered more relevant for nurses (phlebitis, local pain, extravasation and hematoma).

Discussion: This data support previous studies that reflect that the attitudes of professionals about objective risks on health interventions is subjected to various influences like the years of occupation or the education level. On the other hand it seems to have control in the practice makes perceive a minor risk, which may explain the attitude of nursing on venous channeling.

Conclusions: The perceived risk of interventions is poorly correlated to the objective relevance of them, and it is possible that the patient information and precautions to increase the safety of interventions could be affected by attitudes to risk.

V-201
DIFFICULTIES USING GRADE WITH GUIDELINES FOR INTERMEDIARY PROCESS

P. Rodríguez-Torres[1], M. Martínez Rísquez[1], G. Morillo Leco[1], A. Romero Alonso[2], C. Alonso Ortiz del Río[2], F. Ruiz-Ruiz[1], E. Calderón Sandubete[1], F. Medrano Ortega[1]

[1]Department of Internal Medicine. Hospital Virgen del Rocío. Sevilla, Spain. [2]Department of Internal Medicine. Complejo Hospitalario Nuestra Señora de Valme. Sevilla, Spain.

Objectives: Elaborating a Clinical Practical Guideline (CPG) of intravenous therapy there was disagreement in selection of adverse outcomes, which is a necessary point in intermediary process using GRADE system. Relation between intervention and outcomes are considered direct, while this relationship is indirect with intermediary process. The intermediary process behaves like a silent witness factor. Therefore authors could have difficulties to understand outcomes as a consequence of the intermediary process.

Material and method: Using GRADE system, an authors panel selected the clinical importance between a list of 22 proposed results related to intravenous lines. In a two-round individually voting 14 panelists scored the adverse outcomes with a 1-9 point scale. We develop a discussion meeting on the clinical relevance of the proposed outcomes in between both rounds. We calculated the median and frequency of deviations from the median in plus/minus three points of the scale, to check dispersion among experts.

Results: We found great differences between the two rounds (see table). In the second round, death passes from the fifth to the first in importance with nearly unanimous decision.

Discussion: CPG should be based upon the best available research evidence and practice experience, but if every author don't understand as the same the intermediary process, which is vote the adverse outcomes, clinically-relevant factors like the magnitude of effect of interventions we try to improve wouldn't be reliable.

Conclusions: Outcomes perceived to be indirectly related to the intervention are considered of little importance, in spite of its great clinical relevancy (death). It seems that raters could be first considering the probability or frequency for the outcomes to take place, than the importance of the result same for the patients.

V-202
GASTROINTESTINAL COMPLICATIONS OF DIABETES

E. Rusu[2], M. Jinga[2], S. Ateia[3], H. Popescu[2], C. Parpala[1], R. Nan[2], R. Dragut[2], G. Radulian[2]

[2]Department of General Medicine. University of Medicine Carol Davila. Bucharest, Romania. [3]Department of Diabetes. Medas Clinic. Bucharest, Romania. [1]Department of Diabetes II. National Institute of Diabetes, Nutrition and Metabolic Diseases Prof. N. Paulescu. Bucharest, Romania.

Objectives: Gastrointestinal (GI) disorders caused by diabetes include gastroparesis, intestinal enteropathy (which can cause diarrhea, constipation, and fecal incontinence), and nonalcoholic

Table 1 (V-200)

Adverse outcome	Median doctors	Median nurses	Global median
Exitus	9	4	7
Secondary complications to surgery	8	4	5
Phlebitis	6	8	7
Obstruction	6	3	3
Central thrombosis	8	5	5
Catheter sepsis	7	5	6
Pain	6	8	7

Table 1 (V-201)

Complication type	1st round scores median	1st round scores desvme ± 3	1st round scores% desv	2nd round scores median	2nd round scores desvme ± 3	2nd round scores% desv
Exitus	7	3	33.33%	9	1	7.69%
Catheter sepsis	6	0	0.00%	9	0	0.00%
Surgery complication	5	3	33.33%	8	1	7.69%
Puncture repetition	8	2	22.22%	4	1	7.69%
Quality of life related to health	4	3	3.33%	7	3	23.08%

fatty liver disease. The purpose of this study was to evaluate gastrointestinal complications in patients with diabetes.

Material and method: We retrospectively analyzed the data from patients hospitalized in National Institute of Diabetes, Nutrition and Metabolic Diseases Prof. N. Paulescu in 2011 (6,668 patients).

Results: Approximately 2.06% (138 patients) of patients with diabetes reported symptoms consistent with gastroparesis. Gastroparesis was most common in women. Neuropathic diarrhea prevalence was 1.1% (80 patients). 4.9% of patients with diabetes reported symptoms of constipation or increased use of laxatives. Prevalence of hepatitis C in patients hospitalized with diabetes was 2.9% (195 patients). 1.5% of patients had hepatitis B (101 patients). Cirrhosis was present in 2.65% of patients, the most common causes were chronic hepatitis C, chronic hepatitis B virus, alcoholic liver disease.

Conclusions: Gastrointestinal complications in diabetic patients are undervalued and require active screening measures at each visit.

V-203
HYPOMAGNESEMIA AND PROTOM-PUMP INHIBITORS: PRESENTATION OF THREE PATIENTS AND REVIEW OF THE LITERATURE

E. López Fernández[1], E. Fonseca Aizpuru[2], D. Cuervo Blanco[2], R. Fernández Madera[2], K. Mendez Mejía[1], C. Blanco Cristóbal[3], R. García[1], J. Morís de la Tassa[2]

[1]Department of Gastroenterology, [2]Department of Internal Medicine, [3]Department of Biochemistry. Hospital de Cabueñes. Gijón, Asturias, Spain.

Objectives: Analyze clinical features and evolution of patients diagnosed with hypomagnesemia associated with proton pump inhibitors (PPI) in our hospital and review of the literature.

Material and method: We conduced a descriptive and retrospective study of patients diagnosed of hypomagnesemia associated with PPI, in our hospital (Cabueñes hospital has a population of 300.000 inhabitants), from June 2005 to June 2011. We studied demographics, clinical, biochemical data and clinical course. Patients with parenteral/enteral nutrition, those admitted to intensive care unit and with inflammatory bowel disease and/or intestinal surgery were excluded. Statistical Package for the Social Sciences (SPSS) was used for the analysis.

Results: Three cases were diagnosed with hypomagnesemia and PPI. To date there have been reported 28 cases in the literature –Pubmed. 17 (54.83%) were females and 14 (45.16%) males. The mean age was 68 ± 10.64 (39-83) Omeprazole 26 (83.87%) was the most frequent PPI, for 6.88 ± 3.42 (1-13) years; followed by esomeprazole 3 (9.67%), pantoprazole 1 (3.22%) and lansoprazole 1 (3.22%). The indication of treatment was gastroesophageal reflux 9 (29.03%), non-steroidal antiinflammatory (NSAIDs) 6 (19.35%), ulcer 4 (12.90%), Barretts esophagous 1 (3.22%), duodenitis 2 (6.45%), hiatal hernia 1 (3.22%). Note that, at least, 11 (35.48%) was holding diuretic therapy, no cases of digoxin therapy. The most frequent clinical features are neuromuscular symptoms, and ECG abnormalities. Concerning clinical data is remarkable that: 8 (25.80%) complained paresthesias, 6 (19.35%) cramps, 5 (16.12%) muscle weakness, 4 (12.90%) seizures, 4 (12.90%) tetany, 3 (9.67%) syncope, 3 (9.67%) dizziness, 2 (6.45%) tremor, 4 (12.90%) acute confusional syndrome, 2 (6.45%) spasm carpopedal and 1 (3.22%) hallutinations. Nine (29.03%) patients had ECG changes: 2 (6.45%) had a long QT, 2 (6.45%) ST-segment decrease. And the remainder had: atrial fibrillation, flutter, extrasystoles and ventricular tachycardia. Treatment carried out in most cases was discontinuation of PPI and replaced by ranitidine, and supplementation of magnesium orally or intravenously.

Discussion: PPI are high efficiency well tolerated drugs, widely available and used, but with occasionally serious side effects. The Food&Drug Administration (FDA) has published a warning -February, 2011- that alerts for patients in long term treatments of the risk of severe hypomagnesemia associated with potentially fatal arrhytmias. The first description in literature was in 2006. The mechanism and frequency of PPI-induced hypomagnesemia still remains unclear. It has been hypothesized that PPI impairs the intestinal active transcellular magnesium transport, due to malfunctioning of channel membrane proteins (TRPM6 & 7). Hypomagnesemia is a drug class characteristic and has been reported with all available PPIs. The clinical and demographic features are similar to those previously published. Neuromuscular and cardiac complaints, weakness, tetany, seizures and rhythm disorders are adverse effects frequently reported. The severity is related with the emergence of serious arrhythmias (atrial fibrillation, ventricular tachycardia) and/or abnormal electrocardiographic findings (QT elongation). Patients treated with diuretics and digoxin are prone to increased risks of hypomagnesemia. Magnesium supplement is the treatment of choice, associated with disruption of PPIs.

Conclusions: Monitoring magnesium levels in PPI treated patients is desirable, especially when neuromuscular and cardiac rhythm disorders are present.

V-204
THE PRODUCT OF TRIGLYCERIDES AND GLUCOSE AND METABOLIC SYNDROME

S. Ateia[1], E. Rusu[2], D. Traistariu[3], G. Radulian[2], D. Cheta[4], M. Jinga[2]

[1]Department of Diabetes. Medas Clinic. Bucharest, Romania. [2]Department of General Medicine. University of Medicine "Carol Davila". Bucharest, Romania. [3]Department of Diabetes II. Diabetes, Nutrition and Metabolic Diseases Institute Prof. N. Paulescu. Bucharest, Romania. [4]Department of Diabetes. Healty Nutrition Foundation. Bucharest, Romania

Objectives: The objective of this study was to assess the relationship between fasting proinsulin (PI), the product of triglycerides and glucose (TyG index) and metabolic syndrome in normal, overweight and obese adults.

Material and method: A random population-based sample (n = 656) of Romanians (26–80 years) was studied; persons with diabetes (n = 407) were excluded from this analysis. All participants underwent anthropometric measurements and blood tests (fasting plasma glucose, HbA1c, lipids, aminotransferases, insulin, proinsulin and C-peptide). Homeostasis model assessment of insulin resistance (HOMA-IR), HOMA-B, and Quicki index were also calculated. The diagnosis for metabolic syndrome (MetS) was made according to International Diabetes Federation. TyG index was calclulated using a previously published formula [Ln(fasting triglycerides) (mg/dl) × fasting glucose (mg/dl)/2].

Results: The study group included 59% women (n = 147), with median age 60 years. 31.7% (n = 79) had obesity (BMI > 30 kg/m^2), 37.8% (n = 94) presented overweight (BMI = 25-29.9 kg/m^2), 28.5% (n = 71) had MetS. Patients with MetS had significantly higher values for TyG index, insulin, C peptide, proinsulin (all $p < 0.0001$). The ratio of the fasting levels of proinsulin to insulin did not differ significantly between the groups ($p = 0.9$). When ROC curve analysis was used to see the suitability of trygliceride*FPG to identify MetS area under curve was found to be significant (AUC 0.7480, $p = 0.0001$) and greater than that for HOMA-IR (AUC = 0.748, $p = 0.001$).In univariate analysis, TyG index correlated significantly with age ($r = 0.35$, $p = 0.001$), C peptide ($r = 0.53$, $p = 0.001$), HOMA-IR ($r = 0.606$, $p = 0.0001$), proinsulin ($r = 0.489$, $p = 0.0001$) and negatively with HOMA-B ($r = -0.606$, $p = 0.0001$).

Conclusions: Plasma TyG index increased in patients with MetS compared to healthy subjects. These results suggest that IR, insulin

secretion, proinsulin are affected early in patients with overweight and obesity and diabetes prevention measures must be applied at this stage. Subsequently, we also found that TyG index above the cut-off point may help the clinician to predict MetS.

V-205
RELATIONSHIP BETWEEN SERUM RESISTIN CONCENTRATIONS AND INSULIN RESISTANCE IN OBESE PATIENTS WITH CHRONIC HEPATITIS C

M. Jinga[1], E. Rusu[2], F. Rusu[3], R. Dragut[2], R. Nan[2], C. Parpala[1], H. Popescu[2], G. Radulian[2]

[1]Department of Diabetes I. National Institute of Diabetes, Nutrition and Metabolic Diseases Prof. N. Paulescu. Bucharest, Romania. [2]Department of General Medicine. University of Medicine Carol Davila. Bucharest, Romania. [3]Department of Urology. Emergency Military Hospital Carol Davila. Bucharest, Romania.

Objectives: The aim of the current study is to determine the circulating resistin levels in patients with chronic hepatitis C (CHC) and to correlate them with insulin resistance and hepatic histological features.

Material and method: We selected 176 patients who were divided in 2 groups: group A - 105 patients with chronic hepatitis C without obesity (CHC-O) and group B - 71 patients with chronic hepatitis C with obesity (CHC+O). IR was determined using Homeostasis model assessment (HOMA-IR).

Results: Serum resistin was higher in women than in men in the whole group but without statistical significance (21.4 ± 14.6 ng/ml versus 19.5 ± 13.9 ng/ml, p = 0.28). Resistin levels were higher in CHC patients with obesity (p = 0.0001). Serum resistin levels increased parallel with increasing body mass index. Resistin correlated positively, but not very strong with BMI (r = 0.338, p = 0.008) and HOMA-IR (r = 0.34, p = 0.007). In patients with CHC, resistin correlated with some components of metabolic syndrome (MetS) (HTA, r = 0.254, p = 0.009; CA, r = 0.234, p = 0.016; BMI, r = 0.288, p = 0.003), also with the presence of MetS (r = 0.314, p = 0.001). In multivariate logistic regression controlled for age, sex and BMI, serum resistin levels were associated with hepatic steatosis and hepatic fibrosis.

Conclusions: This study demonstrated the relationship between resistin and IR. There is an explanation for this, as resistin is related to IR, resistin may contribute to hepatic steatosis by promoting IR and insulin signal changes in hepatocytes.

V-206
LOOKING AT PRESCRIPTIONS ON AN INTERNAL MEDICINE WARD (JANUARY-MARCH 2012), REGARDING THE VERY OLD, USING THE START (SCREENING TOOL TO ALERT DOCTORS TO RIGHT TREATMENT) CRITERIA

E. Ferreira, H. Esperto, E. Meira, F. Santos, M. Teixeira Veríssimo, J. Nascimento Costa

Department of Internal Medicine. Centro Hospitalar e Universitário de Coimbra. Coimbra, Portugal.

Objectives: To show if older patients are indeed inappropriately medicated by default (inpatients).

Material and method: We retrospectively studied prescription data from 18 patients aged > 85 years old on acute Hospital admission, from January to March 2012, using the START Criteria (Gallagher et al. Int J Clin Pharm Ther 2008).

Results: The most frequent main diagnosis on admission was heart failure. The median length of Hospital stay was 9.4 days. The median number of medications on admission was 5.9. Eight of our patients should have started on drug (concerning the cardiovascular system), five of them two drugs (concerning both the cardiovascular and the respiratory system), the remaining five patients three drugs (also concerning the cardiovascular and the respiratory system).On Hospital discharge the median number of medications was 5.3. Eight patients actually did start at least one drug.

Discussion: We studied a small amount of patients for short period of time; this reflects the fact that the very old patients still correspond to a small percentage of our inpatients and that perhaps we could extend the study further in time. Nevertheless, the data presented demonstrates that our elderly patients are not as well prescribed as they should be, because, when we used the START criteria, it became clear that we had to add at least one drug to all of them, which was empirically done at the time in eight patients.

Conclusions: Inadequate prescription should be a major concern these days, especially for the elderly. There are no perfect systems to evaluate this, but the authors think the START Criteria are a very good and easy method to be used.

V-207
MESENTERIC PANNICULITIS: OUR EXPERIENCE ON AN ONGOING PROBLEM

P. Esteve, J. Seguí, J. Peris, S. Bañón, P. Roig, D. Bonet, G. Lloret, J. Merino

Department of Internal Medicine. Hospital Universitari Sant Joan d'Alacant. Alicante, Spain.

Objectives: Our goals were to assess clinical and radiological characteristics in patients with mesenteric panniculitis (MP) and the association with malignant disease.

Material and method: We retrospectively reviewed every MP followed at our Department from January-08 to April-12. Eleven patients were found to have been diagnosed with MP during this period. Baseline characteristics, clinical presentation and management are collected and tabulated.

Results: We report 8 females (72.7%) and 3 males (27.3%) with MP (n = 11). Mean age in our series was 68 years. All patients had clinical manifestations at the time of diagnosis. The most common manifestations were abdominal pain (n = 9), nauseas and/or vomiting (n = 4).None had a background of abdominal trauma, while two had previously undergone abdominal surgery more than ten years earlier. CT scan was the diagnostic imaging tool (n = 11), demonstrating MP. Aditional 8 PET/CT was positive in five cases. A biopsy demonstrated chronic inflammation in two cases and malignant disease in 5 cases (3 follicular lymphoma, 1 intestinal-T-Lymphoma and 1 gastric tumor); interestingly, all patients with malignant condition had a positive PET/CT study. MP was associated with malignant disease in five cases (45.5%) and all received treatments according with oncologic protocols. The patient with intestinal associated T lymphoma died 1 year after diagnostic of type 2 refractory coeliac disease. One symptomatic patient without malignant condition in biopsy received corticosteroids regimen with optimal response and evolution. Five patients received none treatment and additional case is pending to decision according the next results. All data are summarized in a table.

Discussion: Mesenteric panniculitis (MP) is a rare inflammatory condition that is characterized by chronic and non-specific inflammation changes within the mesentery. The disease is more common in men (ratio of 2-3:1) and incidence increases with age. Our series is according with a slight female predominance reported in a single publication. The pathogenic mechanism seems to be a non-specific response to a wide variety of stimuli and although the precise etiology remains unknown, some cases have been associated with a number of malignant diseases. The proportion of cases associated with an underlying malignancy has ranged from 1 to as

high as 70% in many reports. A variety of malignancies have been reported (lymphoma, breast cancer, gastrointestinal adenocarcinomas, gynaecologic carcinomas and many others involving lung, liver, renal, skin, prostate...), these associations have led to speculate that MP represents a nonspecific response to an underlying malignancy. We report malignant disease in 45.5% of cases in our short series. The differentiation between benign and malignant causes could not be made with confidence based on the CT findings. Our results suggest a potential role for integrated PET/CT in the assessment of MP and can be used to correctly exclude malignant disease.

Conclusions: 1. MP is a complex and poorly understood phenomenon and its clinical manifestations can be nonspecific. 2. CT plays an important role and may be the first imaging modality to suggest the diagnosis in patients undergoing abdominal CT. A negative PET has high diagnostic accuracy in excluding malignant disease associated, while increased uptake may suggest the coexisting of malignant deposits, particularly in lymphoma, and require diagnostic biopsy. 3. MP could be a paraneoplastic syndrome and we recommend follow-up for exclude the development of malignant disease. 4. Our study are limited by the relative small number of cases and the lack of a pathological proof for all lesions, not all detected lesions have histological diagnosis and their nature is sometimes based on clinical and imaging follow up. Validation of our findings in larger patient groups is warranted.

V-208
PREDICTORS FOR IN-HOSPITAL MORTALITY AND LENGTH OF STAY IN UPPER GI BLEEDING

D. Balaban[1], B. Florea[2], A. Cazan[2], V. Jinga[2], G. Cherana[1], M. Botescu[1], F. Ionita Radu[1], M. Jinga[1]

[1]Department of Internal Medicine and Gastroenterology. Dr Carol Davila Central University Emergency Military Hospital. Bucharest, Romania. [2]Carol Davila University of Medicine and Pharmacy. Bucharest, Romania.

Objectives: To identify the predictors of in-hospital mortality and length of stay (LOS) in patients with UGIB.

Material and method: We conducted a retrospective study on 151 patients admitted to our unit with upper GI bleed between 1st January 2007 and 31st December 2011. Clinical, biological and endoscopic data were collected from their charts. We calculated the clinical and complete Rockall and Glasgow-Blatchford risk scores and performed an analysis of their predictive value for in-hospital mortality and length of stay.

Results: Of the 151 patients enrolled, 69% were male and 31% female, with a mean age of 59.48 ± 13.41 (23-88). 13.2% were smokers and 21.9% reported chronic alcohol intake. One in three patients had a history of chronic liver disease and one in eight had a previous episode of UGIB. Regarding drug-related GI bleeding risk, 17.9% of patients were on NSAID, 5.3% on antiplatelets, 6% on oral anticoagulant and 1.2% on combinations of these. Clinically, 58.2% of the patients presented with melena, 18.5% with hematemesis and 23.1% with both hematemesis and melena. 22% of cases were variceal hemorrhages and 78% non-variceal. 16 patients died during hospitalization and the mean LOS was 8 days (1-39). The prognostic accuracy of all three scores for in-hospital death was good, the complete Rockall score having the best performance (AUROC 0.849).

Conclusions: The Rockall and Blatchford scores were good predictors of mortality and LOS in our study. The good predictive performance of these scores highlight the need for their use in day-to-day practice to select patients with likelihood of poor clinical outcome.

V-209
MEGALOBLASTIC ANAEMIA IN AN INTERNAL MEDICINE WARD

A. Montez, E. Oliveira, M. Pires, M. Sousa, N. Gata, M. Sousa, E. Rocha, M. Filipe

Department of Internal Medicine. Centro Hospitalar do Baixo Vouga- Hospital Infante D. Pedro. Aveiro, Portugal.

Objectives: To find out the contribution of folate and cobalamin deficiencies in causing megaloblastic anaemia in our patient population and to characterize it considering epidemiologic and clinical features.

Material and method: Retrospective analysis of megaloblastic anaemia cases admitted between 2006 and 2011 in an Internal Medicine Ward.

Results: Fifty three patients, with a mean age of 68.27 ± 16.9, with an equal distribution for both genders. The results showed cobalamin deficiency in 24 patients (45.83%) and folate deficiency in 26 patients (54.17%). In the majority of the cases the diagnosis of cobalamin deficiency was made during the admission but only in 12 of them (50%) the etiologic investigation was performed. Five patients were diagnosed with pernicious anemia, three with chronic gastritis and three had been previously gastrectomized. Forty four percent of the patients with cobalamin deficiency had severe anemia (Hb < 8 g/dl); and the mean value of hemoglobin was 8.91 mg/dl. The prevalence of folic acid deficiency was equal in both genders. In these patients the diagnoses was already known and mean cause was alcohol consumption.

Discussion: Folate and vitamin B12 deficiencies have been known to cause megaloblastic anaemia and have a high prevalence in elderly. They are associated not only with macrocytosis but also with neurologic deficits, requiring its diagnosis and treatment. Based on the western literature the folate deficiency is the main cause of megaloblastic anaemia. In our hospital folate deficiency was also responsible for the majority of cases (54.17%) of megaloblastic anaemia and these cases are mainly associated with alcohol abuse and malnutrition. However, Vitamin B12 deficiency has also a great contribution as a cause of these type of anaemias. Severe megaloblastic anaemia is not uncommon among patients who present with symptomatic anaemia in hospitals, which is confirmed in our patient population.

Conclusions: Vitamin B12 and folic acid deficiency both have a large contribution to megaloblastic anaemia in our study population. Inadequate dietary intake and poor absorption contribute to cobalamin deficiency. However further efforts are needed to achieve a correct etiologic diagnosis in these cases. History of alcohol consumption and inadequate dietary intake are associated with the higher prevalence of folic acid deficiency of this population.

V-210
METABOLIC CONTROL- RELATION TO SOCIO-ECONOMIC CHARACTERISTICS AND QUALITY OF LIFE IN DIABETES MELLITUS

H. Vieira Dias, B. Pedro, Y. Abuowda, C. Teixeira Pinto, C. Vitorino, A. Matos, C. Esteves, F. Roque

Department of Nucleo Diabetes. Hospital de Santarém EPE. Santarém, Portugal.

Objectives: Diabetes Mellitus (DM) is a chronic metabolic disease, a major health problem with wide implications for well-being and social life. The aim of this study was to examine the relationship between, metabolic control and quality of life (QOL) among individuals suffering from type two diabetes accompanied by a Hospital diabetic team.

Material and method: A cross-sectional, observational study was performed, based on data obtained from patients interview and analysis of the clinical files of all patients attending appointment at District Hospital in a 2 week period. All patients underwent a self-administered questionnaire the WHOQOL-bref. The studied variables were: gender, age, comorbidities and the presence of diabetic complications, metabolic control parameters (% of HbA1c), monthly income, educational level, and WHOQOL-bref score. Statistical analysis was performed using SPSS for Windows v17.0. We used T-student test for comparison between groups and simple correlation between numeric variables. A 0.05 level of significance was adopted.

Results: We evaluated 150 patients, 46% male. Mean age was 60.13 years (28-98), being women older (mean = 65.85 years; $p < 0.05$). Patients were diagnosed, in mean, 13.9 years ago; 8% were smokers, 13.3% declared alcoholic consume, 78% had high blood pressure. In general, patients had average hemoglobin A1C levels of 7.78% (40% had a good metabolic control with levels < 7%), with no differences in gender. Women had significantly lower education and income compared with men ($p < 0.05$). Average WHOOL-bref was 16. Patients scored lower in QL were older or after more than 16 years from diabetes diagnosis ($p < 0.05$). There were no differences regarding HbA1c levels. The presence of cerebrovascular disease and retinopathy were associated with lower scores in QL ($p < 0.05$), but no difference was found for other macro or microvascular complications. Women, lower incomes (< 500 euros per month) and low education level (less than primary school) were also associated with lower QL ($p < 0.05$).

Discussion: Patients had in general a bad metabolic control, were obese, old, but had in general a good QOL. Women had lower QOL, which could be explained in our study for being older and having lower education level.

Conclusions: Our findings justify the efforts to assess QOL perception in diabetic patients in order to facilitate achieving better metabolic control.

V-211
HEREDITARY ANGIOEDEMA: AN UNCOMMON DISEASE BUT WE MUST BE AWARE

L. González Vázquez[1], C. Casas Hernández[1], M. Rodríguez Arias[1], L. Valle Feijoo[1], A. Fernández Villaverde[2], S. López Agreda[1], J. Zabaleta Moreno[1], J. de la Fuente Aguado[1]

[1]Department of Internal Medicine, [2]Department of Gastroenterology. Povisa. Vigo. Pontevedra, Spain.

Objectives: Hereditary angioedema (HAE) is a rare disease characterized by recurrent episodes of submucosal or subcutaneous reversible edema at various locations (mainly face, extremities, gastrointestinal tract, genitals, and larynx). It's a genetic autosomal dominant disorder characterized by decreased expression or loss of function of C1 esterase inhibitor (C1-INH). The incidence of this disease is 1 in 10,000 - 50,000 people. Our objective is to analyse the main clinical characteristics and the evolution of the patients diagnosed of HAE in our hospital.

Material and method: Descriptive study designed to describe all the patients diagnosed of HAE in the Hospital POVISA. We analysed all the epidemiological information, consultation motives, family history, clinical manifestations, levels of C4, C1-inhibitor (functional and quantitative), treatment and evolution.

Results: Eleven patients were identified (4 male and 7 female) with HAE belonging to 5 families. All of them began with the symptoms in the youth, and only one of them was diagnosed at 76 years. The consultation motives were: facial edema in 6 cases, familiar study in 3, laryngeal edema with breathing difficulty in 1 and abdominal pain in one. The clinical manifestations were episodes of facial edema in 6, genital edema in 2, extremities edema in 5, crisis of abdominal pain in 6 and one patient with laryngeal edema that needed mechanical ventilation. One patient was completely asympthomatic, but it was diagnosed during a familiar study. Regarding to blood tests findings 10 patients (91%) showed a quantitative deficit of C1 inhibitor and in 7 decrease of the activity of C1. In addition 6 were presenting decreased level of the C4. In one patient, the determination of the C1 INH was normal (quantitative and functionally), as well as the C4 and the crises improved with withdrawal of the oral contraceptives. This patient was diagnosed of HAE without C1-NH deficiency (previously called type III). We did not identify an specific trigger although a patient had crisis in relation to minor traumatism. Two received prophylaxis with anchafibrin, 2 with danazol and 1 with estanozol, resulting in the decrease of the number of the episodes a year.

Conclusions: We must suspect HAE in patients with edema of upper airways or in other locations, on recurrent episodes of abdominal pain. Because this disease is very rare, it is not uncommon for patients to remain undiagnosed for many years It is important to ask about family history and for the detailed characteristics of the episodes since in some cases they consult when the episode has been already solved.

V-212
INCIDENCE AND SYMPTOMS OF COMMON ALLERGIC REACTIONS IN INPATIENT AND OUTPATIENT CLINIC OF DEPARTMENT OF INTERNAL MEDICINE IN SECONDARY HOSPITAL

A. Rachioti, G. Chosnis, K. Theodoropoulos, A. Loidoris, P. Roumelis, E. Kalavri, E. Zaronakis, M. Rapti

Department of Internal Medicine. General Hospital of Livadeia. Livadeia, Greece.

Objectives: Skin Drug Reactions are the most common clinical presentations of drugs' side effects Detection of allergic reactions and the study of clinical and laboratory results.

Material and method: Retrospective study of 275 patients with allergies, hospitalized or admitted at the ER in the period 2009-2011.

Results: 20% hospitalized patients in Department of Internal Medicine. 5% admitted at the ER. 0.1% life threatening situations. Males 60%. Females 40%. See Table.

Conclusions: 1. Allergic skin reactions tests (patch/pricks) are reliable and may detect and justify the causes of skin drug reactions. 2. Allergic reaction high suspiciousness when: a) recent opening of a new drug substance, b) accompanying symptoms (fever-lymphadenopathy-eosinophilia), c) prior infection (2-3 weeks earlier). 3. Allergic reactions are common in respiratory infections probably due to atopy. 4. Skin Drug Reactions are not always identified in the early stage and might have systemic complications.

V-214
POSTGRADUATE EDUCATION IN INTERNAL MEDICINE IN EUROPE

M. Cranston[1], M. Slee-Valentijn[2], C. Davidson[3], S. Lindgren[4], C. Semple[5], R. Palsson[6]

[1]Acute Medicine. West Suffolk Hospital. Bury St Edmunds, United Kingdom. [2]Department of Medicine. Leiden University Medical Centre. Leiden, Netherlands. [3]Department of Medicine. Brighton. Brighton, United Kingdom. [4]Department of Medicine. University Hospital, Malmö, and Lund University, Lund. Malmo, Sweden. [5]Department of Medicine. Southern General Hospital, Glasgow. Glasgow, United Kingdom. [6]Department of Medicine. Landspitali-The National University Hospital of Iceland. Rejykavik, Iceland.

Objectives: The requirements for qualification and certification in Internal Medicine are known to vary between countries but

Table 1 (V-212)

1. Most common allergic reactions	- Urticaria and angioedema 150 (54%) - Maculopapular rush 93 (33%) - Fixed drug eruption 27 (9%) - AGEP 3 (1%) - Stevens - Johnson syndrome 2 (0.7%)
2. Most common clinical and laboratory findings	- Syncope 7% - Diziness/nausea 5% - Fever 30% - Lymphadenopathy 25% - Eosinophilia > 1500/?L, 45% - Atypical Lymphocytes 15% - High E.S.R. 25% - High AST, ALT, GGT 8% (amiodarone, sulfonamides, phenitoine) - Asthma-dry cough-bronchospasm 37%
3. Comorbidity	- Respiratory infections: acute bronchitis 75 (27%), pneumonia 15 (5%), flu syndrome 35 (12%) - Urinary tract Infections 48 (17%) - Herpes 2 (0.7%) - Neurological diseases (brain insults-epilepsy) 40 (14%) - Other (anaemia, high tumour markers, etc.) 60 (21%)

information on the differences is not readily available. This could potentially pose problems when certified internists move to a new country within the European Union and are expected to be competent in a number of tasks for which they have not received proper training. Thus, the harmonization of postgraduate medical education and qualification in Europe has become more important than ever before. We describe the results of a survey of postgraduate education in Internal Medicine in Europe.

Material and method: In 2008 and 2009, the European Board of Internal Medicine launched two online surveys of Internal Medicine in Europe, one on the practice of internists and the other on postgraduate training in Internal Medicine. An invitation to participate was sent by e-mail to the presidents and secretaries of national Internal Medicine societies of all 30 member states of the European Federation of Internal Medicine. The responses were reviewed by Internal Medicine residents from the respective countries. Descriptive analysis of the data on postgraduate training in Internal Medicine services was carried out.

Results: Twenty-seven countries (90%) responded and approved their datasets. The length of training ranged from four to six years and was frequently five years. The majority of countries offered training in Internal Medicine followed by a sub-specialty. A 2- or 3-year common trunk of Internal Medicine was commonly a component of sub-specialty training programmes. Hospital inpatient service was the predominant setting used for training. Qualification was frequently determined by the duration of training. A final certifying examination was in place in nearly half of the countries.

Discussion: This survey is the first attempt to generate information on postgraduate education in Internal Medicine in Europe. The results demonstrate some similarities and significant differences in Internal Medicine training between individual countries. The length of Internal Medicine training is broadly similar, averaging 5 years, and remains the main component required for qualification. Training in both Internal Medicine and a sub-specialty appears to be common. A common trunk of Internal Medicine is required in sub-specialty training programmes in the majority of countries.

Conclusions: There appear to significant differences in the structural framework, content and governance of postgraduate training in Internal Medicine between countries in Europe. Harmonisation of the curriculum of training programmes and the requirements for specialty qualification in Internal Medicine in Europe would be highly desirable.

V-215
FABRY DISEASE: A PURPOSE OF AFFECTED MEMBERS IN TWO NAVARRESE FAMILIES

I. Villar García[1], J. Manrique Escola[2], E. Martínez Litago[1], S. Pérez Ricarte[1], M. León Rosique[1], J. Arteaga Coloma[2], C. Purroy Irúrzun[2]

[1]Department of Internal Medicine, [2]Department of Nephrology. Hospital de Navarra. Pamplona-Iruña. Navarra, Spain.

Objectives: Review of the clinical presentation of Fabry disease in two Navarrese families.

Material and method: Retrospective study by reviewing the medical records of 9 cases of Fabry disease. Parameters taken: demographic variables, clinical presentation at diagnosis, diagnostic methodology, multiorgan involvement, clinical course and treatment. The genetic diagnosis was based on the detection of alpha-galactosidase gene mutation (GLA) in patients with high clinical suspicion or compatible explorations (glomerular deposition in renal biopsy or myocardial involvement in RM) (index cases, n = 3). Subsequently other 6 cases were diagnosed by a family genetic study from the index cases.

Results: In our series 9 patients presented the mutation, 7 of them with clinical involvement (4 females, 3 males) and 2 asymptomatic (1 male, 1 female). The mean age at diagnosis was 54 years (range 34-83). The presentation of the index cases was in the form of acute renal failure in 2 cases, and as retrieved sudden cardiac death in another case. The mean age at diagnosis of index cases was 39 years (range 34-48). Of all of the studied subjects 7 (77.8%) had cardiac involvement between the third and fifth decades (6 cardiomyopathy, 4 deposit RM, 4 valvulopathy, 7 arrhythmia).Renal involvement was observed in 2 patients (22.2%) between the second and fourth decade: 1 with hypertension and acute renal failure requiring renal replacement therapy, and another with renal failure and not nephrotic range proteinuria. 4 patients (44.4%) had neurological symptoms, stroke remains the dominant problem (3 patients). Of the other symptoms associated with the disease, 2 patients had corneal verticilata, 2 bilateral neurosensorial hearing loss, 2 with changes in bowel habits, 1 angiokeratomas, 2 psychiatric disorders (depression) and 1 musculoskeletal involvement. The 3 index cases and 1 patient with heart disease progression, received from the diagnosis the enzyme replacement therapy. In the subsequent evolution

(average rating 54 months) no data of progression of the disease was found.

Discussion: Fabry disease is a disorder of glycosphingolipid metabolism, deficiency of the lysosomal enzyme alpha-galactosidase (GLA), which causes the accumulation of ganglioside Gb3 within the lysosomes. It is an inherited X-linked disorder predominantly in men, although in our series there is similar gender distribution (male vs female 55.5% 45.5%). Although the estimated prevalence of the disease in the general population is low, the presence of 2 families carrying the mutation in our community makes the prevalence higher than the expected. The clinical expression is variable, predominantly in Navarre late-onset forms from the 3rd decade and usually incomplete. It is noteworthy that cardiac involvement is widespread, with great clinical heterogeneity. Although nephropathy is described in the literature often associated with Fabry disease, only 2 patients had renal involvement. Neurological involvement is also seen significantly. Other typical symptoms (angiokeratomas, acroparesthesias, anhidrosis, etc.) have not been seen so often in this study.

Conclusions: According to the number of cases studied, the prevalence of this disease could be underestimated. Some nonspecific symptoms in young adults, including heart disease, stroke or chronic kidney disease, not justified by other causes, may lead to the diagnosis. Early diagnosis allows access to a specific treatment that can slow the progression of the disease. The main limitation is its high cost. Consequently it could help more targeted determinations of enzyme activity to select candidates for the treatment. The multisystem involvement in Fabry disease requires a multidisciplinary approach for diagnosis, treatment and monitoring of this complex pathology.

V-216
GOALS AND PITFALLS IN OXYGEN THERAPY IN AN INTERNAL MEDICINE WARD

P. Beirão, F. Gonzalez, M. Coelho

Department of Internal Medicine. Hospital Garcia de Orta. Almada, Portugal.

Objectives: The objective of this study was to evaluate the procedures for oxygen therapy in an Internal Medicine ward, comparing it with the criteria established by the British Thoracic Society (BTS) in the consensus document "BTS guideline for emergency oxygen use in adult Patients".

Material and method: On 23rd September of 2011 were audited procedures for oxygen of all patients admitted to the Medicine Department of our Hospital on oxygen therapy or with oxygen therapy prescribed. Data was collected on prescribing, administering and monitoring oxygen therapy.

Results: Of 76 inpatients, 33 met the inclusion criteria. There was a prescription for oxygen therapy in 91% of cases. All prescriptions were for a fixed dose, but none of them defined all the necessary parameters. The absence of the duration of oxygen therapy and monitoring were the most frequent errors. Oxygen was administered to all patients for whom it was prescribed. Although only 31% of prescriptions were set FiO_2 or debit card, the system of administration corresponded to that prescribed in all patients. No patient had a prescription for SpO_2 goal.

Discussion: The oxygen treatment is common and important in the wards of Internal Medicine. However, several studies show that it is not practiced according to the best care. There were several errors in the procedures of oxygen, particularly in the requirements for a fixed dose, putting patients at risk.

Conclusions: Although recommended by the BTS, the specifications of the objective of oxygen by SpO_2 range are still a minority.

V-217
ELECTRONIC CLINICAL RECORDS, COMPLEMENTARY EXAMS AND PRESCRIPTION SOFTWARE: CAN WE HAVE THE PERFECT SYSTEM?

R. Gomes, J. Lino, V. Goric, Z. Soares, A. Silva, T. Camacho, M. Alves

Department of Internal Medicine. Hospital de Vila Franca de Xira. Vila Franca de Xira, Portugal.

Objectives: The objectives in this survey are to determine adequacy and the possible causes of failure in computerized hospital information systems (CHIS) of a Distrital Hospital, and therefore to conclude how can we improve the future applications and adapt them to our necessities as healthcare workers.

Material and method: We conducted an anonymous online Survey, data was collected about: sex, age, healthcare professional group, rate of satisfaction about design, interface, overall performance, adequacy to clinical practice, ease of use, response, interaction with other applications and Technical Support response time. The data was analyzed using the open-source software Statistics Open For All (SOFA) and Microsoft Excel (R).

Results: In total 70 persons completed the survey: most were females (76%), 40% with ages between 20 and 30; 27% doctors and 50% nurses; the majority were not so happy about the interface and adequacy to clinical practice, although 50% claim that the technical support is fast, most are unhappy with the number of computers available and their performance. The majority of workers are not against computerized hospital information systems (CHIS) but want better, more intuitive and less time consuming applications.

Discussion: Most of studies in this field reveal that great investment has gone into computerized hospital information systems (CHIS) worldwide, but more than 3/4 is considered to have failed improving the productivity of health professionals. And it is a well known fact that CHIS are bringing dissatisfaction on those cases by underestimate their necessities. In our survey, the overall healthcare workers are unhappy with their CHIS, most say that the applications are too complex and not adequate for clinical practice, consuming a great amount of time for data input. There seems to be a reduced number of computers available for the demands and their performance is lower than expected. Computer virus/malware is appointed as the main reason for reduced performance on our windows OS based computers.

Conclusions: We believe that healthcare companies could provide more versatile and simple applications, relying on field testing and providing free updates more frequently to accurately meet the high requirements of healthcare professionals. When introducing a new system, there must be a field based implementation phase with the involvement of healthcare workers of different departments. These Key-Players should work together with the Information Technology Department, providing constant feedback on the applications, so they can be more easily adapted to the reality and chaos of the Hospital work.

V-218
UTILITY OF THE QUANTIFICATION OF HIGH FLUORESCENCE CELLS IN PLEURAL AND PERITONEAL FLUID FOR NEOPLASM DIAGNOSIS

S. Herrera[1], A. Supervía[1], F. del Baño[1], C. Vilaplana[1], T. Torrella[1], O. Pallás[1], R. Ribeiro[2]

[1]Department of Internal Medicine. Hospital del Mar. Barcelona, Spain. [2]Department of Internal Medicine. Hospital de Viladecans. Viladecans (Barcelona), Spain.

Objectives: To evaluate whether the detection and quantification of cells with high fluorescence in an automatic counter Sysmex XT

4000® in pleural and peritoneal fluid is associated with a diagnosis of malignancy.

Material and method: We evaluated retrospectively the pleural and peritoneal fluid that had been analyzed by Reference Laboratory of Catalunya at the Hospital del Mar de Barcelona. The Reference Laboratory had a definitive diagnosis. Samples had had to be collected into tubes containing EDTA 3K. High fluorescence cells were quantified. Fluids were divided into two groups: neoplastic and non neoplastic origin. Fluids with incomplete data were excluded. Breakpoints were searched for discriminating malignancy. Chi-square test with Fisher's correction was applied when necessary for proportions comparison.

Results: During the period 2009-10 168 fluids were analyzed (62 pleural and 106 peritoneal). Of these, 18 pleural and 8 peritoneal fluids had a neoplastic cause. In the case of the pleural fluids, a percentage of fluorescence cells greater than or equal to 4% was associated with the diagnosis of neoplasia (16 of 18 neoplasic liquid (88.9%) versus 20 of 44 non-neoplastic (45, 5%), p = 0.0016). When the cutoff was at 5%, it remained statistically significant (14 of 18 vs 77.8% neoplastic liquids 19 of 44 non-neoplastic (43.2%), p = 0.013). In contrast, no association was found between a high percentage of fluorescent cells as above 4% and malignancy in the peritoneal fluid (4 of 8 liquids neoplasic (50%) vs 57 of 98 non-neoplastic (58.2%).

Discussion: We define high fluorescence cells as those cells that are not classified by the automatic cell counter Sysmex XT 4000® from pleural and peritoneal fluids. This subset of cells are not leukocyte lineage and interpretative value is unknown. We wanted to evaluate whether the detection and quantification of cells with high fluorescence in an automatic counter Sysmex XT 4000® in pleural and peritoneal fluid is associated with a diagnosis of malignancy. In pleural fluid, automatic identification of a percentage of 4% or greater of cells with high fluorescence is associated with the diagnosis of neoplasia. In the other hand, this association has not been found in peritoneal fluid.

Conclusions: The 4000® autoanalyser Sysmex XT identifies a cell type which is non-leukocyte lineage and designated as high fluorescence. In pleural fluid, automatic identification of a percentage of 4% or greater of cells with high fluorescence is associated with the diagnosis of neoplasia.

V-219
HOME HOSPITALIZATION IN CANCER PATIENTS

J. Aibar[1], J. Pericás[2], C. Fehér[2], N. Seijas[1], B. Ibáñez[1], C. Font[3], S. Valls[1], C. Hernández[1]

[1]Department of Integrated Care. Medical and Nursing Direction, [2]Department of Internal Medicine, [3]Department of Oncology. Hospital Clínic. Barcelona, Spain.

Objectives: Hospital at home (HaH) is a program of integrated care unit, depends on Medical and Nursing Direction. The aim of this study is to compare the characteristics and outcome of cancer patients with acute medical complications admitted to a HaH program with a hospitalized control group.

Material and method: Prospective cohort study. The study period was January 2008 to September 2011. 366 cancer patients with acute complications requiring complex medical care were included, 247 of whom were attended in HaH program and 119 received in-hospital care. The statistical analysis was performed by means of Fisher's exact test, Student's t test and logistic regression analysis using the software IBM SPSS Statistics version 20.

Results: There were no significant differences in sex and age between the study groups. No statistically significant differences were found in the proportion of tumor types, being lung cancer the most common malignancy in both groups, followed by gastrointestinal tract tumors, breast cancer and genitourinary malignancies. 64.4% and 77.1% of patients received chemotherapy respectively (palliative or curative), but this difference was not significant. The most common reasons for admission were respiratory infection/pneumonia, febrile neutropenia, fever without a clear clinical focus, urinary tract infection, cellulitis and venous thromboembolism. The diagnosis of cellulitis was more frequent in patients admitted to HaH than in those admitted to the hospital (p < 0.05). Patients in the conventional hospitalization (CH) group had higher Charlson index (5.3 [SD 1.9] vs 6.4 [SD 1.4] respectively, p < 0.001). Patients admitted to HaH had a lower total stay than those admitted to thehospital (7.6 days [SD 4.8] vs 9.2 days [SD 7.6], p = 0.04). During HaH admission 5 patients (2%) consulted the emergency room for medical complications, 11 patients (4.4%) required hospitalization for clinical worsening, and 3 patients died (1.2%). CH patients had a significantly higher in-hospital mortality (12.6%, p < 0.05). There was no statistically significant difference between the 30-day readmission rate (18% in the HaH group and 21% in the CH group) nor in the 30-day mortality (5.3% in the HaH group vs 2.5% in the CH group). Logistic regression showed that hospital admission was an independent risk factor of mortality during admission (OR 12.8 (95%CI: 3.6-45.2). A survey we carried out among our patients and their carers reflect a high degree of satisfaction with our program: 94% of the former and 95% of the latter stated they would repeat HaH admission.

Discussion: Patients in both groups were similar in age, sex, type of neoplasm and reason for admission. Although CH patients had a higher Charlson index, the adjusted mortality during admission was still higher in this group. Furthermore, HaH patients had a lower total stay compared with CH patients with no difference in the rate of hospital readmissions or emergency room visits within 30 days after discharge. An important limitation of the study is the lack of randomization. For this reason it cannot be completely excluded that the increased mortality of CH patients be due to a selection bias, having been these patients rejected by the HaH team because of an increased complexity of care (requirement of a central venous catheter, need of more than one daily visit by the HaH team). Similarly, the shorter overall stay in HaH may be a consequence of this phenomenon.

Conclusions: Cancer patients often have acute complications associated or not with malignancy requiring hospitalization. The HaH model has proven to be a valid alternative to conventional hospitalization in selected patients with data on mortality, length of total stay and need of hospital readmissions comparable to those of the hospitalized population. Moreover, we observed a high degree of satisfaction of both patients and caregivers with the program.

V-220
DIAGNOSIS, PREVENTION AND MANAGEMENT OF CORTICOSTEROID-INDUCED HYPERGLYCEMIA

M. Mafé, J. Marco, B. Boscá, E. Goñi, R. García, R. Fuster, A. Castelló, C. Tornero

Department of Internal Medicine. Hospital Francesc de Borja. Gandía (Valencia), Spain.

Objectives: Hyperglycemia induced by glucocorticoids (GC) is a common clinical problem. The use of GC is common in patients with chronic obstructive pulmonary disease (COPD) requiring hospitalization. GC-induced hyperglycemia is manifested either worsening a known diabetes or precipitating undiagnosed diabetes. Risk factors for its development are patient-dependent (elderly patients and family history of diabetes) and drug-dependent (dose and type of GC).Control of hyperglycemia during hospitalization is associated with decreased mortality and decreased complication rate, which implies a better prognosis and survival. However, GC-induced hyperglycemia is still an underdiagnosed and undertreated

problem, especially in the absence of specific recommendations and consensus documents. We propose both identifying risk factors for exacerbated COPD patients being treated with corticoids who develop GC-induced hyperglycemia during hospitalization and a diagnosis and treatment for this clinical situation by the professionals in our department.

Material and method: Study design: an observational, descriptive, longitudinal and prospective study. Subject selection criteria: 50 patients admitted to the Pneumology Unit or Internal Medicine with admission diagnosis of COPD exacerbation with maintained steroid treatment at the time of registration were randomly selected. Primary endpoint: Alteration of the first baseline fasting serum glucose defined as glucose greater than 110 mg/dl as the reference values of our laboratory. Ethical: the project was awarded by the AISSA (non-profit-making Association for Health Research in the region of La Safor made up by health professionals).

Results: We analyzed a total of 50 cases, 15 were excluded for not having a definitive diagnosis of COPD or for having other concomitant causes of stress. As for the results of prevalence of sex, 97.1% of the subjects analyzed were male. The average age of patients was 75.5 years. 51.4% of patients were overweight. In terms of personal or family history of diabetes, 25.7% of cases were known diabetic, 36% had previous hyperglycemia by GC, whereas 35.7% of cases had a family history of diabetes. During hospitalization, 77.1% of patients developed impaired fasting glucose. 60.9% of non-diabetic patients developed GC-induced hyperglycemia defined as fasting serum glucose greater than 125 mg/dl. Although 77.1% of cases developed alterations in blood glucose, digital blood glucose measurements were only performed in 42.9% of patients. As for treatment, nutritional intervention strategies diabetic diet was only administered in 31.4% of cases. As for the hypoglycemic drug therapy, it was administered in 54.3% of cases. For those who received treatment: the most common prescribed regimen was the rapid insulin analogues followed by basal-bolus regimen.

Discussion: About three quarters of patients hospitalized with COPD exacerbation and steroid therapy developed alterations in carbohydrate metabolism. Most patients were elderly overweight men and about one third of cases had a family history of diabetes and/or had developed glucose abnormalities prior to GC use. However, despite the high prevalence of risk factors already described and the objectified changes in fasting glucose, there were neither controls for digital blood glucose nor appropriate glucose-lowering treatment was given.

Conclusions: Corticosteroid-induced hyperglycemia in patients with COPD is an underdiagnosed and undertreated problem. More studies are needed to establish the risk factors for development of hyperglycemia induced by CG in order to prevent and diagnose it early. Consensus documents are also needed to tackle the clinical problem to avoid underdiagnosis and undertreatment and to get a greater involvement by professionals.

V-221
PLANE LACTATE CURVE IN FOREARM ISCHEMIC EXERCISE TEST (FIET) IN GLUCOGENOSIS OTHER THAN MC ARDLE´S DISEASE

C. Cardozo Espínola, J. Milisenda, P. Moreno-Lozano, V. Lazo, V. Vilela, J. Grau

Department of Muscle Research. CIBERER. Centre Sociosanitari Hospital Clínic i Provincial de Barcelona. Barcelona, Spain.

Objectives: The aim of this study is to describe the functional and clinical findings in patients with plane lactate curve in the FIET, in which Mc Ardle's disease was definitely ruled out.

Material and method: We selected the patients who showed a plane lactate curve in the FIET, in which the muscle biopsy and histochemical exam ruled out Mc Ardle's disease. All these tests were performed by the Muscle Research Unit of the Hospital Clínic of Barcelona.

Results: From all the FIET performed in our Hospital in the past 8 years (n = 180), three patients with plane lactate curve (graphic 1) and non Mc Ardle's disease were identified. One was a female. In all cases, the symptoms started at 20-25 years-old. Two presented with repetitive rhabdomyolysis and cramps, as well as exercise intolerance. The third case as an exercise intolerance and a chronic non-autoimmune hemolytic anemia. None of them referred second wind phenomenon. Two patients had elevated CK levels in serum. The muscle biopsies and histochemical tests (myophosphorilase) were normal in the three cases. In one case, low levels of phosphofructokinase (PFK) in red boold cells could be demons-trated.

Discussion: There are many clinical similarities between Mc Ardle's disease and the other glucogenosis with plane lactate curve at FIET, except perhaps for the characteristic second wind phenomenon present in Mc Ardle's disease. The FIET allows us to establish groups of patients considering the findings in the test results. In the plane lactate curve group, Mc Ardle's disease is the most prevalent diagnostic, but there are others glucogenosis to be considered. By careful muscle biopsy and the histochemical analysis we could ruled out Mc Ardle's disease in these three patients, and in one of them PFK deficiency was diagnosed. In the other two cases, the levels of phosphofructokinase, phosphoglycerate mutase, phosphoglycerate kinase, and lactate dehydrogenase were normal in red blood cells, but the respective muscle levels remains to be determined yet. One important point to be considered is that any of these diseases have a specific treatment so far.

Conclusions: FIET is considered as a very important screening test in metabolic myopathies, since it represents a cheap, safe, fast and easy test that provides crucial information in the evaluation of these diseases. The plane lactate curve group includes an important group of diseases besides Mc Ardle's that should be evaluated.

V-222
INTERNAL MEDICINE AND MINORITY DISEASES: A 25-YEARS EXPERIENCE IN INBORN ERRORS OF PURINE METABOLISM

R. Torres[1], J. Puig[2]

[1]Department of Clinical Biochemistry; [2]Department of Internal Medicine. Vascular Metabolic Unit, Hospital Universitario La Paz, IdiPaz. Madrid, Spain.

Objectives: Purine metabolic disorders include a variety of clinical syndromes including hyperuricemia and gout, nephrolithiasis, immunodeficiencies, anaemia, diseases of the peripheral and central nervous system and myopathies, all of which may be expressed by considerable variations in serum urate concentrations and urinary uric acid excretion rates. Since 1985 we have coordinated the study of patients with a myriad of purine metabolic minority diseases and we report herein our experience.

Material and method: We have developed a normogram to assess whether hyperuricemia or hypouricemia could be related to increased/decreased uric acid synthesis or decreased/increased uric acid excretion. The specific diagnosis of a given purine metabolic disorder was performed on the basis of clinical, biochemical, enzymatic and molecular data.

Results: We have diagnosed two patients with phosphoribosyl-pyorphosphate synthetase overactivity, 45 patients with hypoxanthine phosphoribosyltransferase deficiency (HPRT, 30 with Lesch-Nyhan disease and 15 "variants"), two patients with xanthine oxidase deficiency, three with renal hypouricemia and 5 families with uromodulin disease. This is most extensive series of HPRT deficient patients followed by a single medical team which enabled,

in addition to carrier detection and prenatal diagnosis, a novel phenotypic classification (type 1, absent or minor neurological manifestations; type 2, evident neurological manifestations that do not preclude an independent life; type 3, dependent life with no self-injury behaviour; and type 4, markedly dependent life with self-injury behaviour).

Conclusions: An internal medical team, provided with clinical genetists, may diagnose and coordinate the medical needs of patients with minority diseases related to inborn errors of purine metabolism.

V-223
PROFILE PATIENTS DIFFERENCES REFERRAL FOR PAIN TO INTERNAL MEDINE CONSULTATION OFFICE (IMCO) OR TRAUMATHOLOGY CONSULTATION OFFICE (TCO)

S. Romero Salado, M. Escobar Llompart, A. García Egido, O. Mera Gallardo, G. García Dominguez, V. Lechuga Flores, V. Manzano Román, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario d e Puerto Real. Cádiz, Spain.

Objectives: The global management carried by internal medicine professional makes him able to deal musculoskeletal pathology, musculosketal pain is the main reason for consultation. The aim is to recognize different patient profile referral to TCO and differences with referral to IMCO.

Material and method: From every patient assisted on our IMCO specialized on musculoskeletal pathology. During two months they were selected those patients referral for musculoskeletal pain. Same thing was done with patients referral for same reason to TCO. We made up a descriptive chart analysis from pain location, reason for consultation.

Results: Finally 1408 patients assisted on both CO (725 IMCO/683 TCO), they were selected every patient with musculoskeletal pain obtaining: 213 IMCO/115 TCO. Per pain location area we found: cervical spine 25/33, cervical spine and thoracic spine 0/3, cervical spine and low back pain 2/6, low back pain 3/21, thoracic and low back pain 2/3, low back pain 80/9, knee pain 10/8, metatarsus pain 33/20 and shoulder pain 7/2.

Discussion: On our centre, most patients referral for musculoskeletal pain to IMCO location was column, most low back pain opposite TCO where was more frequent cervical and thoracic spine pain. Also was more frequent metatarsus and shoulder pain management on IMCO and nearly equal for knee pain. Most cases were related to arthrosis on both consultation office.

Conclusions: Global assistance carried by internal medicine professional makes him able to make a correct screening and efficient assistance for these patients, making musculoskeletal pain differential diagnosis. Even degenerative pathology is the main ethiology, we mustn't forget other diagnosis possibilities, included systemic pathologies, and comorbidity.

V-224
CLINIC PROFILE DURING HIGH ASSISTANCE PERIOD ON A HOSPITALARIAN URGENCY OFFICE ON A SPECIALIZED HOSPITAL

R. Aranda Blázquez, M. Escobar Llompart, G. Ruiz Villena, M. Guzmán García, E. Sánchez Relinque, L. Fernández Ávila, R. Tinoco Gardón, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: Describe clinic and assistance patient profile, assisted on an urgency office during high assistance period.

Material and method: They were included patients assisted on an urgency office by two internal medicine residents, two days, during high assistance period (first of February) 2012. Variables studied: age, sex, time spent on assistance, complementary tests, and development. We create and analyzed a database, making up a descriptive-chart study.

Results: 50 patients. Age between 13 months and 96 years old. 62% men, 38% women. Average time spent 3 hours 28 minutes (maximum 8h 49 min/minimum 18 min). Complementary tests: laboratory tests 36, X-rays 23, EKG 15, CT 1, and ecography 1. Develop: 52% referred to primary assistance, 24% to specialized assistance. 6% to observation, 10% were hospitalized and 4% escape. Reaming were discharge without continued assistance.

Discussion: In our centre clinic assistance profile during high assistance period, is defined by patients, most men, wide age range, most of them (95%) were assisted and tested (lab., X- Rays, EKG) without spending more than 5 hours. Most of them were referred to other Services, 10% hospitalized. (See how 4% escapes).

Conclusions: During high assistance period, urgency average time spent becomes higher also; increase pluripathology patients number assisted, being essential internal medicine resident vocation to deal with pluripathology patients and efficient assessment as complementary tests correct indication.

V-225
BED CLINICAL PROFILE TURNOVER ON INTERNAL MEDICINE DEPARTMENT ON A SPECIALIZED HOSPITAL FROM SAS

R. Aranda Blázquez, M. Escobar Llompart, G. Ruiz Villena, G. García Domínguez, M. Guzmán García, O. Mera Gallardo, L. Fernández Ávila, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: Recognize patient clinic profile, hospitalized on a bed at Internal Medicine Department.

Material and method: We choose a bed from IMD in our centre, where patients from other Services can also be hospitalized, during one-year (May 2011- April 2012) and made up with them a descriptive prospective - chart study. Studied variables: patient basic profile, original service, diagnosis and reason for hospitalization, development and time spent on hospital.

Results: Considered bed closure for making improvements on floor or holyday summer period. 31 patients. Age: average 72 (25-90). Sex: 54.84% men/45.16% women. Hospitalization department: 77.42% on IMD, Neumology (9.68%), Cardiology (6.45%), Urology (3.23%) others (3.23%). Original Service: Emergency Services referred 83.87% (Consultation office-64.52%, observation 19.35%). Patient from other Services, Medical Services and ICU 6.45%, Medical Day Hospital 3.23%. Reason for hospitalization: 32.6% dyspnea, 16.13% fever, chest pain and gastrointestinal symptoms 9.68% each, 6.45% fast auricular fibrillation (FAF) and miscellany (highlighting pleural effusion, paresthesias and lower limb edema). Discharge diagnosis: 25.8% sepsis (most of urinary sepsis - 19.35%) 19.35% heart failure (HF), 16.13% respiratory infection, 9.68% neoplasia, 6.45% FAF, 3.23% miscellany (decubitus ulcer infection, chronic renal failure, ischemic heart syndrome, diarrhea, pancreatitis, prostate surgery, pleural effusion for study). Develop: 30 patients discharged, one transferred to private center. Average time hospitalized: 10.26 days.

Discussion: In our study, patient profile: men (over 50%) average age 72, referred from Emergency Department (over 80%), dyspnea on fever context; being diagnosis discharge, after average time

spent hospitalized 10 days, sepsis followed by heart failure. These data analyzed on a single bed during a year in IMD, nearly same patient profile it is found on every bed from IMD.

Conclusions: On patient hospitalized profile usually appears multimorbidity. In this group is frequent reentry for acute fever syndrome which makes unbalance on comorbidity. Global view made by internal medicine professional makes him able for effective management and deal with multimorbidity patients.

V-226
CREATIVITY AND DEPRESSION IN CONTEMPORARY TALENTED ARTISTS WOMEN

J. Montes Santiago[1], Y. Carbajales Ferreiro[2]

[1]Department of Internal Medicine. Complejo Universitario de Vigo. Vig (Pontevedra), Spain. [2]Bellas Artes. Bellas Artes. Vigo (Pontevedra), Spain.

Objectives: Although there have been several studies on psychopathology and creativity in great artists, they have focused almost exclusively on male authors and still very few studies have addressed this issue among women well-known creators. This work explores the prevalence of depressive disorders and suicide among women recognized artists of the XXth century.

Material and method: Because the difficulty of selecting relevant artists with a consensus we have chosen as selection method the consultation of 10 prestigious publications, historic and modern comprehensives, in the field of "Women and Arts". Relevant spanish literature also was included to minimize the bibliographic English bias [Linda Nochlin Essay (1971), Guerrilla Girls Manifesto (1987); W. Chadwick book (1992), ABC Art book (1999); U. Grosenick book (2003), Latest Art Monographic (2006), V. Combalía book (2006), M. Illán book (2007), Wikipedia Women Artists on-line (2010), Modern Women at the MOMA book (2010)]. We also examined the lists of artists of 3 major expositions on the subject in the last 5 years [Kiss Kiss Bang Bang, 45 years of Art and Feminism -Bilbao-2007 (44 artists)-; Amazons of the New Art, Madrid-2008 (40 artists)- and elles@centrepompidou -Paris-2009 (132 artists). Artists who appeared in 2 or more of these publications or expositions were included. We examined the artists who died in the XXth century/first decade of XXIth century. We analyzed their biographic data with special attention to a diagnosis, treatment or income for depression.

Results: From the bibliographic sources were examined the references from 550 women contemporary artists. Of these 156 met the criterion of > 2 mentions in relevant literature. Of these 79 were died in XX/XXIth century and were analyzed. These include such famous personalities as Louise Bourgeois, Leonora Carrington, Frida Kahlo, Louise Nevelson or Georgia O'Keeffe. Of these at least in 38 cases (48%) a prominent depressive episode was recorded in their biographies. In 7 cases (9%) suicide attempts occurred, not accomplished in 3 (C. Calhoun, L. Carrington, A. Neel), possibly accomplished in 2 (F. Kahlo, A. Mendieta) and completed in 2 (D. Arbus, K. Sage). Despite these disorders such artists generally achieved longevity and, of nonsuicidal women, the median of survival was 75.0 years and 68% (51/75) exceeded 70 and 43% (32/75) 80 years, respectively.

Discussion: Due to the traditional "invisibility" of women in art a high prevalence of significant episodes of depression among creative artists has gone unnoticed. A significant percentage ended with suicide attempts.

Conclusions: In 5 out of 10 contemporary recognized artists women there was significant depressives episodes that led to attempts or completed suicides in about one out of 10. However, in general, such disorders permitted a prolonged survival because 7 out of 10 of such women exceeded 70 years.

V-227
OBSERVATIONAL STUDY OF CARDIOVASCULAR RISKS ON HOSPITALIZED PATIENTS WITH CHEST PAIN DURING A PERIOD OF 3 MONTHS IN A HOSPITAL OF SECOND LEVEL

E. Sánchez Relinque, M. Guzmán García, M. Escobar Llompart, G. García Domínguez, O. Mera Gallardo, V. Lechuga Flores, V. Manzano Román, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: Cardiovascular disease is the leading cause of death and disability starting at middle age in developed countries. We propose monitoring the most important cardiovascular risk factors in patients admitted with chest pain.

Material and method: We selected patients for a period of 3 months who were admitted in our cardiology unite with chest pain for a possible ischemic etiology. The study variables were: age, sex, cardiovascular risk factors present, height, weight, waist circumference perimeter. We analyzed the results based on the characteristics of a descriptive study.

Results: There were 68 patients admitted for this cause, 51 (75%) were men. The average age was: 65.45 years (men 66.22, women 63.12) and the BMI was 30.23 (32.07 women, 29.61 men). 60.41% of men exceeded the barrier of 102 cm in abdominal circumference, and 87.50% of women exceeded 88 cm. 72.6% smoked or they did it in the past, the percentage rises at 85.41% if we were referring to men (18.75% active) and 37.5 (25% active) if they were women. The 70.83% of men and 75% of women were dyslipidemic. The 40.62% were diabetic, and there weren't significant differences regarding to gender. About hypertension, there were a 64.58% of men and an 81.25% of women. They admitted having a sedentary life in a 70.31% of the case, without differences between sexes. The CRP was elevated in the 48.43% of the cases which ended in hospital. Women reported not to drink alcohol, although the 41.66% of men admitted doing it indeed.

Discussion: Although public information about cardiovascular risk factors spread by professionals and population, 5 million people enter our hospitals for heart disease in our country. In Spain the 17.65% of the population (SEN) smoke, our patients smoked in the 20.3% of the cases. Women came up to 25%, confirming the tendency to overcome this habit to men. Dyslipidemia was the most prevalent factor of cardiovascular risk, with the 71.9% followed by the HBP with the 68.75%, hypertension is pointed out as the most prevalent in previous studies. In our country it is estimated of having sedentary lifestyle a 55% (WHO) of the population, in our study this figure rose up to 70.31%. In Andalusia there are 12% of diabetics (INE), and it is one of the communities with the highest prevalence, while its patients were diabetics in 40.62% of the cases.

Conclusions: It is well know the relationship between cardiovascular risk factors and coronary heart disease events. However, we can see in our study that every factor was highly prevalent. They are higher than in previous bibliographies, which would indicate the population tends bad heart-healthy habits, probably it is related to social and economic changes of the recent years. In short, we believe it is necessary to reconsider the health educational plans we are offering to our patients.

V-228
CHANGE IN FAMILY DECISION MAKING WHEN IT COMES TO AN ADVANCE HEALTH-CARE DIRECTIVE FORM AFTER A FAMILY MEMBER LIVES AN INTENSIVE CARE UNIT EXPERIENCE (ICU) IN A TERTIARY CARE HOSPITAL THE EXPERIENCE OF A THIRD YEAR INTERNAL MEDICINE RESIDENT

V. Manzano Román, S. Romero Salado, V. Lechuga Flores, O. Mera Gallardo, G. García Domínguez, M. Guzmán García, L. Fernández Ávila, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: We are aware of the possibility of filling in an advance Health-Care directive form but there are few patients that have done so. The object of this study is to discover if there is a change after living through the experience of a having a family member treated in an ICU.

Material and method: Those included were the immediate family members of patients admitted to the ICU for more than 24 hours in a three month period (the duration of a third year Internal Medicine resident rotation). As soon as the patients were discharged their families were given a questionnaire which asked the following question: After going through the experience of having a relative treated in the ICU would you of previously formalized the Advance Health-care directive form? Foreign patients and those that ended in exitus were excluded. Another study variable: discharge diagnosis. Data was analyzed according to the typical features of a descriptive study.

Results: Out of 28 possible respondents, 21 relatives answered the questionnaire. 76.2% of the relatives change their opinion and would have previously formalized an advance health care directive form. The diagnoses of these patents were: 5 non-ST-segment elevation acute coronary syndrome/St-segment elevation acute coronary syndrome (one of them needed CPR), the rest (sepsis with a variety of origins such as respiratory, urinary, abdominal, peritonitis, acute meningoencephalitis and a high risk post operation hip replacement). The diagnoses of those patients whose relatives did not change their opinion were non-ST-elevated acute coronary syndrome/ST-elevated acute coronary syndrome.

Discussion: Most of the respondents agreed that they would of formalized the advance health care directive form due to the experience lived by their relatives in the ICU. In the case of those relatives who did not change their opinion the diagnosis was non-ST-segment elevation acute coronary syndrome/St-segment elevation acute coronary syndrome.

Conclusions: It is important to be aware of whether or not a critical patient has registered an advance health care directive form. Most patients do not which means that the decision making falls onto immediate family. This experience makes the family members rethink their decision to register an advance health care directive form.

V-229
ADAPTING THE INFORMATION IN BETWEEN THE FAMILY AND THE MEDICAL STAFF IN A CRITICAL CLINICAL SITUATION

V. Manzano Román, V. Lechuga Flores, S. Romero Salado, E. Sánchez Relinque, G. Ruiz Villena, M. Guzmán García, R. Aranda Blázquez, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: To know the family's satisfaction as regards to the information given to them concerning their relatives admitted to the intensive care unit (ICU).

Material and method: relatives of adult patients admitted to the ICU for more than 24 hours were included. On patient discharge the following personal survey was carried out among the immediate family: 1st. During admission, were you informed of the clinical status of your relative? 2nd. Would you rather speak to or be informed by the same doctor during your relative's stay in the ICU? 3rd. The daily information you have received as regards to your relative has been: clear, not clear enough, not clear at all. 4th. Do you agree with the time scheduled for the status update? 5th. Relations with the nursing staff were: fluid, not fluid enough, non existent. Results were analyzed according to the features of a prospective descriptive study.

Results: Total surveyed: 28 (21 answer the survey) 1st. Question: yes, 85.71%. 2nd. Question: yes, 77%. 3rd. Question: clear 57.1% 4th question: yes, 76%. 5th question: fluid 62%, not fluid 19%, and non existent the rest.

Discussion: Most family members were satisfied with the treatment/care they and their relatives received in the ICU, although we have detected the need to improve certain aspects of communication between relatives and the medical staff, apart from the fact that people prefer to be informed by the same attending doctor during their relatives' stay ICU.

Conclusions: It is very important to adapt the flow of information between families and medical staff in Internal medicine and critical care situations. The complexity of the situation makes this difficult to achieve and it is really important for medical assistance to be provided by the same doctor.

V-230
FROM HEART ENZYMES SERIALIZATION TO CORONARY CATHETERISM DESCRIPTIVE PATIENT ANALYSIS WITH HEART ENZYMES CHANGES AND CORONARY CATHETERIZATION ON A SPECIALIZED HOSPITAL FROM SSAP

O. Mera Gallardo, M. Escobar Llompart, M. Guzmán García, R. Aranda Blázquez, G. Ruiz Villena, E. Sánchez Relinque, L. Fernández Ávila, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: Recognize percutaneous transluminal coronary angioplasty (PTCA) importance on patients from Emergency Department with chest pain who have, or not, biochemical changes sings for myocardial damage on our center.

Material and method: Patients from Emergency Department assisted for chest pain with biochemical changes sings, or not, for myocardial damage, 12-24 hours before, during 2011, were included. Studied variables: heart enzymes change (sing for myocardial damage), develop on acute ischemic coronary syndrome (AICS) and PTCA done.

Results: 392 patients. Troponin, CPK and CPK-MB, 12-24 hours before with changes on 38.9%. Develop AICS on 57.6%. Done PTCA on 96.46% patients.

Discussion: Our aim is to prove biochemical parameters for myocardial damage do not turn positive early enough on patients who need invasive techniques immediately, being necessary to make a global ischemic evaluation (biochemical data, clinical and electrocardiographic changes).

Conclusions: Ischemic coronary syndrome is increasing on population. Now patients are older and carry more comorbidity, these patients are usually hospitalized on Internal Medicine Department when, no invasive or surgery techniques are not going to be done. Comprehensive assessment for acute ischemic coronary syndrome (biochemical, clinical and ECG changes) is important to make an effective approach on this clinical entity.

V-231
CLINIC MEN PROFILE, HOSPITALIZED ON CRITICAL CARE UNIT FROM A SPECIALIZED HOSPITAL FROM SAS

G. García Domínguez, V. Manzano Román, O. Mera Gallardo, R. Aranda Blázquez, V. Lechuga Flores, G. Ruiz Villena, M. Guzmán García

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: Identify clinical and epidemiological men profile, hospitalized on Critical Care Unit (CCU) on our hospital, during 9 months between 2011-12.

Material and method: Descriptive chart study 240 men included (72.2%) about 330 patients from Emergency Department who were referred to CCU during this period. We analyze variables such as age, sex, reason for hospitalization, time spent on hospital, toxic habits, cardiovascular risk factors, concomitant diseases and diagnosis. Analysis was done by SPSS 15.0 statistic program.

Results: Average age 60 years. 67.1% referred from Emergency Department, 5.8% Surgery, 4.6% Cardiology and 4.5% Critical Care Unit from other hospitals. 17.5% Died. Regarding cardiovascular risk factors (CVRF) we noticed 19.2% were smokers, out-smokers 9.2%, alcohol abuse 21.7% previous alcohol abuse 2.9%. 35% were diabetic, hypertensive 32.9%, 12.5% obese and 26.7% dislipidemic patients. 58.3% precious ischemic coronary syndrome, 40.8% PDCO, heart failure 23.8%, oncologic illness 8.3%, chronic renal failure 7.1% and 3.3% stroke. Most prevalent reason for hospitalization was acute coronary syndrome 43.3%, followed by septic shock 3.3% and stroke 4.6%. Average time spent on CCU was 4.47 days whit diagnosis discharge acute coronary syndrome 42.2% followed by stroke 5%, severe pneumonia 4.6%, shock 4.2% complicated surgery 2.9% and pancreatitis 2.9%. Discharge Services were: Cardiology 56%, Internal Medicine 13.1%, Surgery 5.6%, another CCU 5.5%, Neurology 3.5% and Digestive 3%.

Discussion: Results show patient hospitalized on CCU mainly come from Emergency area, who have a considerable global cardiovascular risk. Main reason for admission is acute coronary syndrome situation beings referral afterwards to Cardiology during next 24h.

Conclusions: Men clinic patient profiles admitted on CCU: 60 years old, CVRF and previous Myocardial Ischemia, more than half sample entered on CCU for new coronary event or stroke. Target main service: Cardiology followed by Internal Medicine (13.1%) probably for making a global approach on these patients.

V-232
EFFECTIVENESS OF A SIMPLE REMINDER INTERVENTION TO REDUCE THE DURATION OF URINARY TRACT CATHETERIZATION AND INTRAVENOUS FLUID THERAPY

F. Gomes Martín, P. Carreño Borrego, S. Isasi de Isasmendi Pérez, P. Pueyo Tejedor, P. Lambán Aranda, S. Alcubierre Iriarte, J. Díez Manglano and the Researchers of Impimi Study

Department of Internal Medicine. Hospital Royo Villanova. Zaragoza, Spain.

Objectives: To determine whether a simple reminder intervention decreases the duration of urinary tract catheterization and intravenous fluid therapy.

Material and method: In October 2010 a ward of the internal medicine department began a daily meeting of clinicians and nurses in which twice a week a recommendation to remove indwelling urinary catheter was reminded. This meeting was not performed in other wards. We retrospectively reviewed the nursing records of the patients admitted to internal medicine in October 2010, January 2011, May 2011 and October 2011. The patients were divided into two groups: group I, patients attended by the team with reminder intervention and group II patients attended by other teams without this intervention. For each patient we collected data for age, gender, living in nursing residence, Barthel index, Norton scale, intravenous fluid therapy, urinary catheter placement, duration of urinary catheterization, delirium during hospitalization, major diagnostic category, and length of hospital stay and weight of the diagnostic related group. Quantitative data are presented as mean (standard deviation) and qualitative data as absolute frequencies (percentage). Comparison between the two groups was performed using Mann-Whitney U-test and Chi^2 test. In all analysis P-values < 0.05 were considered statistically significant.

Results: During the study period there were 768 admissions and we included 747 (97.3%). The mean age was 74.3 (15.1) years and 389 (52%) patients were women. During hospitalization 260 (15%) had an indwelling urinary catheter inserted and 519 (69%) intravenous fluid therapy. The majority of patients (172, 64.9%) were catheterized in the emergency department, 60 (22.6%) in the internal medicine unit and 29 (10.9%) were permanent carriers. The score on Norton scale was worse in Group II patients (14.5 ± 4.6 vs 15.3 ± 4.7; p = 0.02) but there were no differences in Barthel index (64 ± 38 vs 67 ± 39; p = 0.32). Group II patients were most frequently catheterized (39.1% vs 31.7%; p = 0.03), for more days (7.9 ± 7.2 vs 6.0 ± 6.4 days; p = 0.03) and more frequently were catheterized at discharge (15.2% vs 10.1%; p = 0.04). There was no difference in the frequency of use of fluid therapy but duration was longer in group II (5.2 ± 4.6 vs 4.1 ± 4.0 days: p = 0.004). There was no difference in the presence of pressure ulcers nor in the incidence of delirium. The average length of stay trended to be higher in the Group II (9.97 ± 8.19 vs 8.92 ± 6.84 days; p = 0.058).

Discussion: Inappropriate use of indwelling urinary tract catheters is widespread and is associated with urinary tract infections. In our study a simple reminder intervention was associated with less use of urinary catheters and with a decrease in the duration of urinary catheterization and intravenous fluid therapy.

Conclusions: A simple reminder intervention can help to decrease the indwelling urinary catheterization and to short the duration of urinary catheterization and intravenous fluid therapy.

V-233
CLINICAL PROFILE OF PATIENTS WITH DIAGNOSIS OF GESTATIONAL DIABETES (GD) IN A HOSPITAL OF SPECIALTIES OF THE SAS

S. Romero Salado, V. Lechuga Flores, M. Escobar Llompart, V. Manzano Román, G. García Domínguez, O. Mera Gallardo, E. Sánchez Relinque, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Puerto Real (Cádiz), Spain.

Objectives: The GD is an entity that generates increased risk of fetal-neonatal, taking as a feature be symptomatic in the mother. For this reason knowledge of risk factors is important for making the detection and diagnosis of GD and can introduce treatment and multidisciplinary follow-up of pregnant women, in order to reduce maternal and perinatal morbidity and mortality.

Material and method: It is a descriptive study in which during 9 months (June 2011-February 2012) patients with diagnosis of GD were analyzed. Study variables: age, number of previous pregnancies/miscarriages, risk factors for GD, month and method of diagnosis, treatment.

Results: Total of patients: 28. Middle ages: 31 years. Of these patients the 35.7% were first-time mother, had a previous pregnancy the 32.1%, two previous pregnancies the 21.4% and three previous pregnancies 3.6%. A history of miscarriage was present in the 21.4% of patients and two abortions in 3.6% of patients. The most frequent risk factors among these patients were: age 25 (96.42%), family

history of diabetes mellitus (35.7%), Overweight/obesity (32.14%), polycystic ovary syndrome (14.2%), previous GD (10.7%) and glucose intolerance (3.57%). The month of diagnosis of DG was: 3rd month (14.2%), 4th month (17.8%), 5th month (25%), 6th month (21.4%), 7th month (17.8%) and 8th month (3.5%). Patients with more than two risk factors, taking into account the age as one of them, were the 42.8%, which were diagnosed the 17.8% before the 5th month and the 82.2% from the 5th month. With 50 g of glucose screening test was used for the diagnosis of GD to weeks 24-28 and confirmation with 100 g of glucose test (basal, 1st time, 2nd time, 3rd time). Showed alterations in the four values 17.8% of patients, three values the 21.42%, two values the 39.2% and 1 value (repeated on two separate occasions) the 7.14 per cent. Became valuation of treatment, either diet, exercise and/or insulin in order of frequency from the: 5th month (28.57%), 6th month (25%), 7th month (25%), 4 month (17.8%), 3rd month (7.14%) and 8th month (3.5%). They needed insulinotherapy the 32.14% of patients.

Discussion: GD usually begins in the middle of the pregnancy. The fact of knowing the risk factors for gestational diabetes, prenatal screening tests should be made before 24 and 28 weeks, however, our study shows that this only occurs in 30% of cases. Age, family history of diabetes, and overweight/obesity were risk factors that most were related to the development of diabetes. Of the total of patients, they needed insulin around 30% coinciding with the percentage described in the bibliography, the rest was controlled with diet and moderate regular physical exercise.

Conclusions: It is important to make a diagnosis and early treatment of patients with GD for prevention of possible complications both the fetus and the mother.

V-234
COMMUNICATION VARIABILITY IN AN INTENSIVE CARE HEALTH SITUATION PERCEIVED BY THE MEDICAL/ NURSING STAFF ARBITRATE BY AN INTERNAL MEDICINE RESIDENT IN AN ANDALUSIAN HEALTH SERVICE HOSPITAL

V. Manzano Román, V. Lechuga Flores, M. Escobar Llompart, G. García Domínguez, O. Mera Gallardo, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Puerto Real (Cádiz), Spain.

Objectives: To discover the variability of communication in an extremely serious clinical situation as perceived by the medical and nursing staff in the ICU (Intensive Care Unit) analyzed by an Internal medicine resident.

Material and method: An Internal Medicine resident carried out a survey concerning the personal satisfaction of family members.

among ICU medical and nursing staff. The survey includes the following questions: 1st. Is it easy for relatives to find the ICU on the first day? 2nd. Are the family always informed of the clinical situation of their relatives when they are admitted? 3rd. Do you think family members understand the information received during the admission of their relative? 4th. Do you think that the family receives enough information concerning visiting hours, unit rules, etc. from the nursing staff on admission? 5th. Do you think the family should always receive information from the same doctor? 6th. Do you think that family members would rather sit down beside their relatives during visiting hours? 7th What do you think the family-nurse relationship is like? (very fluid, fluid, non existent) 8th. Do you think that the family receives help from the nursing staff to facilitate communication with their relative? A prospective descriptive study design was applied in the ICU over a three month period.

Results: Total surveyed: 33 (15 doctors/18 nurses). 1st question: yes, 33.3% doctors/35% nurses. 2nd. Question: yes, 83.3% doctors/58.8% nurses. 3rd. Yes 67% doctors/23.5% nurses. 4th. Yes: 92% doctors/89% nurses. 5th. Yes: 75% doctors/95% nurses. 6th. Yes, 58.3%doctors/59% nurses (17.63% no answer). 7th. fluid, 75% doctors/58.8% nurses: yes, 83.3% doctors/76.47% nurses.

Discussion: The majority of doctors and nurses agree that it is difficult to find the ICU on the first day. They are also satisfied with the information received by the family concerning the clinical situation of their relatives on admittance and the care provided by nurses. More nurses agree that the family should receive information from the same doctor than do the doctors themselves. However, almost 50% of nurses think that the family is not always informed of the situation of their relative on admittance versus 83.3% of doctors who believe it is. Moreover, the majority of doctors think that relationships between the family and the nursing staff are fluid, while, in the opinion of 42% of nurse it is low or non-existent.

Conclusions: Doctor-patient, doctor-nurse, family-medical staff communication is very important. It is in situations of extreme gravity when it becomes of greater importance to establish good patient-family-medical staff communications and relationships. It is however, more difficult to achieve. However, it is also more difficult for this to be achieved under these circumstances.

V-235
DOES SEASONAL VARIATION AFFECT ON THE AVERAGE STAY OF PATIENTS WITH ACUTE COPD?

C. Josa Laorden, S. Luna García, L. Royo Trallero, M. Aibar Arregui, M. Sánchez Marteles, F. Ruiz Laiglesia, J. Pérez Calvo

Department of Internal Medicine. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: During the last years the Chronic Obstructive Pulmonary Disease (COPD) prevalence and comorbidity have increased. The aim of this study is to determine whether there are differences in the average stay of patients requiring admission for acute COPD in the different seasons of the year.

Material and method: Observational, retrospective, transversal and descriptive study, in which we have reviewed the reports of patients discharged consecutively at the Hospital Clínico Universitario Lozano Blesa from Zaragoza in the period from January to December 2011, being the first or second diagnosis COPD (ICD 491), emphysema (ICD 492) and chronic airflow obstruction (ICD 496). We reviewed a total of 516 reports, extracting demographic data and average stay. To analyze the information we have classified the patients in quarters, considering the first quarter, December, January and February, second quarter, March, April and May, third quarter, June, July and August and fourth quarter, September, October and November. Statistical analysis of the information has been realized considering significant differences $p < 0.05$.

Results: There have been checked a total of 516 cases, 20% of the included patients were women (N = 77) and 80% men (N = 299) with an age average of 74.4 years (SD: 10.72 years). The average patient stay was 12.75 days (SD: 10.77 days) with the following distribution for quarters: the first quarter 196 cases (38%) with and average stayof 13.07 days (SD: 13.12 days), the second quarter 117 cases (22.7%) with average stay of 11.62 days (SD: 7.69 days), the third quarter 93 cases (18%) and average stay of 11.88 days (SD: 7.97days) and fourth quarter110 cases (21.3%) with average stay of 14.11 days (SD: 10.96 days). Comparing the average stay for quarters no statistical significance differences were found ($p = 0.283$).

Discussion: Analyzing the information obtained in our study, we can observe that seasonal pattern exists, with a major number of cases in the coldest months of the year. The first quarter is the one with higher prevalence, with 196 cases (38%), and within this, the month of January (80 cases, 15.5%). As well as other similar studies undertaken in the same way, no statistical significance differences were found for the average stay of these patients on the different

seasons of the year. It would be necessary to extend the study to analyze differences considering confounding factors such as age, sex and comorbidity.

Conclusions: COPD exacerbation admissions show a clear seasonal trend in our country, however, the length hospital stay is not significantly dependent on the time of year when income occurs.

V-236
SEVERE HYPERKALEMIA: CLINICAL AND ANALYTICAL PRESENTATION

J. Benítez Macías[1], V. Reina Lora[1], D. García Gil[1], M. Bailén García[2], M. Moreno Gómez[1]

[1]Department of Hospital Emergency, [2]Department of Clinical Analysis, Hospital Universitario Puerta del Mar. Cádiz, Spain.

Objectives: To describe the clinical characteristics of patients with marked elevation of serum potassium concentrations attending emergency department (ED) metropolitan hospital. It also aims to show factors and consequences related to this electrolyte disturbance.

Material and method: A retrospective study, through review of medical and laboratory reports, was carried out for all patients presenting to ED (medical ward) with serum potassium levels greater than 6.5 mmol per litre (mmol/L), over one-year period (2011). This survey was conducted to identify demographic features, main admission symptom, medical history, laboratory results: levels of serum potassium (mmol/L), glomerular filtration (GF) estimated by abbreviated Modification of Diet in Renal Disease equation (ml/min/1.73 m^2)), electrocardiographic manifestations and consequences. Descriptive and analytical research methods were used. Qualitative variables were expressed as frequencies (percentages) and quantitative variables as medians (25th and 75th percentiles). Statistical analysis was performed using non-parametric tests and linear regression. A two-tailed p value less than or equal to 0.05 was considered statistically significant.

Results: A total of 57,456 emergencies were attended in ED during the study period. Two hundred and twelve subjects had an analytical report with serum potassium levels higher than 6.5. However spurious analytical results were removed and 74 subjects were considered eligible. The median age of patients was 77 (67-84) and female to male ratio 1:1.7. The most common admission symptoms were: systemic (malaise or fatigue) 25 (34), breathlessness 12 (16) and decrease in level of consciousness 10 (14). Fifty seven (77) were hypertensive and 40 (54) patients had diabetes. Thirty-five (47) were already diagnosed as having chronic renal disease, 11 (31) of them had end stage renal disease and were undergoing dialytic support. Chronic heart failure and liver cirrhosis were suffered by 22 (30) and 13 (18) patients respectively. Forty nine (66) subjects were being treated with any diuretic: 40 (82) loop diuretics, 24 (49) potassium-sparing and 21 (43) both drugs regime. ACE inhibitors and angiotensin II receptor antagonists were used by 22 (30) and 23 (31) patients respectively. The median value of kalemia was 6.88 (6.72-7.23) and GF 18 (8-31); significant inverse relationship between kaliemia and GF was observed (B = -0.009; p = 0.017). There was no significant difference in the serum potassium levels when it was compared among patients who were taking any diuretic drug and those who were not. In 45 (61) medical reports was found a described electrocardiogram and the most frequent electrocardiographic manifestations was QRS prolongation (5 (11)). Emergent hemodialysis was required by 11 (15) patients, a temporary pacemaker was inserted in 5 (7) and 54 (73) were hospitalized; 3 (4) died during their stay in ED.

Discussion: Within the proper limits of study design (retrospective, deficiency in contents of the medical record), a series of patients with marked hyperkalemia were reviewed.

Conclusions: In this survey severe hyperkalemia mostly appeared in male elderly patients, who went through systemic symptoms as predominant clinical presentation. Nearly a half of subjects suffered from chronic renal disease and one-third in end stage, requiring dialytic support. No significant difference in kalemia was found among patients with diuretic therapy and those without. Few electrocardiograms were reported by ED physicians and the most common change was QRS enlargement. Invasive techniques were required in a few patients.

V-237
A DESCRIPTIVE STUDY ABOUT HOSPITAL ADMISSION ADEQUACY FROM EMERGENCY SERVICE IN A GENERAL REFERENCE HOSPITAL, USING TAEP (THE APPROPRIATENESS EVALUATION PROTOCOL)

R. Boixeda, L. Arbones, R. Soultana, J. Fernández-Fernández, M. Delgado-Capel, A. Felip

Department of Internal Medicine. Hospital de Mataró. Mataró (Barcelona), Spain.

Objectives: 1. To assess the hospital admissions adequacy from Emergency Service using TAEP. 2. To compare the TAEP criteria with clinical opinion. 3. To compare the results of two years study before and after agreeing strategies of action to prevent inadequate admissions.

Material and method: Design: Descriptive two cross-sectional observational study. Study population: Patients who had been admitted to the Medical Department of a regional Hospital from the Emergency Service, in February 2011 and February 2012. Measurements: Clinical, analytic and sociodemographic variables were extracted from medical histories. The adequacy of admissions was examined using TAEP and with the clinical opinion of three emergency expert clinicians. We made a descriptive cross-section in February 2011 and then we made another one in February 2012 to compare results. We compare the results of both cross-sections, before and after agreeing strategies of action to prevent inadequate admissions.

Results: In the comparative phase we analyzed the admitted patients in February 2011 and in February 2012. There were no significant overall difference between both groups: 45% of the patients were men and the mean ages were 75 years. The hospital stay was from 8.4 and 9.6 days respectively. 10% of patients were derived from PADES' department or from Pneumologic or Oncologic Ambulatory Hospital and 10% of theme were institutionalized patients. A 30% of patients were derived from another medical professional and a 70% came to emergency by themselves. A total 30% of the patients were readmitted patients (more than three admissions in the last five years or more than two admissions in the last year). As a comorbilities, there were no relevant differences between both groups (29% had diabetes, 58% HTA, 38% dyslipidemia, 36% COPD, 54% cardiopathy and 25% oncologic pathology). Most patients' visits were visited in the morning (66%). The cause of admission was to avoid the delay of the ambulatory studies in 11% of patients. There is no relation between the appropriateness and the age of patients (p = 0860 and p = 0.787 respectively). The two groups did not differ significantly with respect of adequate admissions based in TAEP criteria (80% February 2011, 85% February 2012, p = 0.35). In the other hand, there was a significant difference about the adequation of admissions between two groups since the point of view of clinicians (69% February 2011, 84% February 2012, p = 0.012).

Conclusions: A fifth part of the admissions to the Medical Department could have been prevented. The proportion of inappropriate admissions was 20% by TAEP and 17% by medical

criteria. Since strategies to prevent inadequate admissions were applied, there was a tent to reduce the inappropriate admissions according to TAEP criteria (20% and 15%) and a significant droop of the inadequate admissions according to clinician opinion (31% and 16%).

V-238
COMORBIDITY AND COPD: DOES IT MATTER?

M. Sánchez Marteles, M. Aibar Arregui, C. Josa Laorden, L. Royo Trallero, S. Luna García, V. Garcés Horna, F. Ruiz Laiglesia, J. Pérez Calvo

Department of Internal Medicine. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: During the latest years, medical community is becoming aware of the importance of the association of chronic obstructive pulmonary disease (COPD) with other diseases. Heart failure (HF), diabetes mellitus, atrial fibrillation and ischemic heart disease (IHD) are some of the most commonly associated conditions. There are however few studies analyzing the influence of comorbidity on outcomes, such as mortality, and length of hospital stay among patients suffering COPD exacerbations. Objectives: 1. To know the frequency of associated conditions in patients admitted at hospital for COPD exacerbation. 2. To study the influence of comorbidity on outcomes, in terms of mortality, length of hospital stay and readmissions during follow-up.

Material and method: A transversal, retrospective and observational study was made. The study was developed at HCU "Lozano Blesa". All discharged reports made with the main or second diagnosis of COPD exacerbations (ICD 491, 492, 496) in the year 2011 were reviewed. Comorbidity, age, sex, chronic oxigenotherapy, readmissions, intensive care units stay. Charlson index was determined and statistical analysis was made. Statistical study was made with the SPSS software 13.00. A descriptive study and normality study with Kolmogorov-Smirnov and Shapiro Wilk tests were made. Subsequently, the comparisons were in accordance with these previous results.

Results: 516 reports were reviewed. 80% were male, mean age was 74.44 years (Confidence Interval (IC) 95%: 74.4-75.36). 435 (43%) were admitted in Internal Medicine, 48.3% in Pneumology and 8.7% in other Units. 93 patients (18%) had been admitted in hospital, at least once, during the three previous months. 50 patients (9.7%) were admitted during the first month after discharge. HF (29.3%), IHD (16.3%), diabetes mellitus (18.4%) and vascular disease (19.6%) were the most frequently associated diseases. Mean Charlson index was 4.91 (SD: 2.13) for the entire cohort. The difference in Charlson index among patients admitted in Internal Medicine or Pneumology was highly significant (5.56 vs 4.38, $p < 0.01$). Mean length of hospital-stay was 12.76 days (SD 10.77 days $p = 0.05$). ICU admission was required in 4.5%. Mortality was for the entire cohort was 4.7%.

Length of hospital-stay increased with comorbidity ($p < 0.05$) but was independent of age. Charlson Index was higher among deceased as compared to survivors (6.2 vs 4.85; $p < 0.05$) The need for admission in intensive care unit was neither related with early or late readmissions nor with comorbidity. ($p = 0.34$; $p = 0.36$ and $p = 0.83$).

Discussion: Although comorbidities are linked to ageing, they seem to be further more than a simple and innocent association. According to our results, comorbities, especially vascular diseases, are common in patients admitted at hospital for COPD exacerbations. In addition, the burden of such comorbidities has an actual impact on outcomes among patients with COPD. Readmission rate and mortality are correlated with the number of associated conditions. Charlson index, an easy and reproducible item seems to be useful in evaluating prognosis of patients admitted for COPD exacerbations and might help for risk stratification.

Conclusions: 1. Comorbidities are common among patients admitted at hospital for COPD exacerbations. 2. Comorbidities but not age are correlated with poorer outcomes in terms of readmission and mortality 3. Charlson index might help in risk stratification of patients with COPD exacerbation.

V-239
CLINICS CHARACTERISTICS OF HOSPITALARIAN CONSULTATIONS ASK DURING ONE YEAR BY MEDICAL AREA TO INTERNAL MEDICINE (IM) FROM A HOSPITAL OF SPECIALITIES FROM SSPA

V. Lechuga Flores, M. Guzmán García, S. Romero Salado, V. Manzano Román, O. Mera Gallardo, G. García Domínguez, E. Sánchez Relinque, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: Know clinic characteristics of patients consulted for IM by other medical areas on our hospital.

Material and method: They were included consultations registered on IM Clinical Management Unit, from other medical areas between January 2011 and December 2011. Variables studied: age, sex, number of reports per month, origin, consultation character, reason for consultation. Information was analyzed based on proper characteristics of descriptive study.

Results: Total request: 68. Middle Age: 65 years (average 72 years). Sex: 58% men. Month on which more consults were realized was January (19.11%) and least, October (1.5%). Origin: Digestive System (26.5%), Cardiology (22%), Psychiatry (16.2%), Neurology (14.7%), Pneumology (11.7%), Nephrology (7.35%), Hematology (1.5%), others (0.05%). Consultation character: ordinary (22%), urgent (19.2%), priority (2.9%) and very priority (1.5%). Main reason for consultation: IM service patient transfer (29.5%), service most requests: Digestive System (35%), followed by Neurology (20%), Pneumology (15%) and Nephrology (15%), Cardiology (10%) and Hematology (5%). Middle age of these patients was 71 years old and main reason to transfer was for treating itself about pluripathology patients or with infectious associated process. Secondly, consults were done for diagnosis from a sign or symptom on 27.9%, (except fever and infectious processes): low conscience level, dyspnea, constitutional syndrome, anemic syndrome, etc. Other consults objective was treatment adjustment or beginning pharmacological treatment (19.11%), mainly about arterial hypertension treatment (15.4%), antibiotics management (15.4%), ions management (15.4%) and Diabetes Mellitus (7.7%), others (46%). Finally, consultations were realized for managing infectious processes and/or fever on 11.7% and pain control on 11.7%.

Discussion: Main reason for consults realized to our service of Internal Medicine was patients' transfer with age older than 65, and with pluripathology. Services with more number of consultations request were: Cardiology, Psychiatry and Digestive System, latter is the one with more transferred request. An important percentage of consults were done with urgent character.

Conclusions: Relation among different welfare hospitable services is based mainly on medical consultation Internal professional labor based on his integral formation, fundamental on the population clinical management on continuous aging and with a major comorbidity.

V-240
CLINICAL CHARACTERISTICS OF PATIENTS WITH DIAGNOSIS OF HYPOTHYROIDISM DURING PREGNANCY IN A HOSPITAL OF SPECIALTIES OF THE SSPA

V. Lechuga Flores, M. Escobar Llompart, G. Ruiz Villena, O. Mera Gallardo, G. García Domínguez, M. Guzmán García, R. Aranda Blázquez, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Puerto Real (Cádiz), Spain.

Objectives: The hypothalamus-pituitary-thyroid axis presents changes in normal women during their pregnancy. The transplacentary passage of thyroxine (T4) particularly during the first trimester of pregnancy, acquires great importance for fetal development. Therefore we analyze the profile of patients diagnosed gestational hypothyroidism (GH), as well as the personal background and most frequent factors.

Material and method: We analyzed the patients presenting with diagnosis of GH from June 2011 and February 2012. Those patients were excluded from the study with diagnosis and treatment for thyroid disorders prior to pregnancy. Study variables: age, no. pregnancies, intake of iodized salt, clinical history, diagnosis, presence of antithyroid antibodies, beginning of treatment time.

Results: Patients with GH total: 52. Average age: 30 years. First-time mother: 38%. Taking iodized salt prior to pregnancy the 17.3% of patients and were the diagnosis in treatment with supplements of iodine the 78.8%. A family history of thyroid pathology (23.07%), tobacco (13.5%), prior, resolutely and untreated thyroid pathology (13.46%), gestational diabetes (3.84%), diabetes mellitus (1.9%). At the time of diagnosis, TSH levels presented an average value of: 6.72 µUI/ml (figures from 3.43 µUI/ml up to 19.43 µUI/ml). A 19.23% of patients had positive antithyroglobulin antibodies, 34.61% thyroid peroxidase antibodies and 17.3%% of the patients had a goiter. T4L levels showed an average value of 1.04 ng/dl and T3 0.33 ng/dl. The middle of initiation of treatment with thyroid hormone was at 11 weeks.

Discussion: The personal background that is more related to the appearance of GH were: family history of thyroid disease, smoking and prior history of thyroid disorder. Most of the patients had subclinical hypothyroidism. All patients started treatment with supplement with iodine and thyroid hormones, in most of them being the home for better control in the first two quarter (1st T: 55.76% and 2nd T 36.53%).

Conclusions: Maternal T4 is relevant for ripening and fetal brain development both in the first quarter, when the fetus does not produce its own thyroid hormone, as in the second quarter, the clinical impact in the newborn will depend on of iodine deficiency. Therefore, the routine detection in pregnant women, being a single diagnosis by measuring free T4, TSH and antithyroid antibodies is justified.

V-241
ACTIVITY OF A NEWLY IMPLANTED HIGH RESOLUTION OUTPATIENT CLINIC IN A TERTIARY HOSPITAL

A. González Alejos, A. Escandell García, P. Berrocal Gil, A. Toro Parodi, A. Renau Escrig, C. Morata Aldea, J. Todolí Parra, J. Calabuig Alborch

Department of Internal Medicine. Medical Area. Universitari i Politècnic La Fe Hospital. Valencia, Spain.

Objectives: Describe the results obtained after implementation of a high resolution outpatient clinic (HROC) in the Internal Medicine Department during the period of February 1 or October 31, 2011. To quantify the diagnostic results obtained, the time elapsed during the diagnostic process and techniques used. Ask the main limitations and alternatives for improvement in the circuit.

Material and method: Data collected over eight months of all patients referred to the Internal Medicine HROC according to the protocol established by the Service (study of severe microcytic and macrocytic anemia,constitutional symptoms, peripheral lymphadenopathy, masses of different location, fever of unknown origin (FUO) and metastasis of unknown primary). We collected demographic data, days until the first visit, until the end of the process, type of process studied, service of source, procedures carried out, delay in conducting examinations, final diagnoses and final diagnoses by global initial syndrome, as well as successes and failures of the circuit. "Failure" was considered when the patient needs hospitalization.

Results: During a period of 8 months were sent to the HROC 135 patients. We excluded 23 patients (17% of total) by inappropriate referrals conditions not included in the protocol HROC. In the 112 patients included there were 58 males (52%) and 54 women (48%) and a mean age of 63.8 years (SD 17.8 and range 14-93). Were performed a mean of 2.2 visits per patient (SD 0.9).We had 5.2 days on average to the first visit (SD 3.8) and 13.6 days until the second (SD 9.8), 5.6 days until the first diagnostic procedure performed (SD 5.4) and 12.5days until the second (SD 11.9). The mean time from first visit until the end of the process was 19.14 days (SD 17.11). The processes studied were mainly microcytic anemia, followed by constitutional syndromes. The patients source was predominantly Emergency Room (ER) (87.5%), followed by Primary Care (4.46%), and other outpatient clinics (3.57%). The procedures performed were mainly CT (66 total), followed by biopsies (20), endoscopies (18 gastroscopies and 17 colonoscopies), fine needle aspiration (FNA) (15). The destinations HROC discharge circuit were: 30% internal medicine, 19% primary care, and other outpatients clinic of different specialties. The 83% of cases (93) were considered "successes" (defined as "reaching the diagnosis without the patient's income"). Of the patients classified as "successes" were admitted at hospital 8.6% (for biopsy) vs 73.7% of the "failures" (for different reasons, mainly poor clinical situation). This difference at hospitalisation between "successes" and "failures" was significantly (p 0.0001) without sex or age differences.

Discussion: It will be necessary to clarify the concept of success and failure, not only in terms of hospital admission. So, we must consider another fields as totally time to reach a right diagnosis.

Conclusions: The recently implemented HCOR is useful for the rapid diagnosis of common diseases in Internal Medicine. In our group of patients we found that 80% of patients were seen within 7 days, the mainly service of source was ER (87.5%). Also, we registered TC as the most common procedure near from FNA biopsies and gastrointestinal endoscopy. We obtained as mainly final diagnosis the cancer (36% metastatic at diagnosis time) and iron deficiency anemia (21%) of various etiologies. Finally we considered an acceptable number of cases (83%) as ´successes´ avoiding hospital admissions.

V-243
ASSESSING QUALITY OF LIFE IN PATIENTS WITH GAUCHER DISEASE

E. Trigo Esteban, B. Andrés del Olmo, P. Demelo Rodríguez, Z. Jiménez Bretones, L. Pérez Latorre, J. García Castaño, C. Gilsanz Fernández

Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: The objective of this study is to evaluate quality of life in patients with Gaucher disease after initiation of replacement enzyme therapy.

Material and method: We used a validated questionnaire to evaluate quality of life before initiation of replacement enzyme therapy (RET) and after 2 and 4 years in two patients with active

treatment out of three followed in an Internal Medicine department in the last 7 years. We have utilized the questionnaire WHOQOL-BREF (World Health Organization Quality of Life Questionnaire; WHOQOL Group, 1993). This questionnaire is one of the two different versions of quality of life questionnaire made by the WHO. With 26 questions, it evaluates quality of life broken down into four sections: physical health (1), psychological health (2), social relationships (3), and environment relationship (4). This questionnaire is widely validated worldwide.

Results: In the last 4 years, we have started RET in 2 of 3 patients affected by Gaucher Disease in our Internal Medicine department. This questionnaire evaluates the satisfaction rate in the 4 sections previously mentioned. Patient 1: before therapy he presented 38% in physical health, 44% in psychological health, 56% in social relationship and 50% in environment relationship. After 4 years of treatment the results were 56%, 63%, 69% and 56%, respectively. Patient 2: before therapy she presented 56% in physical health, 56% in psychological health, 44% in social relationship and 44% in environment relationship. After two years of treatment the results were: 56%, 56%, 50% and 50% respectively.

Discussion: There are three subtypes of Gaucher disease: Type 1, 2 and 3. Of those, type 1 starts in adulthood, and it is usually defined as non-neuropathic. Since 1993 the substitutive enzymatic therapy with recombinant enzyme (imiglucerase) and velaglucerase alpha is available. Therapy should be initiated individually and focused on achievement of therapeutic objectives established by internationals guides. Main goals are: elimination or improvement of symptoms, prevention of irreversible damages and improvement in global health and quality of life. We decided to initiate RET in 2 of 3 patients with Gaucher Disease in our Internal Medicine department. In the first patient, because of the radiologycal evidence of bone disease. In the second patient, therapy was started because of severe thrombocytopenia despite splenectomy in childhood. In both cases, besides symptomatic improvement and stabilization of disease progression, we found a global improvement in quality of life, with advances in all four categories evaluated. An increased monitoring should be done in these patients to evaluate quality of life in the future, after several years of RET.

Conclusions: A significant improvement in quality of life was shown in patients with Gaucher disease after initiation of Replacement Enzyme Therapy, through a correct symptomatic control and stabilization in disease progression. In the 4 categories evaluated, the biggest increase in satisfaction was found in environment relationship, probably because of increasing availability of resources and treatments for these patients.

V-244
RISK OF NEUROLOGICAL IMPAIRMENT AFTER TRANSFEMORAL AORTIC VALVE IMPLANTATION

I. Pascual Calleja, P. Avanzas Fernández, L. Clavel Conget, R. del Valle, E. Suárez, J. de la Hera, M. Martín, C. Morís de la Tassa

Department of Cardiology. Hospital General de Asturias. Oviedo (Asturias), Spain.

Objectives: The aim of this study was the prospective investigation of neurological impairment after transfemoral aortic valve implantation.

Material and method: The study included patients with severe symptomatic aortic stenosis treated with transcatheter self-expanding corevalve system. Other inclusion criteria were: aortic valve area < 1 cm^2 (< 0.6 cm^2/m^2); aortic valve annulus diameter in the range 20-27 mm; diameter of the ascending aorta at the level of the sinotubular junction minor or equal to 40 mm (small prosthesis) or ≤ 43 mm (large prosthesis), and femoral artery diameter > 6 mm. The endpoint of the study was the presence of any clinical focal neurological impairment after the procedure, until discharge.

Results: The study included 56 patients with a mean age of 77.9 ± 6.5 years, a mean aortic valve area of 0.63 ± 0.2 cm^2 and a mean logistic EuroSCORE of 14% (13.4%). After valve implantation, the maximum echocardiographic transaortic valve gradient decreased from 84 ± 21 to 12.4 ± 5 mmHg. No patient presented with greater than grade 2 residual aortic regurgitation on angiography. The procedural success rate was 100%. No patient died during the procedure. Definitive pacemaker implantation was carried out due to atrioventricular block in 16 patients (28.6%). Regarding neurological evaluation, the endpoint presented in two patients (3.6%) that developed cerebellar ataxias; one of them transient and another persistent.

Discussion: Degenerative aortic stenosis is a pathology related to old population, as in our study. Transfemoral aortic valve implantation is a valid option for old people and for those with high surgical risk, and its safety and security have been demonstrated in several studies. One of the most frequent complications of the Corevalve device is the atrium-ventricular conduction disturbances. The prevalence of permanent pacemaker implantation shown in our study is concordant with this fact, but it is lower in this work. The rate of cerebrovascular strokes appears low.

Conclusions: Our early experience indicates that percutaneous aortic valve replacement is a safe therapeutic option for patients with severe aortic stenosis who are at a high surgical risk. The incidence of neurological impairment due to the procedure is low.

V-245
SEX INFLUENCE ON THE RESULTS OF THE AORTIC PROSTHESIS (COREVALVE) IMPLANTATION ACCORDING THE CRITERIA OF THE VALVE ACADEMIC RESEARCH CONSORTIUM

R. del Valle, I. Pascual Calleja, L. Clavel Conget, P. Avanzas Fernández, M. Martín, J. de la Hera, C. Morís de la Tassa

Department of Cardiology. Hospital General de Asturias. Oviedo (Asturias), Spain.

Objectives: To analyse the results of the transcatheter aortic valve implantation (TAVI) depending on the sex of the patient, following the standardized definitions of security and efficacy proposed by the Academic Research Consortium to facilitate comparisons among different studies.

Material and method: Results analysis depending on the sex of a total of 116 patients with severe aortic stenosis in which TAVI was performed. Statistical analysis with SPSS 19.0 (percentages, χ^2 and Fisher's test for discrete variables, mean and standard deviation and Student t for continue variables; p minor to 0.05 indicates statistical significance).

Results: The 56% of the patients were female. Male patients showed more comorbidity: previous coronary revascularization 21.6 vs 6.2% (p = 0.015), chronic obstructive pulmonary disease (COPD) 29.4 vs 7.7% (p = 0.002), chronic treatment with bronchodilators or esteroids 27.5 vs 12.3% (p = 0.034), dyslipemia 43.1 vs 27.7% (p = 0.082), previous conduction abnormalities 43.4 vs 28% (p = 0.095) and need for percutaneous coronary intervention previously or during the TAVI (13.7 vs 4.6%, p = 0.081). Female patients tended to have more frequent major complications at the vascular access point (12.3 vs 2%, p = 0.038) and percutaneous seal failure (13.8 vs 3.9%, p = 0.065), but there was not any difference in the major vascular complications appearing (6.2 vs 2%, p = 0.27). Acute renal

failure was more frequent in male (19.6 vs 1.5%, p = 0.001). There were no differences concerning the device success (86.3 vs 93.8%, p = 0.14), nor the 30 days mortality (7.8 vs 4.3%) nor the security combined outcome (86.3 vs 83.1%).

Discussion: Transcatheter aortic valve implantation is a consolidated procedure that has become an alternative option to treat severe symptomatic aortic stenosis in those patients with high surgical risk. Recently, the VARC has proposed security and efficacy result definitions to evaluate this technique. In our study, we have considered these definitions to design this study.

Conclusions: We have not found differences between male and female patients according to the success of the device nor the security combined outcome to 30 days. Male patients had more incidence of acute renal failure post-procedure and female patients had more complications at the vascular access point.

V-246
FACTORS ASSOCIATED WITH THE ONSET OF DELIRIUM DURING HOSPITALIZATION IN INTERNAL MEDICINE

E. Del Corral Beamonte, M. Arnal Longares, M. Sevil Puras, C. Fernández Jiménez, P. Al-Cheikh Felices, M. Pardo Díez, J. Díez Manglano and the Researchers of Impimi Study

Department of Internal Medicine. Hospital Royo Villanova. Zaragoza, Spain.

Objectives: To determine the factors associated with the onset of delirium in patients admitted to an Internal Medicine department.

Material and method: We retrospectively reviewed the nursing records and diagnostic related groups of the patients admitted to internal medicine in October 2010, January 2011, May 2011 and October 2011. For each patient we collected data of age, gender, living in nursing residence, Barthel index, Norton scale, intravenous fluid therapy, urinary catheterization, onset delirium during hospitalization, presence of pressure ulcers, major diagnostic category, length of hospital stay and weight of the diagnostic related group. Quantitative data are presented as mean (standard deviation) and qualitative data as absolute frequencies (percentage). Comparison between the two groups was performed using Mann-Whitney U-test and Chi^2 test. We performed a logistic regression model with the significant variables in the univariate analysis. In all analysis p-values < 0.05 were considered statistically significant.

Results: During the study period there were 768 admissions and we included 747 (97.3%). The mean age was 74.3 (15.1) years and 389 (52%) patients were women. During hospitalization 97 (13%) patients had delirium. Patients with delirium were older (81.5 (11.0) vs 73.3 years (15.4); p = 0.0003, lived more frequently in nursing residences (43.7% vs 20.2%; p = 0.0001, and scored lower on Barthel index [41 (37) vs 69 (37); p = 0.0002] and on Norton scale [11.9 (4.3) vs 15.3 (4.6): p = 0.0003]. Respiratory diseases were more frequent in patients with delirium (32.0% vs 20.3%; p = 0.02) and the digestive ones less (9.3% vs 18.9%; p = 0.005). There was no difference in diseases of the nervous system. Indwelling urinary catheterization (58.8% vs 31.9%; p = 0.006), intravenous fluid therapy (81.4% vs 67.6%; p = 0.006) and presence of pressure ulcers (23.7% vs 12.9%; p = 0.005) In the multivariate analysis only age [HR 1.03 (95%CI 1.00-1.06); p = 0.02] and urinary tract catheterization [HR 1.80 (95%CI 1.05-3.08); p = 0.03) were associated with delirium. The average length of stay [11.5 (8.6) vs 9.1 days (7.4); p = 0.007] and the expected health resource consumption measured by the weight ofGRD [2.00 (1.07) vs 1.61 (0.94); p = 0.0007] were higher in patients with delirium.

Discussion: Patients of Internal Medicine departments are old and often have more than one disease. Using records of nursing 13% of them suffer delirium during hospitalization and indwelling urinary catheterization is associated with the onset of delirium. We think that nursing records can be useful to identify situations and procedures associated with the onset of delirium. Intervention studies to determine whether a decrease in urinary catheterization is followed by a decrease o onset of delirium could be very interesting.

Conclusions: Using nursing records and administrative database, the onset of delirium during hospitalization is associated with age and urinary catheterization.

V-248
PRIMARY MITOCHONDRIAL ENCEPHALOMYOPATHIES. CLINICAL PRESENTATION AND OUTCOMES OF 23 PATIENTS

P. Moreno Lozano[1], M. Catalán[2], J. Milisenda[1], C. Cardozo Espínola[1], E. Coloma Bazán[1], J. Grau Junyent[1]

[1]Department of Muscle Research and Internal Medicine. Hospital Clínic. Barcelona, Spain. [2]Idibaps. Universidad de Barcelona. Barcelona, Spain.

Objectives: The objective of this study is to present our experience in the clinical presentation, diagnosis, treatment and outcome of a cohort of the primary mitochondrial encephalomyopathies (PME) diagnosed and followed-up in our institution in the last 20 years.

Material and method: An observational analysis of a retrospective cohort of 23 patients who received the diagnostic of PME, studied in the last 20 years in the Hospital Clinic of Barcelona. The diagnosis was made on the basis of clinical phenotype together with muscle biopsy and/or genetic studies and/or biochemical study of mitochondrial respiratory chain. The time of follow-up was 12-240 months and the functional status measured by the validated (NMDAS) Newcastel Mitochondrial Disease Adult Scale. On the basis of clinical complaints, two groups of patients were considered. Those who received specific treatment (vitamins, coenzyme Q10) n = 11, and those receiving only symptomatic treatments (anticonvulsivants, pacemaker...) (n = 11).

Results: The male/female ratio observed was 43/57%. The most common symptoms at diagnosis were weakness, ptosis and hearing loss with a prevalence of (48%, 43%, 35% respectively). The most frequent identified syndromes were MELAS (17%) and Kearns-Sayre with 17%. In all of the 21 muscle biopsies performed RRF (ragged-red fiber) in some percentage were recorded. Genetic abnormalities were found in 73% of the 8 patients studied, and mitochondrial respiratory chain disturbance were observed in 82% of the 9 patients studied. The average rating was 29.7 points (range 4-97) over 145 in the NMDAS scale, with values above the average in the case of patients with Kearns-Sayre and NARP syndrome (66 and 31.5 points) respectively. While 8 patients from the specific treatment group clearly worsened through the follow-up, such figure does occur only in 3 patients from the no specific treatment. Full and maintained recovery was documented only is two brothers suffering from Pearson´s syndrome that were specifically treated. The mean score in the NMDAS of patients with specific treatment was superior to that of patients who had received supportive care.

Discussion: As occurs in other clinical series, a strong clinical variability is documented in the present cohort of PME. The fact that muscle complaints were the main clinical manifestation in all of patients, clearly represent a bias, since all the patents were visited at Muscle Research Unit. Except for the two brothers suffering from Pearson's syndrome, the clinical worsening over time is the rule in PME.

Conclusions: In the present series of PME an heterogeneous clinical presentation together with common progressive disability is clearly demonstrated.

V-249
PANCREATIC MALIGNANT EPITHELIAL NEOPLASMS. ANALYSIS FROM TUMORS REGISTRY OF THE HOSPITAL UNIVERSITARIO 12 DE OCTUBRE FOR 11 YEARS (1999-2009)

B. de Miguel Campo[1], E. Muro Fernández de Pinedo[1], A. Morales Cartagena[1], M. Pilas Pérez[2], J. Vila Santos[1], G. López Alonso[3], F. Colina Ruiz Delgado[2], J. Guerra Vales[1]

[1]Department of Internal Medicine, [2]Tumors Registry, [3]Department of Pathology. Hospital 12 de Octubre. Madrid, Spain.

Objectives: To describe the demographic, histological and prognostic features of pancreatic malignant epithelial neoplasms (carcinomas) treated for 11 years at the Hospital Universitario 12 de Octubre (H12O) of Madrid (Spain).

Material and method: In the H12O Tumors Registry (H12OTR) there is a record of all malignant tumors totally or partially seen in our center. There were a total of 26,526 malignancies registered between January 1999 and December 2009 with full follow-up (diagnosis, treatment and posterior monitoring) in our center, of which 513 (1.94%) corresponded to pancreatic neoplasms. The collected information: filiation data, sex, age, date of diagnosis, basis for the diagnosis (i.e. confirmation of malignancy), extension LRD (local, regional or disseminated), type of oncologic treatment, other simultaneous malignancies, final clinical outcome (survival or not), date of death (obtained from the National Death Index) and months of survival. Mesenchymal neoplasms (n = 1), epithelial neoplasms without cyto-histological confirmation (n = 149), epithelial neoplasms of uncertain malignancy (n = 19) and neuroendocrine tumors (n = 33), were excluded from our study.

Results: Of the 311 cases finally included, 180 were men (57.9%) and 131 women (42.1%). The mean age at diagnosis was 65.3 ± 11.6 years. When analyzing the distribution according to cytohistology we found 253 ductal adenocarcinomas (81.4%), 50 SAI (sine alter inscriptio) carcinomas (16.0%), 8 cystadenocarcinomas (2.6%) and 1 acinar cell carcinoma (0.3%). At diagnosis, most tumors were disseminated (n = 183, 58.8%) or had regional (n = 77, 24.8%) extension, with infrequent localized (n = 46, 14.2%) or in situ (n = 3, 0.1%) stages. Regarding the choice of first-line treatment, 30.9% (n = 94) underwent surgery, and 29.6% (n = 92) received chemotherapy, being equally relevant the number of patients not receiving any oncologic treatment (n = 78, 25.1%) or those who were exclusively prescribed palliative care (n = 26, 8.4%). Finally, the mortality was 94.5% (n = 294), with an average survival of 7.3 ± 19.7 months.

Conclusions: Exocrine pancreatic carcinomas are a group of poor prognosis tumors that frequently show extended disease at the time of diagnosis. This determines a poor survival and limits the possibility of applying targeted diagnostic or therapeutic techniques.

V-250
MANAGEMENT OF DIPLOPIA CASES IN A REGIONAL HOSPITAL

M. Gómez Hernández[1], A. Vergara Díaz[1], M. Romero Rivero[1], R. de la Rosa Morales[1], R. Espinosa Calleja[1], S. Vidal Serrano[1], S. Andrades Segura[2]

[1]Department of Internal Medicine, [2]Department of Community and Family Medicine. Hospital San Juan de Dios de El Aljarafe. Sevilla, Spain.

Objectives: The diplopia of non-ophtalmic etiology is a severe clinic entity and has a very broad spectrum of presentation. We work in a regional hospital, where the medical specialty of Neurology or the sub-specialty of Neuro-ophthalmology do not exist. It is therefore established a protocol in the process of diagnosis, monitoring and treatment of diplopias involving several areas: Emergency, Internal Medicine and Ophthalmology. The importance of this study lies in the absence of clinical practice guidelines in the existing literature, partly due to the existence of multiple etiologies responsible for the development of diplopia. The aim is to conduct a descriptive assessment of the management of the diplopia cases assessed in a regional hospital.

Material and method: We conducted a retrospective descriptive study of a series of clinical cases assessed patients who went by diplopia, first in the Emergency Department and subsequently monitored in the Internal Medicine or the Ophthalmology Areas. This study took place between 1st of January 2009 and the 31st of December 2011. Several variables were analyzed, such as: sex, age, type of diplopia, description of affected cranial nerve type, first contact service, cranial CT scan carrying out, period of time between the debut and the first medical assistance at Ophthalmology or Internal Medicine and etiology of the diplopia.

Results: The sample consists on 56 patients, 26 women (46.4%) and 30 men (53.5%). The mean age is 58.5years old (89-23). The type of diplopia stated on the clinical report was horizontal on the debut for the 38% of the cases, non-specified for the 16% and vertical for the 2%. The affected cranial nerve type was defined for the 27% of the cases, showed variability in its determination by 16% of the patients and VI cranial nerve predominated (23%) followed by III cranial nerve (23%) and IV cranial nerve (12%) amongst the cases where it was defined. Emergency was the service which established the first contact with the clinical case in the majority of the situations (54%); the rest were first assessed in the Ophthalmology or the Internal Medicine Areas. A cranial CT scan was carried out in 59% of the cases. The mean period of time between the debut and the first medical assistance at Internal Medicine was 8 days (from 0 up to 52 days). The classification of etiologies: microangiopathic (DM) 48%, idiopathic 17%, thyroid orbitopathy 5%, and others 30%: neuromuscular pathology (myasthenia gravis), ENT pathology, orbital pseudotumor, ophthalmoplegic migraine, tumor (neurinoma-meningioma), S Tolosa Hunt, supranuclear origin.

Conclusions: Microangiopathic (DM) was the most common etiology of diplopias. The collaboration between the areas of Ophthalmology and Internal Medicine has sped up the global assessment of patients with diplopia. The possibility of carrying out an initial assessment followed by a detailed diagnosis of the neuromuscular dysfunction at the Ophthalmology Service appears to be an interesting area for future improvement.

V-251
PROGNOSTIC VALUE OF RED CELL DISTRIBUTION WIDTH (RDW)

J. Armas González, E. Martín Ponce, F. Santolaria Fernández, R. Alemán Valls, J. López Prieto, C. Martín González, I. Hernández Betancor, R. Ros Vilamajó

Department of Internal Medicine. Hospital Universitario de Canarias. San Cristóbal de La Laguna (Tenerife), Spain.

Objectives: Red cell distribution width (anisocitosis index) is currently used as a diagnostic aid in the etiologic diagnosis of anemia. Recently it has been suggested that red cell distribution width may be a prognostic marker for short term mortality in a large sample (74,784) of patients. Objective: to study if RDW is associated to short and medium term mortality in a short patient sample.

Material and method: We have studied 298 consecutive patients (mean age of 74 ± 13 years, 58% male) admitted to a hospital internal medicine unit. Red cell distribution width is measured and routinely reported on every complete blood count, and 15% was the upper limit considered in our hospital. We also determined creatinine, C reactive protein, albumin, ferritin, B12 vitamin and

folic acid serum levels. We assessed short term mortality as in-hospital one and medium term mortality including these patients death after discharged.

Results: Forty patients (13.4%) died as inpatients, and 45 other after discharge (mean follow-up of 574 ± 23 days). We did not find significant differences between in hospital mortality of 171 patients with low RDW (15 or less), 12.3%, and these of 127 patients with high RDW (greater than 15), 15.0%. However, when we assessed medium term mortality by Kaplan Meyer survival analysis, we found that patients with a RDW greater than 15% showed a shorter survival, RR (95%CI) 1.83 (1.19-2.8). RDW significantly correlated with age, hemoglobin, creatinine, ferritin and B12 serum levels. By multivariate analysis, Cox regression with covariates, we observe that the RDW medium term predictive value was independent of age, hemoglobin, serum creatinine, ferritin, CRP, B12 and albumin levels.

Discussion: It has been shown that RDW is a prognostic predictor of death in several studies. Moreover, RDW has proved to be an independent and strong mortality predictor. In our study we show the higher RDW, the higher medium term mortality. The mechanisms underlying the association between RDW and mortality are unknown.

Conclusions: Red cell distribution width, better than to inpatients mortality, is related to medium term mortality. This relation was independent of other factors related to RDW or mortality.

V-252
INDICATIONS OF PLAIN ABDOMINAL X-RAY

J. Aparicio Oliver[1], B. Domínguez Fuentes[1], J. Benítez Macías[2], M. Cousinou Toscano[1], D. García Gil[2]

[1]Department of Emergency. Hospital Universitario Puerto Real. Puerto Real. Cádiz, Spain. [2]Department of Emergency. Hospital Universitario Puerta del Mar. Cádiz, Spain.

Objectives: Plain abdominal X-ray (PAx) emits 35 times more radiation than chest X-ray and it is often required to implement a routine protocol. Recently guidelines for using PAx in emergency departments (ED) have been published: 1) abdominal pain and ileus suspected; 2) toxic or sharp foreign body suspected. To know indications used by ED physicians to require a PAx, as well as adequacy of them, a study has been carried out.

Material and method: Retrospective and descriptive survey was realized in an ED used by a region with 285,000 people and where 85,685 emergencies were attended in 2008. One hundred and forty PAx were randomly selected among the total of PAx required by ED during February 2009. A review of medical records was carried out to identify demographic features, main admission symptoms, radiologic diagnosis, final diagnosis and consequences. Qualitative variables were expressed as frequencies (percentages).

Results: During the study period, 6,468 emergencies were attended, daily average: 231. Seven hundred and fifty one PAx were performed (27 per day). Mean age was 45 years and 49% were male. Undifferentiated abdominal pain 75 (54), low back pain 18 (13), vomiting 10 (7), malaise 10 (7) and diarrhea 9 (6) were the symptoms which encouraging to request PAx. Among PAx required by ED physicians to diagnose undifferentiated abdominal pain, sixty two (83) did not show any change and 2 (3) were useful to diagnose (ileus and perforation of the gastrointestinal tract). In cases of low back pain, 13 (72) were diagnosed as renal colic and in 1 (8) an image consistent with urinary tract lithiasis was observed. In a patient who was vomiting, intestinal ileus was seen in PAx. The most frequent outcome was discharge home 100 (71) and 6 (4) patients were all brought to urgent surgery.

Discussion: PAx has a limited role in ED. Investigations are useful when the results affect clinical management by confirming or excluding a diagnosis. Although there are clear guidelines to use PAx in ED (ileus and toxic/sharp foreign body suspected), is a common practice the overuse of this radioactive exam with poorly results.

Conclusions: In this survey, PAx is over-required to try to find a diagnosis of syndromes as undifferentiated abdominal pain or low back pain, however mostly radiological findings are clinically not relevant.

V-253
LIMITATION OF THE THERAPEUTIC EFFORT IN INTERNAL MEDICINE

M. Del Castillo Madrigal[1], I. Macías Beltrán[2], A. Merlo Serrano[1]

[1]Department of Internal Medicine, [2]Department of Family Medicine. Hospial Infanta Elena. Huelva, Spain.

Objectives: The limitation of the therapeutic effort (LTE) consists in not applying extraordinary or disproportionate measures regarding the therapeutic finality that is based on a patient with a poor vital prognosis and/or poor quality of life. Our objective is to analyse how LTE is valued in our Service, how it is reflected in the Medical Record and in what conditions is it performed.

Material and method: We carried a descriptive retrospective study of the LTE in an Internal Medicine Service of a 3rd level Hospital. In order to accomplish it, we analysed all the deaths produced in our Service in the first trimester of 2012. From such records we collected information on variables like age, gender, day of admission, type of advanced state chronic disease, basal quality of life, severity at admission time, complications during hospitalization, LTE performance, the indicating of palliative actions, the informing of relatives or patients and consensual decisions agreed with the latter, if the termination of the active intervening is established, and finally if the assessment is made in a programmed manner by the responsible doctor or by the doctor in charge at the moment of agony.

Results: In the first trimester of 2012 our service recorded an overall of 90 deaths from which 64% were males. The average of ages involved was 80yo (percentile 75 = 84yo and percentile 25 = 76yo). The most frequent reason for admission was decompensate heart failure, decompensate respiratory failure, community-acquired pneumonia and ischemic stroke. The average number of hospitalization days was 8.28. 72.46% showed advanced chronic disease and 56% poor basal quality of life. 7% had no data on the past records of chronic disease and for 24% there were no records of their basal quality of life. Concerning the vital prognosis at the time of admission, there were no records for 33% of the patients, 4 were admitted in a situation of extreme gravity, 37.6% showed poor general condition at admission, 6% change in overall condition and 20% good general condition at admission time. 40.5% suffered severe complications during hospitalization. From the patients showing LTE, those with chronic diseases in an advanced state and with previous poor life quality (50%) were reflected in the medical record limitation proceeding of 20% as non-CPR indication, 34.2% as decision of non-referred the patient to ICU, 51.42% adopting a conservative decision. Palliative measures were adopted for 54.28% of the cases. Active intervention was adopted for 40% of these patients. Decision was made in agreement with the family in 54.28% of the cases. Only 6 patients were treated by the responsible doctor on the time of death.

Discussion: There are only a few studies in Internal Medicine on LTE, and basically are tests of praxis in isolated cases and discussion papers on the subject, so we could not compare our study with similar ones. The profiles of people who die in our hospital are ancient with advanced chronic disease and poor life quality at baseline. However, as much as 31% of patients are not included

some of these aspects in their personal medical record to determine the attitude key to continue with the patient. Up to 33% are not collected the forecast impression in the first evaluation of the patient. The LTE decisions are reflected few times in the medical record, but in fact they are taken.

Conclusions: There's a need for greater reflection about LTE in Internal Medicine Service given the large number of elderly patients with chronic deterioration that are treated in this specialty, which would improve the quality of care in the process of dying. It is necessary to record a history of chronic disease and basal involvement in deciding the attitude to take. It is also necessary to record the attitudes that are decided to take on the LTE, in order to facilitate the work with the patient and with other physicians who care for the patient in situations of decompensation and agony.

V-254
CANCER OF UNKNOWN PRIMARY SITE IN INTERNAL MEDICINE. OUR EXPERIENCE IN THE LAST TEN YEARS

M. Fraile Villarejo, S. Márquez Batalla, I. González Fernández, A. Bello Conesa, Á. Romero Alegría, A. García Mingo, N. Cubino Bóveda, J. Martín Oterino

Department of Internal Medicine I. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca, Spain.

Objectives: To analyze the epidemiological characteristics and the clinical evolution of patients with diagnosis of cancer of unknown primary site (CUP) in an Internal Medicine Department in Salamanca.

Material and method: We reviewed the medical records of all patients diagnosed of cancer of unknown primary site in our Internal Medicine Department from May 2002 to May 2012, and collected these data: year of diagnosis, age, gender, metastases location, reason for admission, chemotherapy, surgical treatment, palliative care, days of admission, histological diagnosis, and exitus during hospitalization.

Results: 28 of 12063 admissions from May 2002 to May 2012 were diagnosed of cancer of unknown primary site (0.23%). Sex distribution was 60.7% men and 39.3% women. The mean age was 71 years and the median 76 years, with a range from 43 to 89 years old. The symptoms leading to admission was: 25% abdominal pain, 21% dyspnea, 18% neurological manifestations, 18% constitutional syndrome, and 4% chest pain. The location of metastases was: liver (12), peritoneal carcinomatosis (8), bone (6), brain (5), pleura (3), lung (2), mediastinal lymphadenopathy (2), cerebellum (1) and adrenal gland (1). 71.4% were unique and 28.6% were multiple location. Only in 17.9% of cases the histological diagnosis was obtained. 25% of patients received chemotherapy, none received surgical management, and 75% received palliative care after diagnosis. 14.3% died during hospitalization. The duration of admission ranged from 2 to 43 days, with an average of 15 days and a median of 11.

Discussion: The diagnosis of cancer of unknown primary site is uncommon; it only comprises an average of 3 cases per year in our Internal Medicine Department, with a range from 1 to 6 cases per year in the last ten years. It is often not reach a histological diagnosis in our patients. This is due to two main circumstances: the advanced age of our patients and the advanced stage of their neoplastic disease at diagnosis. The cancer of unknown primary site is more common in men, more frequently elderly. The main symptoms leading to admission at hospital are abdominal pain and dyspnea, followed by neurological symptoms and constitutional syndrome. In connection with this, the most frequent metastatic site is liver. It is also common the dissemination as carcinomatosis peritoneal, bone and brain metastasis. Other location is uncommon. In most of the cases the metastases are unique at diagnosis. Related to the management of these patients, most of them received palliative care after diagnosis, only a quarter received chemotherapy and a few died during hospitalization.

Conclusions: Cancer of unknown primary site is not common. The characteristic patient profile is an elderly man diagnosed of liver metastases or peritoneal carcinomatosis in the course of the study of abdominal pain or dyspnea, in whom after laboratory studies and imaging procedures, the primary site cannot be identified. Most patients diagnosed of cancer of unknown primary site in Internal Medicine do not reach a histological diagnosis because of their advanced age and the advanced state of their neoplastic disease. This fact conditions the subsequent management and bad prognosis of patients, so that most of them will be candidates for palliative care.

V-255
PATIENTS DIAGNOSED FOR THYROID CANCER PROFILE ON A SPECIALITIES HOSPITAL FROM ASPH

V. Lechuga Flores[1], S. Romero Salado[1], F. Carral San Laureano[2], R. Aranda Blázquez[1], G. Ruiz Villena[1], M. Guzmán García[1], V. Manzano Román[1], F. Gómez Rodríguez[1]

[1]Department of Internal Medicine, [2]Department of Endocrinology. Hospital Universitario de Puerto Real. Puerto Real (Cádiz), Spain.

Objectives: Thyroid cancer (TC) is a rare cancer characterized by its slow delay and high percentage of cure with surgery. Our aim is to study clinical characteristics of TC diagnosed patients who come for consultations.

Material and method: Select those patients who attend outpatient of Endocrinology with TC diagnosis. We analyze the following data: sex, age of diagnosis, town of origin, cytology initial by slim needle puncture aspiration, histology with histological subtype by surgical specimen and half of tumor size.

Results: Total: 71 patients. Sex: 76.05% were women. Average age: 42 years old. 3 patients with other previous tumor diagnosis (breast 2, pancreas1). Original Town: 90.15% Puerto real hospitalary area (El Puerto de Santa María 22.53%, Chiclana 22.53%, Puerto Real 14.08%, Conil de la Frontera 7.04%, Barbate 7.04%, Rota 4.22%, other location area 11.26%. Reaming patients belonged to other area than our hospital 9.85% (of these, 4.22% foreign patients were from: Morocco, Indonesia and Romania). According to the initial cytology by PAAF, result was: insufficient sample.

(11.26%), benign (14.08%), nodular hyperplasia (11.26%), follicular proliferation (8.45%), thyroiditis (1.4%), Colloid material (7.14%), oncotic/Hurthle cell changes (4.22%), suspicious of malignancy (7.04%), Ca. papillary diagnosis (9.96%), resulting on 25.35% cases. According to surgical histology specimen: Papillary (76.56%), follicular (21.87%) and spinal (1.57%). If we divide them according to histological subtype: classic papillary (50%), follicular papillary variant (2035%), diffuse papillary (1.56%), micropapillary (4.68%), macrofollicular (7.81%), invasive follicular (4.68%), follicular cells Hurthle variant (6.25%). Average tumor size was 8.34 mm (45 mm up to 2 mm), 13.10% patients had multifocallity and 12.67% had thyroiditis on surgical specimen.

Discussion: According to bibliography, TC affects more often women than men and usually occurs among people aged between 25 and 65 years old, data that match our patient's series. Making through sample PAAF guided with thyroid ultrasound decision was suspicious or malignancy diagnostic on 29.67% cases. Most thyroid cancers are composed of two ways of cancer well papillary differentiated (76.56%) and follicular (21.87%), coinciding with bibliography. Medullary cancer found on our patient's series on a percentage less than one described on revisions (1.56%).

Conclusions: TC cannot cause early symptoms. Most time it debuted with nodule presence on thyroid gland, although it should be noticed only 5% of such nodule is malignant. Diagnostic techniques, as high-resolution ultrasonography and fine needle puncture aspiration (PAAF) allow early diagnosis.

V-256
PARTICIPANT OBSERVATION AS METHOD TO KNOW PERCEIVING QUALITY IN A HOSPITAL EMERGENCY DEPARTMENT: ACCOMPANYING TO A PATIENT AND RELATIVES

J. Aparicio Oliver[1], D. García Gil[2], J. Benítez Macías[2]

[1]Department of Emergency. Hospital Universitario Puerto Real. Puerto Real. Cádiz, Spain. [2]Department of Emergency. Hospital Universitario Puerta del Mar. Cádiz, Spain.

Objectives: To know, using the principles of the participant observation (PO), positive and negative aspects in the attention provided to the patient and relatives in the Emergency Department (ED). To incorporate in the formation of the specialist the experience of the patient and/or caretaker during the healthcare process in the ED.

Material and method: Study carried out in the University Hospital Puerto Real (Cádiz), center located in a state highway that offers healthcare cover to a population of about 300,000 habitants and has 400 beds of hospitalization. Six doctors were selected (fictitious users) in their first year of specialized formation, with different profiles and without previous contact with the health system. With the consent of the patient and/or main caretaker, to each doctor was assigned a patient who was demanding urgent attention, acting like a relative in all healthcare act. In order to be a suitable observation, the initiative was not well-known by the professionals of ED or by other specialists in formation. The participating doctors had got a field notebook in which the different aspects from the system were written down (circuits, information, professionals who take part, duration of the process, impressions and experiences, tangible aspects and suggestions of improvement). Later, it was made a joint session with the residents of first year, people in charge of emergencies, teaching committee and management team to analysis the results and proposals of improvement.

Results: Results and information were analyzed according model SERVQUAL (Service Quality Framework). The negative tangible aspects were related to the signs of the different dependencies from ED, cleaning of the waiting room and simultaneous staying of adult and pediatrics patients. The other aspects were positive. Scientific-technical quality was valued as positive in all the patients and caretakers. In the accessibility was negatively valued the time of delay and the "geographic barrier". As far as the information/communication, the identification of the professionals, the privacy and the lack of a regular and confidential information were the most negative aspects.

Discussion: The PO can allow to improve negative aspects that are common in EDs, specially with respect to communication-accessibility, information, confidentiality, privacy and times of delay. In conclusion, an improvement acting from the citizen perspective. Later, all the actors initiated their health care activity in ED and emphasized in the different vision that has of ED as a professional and as a patient/caretaker.

Conclusions: The PO is an useful tool to value ED quality and the aspects that can be improved. In addition, young doctor´s experience from patient/caretaker´s perspective is enriching in their medical training and human development.

V-257
NONSECRETORY MULTIPLE MYELOMA. REPORT OF 3 CASES AND REVIEW OF THE LITERATURE

R. Alcaraz[1], E. Pérez[1], C. Cela[2], C. Marín[1], A. Cerón[1], L. Strobosch[1], F. Herrero[1]

[1]Department of Internal Medicine, [2]Department of Community and Family Medicine. J.M. Morales Meseguer Hospital. Murcia, Spain.

Objectives: To describe the clinical findings and complementary investigations that can guide the diagnosis of nonsecretory multiple myeloma.

Material and method: Review of 3 cases diagnosed in the Internal Medicine department of our hospital. We present a summary of the clinical history and complementary investigations of each case. CASE 1: A 73-year-old woman, with a history of solitary plasmacytoma involving the left iliac blade, treated with radiotherapy in 1998, and left otomastoiditis of a year of evolution, consulted for left peripheral facial palsy. Cranial CT scan showed osteolytic lesion of the left petrous bone, associated soft tissue mass extending into the eardrum, and lytic lesions in cranial vault. Tympanic mass biopsy showed proliferation of mature plasma cells with no other apparent cellularity. Bone marrow aspirate revealed 9% of myelomatous plasma cells. CASE 2: A 60-year-old woman with a history of right mastectomy due to malignant tumor in the year 1989 (not treated with chemo or radiotherapy), was admitted in the hospital with pain in the lower back and right hip. Lytic bone involvement of the entire axial skeleton with soft tissue mass adjacent to the right acetabular roof was observed in plain-film radiography and CT images. Right iliac blade biopsy showed intramedullary plasmacytosis, and bone marrow aspirate revealed 20% of atypical plasma cells. CASE 3: A 54-year-old woman who consulted for musculoskeletal pain, more pronounced in the shoulder girdle, during the past five months. Shoulder ultrasound showed the presence of a solid mass in the depth of the biceps tendon with cortical disruption of the humerus, suggestive of pathological fracture. Skeletal survey and CT scans demonstrated lytic bone lesions of the left humeral head, right scapula, right ischiopubic ramus, D2 vertebral body and right femur. The right scapula biopsy showed a marked infiltration by monomorphic population of mature plasma cells. Bone marrow aspirate revealed infiltration by atypical plasma cells (7%). At the time of diagnosis only patient in case 2 had anemia (Hb 8.9 g/dL) and high beta2-microglubilina (3.4 mg/L, nv < 2.40). In all cases, renal function, serum calcium, erythrocyte sedimentation rate (ESR), proteinogram and lactate dehydrogenase (LDH) were within normal values. Serum and urine immunoelectrophoresis, as well as Bence-Jones proteinuria in 24-hour urine collection were negative.

Discussion: The nonsecretory multiple myeloma is a low incidence disease (< 1% of hematologic malignancies), with a varied clinical presentation and limitations in laboratory findings, as seen in the three cases presented above. When diagnosis is made, these patients often have a more advanced stage of the disease and bone fractures are more common than in secretory myeloma. Therefore it should be considered in the differential diagnosis of patients with persistent bone pain and lytic lesions in radiological examinations.

Conclusions: 1) For the diagnosis of nonsecretory myeloma it is essential to establish a presumptive diagnosis by medical history, due to the absence of analytical repercussion and the atypical clinical presentation. 2) A biopsy of the affected tissue is essential for diagnostic confirmation.

V-258
IMPACT OF HIGH RESOLUTION OUTPATIENT CLINIC I N INTERNAL MEDICINE

A. González Alejos, E. Amor Bort, P. Berrocal Gil, A. Renau Escrig, A. Toro Parodi, J. Todolí Parra, C. Morata Aldea, M. Gómez Gómez

Department of Internal Medicine. Medical Area. Universitari i Politècnic La Fe Hospital. Valencia, Spain.

Objectives: Analyze the impact on average length of stay (AS) of Internal Medicine after implantation of the high resolution outpatient clinic (HROC) during the period of February 1 or October 31, 2011.

Material and method: Data were collected over eight months of all patients referred to the Internal Medicine HROC according to the protocol established by the Service. We included processes that are (traditionally in our clinical practice) under inpatient study (iron deficiency anemia, constitutional symptoms, peripheral lymphadenopathy, masses of different locations, fever of unknown origin (FUO) and bone metastases of unknown primary). We evaluated the impact of this intervention on the Service average length of stay comparatively on the hospitalization data for the past two years.

Results: In the last two years we had 69 cases of iron deficiency anemia (AS 9.9), 159 constitutional syndromes (AS 11.5), 12 peripheral lymph nodes (AS 10.8), 69 multiple hepatic lesions (AS 9.5), 56 masses of different locations (AS 10.4), 51 FUO (AS 9.9), and 7 bone metastases of unknown primary (AS 6.6). Compared with the eight months to monitor the HROC, and estimating the number of cases that would have entered this period, we found an important impact on inpatient days. For processes, we have avoided 118.1 days of hospitalization in iron deficiency anemia, 115 days in constitutional syndromes, 75.6 days in peripheral lymph nodes, 47.5 days in multiple hepatic lesions, 39.6 days in FUO, 62.4 days in mass of different locations and 6.6 days in bone metastases of unknown primary.

Discussion: Although the information collected a limited period in time, it is expected that the operation of the QHR causes a significant drop in the average length of stay of the Internal Medicine Department.

Conclusions: Process management for HROC has been an important impact on the average length of stay of service. The processes that have been most affected are iron deficiency anemia and constitutional syndrome. Since the operation of the HROC is still incipient, and would require a further economic study, the data suggest that this formula for frequent process management is an effective and advantageous method to optimize existing resources.

Table 1 (V-258). Average stay in the past two years

Bone metastases	6.6
Masses	10.4
FUO	9.9
Hepatic lesions	9.5
Perypheral lymphadenopaty	10.8
Constitutional syndrome	11.5
Iron deficiency anemia	9.9

Table 2 (V-258). Estimated average length stay of the cases seen in HCOR if they had admitted

Bone metastases	6.6
Masses	62.4
FUO	39.6
Hepatic lesions	47.5
Perypheral lymphadenopaty	75.6
Constitutional syndrome	115
Iron deficiency anemia	188.1

V-259
NUTRITIONAL STATE INFLUENCE IN HOSPITAL ADMITTED PATIENTS DIAGNOSED WITH PNEUMONIA

N. Gago[1], G. Llerena[1], A. Pellicer[1], V. Granell[2], F. González[1], K. Antelo[1], J. Monzo[1], F. Pedro[1]

[1]Department of Internal Medicine, [2]Department of Nutrition. Hospital General Universitario de Valencia. Valencia, Spain.

Objectives: Analyze nutritional features in patients admitted to the Internal Medicine Ward with the diagnosis of respiratory infection, and the impact of their nutritional status in their follow up and prognosis.

Material and method: Prospective, observational study of all patients admitted to the Internal Medicine Ward of the University General Hospital of Valencia from November 2011 and April 2012 with the diagnosis of low respiratory tract infection. A hundred and eleven patients were analyzed, of whom nutritional assessment was only provided to the ones over 75 years of age (78 patients, 70.2%). Demographic, background, clinical, radiological and biological findings, functional and severity scales, therapy and progress data were collected. Referring to the nutritional analysis (which was performed by the hospital nutritionist), a nutritional diagnosis was established according to the biochemical nutritional parameters collected and the anthropometric study.

Results: Of the 111 patients studied, 56.8% were women and the mean age was 83.55 years, with a mean Barthel index at admission of 30.97 (median 10) and a median Charlson index of 7. Almost half of the patients had been admitted over 2 days during the last year (45.9%) and the 17.1% had received cures by healthcare professional at home on the same period. Frequent visits to the emergency department were observed (64.9%). From all respiratory tract infections, 54.1% were health-care associated pneumonia (HCAP), 12.6% hospital-acquired pneumonia (HAP) and 33.3% community-acquired pneumonia (CAP). Average length of stay (ALOS) was 13.98 days (median 10) and 27% died during hospitalization. Some type of malnutrition was present in 82.8% of patients (37.9% protein, 9.2% calorie and 35.6% protein-calorie), being moderate or severe in 69.4% of cases. Deglutition disorder was find in 47.7% of patients at admission and 3.7% carried a nasogastric tube, although these were not related to a worse nutritional state. A more severe malnutrition status was observed in patients coming from a nursing home (36%, expected 32.1%) with no statistical significance ($p = 0.081$) and in the ones who had had a previous pneumonia (32.7% compared to expected 28.2%, $p = 0.078$). Non-significant difference was found between functional scales (Charlson, Barthel and Performance status) and nutritional state, although there is a trend towards a worse result in Barthel index for the ones with severe malnutrition. A worse nutritional state stands out in patients with criteria for HCAP (62% compared with 56% expected), as well as in those with severe pneumonia (CURB-65 > 3) in whom 35% appears with severe malnutrition, both results with $p = 0.006$. A major trend towards infectious complications in malnourished patients is observed, but with no statistical significance. ALOS in those patients with worse nutritional state (severe malnutrition) was 22.89 days compared to 13.19 days in mild or moderate malnutrition ($p = 0.039$), and there is a higher mortality in moderate-severe malnourished patients (29% compared to 24.1% expected, $p = 0.007$).

Conclusions: Respiratory tract infections are the first cause of admission at the Internal Medicine Ward. It is a pathology with a high morbimortality that affects the elderly and those with important comorbidities. More than half of these cases are associated with healthcare. In patients admitted with pneumonia, the nutritional state declining influences negatively on mortality and ALOS and it also correlates with a greater severity (CURB-65) and a trend towards infectious complications. All of this leads to a difficulty on the management and therapy, and probably on increasing costs. It would be advisable to set up measurements for

an earlier diagnosis of the earlier stages of malnutrition in risk population, to start strategies for its control.

V-260
TREATMENT AND DEVELOPMENT OF BRADYARRHYTHMIAS IN STEMI IN A PRIMARY ANGIOPLASTY PROGRAM

E. Cambronero Cortinas, M. Fernández Anguita, A. Goméz Pérez, M. Corbí Pascual, J. Navarro Cuartero, C. Llanos Guerrero, F. Salmerón, D. Prieto Mateos

Department of Cardiology. Hospital General de Albacete. Albacete, Spain.

Objectives: Acute myocardial infarction with ST elevation (STEMI) can be complicated by bradyarrhythmias such as atrioventricular block (AVB) completed. The development and management of bradyarrhythmias in a program of primary percutaneous coronary intervention (PCI) are poorly defined. PURPOSE: The aim is to investigate the characteristics and outcomes of patients (P) admitted with a STEMI complicated with complete AV block, advanced or extreme bradycardia in a hospital with primary PCI program.

Material and method: Are realized a prospectively analysis of 37 consecutive P with STEMI and heart rhythm disturbances undergoing primary angioplasty or rescue PCI from June 2008 and June 2011. Analyzing baseline variables, the therapeutic approach against bradyarrhythmia (drug treatment, need for temporary pacemaker insertion and final pacemaker), the use of beta blockers (BB) at discharge and the presence of hospital adverse cardiovascular events, defined as recurrent ischemia, revascularization and stroke and cardiovascular death during admission and follow-up.

Results: Mean age was 68 ± 13.38 years. 7.4% were women, 21.9% were active smokers, 11.2% had previous ischemic, 55.6% were hypertensive, 25.9% had dyslipidemia and 14.8% were nephropathy. 14.8% of patients were on prior treatment with beta blockers. The incidence of heart rhythm disturbances was the atrioventricular block (AVB) completed (n = 27), advanced AVB (n = 4) or extreme bradycardia (n = 5). The main artery of AMI was the right coronary artery (63%). In 70% of patients underwent complete revascularization. With regard to treatment of bradyarrhythmia atropine was used in 63% of patients and dopamine in 8%. It took the introduction of a transitional MP at 7.4% of cases and a final MP at 5.4%. During hospitalization, 25.9% of these patients had cardiovascular complications and hospital mortality was 11.1%. The use of beta blockers at discharge was 52%.

Conclusions: The effective primary PCI is associated with a rapid rate recovery in patients with STEMI complicated by severe bradyarrhythmias. The need for temporary or permanent pacemaker was very low in this population.

V-261
PROGNOSTIC IMPLICATIONS OF DIASTOLIC DYSFUNCTION IN PATIENTS WITH MYOCARDIAL INFARCTION WITH ST ELEVATION

E. Cambronero Cortinas, M. Corbi Pascual, J. Navarro Cuartero, A. Tercero Martínez, J. Jiménez Mazúecos, I. López Neyra, J. Córdoba Soriano, F. Salmerón Martínez

Department of Cardiology. Hospital General de Albacete. Albacete, Spain.

Objectives: The aim is to investigate the prognostic value of patients (p) admitted with a STEMI according to their diastolic function, classified into four types of LV filling patterns: Normal (1), impaired relaxation (2), "pseudonormalization" (3), and restrictive (4).

Material and method: Are realized a prospectively analysis of 169 p with myocardial infarction with ST elevation (STEMI) undergoing primary angioplasty from June 2008 to June 2011. Analyzing the incidence of cardiovascular events defined as death, recurrent ischemia, revascularization and stroke during admission and follow-up.

Results: 23% are women, 21.9% were active smokers, 11.2% with previous history of CAD, 65.7% hypertensive, 17.8% obese and 9.5% were nephropathy. The mean age of patients was 69 ± 12.5 years. Based on the filling pattern: 40.8% showed pattern (1), 28.3% pattern (2), 22% pattern (3) and 9.7% pattern (4). Baseline characteristics were similar in all groups. There were no significant differences in symptom onset-to-balloon time or door-to-balloon time. Restrictive pattern was associated with severe left ventricular dysfunction (0%, 5.4%, 14.9%, 21.4%, p = 0.014) and cardiogenic shock (0%, 4.2%, 2.2%, 7.5%, respectively, p = 0.0001). During hospitalization had more cardiovascular events (0%, 18.9%, 6.3%, 33.3%, p = 0.004) and continued to rise during follow-up (10.7%, 13.5%, 4.2%, 46.7%, p = 0.0001). Restrictive filling was associated with total mortality (0%, 5.4%, 0%, 13.3%, p = 0.0001).

Conclusions: The presence of abnormal diastolic function has a worse prognosis both during hospitalization and follow-up of patients with STEMI, particularly in restrictive filling patterns.

V-262
INFLUENCE OF RESIDUAL LEFT VENTRICULAR FUNCTION IN A RESIDUAL PRIMARY ANGIOPLASTY PROGRAM

E. Cambronero Cortinas, M. Corbi Pascual, J. Jiménez Mazúecos, I. López Neyra, V. Hidalgo Olivares, C. Llanos Guerrero, M. Fernández Anguita, D. Prieto Mateos

Department of Cardiology. Hospital General de Albacete. Albacete, Spain.

Objectives: Numerous studies have found that severe ventricular dysfunction during acute myocardial infarction confers a poor prognosis. Objectives: the aim is to investigate the prognostic value in patients admitted with a ST elevation (STEMI) according to their left ventricular dysfunction (LVEF), classified into two types of patterns: severe or not.

Material and method: Are realized a prospectively analysis 312 consecutive patients with STEMI undergoing primary angioplasty (PA) or rescue from June 2007 to June 2010 at the University Hospital Center. Analyzing the incidence of mortality and cardiovascular events defined as death, recurrent ischemia, revascularization and stroke during hospitalization and follow-up. Analysis is performed using SPSS 15.

Results: 8.5% of patients had severely depressed LVEF. 82.1% were male, 42.9% had dyslipidemia, 46.4% had hypertension, 35.7% were diabetic. All baseline characteristics were similar in both groups. There were no significant differences in the type of revascularization treatment employed. Complete revascularization was in 70.4% of patients, similar use of drug-coated stents and antiplatelet agents. During hospitalization they had more cardiovascular events (29.8% vs 14.8, p = 0.048) and they were associated with worse stage of the Killip classification (state 4: 39.3% vs 4%, p = 0.001). In addition, this group of P have a five times higher total mortality (22.2% vs 4.3%, p = 0.001), both during hospitalization (17.5% vs 10, p = 0.002), and follow-up (10.7% vs 1.2%, p = 0.001). We could make follow up with a median of 556 days. A After three years, patients with severe ventricular dysfunction had a survival 40% vs 92% of patients with higher LVEF (long rank: 5.912, p = 0.015).

Conclusions: Patients with severe ventricular dysfunction have a worse prognosis, with more complications and mortality, regardless of the therapeutic strategy chosen.

V-263
DIAGNOSIS OF UNINTENTIONAL WEIGHT LOSS: COMPARISON OF A QUICK DIAGNOSIS UNIT AND CONVENTIONAL HOSPITALIZATION

J. Pericás, P. Moreno, A. Jordán, A. López Soto, X. Bosch

Department of Internal Medicine. Hospital Clínic. Barcelona, Spain.

Objectives: We investigated the differences in the diagnosis of unintentional weight loss (UWL) between a Quick Diagnosis Unit (QDU) and conventional hospitalization (CH) in the Internal Medicine Department (IMD) of our institution.

Material and method: Analysis of a prospectively collected database of patients evaluated for UWL in QDU and CH from 1st January 2002 to 31st December 2011. One-hundred patients, 50 in each group (QDU and CH) were included. Only patients who concluded the study in one of these units were included. Epidemiological and clinical data, as well as diagnosis-related procedures were collected. Times to diagnosis (TTD) as well as delay in testing (DIT) were collected. Statistical analysis comparing both groups was performed using SAS 9.1. We used chi-square test for categorical variables and t-test for quantitative variables. We applied the Mann-Whitney test when samples did not accomplish normality.

Results: Mean age was 68.64 years (range: 18.5-84.5). Mean age in CH group was 10 years higher (95%CI: 3.63-15.97). CH patients were mainly referred from the emergency department (ED) (66%), while QDU patients were referred from ED (48%) and primary care practitioners (44%). Overall, for both QDU and CH, most common diagnoses were: solid neoplasm (22%), metabolic disorder and chronic liver disease (19%), psychiatric disorder (15%) and functional abnormalities (e.g., achalasia, irritable bowel syndrome) (13%), with no significant differences between the two groups. Overall, for both QDU and CH, mean time to diagnosis (TTD) was 22.92 days. A diagnosis was achieved in 98% of QDU patients and 100% of CH patients. Mean TTD was 10 days longer in the QDU group (95%CI: 2.2-17.8). General blood tests, chest X-ray and tumor markers were performed in 100%, 26% and 100% patients in the QDU group and in 100%, 98% and 70% patients in the CH group, respectively. No nuclear medicine imaging tests were ordered for QDU patients, while 10 were ordered for CH patients. Significantly fewer complementary exams were performed in QDU than in CH in order to achieve a diagnosis (1.08 in QDU and 2.70 in CH; $p < 0.001$). Regarding complementary exams, significant differences were found in the DIT for CT scans (23.3 days in QDU and 4.8 in CH, respectively; $p < 0.001$) and ultrasonography (6.5 days in QDU and 3.0 in CH, respectively; $p = 0.008$) between the two groups. No differences were found in the DIT for MRI, colonoscopy, gastroscopy, other endoscopic procedures, biopsy/needle-aspiration and bone marrow aspiration.

Discussion: Results from our study reveals that TTD was shorter in hospitalized patients, which is mainly explained by DIT, implying that, in some cases, patients had to be hospitalized because of a worsening clinical situation (data not shown here). While a diagnosis was achieved in almost 100% of patients in both QDU and CH, QDU patients required fewer explorations to achieve it.

Conclusions: QDUs are a useful alternative to CH for the study and diagnosis of UWL, with potential economic implications. However, there is the need to explore ways to shorten the time elapsed between ordering and performing complementary exams in QDU. Further studies comparing both services are warranted.

V-264
ROLE OF MICROARN IN ETHANOL-INDUCED MONOCYTE/ MACROPHAGE ACTIVATION

M. Fernández Regueras[1], J. García Hernández[2], J. Almeida Parra[3], J. González Valero[2], I. Pastor Encinas[1], A. Orfao[2], J. Laso Guzmán[1], M. Marcos Martín[1]

[1]Unit of Alcoholism. Department of Internal Medicine. Hospital Universitario de Salamanca. Hospital Clínico-IBSAL. Salamanca, Spain. [2]Instituto de Estudios de Salud de Castilla y León (IESCyL), Spain. [3]Cytometry General Service. Department of Medicine. Centro de Investigación del Cáncer (IBMCC-CSIC/USAL), Universidad de Salamanca. Salamanca, Spain.

Objectives: Excessive and chronic alcohol intake causes monocyte/macrophage activation, which relates to ethanol-induced damage to several organs and tissues. This project is aimed to delineate the microRNA expression profile in peripheral blood monocytes from alcoholic patients compared with control subjects. Thus we will be able to analyze their involvement in ethanol-induced pro-inflammatory response.

Material and method: Peripheral blood samples were obtained from 20 alcoholic patients with excessive daily ethanol intake (over 60-100 g/day) and from 20 age and sex-matched control subjects. Monocytes were sorted in order to obtain CD14+ and CD16+ cells. MicroRNA profile of CD14+ cells was identified by microarray analysis of 11 cases and 4 controls (mirCURY LNA microRNA array system).

Results: Approximately 9 microRNAs were significantly down-regulated in the alcoholic group when compared with control subjects (such as mir-489) and 7 microRNAs were significantly up-regulated (e.g., miR-26-a-2-3p).

Discussion: MicroRNAs are small noncoding oligonucleotides with an important role in posttranscriptional regulation of genetic expression. Several studies show that microRNAs play important roles in multiple biological processes, such as cell proliferation and immune response. Our data suggest that certain microRNAs are up-regulated in alcoholic patients, and this fact could be related to ethanol-induced alteration of immune response. These data must be confirmed by means of quantitative PCR.

Conclusions: Chronic alcohol intake induces a specific microRNA profile expression that could contribute to explain ethanol-induced alterations of the immune response. Acknowledgements: This work was supported by Grants GRS531/A/10 from Castilla-León Regional Government and PI10/01692 from Spanish Ministry of Science and Innovation and European Regional Development Fund "Una manera de hacer Europa".

V-265
XANTHOGRANULOMATOUS PYELONEPHRITIS. SIX CASES OF AN UNCOMMON ENTITY

J. Oliva Navarro, F. Rodríguez Pérez-Reverte, J. Martínez Bordonado, A. Laso Ortiz, A. Garre García, M. Molina Boix

Department of Internal Medicine. Hospital Universitario Virgen de la Arrixaca. El Palmar (Murcia), Spain.

Objectives: Xanthogranulomatous pyelonephritis is a rare entity that could mimic renal mass. The manifestation usually consists in a constitutional syndrome, diagnostic evaluation done by Internal Medicine.

Material and method: We show six cases of xanthogranulomatous pyelonephritis diagnosed in our Hospital during the last 20 years (1992-2012). They are six women with ages between 62 and 77 years old that were admitted in our service for constitutional syndrome.

Results: All of patients admitted to study presented recurrent urinary tract infections for years and in three cases had expulsive

urinary calculi/lithiasis. Main symptoms were asthenia, anorexia, weight loss and urinary tract infection symptoms. Urine cultures were positives for Proteus (3), Escherichia Coli (2) and only one case of sterile bacteriuria. In all cases we found anemia (hemoglobin between 6 and 8 g/dl). PCR (reactive protein C) was elevated beyond 100 in all of the cases. Image studies were performed, ultrasound and TC, observing coral shaped calculi with pyelocalicial dilatation and parenchyma destruction with patchy hypo density areas. In five of the women there was unilateral affectation and only in one it was bilateral. The six patients required nephrectomy and in the histology it was observed substitution of the healthy parenchyma for granulomas with full of lipid macrophages. After surgery clinical and analytic features were normalized.

Discussion: Xanthogranulomatous pyelonephritis is a rare entity that can mimic renal tumor. Clinical and analytical features are insidious, with a typical constitutional syndrome and some radiological findings, among them, lithiasis and renal parenchyma destruction. Because of all this, it is a diagnosis that used to be reached by an Internal Medicine specialist.

V-266
DIAGNOSIS OF CANCER AND DEATH IN INTERNAL MEDICINE (2003-2012). NEED FOR KNOWLEDGE IN PALLIATIVE CARE

I. González Fernández, M. Fraile Villarejo, S. Márquez Batalla, A. Plata Izquierdo, J. Miramontes González, M. Pérez García, J. Martín Oterino, A. García Mingo

Department of Internal Medicine. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca, Spain.

Objectives: To analyze the characteristics of patients diagnosed with neoplastic disease and died during the study in Internal Medicine Service I of Salamanca during the years (2003-2012).

Material and method: We performed a retrospective observational study by reviewing the medical records of these patients checking the following information: age, sex, history with cancer, cancer diagnosis, presence of metastases at diagnosis, associated paraneoplastic syndrome and cause of death.

Results: 48 patients were diagnosed with cancer and died in income during the years of 2003-2012. Gender distribution was: males: 62.5%, females: 37.5%. The mean age of patients was 78. 35% of these patients had other history of cancer. The average number of days of hospitalization was 11 days with a range from 1 to 60 days. Diagnosed tumors showed the follow distribution (table). At the time of diagnosis 79.16% of patients had simple metastases, multiple metastases in 18.75%. 12.5% of patients showed at diagnosis paraneoplastic syndrome, mainly tumoral hypercalcemia and venous thromboembolism. The cause of death were multi organ failure caused by the tumor (79.1%), nosocomial infection (12.5%) and other causes (8%).

Discussion: Neoplasms were diagnosed in our analysis mostly in males. The most common tumors were in lung, stomach and pancreas. Most of them showed metastases at diagnosis and cause of death was multiple organ failure secondary to neoplastic disease.

Table 1 (V-266)

Lung cancer	21%
Stomach cancer	19%
Pancreatic cancer	13%
Bladder cancer	10%
Tumor of unknown origin	8%
Breast cancer	6%
Others	23%

Conclusions: In an internal medicine service are often the diagnosis of neoplastic disease and a considerable number of patients die during the study because of the tumor itself. We consider important knowledge in palliative care internist for the symptomatic approach of these end-stage cancer patients.

V-267
PROGNOSTIC SIGNIFICANCE OF THE INCIDENCE OF THE PHENOMENON OF "NO REFLOW" IN PRIMARY ANGIOPLASTY

E. Cambronero Cortinas, J. Jiménez Mazúecos, J. Navarro Cuartero, M. Corbí Pascual, D. Prieto Mateos, A. Gutiérrez Díez, C. Llanos Guerrero, I. López Neyra

Department of Cardiology. Hospital General de Albacete. Albacete, Spain.

Objectives: Inappropriate reperfusion therapy has a worse prognosis the patients (P) with myocardial infarction with ST elevation (STEMI). The patients with "no reflow" has a worse prognosis. Objectives: the aim is to determine the prognostic value of patient (P) admitted with a STEMI according to their levels of reperfusion and we valued the incidence and impact of "no reflow". It discusses whether the incidence of this phenomenon worsens the prognosis of patients. As the number of cardiovascular complications and mortality, both during hospitalization and follow-up.

Material and method: Are realized a prospectively analysis of 410 P with STEMI undergoing primary angioplasty (PA) or rescue from June 2007 to June 2011 in a hospital with a catheterization alert for 24 hours. Are performed a prospective cohort study established two groups, one composed of patients with normal flow and the other formed by the phenomenon of "no reflow". Analyzing the incidence of cardiovascular complications defined as death, recurrent ischemia and stroke, both during admission and follow-up.

Results: The mean age of patients with "no reflow" was 69.2 ± 12.2 years. 36.4% are women, 72.7% were hypertensive, 36.4% had dyslipidemia, nephropathy in 9.1% and 9.1% ischemic history. Baseline characteristics were similar in both groups. The total number of complications was significantly higher in patients with this complication (27% vs 63.6%), both during hospitalization 17.6% vs 54.5% (p = 0.029), as follow-up (16, 3% vs 54.4%, p = 0.016), in turn, also showed a higher mortality (8.4% vs 45.5%, p = 0.0001).

Conclusions: The phenomenon of "no reflow" increases the number of cardiovascular complications. Therefore, it must implement all current strategies to reduce its incidence.

V-268
PROGNOSTIC IMPLICATIONS OF THE DELAY BY PRIMARY ANGIOPLASTY

E. Cambronero Cortinas, J. Jiménez Mazúecos, A. Gutiérrez Díez, M. Corbi Pascual, A. Gómez Pérez, R. Fuentes Manso, M. Barrionuevo Sánchez, J. Navarro Cuartero

Department of Cardiology. Complejo Hospitalario Universitario de Albacete. Albacete, Spain.

Objectives: Currently the best treatment of acute myocardial infarction (AMI) is the primary percutaneous coronary intervention (PCI) provided that certain conditions, among which the time gate ball (TPUBA) is less than 90 minutes the time interval between when the patient has contact with the emergency until it does, open the vessel responsible for AMI. Objectives: the aim is to

analyze the prognostic value of patients (P) admitted with AMI with ST elevation according to their balloon gate time (TPUBA).

Material and method: Are realized a prospectively analysis 312 patients P with STEMI undergoing primary angioplasty from June 2007 and June 2010. Are established two groups, one consisting of patients with TPUBA less than 64 minutes over 64 minutes. Analyzing the mortality rate during admission and follow-up.

Results: The present TPUBA than 64 minutes. The mean age was of 65.09 ± 13.92 years. 79.2% were male, 25.6% were current smokers, 23.1% were diabetic, 58.5% and 40.1% DL. All baseline characteristics were similar, except the presence of renal insufficiency (11.5% vs 3.5%, p = 0.031). There were no significant differences in the type of treatment, with complete revascularization in 60% of P, similar use of drug-coated stents and conventional. The P with longer had a total mortality up to five times the earliest strategies (10.4% vs 2.4%, p = 0.023), both during hospitalization (5.7% vs 0.4%, p = 0.05) as in monitoring (4.3% vs 2%, p = 0.05).

Conclusions: Patients with longer balloon gate time were higher mortality than patients with early strategies. So, we must join efforts to reduce them, as the "time attack".

V-269
RENAL FAILURE IS IMPORTANT IN THE PROGNOSIS OF PATIENTS WITH ACUTE CORONARY SYNDROME IN A PRIMARY ANGIOPLASTY PROGRAM

E. Cambronero Cortinas[1], J. Jiménez Mazúecos[1], A. Gutiérrez Díez[1], M. Corbi Pascual[1], D. Prieto Mateos[1], C. Olmeda Brull[2], J. Córdoba Soriano[1], I. López Neyra[1]

[1]Department of Cardiology, [2]Department of Internal Medicine. Hospital General de Albacete. Albacete, Spain.

Objectives: The nephropathy patients (P) perform poorly after an acute coronary syndrome. By presenting a greater number of comorbidities and more advanced coronary disease. Purpose: the aim is to investigate the prognostic value of nephropathy patients (CKD) admitted with a myocardial infarction with ST elevation (STEMI). Assessing whether they have higher mortality.

Material and method: Are realized a prospectively analysis of 412 P with STEMI undergoing primary angioplasty (PA) between June 2007 and July 2011 in our Hospital. Are performed a prospective cohort study established two subgroups formed by a P with CKD, compared with P without this condition. Analyzing the incidence of complications during hospitalization and follow-up defined by total mortality or the occurrence of any cardiovascular event (EvCv) as a composite of death, reinfarction, recurrent ischemia and need for new percutaneous coronary intervention.

Results: 8.8% were CKD, with a mean age of 68 ± 15 years. 18% were women, 57% hypertensive, 22.1% were active smokers. All baseline characteristics were similar to those of non nephropathy, except history of hypertension (54.7% vs 83.3%, p = 0.001) and peripheral arterial disease (4.3% vs 25%, p = 0.0001.) In their hospital course were not significant differences in the type of treatment used, except they were increased need for new PCI (5.3% vs 0.5%, p = 0.037). This P were a higher incidence of total complications (25.2% vs 58.8 5, p = 0.0001), during hospitalization (15.4% vs 52.9%, p = 0.0001) and during the follow-up and they were higher mortality (8.4% VS20, 6%, p = 0.02). CKD was an independent predictor of complications (OR: 3.3, p = 0.038, CI: 1,6-9, 35), set for possible confounding variables.

Conclusions: We found that the presence of CKD, is a predictor of adverse cardiovascular events. Therefore, it must make a close monitoring and optimal therapeutic control of these patients.

V-270
PET-CT FOR THE STUDY OF FUO AND ANOREXIA-CACHEXIA SYNDROME

E. Pérez Macho[1], D. Filella Agulló[1], J. de Llobet Zubiaga[2], J. Casademont Pou[1]

[1]Department of Internal Medicine, [2]Department of Rheumatology. Hospital de la Santa Creu i Sant Pau. Barcelona, Spain.

Objectives: To evaluate the utility of positron emission tomography-scan (PET-CT) in patients hospitalized in an internal medicine department for evaluation of fever of unknown origin (FUO) and persistent anorexia-cachexia syndrome after the usual diagnostic work-up has been inconclusive.

Material and method: A review of all PET-CT requested in an internal medicine department of a tertiary hospital over a period of two years was undertaken. We selected patients with fever or anorexia-cachexia syndrome in whom additional studies had been inconclusive: analytical (including autoimmunity, serology, tumor markers), imaging (computed tomography-CT-), microbiological (blood and body fluids cultures,) and cytological studies. We evaluated the results of the PET-CT according to the pre-test clinical suspicion and laboratory tests carried out previously. In the cases of study of FUO, we defined three subgroups: persistent fever after appropriate treatment of an previous infectious process, positive blood cultures without evidence of a primary focus, and fever suspected to be secondary to an haematologic malignant process. In the study of anorexia-cachexia syndrome we defined 3 subgroups: lesions in CT that might suggest a neoplastic process, symptoms suggestive of a paraneoplastic syndrome and no findings in CT studies, and clinical and analytical findings suggesting an haematological disease.

Results: We revised a total of 116 PET-CT: 41 patients met study criteria of FUO (16 patients) or anorexia-cachexia syndrome (25 patients). In the group of FUO, PET-CT was requested because of persistent fever after appropriate treatment of a previous infectious process in 9 cases. PET showed alternative foci in 5 cases, the rest showing findings already known or no abnormalities. In 3 patients, PET was performed after detection of positive blood cultures without clear focus. PET was useful in a patient with Staphylococcus aureus bacteremia. In 4 patients, PET-CT was ordered because of fever and a blood count suggestive of a haematological process. PET did not provide further diagnostic information to conventional studies. In the group with anorexia-cachexia syndrome, 12 patients presented with nonspecific lesions in previous CT (3 in lung, 5 in gastrointestinal tract, 1 in spleen, 1 in spinal cord, 1 in lymph nodes, and 1 in parotida). PET was useful to rule out cancer in 6 patients with nonspecific findings and in 1 case of high suspicion of recurrence on surgical site with negative CT scan. In the remaining 5 patients, PET did not provide further information. Seven patients presented with anorexia-cachexia and the suspicious of a paraneoplastic syndrome (2 with thrombotic events, 3 with inflammatory myopathy, 1 with hypercalcemia and 1 with refractory hypertension). PET only detected a cancer in a patient with a normal CT. We identified 6 patients with anorexia-cachexia syndrome and data suggestive of an haemathological neoplastic disease with normal CT (3 patients with pleuropericardial effusion, 1 with pleural effusion, 1 with bicytopenia, 1 with digestive symptoms). PET didn't provide information over previous CT.

Discussion: In patients with FUO, PET was useful in the subgroup of persistent fever and fever with bacteremia (total 6/12). However, in the subgroup of suspected haematologic malignancy without findings on CT, PET-CT provided no further information (0/4). In the group of patients with anorexia-cachexia syndrome, PET was useful to rule out malignancy in lesions detected by CT of doubtful pathological significance (7/12). In the group of patients with suspected paraneoplastic syndromes, cancer was detected only when other options were ruled-out previously (1/7). When there

were no diagnostic lesions on CT, PET did not provide added information.

Conclusions: The PET-CT proved to be useful in patients with persistent fever and lesions of uncertain pathological significance by CT. It seems that if there is a good pre-test diagnostic hypothesis, the diagnostic yield is higher. We conclude that is very important to have a previous good clinical assessment (history and physical examination) to obtain the best performance with the application of PET-CT.

V-271
DOES WOMEN ALSO HAVE A WORSE PROGNOSIS IN A PRIMARY ANGIOPLASTY PROGRAM?

E. Cambronero Cortinas, M. Corbi Pascual, J. Jiménez Mazúecos, J. Navarro Cuartero, G. Gallego Sánchez, M. Fernández Anguita, M. Fernández Anguita, I. López Neyra

Department of Cardiology. Hospital General de Albacete. Albacete, Spain.

Objectives: Women present a worse evolution than men. These differences have been explained by the presence of atypical symptoms, comorbidities such as diabetes, hypertension and an older age. Objectives: our aim was to determine the prognostic value according to the sex of patients that have suffered a stroke (P) admitted with a Acute Myocardial Infarction with ST elevation (STEMI) studying if women present a biggest rate of mortality and complication, during the time in hospital as well as its following-up.

Material and method: We analyzed 312 patients 312 P with STEMI undergoing primary angioplasty (PA) or rescue from June 2007 to June 2010 in Albacete's hospital. We performed a prospective cohort study establishing two groups, one composed of men and the other formed by women. We evaluate the incidence of cardiovascular complications defined as death, recurrent ischemia and stroke, both during admission and the following-up.

Results: 17% were women. The average age of women was 70.2 ± 12.2 years. Baseline characteristics were similar to those of men, except for the frequency of hypertension 73.2% vs 53.6% (p = 0.007) and more prone to DM 30.4% vs 20.6% (p = 0.06). There were no significant differences in symptom-door times, gate ball, or the type of treatment done. However, women showed the highest number of total cardiovascular complications, 40% vs 23.8% (p = 0.016), during the check in and the following-up, being it during hospitalization of 27.3% vs 16% (p = 0.048), in the following-up done with an average of 529.50 days 12.84% vs 4.75%, (p = 0.01).

Conclusions: Women show a higher number of complications. So, they require an appropriate monitoring and optimal treatments that are performed to this collective.

V-273
TEMPORAL DISTRIBUTION OF EMERGENCIES FOR INTRACRANIAL HEMORRHAGE

A. Sobrao López[1], A. Melgarejo González[1], F. Sarabia Marco[1], B. Medina Tovar[1], J. Gómez Verdú[1], S. Valero Cifuentes[1], F. San Eustaquio Tudanca[2], J. Fernández Pardo[1]

[1]Department of Internal Medicine, [2]Department of Clinical Documentation. Hospital General Universitario Reina Sofía. Murcia, Spain.

Objectives: To determine the incidence and temporal distribution of emergency department (ED) admittances for intracranial hemorrhage (ICH) episodes in our hospital.

Material and method: Based on the computerized medical records of all assisted processes in the ED of our hospital for any cause during four consecutive years (from January 2008 to December 2011), and in preserving patients anonymity, we collected information on the age, sex, first-listed diagnosis (which was subsequently coded according to ICD-9 MC, using an application software developed by our Clinical Documentation Dept.), date and entry time of all patients attended. All these variables were imported into a database and, using the computer program SPSS® 15.0, we conducted a descriptive study and a statistical data analysis, with the objectives set out, for patients who presented ICH (including subarachnoid, intacerebral, extradural, subdural and other unspecified intracranial hemorrhages [ICD-9 MC codes 430 to 432]) as first-listed diagnosis.

Results: The total number of patients visiting our ED from all causes during the study period was 401678. The patients mean age (± standard deviation) was 43.7 ± 21.4 years and 50.3% were women. Among the total assisted 205 patients (0.05%) were primarily because of ICH. Of these, 106 (51.7%) were men, with a mean age of 69.9 ± 17.4 years and 99 (48.3%) were women with a mean age of 73.1 ± 15.9 years. Nearly a 75% patients assisted by ICH were over 65 years. Season with higher incidence of ICH was winter (from December to February) with a 32.2% (December and January were the months of highest incidence [12.7% per month]) and spring was the lowest (from March to May) with 21% (May was the lowest [6.3%]). Thursdays and Mondays were the days of greater demand for ICH (17.1% and 16.4% respectively), and Fridays with the lowest (11.7%). Most patients with ICH (46.5%) were attended during the morning (8h to 15h), with a peak between 10h and 13h (26.9%), and there was a lower incidence (14.8%) during the night (22h to 8h). The time span of lower attendance happened between 3am and 6 am with 1.5% of income for ICH.

Conclusions: We find important changes in the ED rate of admissions for ICH between different months along the year, days of the week and hours of the day. It is found a higher incidence in winter and during the morning period, as well as a lower incidence on Fridays.

V-274
VALUATION OF RENAL INSUFFICIENCY THROUGH MDRD-4 IN EMERGENCY SERVICE: IMPORTANT PREVALENCE OF OCCULT RENAL INSUFFICIENCY

P. de Santos Castro[1], A. Almaraz Gómez[2]

[1]Department of Emergency. Hospital Clínico Universitario de Valladolid. Valladolid, Spain. [2]Department of Preventive Medicine and Public Health. Facultad de Medicina. Valladolid, Spain.

Objectives: To know the prevalence and characteristics of patients with occult renal insufficiency (ORI) (glomerular filtration (GF) < 60 ml/min/1.73 m^2 with normal values of serum creatinine (SCr)).

Material and method: Observation, prospective study, determine SCr and MDRD-4 to predict GF in patients that we made a biochemistry.

Results: We studied 153 patients, 52.9% female, mean age 65.14 years old. We found renal insufficiency in 17.0% (26) patients using SCr, and 30.7% (47) using the MDRD-4. Therefore, the ORI is 13.7% (21). This group had a mean age of 78.48 years old (80.9% were > 70 years old), and 81.0% were female. In our sample, using the MDRD-4 in patients > 70 years old and women with SCr > 1 mg/dl had been only 1 (0.6%) case of ORI.

Discussion: We need a proper evaluation of renal function for management of urgent disease (need for diagnostic tests, doses of drugs...). To do this, we can't rely solely on SCr, but is useful to use equations to estimate the GF. Various guidelines recommend the use of the MDRD-4. We didn't find studies that evaluate ORI in emergency services, but our study had higher prevalence of ORI that others studies in ancient, HTA or DM patients.

Conclusions: We suggest to value renal function with equation to predict GF (MDRD-4) in patients > 70 years old and women with SCr > 1 mg/dl.

V-278
HYPONATREMIA AS THE PRESENTING MANIFESTATION OF EMPTY SELLA SYNDROME: TWO CASE REPORT

G. Buyukturan[1], N. Somak[1], B. Yildiz[1], R. Acar[1], T. Dogan[1], M. Cakar[1], R. Ocal[2], E. Arslan[1]

[1]Department of Internal Medicine, [2]Department of Intensive Care. Gülhane Military Medical Academy and Medical School. Ankara, Turkey.

Objectives: An empty sella refers to an enlarged sella turcica that is not entirely filled with pituitary tissue. Hyponatremia as the presenting manifestation of empty sella syndrome is rare. We describe here the cases of two elderly patients who were diagnosed as empty sella syndrome presented with hyponatremia. Case-1: A 77 years old woman was referred to the hospital because of hyponatremia. She had presented with nausea, vomiting, dizziness one week before admission. She has normovolemic hyponatremia (serum sodium: 118 mmol/l) with secondary adrenal insufficiency as shown by basal cortisol measurements and ACTH level. Other hypophysial hormone levels were within the normal reference ranges. Laboratory data were as follows: TSH: 0.21 mIU/ml, FT3: 1.22 pg/ml FT4: 0.39 ng/dl. Magnetic resonance imaging led to a diagnosis of empty sella. Case-2: A 81 years old woman patient came with complaints of fatigue and nausea. There was no history of postpartum hemorrhage responsible for postpartum hypopituitarism, and no history of drug therapy. There was no family history of endocrine or autoimmune disorders. She was admitted to hospital when hyponatremia (116 mEq/L) was found. Hyponatremia developed again 3 days after the withdrawal of hypertonic NaCl administration. Laboratory data were as follows: urea:16 mg/dl, creatinin:0.66 mg/dl, K: 3.63 mmol/L, cortisol:2.19 µg/dl, ACTH: 30.3 ng/ml, FT4: 0.65 ng/dl, TSH: 2.23 mIU/ml, FSH: 0.22 IU/L, GH: < 0.05 ng/ml, LH: 0.07 IU/ml, prolactin: 2.40 ng/ml. Magnetic resonance imaging (MRI) showed an equal intensity of both the sella turcica and the cerebrospinal fluid.

Results: After treatment with i.v. fluids and hydrocortisone, the patient's clinical condition and biochemical alterations improved, and normalized over time with oral cortisone acetate and L-thyroxine combination therapy.

Conclusions: Empty sella syndrome seems to be a frequently overlooked and rare cause of severe hyponatremia. Treatment with hydrocortisone is very effective. A high level of suspicion is the best way to recognize the underlying disorder.

V-279
GABRA1 AND GABRA6 POLYMORPHISMS AND ALCOHOLIC DEPENDENCE

S. Gómez Lesmes[1], I. Pastor Encinas[1], I. Novo Veleiro[1], M. Marcos Martín[1], C. Cieza Borrella[2], H. Llorente Cancho[1], R. González Sarmiento[3], J. Laso Guzmán[1]

[1]Department of Internal Medicine. Hospital Universitario de Salamanca. Instituto de Investigación Biomédica de Salamanca (IBSAL). Salamanca, Spain. [2]Department of Molecular Medicine. Department of Medicine. Universidad de Salamanca. Salamanca, Spain. [3]Institut of Molecular and Cellular Biology of the Cáncer (IBMCC). Universidad de Salamanca – CSIC. Salamanca, Spain.

Objectives: The aim of our study was to analyze the association of rs2279020 GABRA1 polymorphism and rs1992647 GABRA6 polymorphism with alcohol dependence.

Material and method: We conducted a case-control study including 300 alcoholic patients and 160 abstinent controls, all of them male. DSM-IV criteria were applied to classify alcoholic patients as dependent or abusers. GABRA1 IVS11+15 A > G (rs2279020) polymorphism and GABRA6 rs1992647 polymorphism were analyzed by means of allelic discrimination by real-time PCR using TaqMan® SNP genotyping assays. The relationship between these polymorphisms and the presence of alcohol dependence was assessed by the Chi-square test. SPSS statistical program v. 19.1 was used.

Results: Mean age of our total sample was 50.31 (SD = 15.46) years. Among alcoholic patients mean age was 52.23 (SD = 12.48) and mean age of non-alcoholic patients was 46.61 (SD = 19.52). Among alcoholics, 62% met alcohol dependence criteria and 38% had alcohol abuse. Genotype frequencies of GABRA1 rs2279020 polymorphism were as follows: 36% AA, 48.8% AG, 15.2% GG for alcoholics; 34.8% AA, 46.8%, AG, 18.4% GG for controls (p = 0.678). We did not find any significant difference when comparing alcohol dependent patients (AA 36.4%, AG + GG: 63.6%) with alcohol abusers (AA: 35.4%, AG+GG: 64.6%) (p = 0.860). Genotype frequencies of GABRA6 rs1992647 polymorphism were as follows: 41.2% TT, 38.3% TC, 14% CC for alcoholics; 40.5% TT, 41.9%, TC, 17.6% CC for controls (p = 0.469). No statistically significant differences were found either when comparing alcohol dependent patients (TT 46.6%, TC + CC: 53.41%) with alcohol abusers (TT: 43.8%, TC + CC: 56.3%) (p = 0.632).

Discussion: In our sample we have not found that the rs2279020 polymorphism of GABRA1 gene and rs1992647 polymorphism of GABRA6 are associated with alcohol abuse or dependence. Nonetheless, these associations are biologically plausible given the involvement of the GABAergic system in neuronal circuits involved in addiction and several authors have previously reported that rs2279020 polymorphism could contribute to the development of dependence to alcohol or other drugs of abuse, such as methamphetamine.

Conclusions: We have not shown an association between rs2279020 polymorphism of GABRA1 and rs1992647 of GABRA6 with alcohol dependence. Further studies are necessary to confirm or discard the involvement of these genes in alcohol dependence.

This work was supported by Grants GRS 203/A/08 from Castilla-León Regional Government and PI10/01692 from Spanish Ministry of Science and Innovation and European Regional Development Fund "Una manera de hacer Europa".

V-280
D-DIMER: A TEST CRITERIA USING

A. Chipepo, C. Andrade, C. Freitas, A. Ferreira, M. Ventura

Department of Medicine 2. Hospital Curry Cabral. Lisboa, Portugal.

Objectives: In this work, the authors propose to perform a retrospective study to evaluate the appropriateness of requests for laboratory quantification of D-dimers in Internal Medicine Service.

Material and method: We selected the medical files of patients admitted in that Service, for which it is required the quantification of D-dimer, over a period of two years (01/01/2010 - 31/12/2011). The authors then proceeded to check in clinical processes, the presence of the diagnosis of thromboembolism.

Results: After application of the method described above, it was found that of 3360 patients admitted in the period under evaluation, 128 (3.8%) were submitted to quantification of D-dimers. Of these, 91 tests (71.1%) were positive, whereas 18 (19.8%) were related to the presence of thromboembolism and 73 (80.2%) without any thromboembolic event associated.

Discussion: Looking at these results it appears that, although most of the tests prove positive, only one fifth of these results are

true positives. In contrast, the majority of positive results are false positives. Thus, it appears that in most cases, the assay of D-dimer, being positive, has led to a continued investigation unsuccessful for the detection of thromboembolic phenomena. These data suggest that the process of clinical research prior to requesting the D-dimer test should be more careful; should, as always, thoroughly explore the history and clinical observation of each patient, in its particular context.

V-282
CLINICAL USE OF BOSENTAN IN A MADRID HOSPITAL. UNIVERSITY HOSPITAL OF MOSTOLES, MADRID

P. González López, O. Álvarez de Toledo, V. Moreno Cuerda, J. Ruiz Galiana

Department of Internal Medicine. Hospital Universitario de Móstoles. Madrid, Spain.

Objectives: Bosentan is a dual antagonist of endothelin receptors used in the treatment of pulmonary hypertension and digital ulcers in systemic sclerosis. This study details the epidemiological characteristics of patients treated with this drug in a hospital in Madrid, its evolution and possible secondary complications presented.

Material and method: It has been performed a retrospective study of cases of patients treated with bosentan in the University Hospital of Mostoles collected by the department of pharmacology. The following fields were covered by the data analysis: age, sex, primary and secondary diagnosis, starting and ending date of bosentan therapy, clinical response, levels of liver enzymes an Hb before and after treatment, associated adverse events, concomitant drugs and echocardiograms done. In cases of pulmonary hypertension pretreatment catheterization values and results of walking test performed before and after treatment were collected.

Results: 17 cases were collected for this study. In 13 cases (76.4%) bosentan was introduced to treat digital ulcers: 2 cases associated with MCTD, 1 associated with Buerger, 2 associated with SLE, 5 to CREST syndrome and 2 to diffuse systemic sclerosis. The mean duration of treatment in these cases was 22.7 months, with only the withdrawal of the drug in one patient (7.69%) for non-response. In the remaining patients the drug was effective with disappearance of ulcers in the first 6 months of treatment. In five patients (38.4%) withdrawal of treatment was tested after 23.4 months on average, with no recurrence in any of the cases after 12 months of clinical follow up. In four cases (23.5%) treatment was introduced to treat systemic sclerosis with both digital ulcers and pulmonary hypertension. The mean duration of treatment in these patients was 29.5 months. All of them showed positive clinical response in digital ulcers. At the start of treatment mean pulmonary arterial pressure was 40.3mmHg. Three patients had NYHA functional class II and one NYHA functional class III. In the treatment follow up one of the patients (25%) progressed to functional class III-IV keeping the rest the same capacity. Two of the patients showed an elevation of liver enzymes, both in the first 6 months of treatment. One patient (5.88%) presented an increase of less than 3 times the normal values that did not require treatment modification. The other patient (5.88%) showed an increase of liver enzymes between 3 to 5 times the normal values that was solved by lowering treatment. Four patients (23.52%) had a drop greater than 1 g/dL in Hb levels in the first 12 months of treatment. In 3 of them concomitant iron deficiency were found and anemia was corrected after iron replacement. In one of the patients the anemia couldn't be justified by other reasons, it worsened with increasing doses of bosentan and resolved after dose reduction. There was no clear relationship between side effects and concomitant drug administration. One of the patients (5.88%) withdrew the drug after two months of treatment for gastrointestinal intolerance (diarrhea) and one (5.88%) had transient headache attributed to drug that did not require dose modification.

Conclusions: The treatment of digital ulcers with bosentan in our environment has presented positive clinical results. The incidence of side effects associated with the drug corresponds to what it is described in the literature.

V-283
ANALYSIS OF OPIOID USE IN DISCHARGED PATIENTS IN A PALLIATIVE CARE UNIT

E. Sifuentes Díaz, F. García Colchero, B. Ruiz Esteve, P. Martín Peral, M. Martín Zamorano, A. Mogollo Galván

Department of Internal Medicine. Hospital Universitario Puerta del Mar. Cádiz, Spain.

Objectives: To know the characteristics of the patients who were discharged on treatment with strong opiodes in our Palliative Care Unit. To analyze the kind and proportion of opioids that we used, reviewing their specific combination. To identify what adjuvant treatments we used for pain management.

Material and method: This is an observational, retrospective study. We analyze the clinical histories of all the patients admitted of our Unit who were on treatment with any opioid, regardless of the indication, between 2007 and 2011. It has been investigated epidemiological features of the patients, opioids that were used, as well as the adjuvant therapies needed to control cancer pain. We have used the IBM SPSS statistic 18 for data analysis.

Results: We have analyzed 237 admissions concerning to 189 patients, 112 (59.2%) were men. Mean age was 65.5 years (SD 12.7). Average hospital stay of 13 days (SD 10.6). A 66.9% of patients had previous comorbidities; all of them had a malignant tumour and were on treatment with opioids because of cancer pain. Gastrointestinal neoplasm was the most frequent in the 27.1% of patients, followed by respiratory (25%), genitourinary (17.4%), head and neck (16.1%), and breast cancer (7.2%). Most patients were admitted because of respiratory symptoms (29.2%), followed by chronic pain (25%) and gastrointestinal events (15.3%). Morphine was used in 35.2% of the patients, fentanile in 24.6%, buprenorphine in 9.7% and oxicodone in 8.9%. Combination of opioids was used only as a rescue therapy for breakthrough pain, when it was necessary. Adjuvant therapy was used in 35.4% of patients, being pregabaline the most used (21.2%), followed by gabapentine (5.1%).

Discussion: Morphine has been for a long time the strong opioid of choice for treating chronic cancer pain.. In the last years, it has been an increase in the use of other opioids that offer some benefits, such as easier posology, different routes of administration or specific indications although its price is higher than morphine. Currently, it exists a marked increase in inappropriate use and prescription of opioids that has become in a cause of social and public health concern and has involved a rise in healthcare costs and changes in treatments. Nowadays there is still a limited evidence to support their indication, however there is evidence that justifies the selection of a specific opioid in certain situations and indications. In this study we confirmed an acceptable management of chronic cancer pain with morphine, others opioids were employed in specific cases, or as an alternative to morphine.

Conclusions: 1. Morphine was the opioid most commonly used, followed by fentanile.2. The proportion of opioids used in our unit follows the pattern recommended by the guidelines of Palliatives Care Societies and scientific literature. 3. We have not used combination of opioids, except as rescue therapy for breakthrough pain. 4. Pregabaline was the alternative most used as adjuvant therapy.

V-284
ANALYSIS OF OXYCODONE USE IN PATIENTS DISCHARGED IN A PALLIATIVE CARE UNIT

E. Sifuentes Díaz, F. García Colchero, B. Ruiz Esteve, A. Fernández Rodríguez, F. Carmona Espinazo, M. Martín Zamorano, A. Mogollo Galván

Department of Internal Medicine. Hospital Universitario Puerta del Mar. Cádiz, Spain.

Objectives: To identify the characteristics of the patients who were discharged on treatment with strong opioids in our palliative care unit. To analyze in which cases were prescribed oxycodone and which were the indications that justified its use. To know if oxycodone was used in combination with adyuvant therapies.

Material and method: This is an observational, retrospective study. We have reviewed the clinical histories of all the patients admitted in our Unit who were on treatment with oxycodone, regardless of the indication, between 2007 and 2011. It has been investigated epidemiological features of the patients, chronic diseases and comorbidities, as well as if adjuvant therapies were needed to control cancer pain. We have used the IBM SPSS statistic 18 for data analysis.

Results: We have analyzed 237 admissions concerning to 189 patients, 112 (59.2%) were men. Mean age 65.5 years (SD 12.7). Average hospital stay of 13 days (SD 10.6). A 66.9% of patients had previous comorbidities; all of them had a malignant tumour and were on treatment with opioids because of cancer pain. Gastrointestinal neoplasm was the most frequent in the 27.1% of patients, followed by respiratory (25%), genitourinary (17.4%), head and neck (16.1%), and breast cancer (7.2%). Most patients were admitted because of respiratory symptoms (29.2%), followed by chronic pain (25%) and gastrointestinal events (15.3%). Morphine was used in 35.2% of the patients, fentanile in 24.6%, buprenorphine in 9.7% and oxicodone in 8.9%. Combination of opioids was used only as a rescue therapy for breakthrough pain, when it was necessary. Adjuvant therapy was used in 35.4% of patients, being pregabaline the most used (21.2%), followed by gabapentine (5.1%). Of the 28 cases in which oxycodone was used, 11 were for neuropathic pain (39.3%), 9 were due to toxicity of another opioid (32.1%), 4 for analgesic failure of another opioid (14.3%) and 4 as a rescue analgesic. Adjuvant therapy was used in 35.4% of patients, being pregabalin the most used (21.2%) followed by gabapentin (5.1%). The patients who were on treatment with oxycodone associated adjuvant in 75.9% of cases, even was necessary to combine two adjuvant in 20.7% of patients, and in these cases pregabalin was again the drug most used (41.4%).

Discussion: Major opioids are widely used by patients admitted in Palliative Care Units, normally to treat chronic pain, achieving an acceptable control of this symptom in a high percentage of patients. There is not enough scientific evidence to suggest the supremacy of one over another when considering to morphine as the "gold standard" opioid. However there is evidence that justifies the selection of a specific opioid in certain situations and indications. Oxycodone is a strong opioid used in both cancer and non-cancer pain; in fact it is also indicated for the management of postsurgical and neuropathic pains. It has proved to be a safe and effective alternative in patients unresponsive to other strong opioids. Oxycodone seems to have some advantages in management of severe and neuropathic pain, although clinical trials comparing to morphine don't show plain superiority of oxycodone. In this study we cannot confirm better results with oxycodone because mostly patients were also on treatment with adjuvant therapies.

Conclusions: Morphine was the opioid most commonly used, followed by fentanile. We used oxycodone mainly in cases of neuropathic pain and toxicity of other opioids, being less used in cases of failure of initial analgesia. In most cases we prescribed oxycodone, it was used in combination with adjuvant therapies.

V-285
ACUTE INTERMITTENT PORPHYRIA. A RARE DISEASE, BUT STILL IN OUR THOUGHTS

J. Nava, P. Guisado Vasco, G. Fraile Rodríguez, V. Gómez del Olmo, G. de Luna, J. Perales

Department of Internal Medicine. Hospital Universitario Ramón y Cajal. Madrid, Spain.

Objectives: Acute intermittent porphyria (AIP) is a hereditary autosomal dominant disease. It is caused by a defect in the enzyme uroporphobilinogen synthetase. Its defective function produces the accumulation of some toxic metabolic products (δ-aminolevulinic acid, uroporphyrin and copropophoryn). Although AIP is more prevalent in Northern European countries, its distribution is actually worldwide and affects every race. In southern Europe AIP is a minority disease, and the patients often have severe symptoms before the disease is diagnosed. To described clinical presentation and the porphyries role in the differential diagnosis of potentially severe and disabling pathologies.

Material and method: We made a retrospective study reviewing the diagnosis of patients studied in the internal medicine department of the university hospital Ramón y Cajal from 1979 till 2012. We found 3 patients, one female and two males, which had clinical symptoms and laboratory dates of compatible with AIP.

Results: The median age of diagnosis was 42 years. All cases had recurrent and intense episodes of abdominal pain associated to constipation, and weakness of legs. In one case, it was detected in electromyogram a sensitive polineuropathy. Both males also described episodes of retrosternal chest pain associated to vegetative symptoms. It was performed in both cases a coronary arteriography, detecting significant vessels lesions. The female underwent a laparotomy, previous to the diagnosis of AIP. One of the three cases developed various episodes of severe hyponatremia. If patients do were asymptomatic, the tests to measure porphyrins were between normal values of the local laboratory. The genetic test was just done in one case (2011).

Discussion: The median ages of our patients were above 35 years. This is an unfortunate fact of the AIP disease, which shows that the diagnosis it is delayed several years in most of cases. The symptoms could be abdominal and chest pain (sometimes mimicking ischemic heart disease). Blank laparotomies previous to the diagnosis of AIP are often made, due to acute attacks can imitate acute surgical abdomen. It is also interesting to value that AIP should be included in the differential diagnosis of the syndrome of inappropriate antidiuretic hormone secretion (SIADH). It is postulated that SIADH is mediated through a neurohormonal mechanism that cause a hypothalamic dysfunction. Physicians must be aware that porphyrins are only detected, in general, during acute attack, but not in the free- symptoms periods. AIP can also be the cause of a sensitive polyneuropathy. So the fact is that AIP should be included as a cause in the differential diagnosis of polyneuropathy, because its delay could potentially lead to progressives incapacitating symptoms, which have an effective and specific treatment.

Conclusions: AIP is a rare disease. Apart from the most known symptoms of recurrent abdominal pain and hypertension, there are also other manifestations of the disease as the sensitive polyneuropathy and SIADH. To wonder about this disease is important to get a faster diagnosis and earlier in time, enabling us to apply therapy that can avoid severe comorbidities, even death, in patients with AIP.

V-286
THE RELATIONSHIP BETWEEN OBESITY AND THYROID FUNCTION AND THYROID ULTRASONOGRAPHY SIZE INVESTIGATION

E. Arslan[1], F. Özçelik[2], C. Yüksel[3], M. Öztosun[2]

[1]Department of Internal Medicine. Gülhane Military Medical Faculty. Ankara, Turkey. [2]Laboratory of Medical Chemistry, [3]Department of Radiology. Gümüssuyu Military Hospital. Istanbul, Turkey.

Objectives: In this study investigated whether a relationship between obesity and thyroid function and thyroid ultrasonography size (TUSGs). In addition, if there was a relationship between TUSGs and thyroid function in obese patients, whether to be a new reference value was investigated.

Material and method: The study included there was not any disease other than obesity and ages 20 to 40 and 85 preobese or overweight (body mass index (BMI) > 25-29.9 kg/m^2), 74 obese patients (BMI > 30 kg/m^2), 50 healthy control men (BMI < 25 kg/m^2). TSH, freeT3, freeT4, weight, height, waist circumference (WC) and TUSGs of patients were measured. BMI data of all groups was calculated using the formula body weight/height^2 (kg/m^2). All data were evaluated using the SPSS 15.0 program.

Results: Data of preobese and obese patients (TSH, BMI, WC and TUSGs) were higher than healthy controls. There was no difference between freeT3 and freeT4 in all groups. In addition, there weren't relationship between BMI and TSH, TUSGs, but there was a positive correlation between WC and TSH, TUSGs ($r = 0.302$ $p < 0.003$ and $r = 0.2617$ $p = 0.042$).

Conclusions: As a result, there was a significant relationship between WC and TUSGs, TSH but this relationship was not reflected thyroid functions. In addition, this relationship between TSH levels and TUSGs in obese patients was not strong enough to require a new reference value.

V-290
USE AND UTILITY OF PET-CT IN AN INTERNAL MEDICINE DEPARTMENT

D. Filella Agulló[1], E. Pérez Macho[1], J. de Llobet Zubiaga[2], J. Casademont Pou[1]

[1]Department of Internal Medicine, [2]Department of Rheumatology. Hospital de la Santa Creu I Sant Pau. Barcelona, Spain.

Objectives: To evaluate the diagnostic utility of PET-CT (positron emission tomography-computed tomography) in patients hospitalized in an internal medicine department.

Material and method: A review of all PET-CT requested in an internal medicine department of a tertiary hospital over a period of two years was undertaken. Demographic variables, reason for requesting the PET, complementary previous tests: image tests, endoscopy, laboratory tests and cytological studies. We classified patients into different study groups. First, the oncologic group: extension study of solid organ cancer, study of haematological malignancy, cerebral space-occupying lesions. Second, the infectious diseases group: evaluation of a suspected organ or foreign body infection and patients with FUO. Third, patients with anorexia-cachexia syndrome with inconclusive additional studies. The last group included patients with suspicion of inflammatory disease, HIV patients with complex clinical process and those for neurological study. We considered usefulness of the PET as the capacity to identify lesions, confirm o discard the suspected diagnosis, taking into account the previous studies performed.

Results: We revised a total of 116 PET-CT. The first group included 43 (37%) patients: 21 for extension study of solid organ cancer, 10 cases for haematological malignancy, 12 cases to study brain lesions. In the group of study of solid organ cancer (20/21 had prior thoracoabdominal CT) 7/20 cases had findings in the PET-CT which broadened the CT staging. In the group of haematological malignancy (8/12 had prior thoracoabdominal CT), 5/8 cases PET-CT allowed new diagnostic extension. In the group of brain lesions, 10/12 cases confirmed the findings of the CT (5 cases with metastasis and 5 primary brain cancer), in 2/12 cases the PET-TC changed the diagnosis (1 intracranial haematoma and 1 primary lymphoma). We indentified 34 patients in the second group (29.3%): 18 cases with a known or suspected focus infection, 16 patients with FUO. Of the 18 cases: 6/18 to study aortic prosthetic infection, 7/18 to study arthritis or osteomyelitis, 3/18 to discard pacemaker infection and 2/18 in a miscellaneous group. Of the 16 patients of FUO, 9/16 because of persistent fever (5 cases useful), 3/16 to study bacteremia (1 case useful), 4/16 on haematological malignancy (no utility in any case). The third group included 25 patients (21.5%) with anorexia-cachexia syndrome: 12/25 to characterize a lesion, 6/25 to search a primary cancer and 7/25 to study a suspected paraneoplastic syndrome. The last group included 8 patients (6.8%) to study an inflammatory disease: 4 patients (3.4%) with HIV and 2 neurological PET (1.72%). In the inflammatory cases: 3/8 for suspected sarcoidosis, 2/8 for inflammatory aortitis, 3/8 with suspicion of giant cell arteritis. In 3 cases confirmed the suspected diagnosis.

Discussion: PET-CT has been useful for staging lesions highly suggestive of solid organ cancer described by CT (7/21). Also, its use has been proved to extend the staging of haematological malignancy (5/12). In the study of brain lesions, PET-CT was useful in 2/12 cases with an unclear diagnosis with the previous tests. In anorexia-cachexia syndrome group, the usefulness of PET is lower and highly dependent on the presence of lesions on CT. We confirmed usefulness to rule out the underlying disease in 7/12 cases to characterize a lesion described by CT. The rest didn't have significant findings. In the study of fever, PET-CT was useful when there was a known or suspected focus. In all patients (6/6) with suspected endovascular infection, in 5/7 of suspected arthritis or osteomyelitis and in all patients with suspected pacemaker infection (3/3). In cases of FUO, PET was more useful in cases of persistent fever (5/16).

Conclusions: PET-CT has proven useful in oncologic patients (for staging or to the diagnosis of solid cancers, haematological cancers and unclair brain lesions) and in patients with a high suspicion or known focus infection. The PET-CT proved to be useful in patients with persistent fever and in patients with lesions of uncertain pathological significance by CT. It seems that the efficiency is higher if there is a good pre-test diagnosis hypothesis.

V-291
IMPACT OF THE COMORBILITY IN THE SURVIVAL OF THE LUNG CANCER IN THE GENERAL HOSPITAL OF SEGOVIA

B. Quevedo Bautista[1], S. Martín Rodríguez[1], G. Estrada Trigueros[2], P. Velasco Martínez[1]

[1]Department of Internal Medicine, [2]Department of Pneumology. Hospital General. Segovia. Segovia, Spain.

Objectives: To know the general characteristics of bronchogenic carcinoma (BC) and to know the comorbilidad influences in the survival BC in our area of health.

Material and method: We include the patients with a diagnosis of BC from January, 2000 until August, 2010. The information is gathered from the reports of Pneumology, Internal Medicine and Oncology. To calculate the comorbility we use Charlson's limited scale (CH) obtaining a global median. We analyze the survival of two groups one over the median and other one below the median.

Results: N = 523, Males 470 (90%). Median 69. Histology: BC not small cells 425 (83%), epidermoid carcinoma 206 (39%),

adenocarcinoma 98 (19%) big cells 37 (7%) other 75 (14%) BC small cells 88 (17%). Clinical stadiums IA 20 (4%), IB 58 (11%) IIA 4 (1%), IIB 16 (3%), IIIA 53 (10%), IIIB 116 (22%) the IV 157 (30%). BC small cells, stadium limited 47 (9%), stadium extended 35 (7%). Not classified 17 (6%). Treatments: surgery 80 (16%), chemotherapy 238 (47%), radiotherapy 30 (6%), palliative 103 (20%), does not consist 47 (8%). The median of global survival of the series is 10 months. Charlson's index was possible to obtain it in 430 patients (84%). The median of the punctuation was of 2, Range from 0 to 9. Two groups were done, the patients with minor or equal index to 2 (CH1) and the patients with a Charlson of 3 or major (CH2). THE CH1: N = 312, median of age 67, males 275 (88%). The CH2 N = 118, median of age 71, males 113 (95%). It exists differences statistically significant between the groups neither in clinical stadiums ($p < 0.07$), nor in the applied treatment ($p < 0.1$). There are fewer women in the GH2 ($p < 0.02$) and they are older ($p < 0.01$). It exists statistically significant differences between the group CH1, with a median of survival of 11 months with regard to the CH2 with a median of survival of 7 months. ($p < 0.03$).

Conclusions: The epidemiological characteristics of our series are not very different to other published series. The average global survival of the series is 10 months. CH's average punctuation is of 2. The survival of the patients who have a minor or equal punctuation to 2 is better than those who have a punctuation of 3 or more, being this statistically significant difference ($p < 0.03$).

V-293
DEATH PROCESSES IN THE HOSPITAL: IS IT POSSIBLE TO DIE WITH DIGNITY?

A. Ortegón Gallego[1], M. López Luque[2], S. García Varo[3], C. Nevado Barbero[1], R. Tirado Miranda[4], J. Ureña Gómez[5]

[1]Nurse Management Case, [2]Physician. Support Team of Palliative Care, [3]Nurse. Support Team of Palliative Care, [4]Physician. Department of Internal Medicine. Hospital Comarcal Infanta Margarita. Córdoba, Spain. [5]Psychologist. Spanish Association Against Cancer. AECC. Córdoba, Spain.

Objectives: Analyze the processes of death in the hospital managed by Nursing Case Management in terminally ill patients with limited support family members to care. Promote professional attention and care to patients (and their families) with death processes: dignity, confidence and quality technical-human. Death with dignity: no pain/suffering family support.

Material and method: Case Review Nurse Manager in derivatives 1st Semester 2011 with situation terminality: expected death < 7 days. Few members to support care at home. High degree of dependence on the patient. Conflicts users/professionals by anxiogenic situations.

Results: Total 13 cases. 6 women, 7 men. Ages 52 years-94 years. 5 neo lung, (4 males, 1 female) 3 neo colon (1 male, 2 female) 2 multimorbidity with brain damage (2 women), cardio-respiratory failure 3. (2 males, 1 female) Efforts were single room in 8 cases. The cases were referred to nursing case manager by physicians, 5 cases of hospital nursing, 4 cases, palliative care unit, 2 cases and active uptake at the request of the family, 2 cases. Families applicants. Patients helpless, fragile. Few family members: absent, distant or nonexistent. Wishes to die in the hospital vs Wishes to die at home. Addresses that do not guarantee care at the end of life. Uncontrolled pain: 5 (38%). Routine procedures: toilet, mobilization... Verbalizac. the patient at rest VAS ≥ 5. Facial expressions and body gestures Anxiety intense family unnecessary Suffering. Pain controlled: 8 (62%). Absence of expressions or gestures. Patient Comfort family. Standardization anticipatory grief -Duel in place necessary.

Discussion: Oxygen therapy with medium and high flows. (Ventimask/Reservoir) Prolonged treatment with curative intent despite the diagnosis: antibiotics, suerotherapies, diuretics, vasoactive drugs... Increased therapeutic efforts. Distress in the care of professionals. The nursing intervention developed by nurse management cases allowed to control the pain in 4 patients: assessment of patient contact + nursing and medical team. Pharmacological adjustment in each case. Family assessment. Family support. Patient comfort in his biographical closure in all cases seen. Therapeutic obstinacy vs Families who refuse aggressive treatement. Withholding Treatment vs Demand to do everything possible. Advance Vital Living Will Declaration.

Conclusions: The processes of death in the hospital are not homogeneous once they reach the stage of terminality closedepending on the sensitivity of the professional quality of care provided to dying and family. In all cases were sent personalized letters of condolence to the week of death, signed by some of the professionals who attended the cases. Dignified death processes are not always guaranteed or at home (for lack of caregivers to guarantee it) or in the hospital (because of poor information management professional or insensitivity). Referral to Case Management Nursing allowed the patient and family welfare in 12 of the 13 cases managed (92.3%). The need for more professional training in social skills of communication and society in general more open mind towards death processes: pedagogy of death.

V-295
JOURNALS AND TOPICS EXPOSED DURING THE JOURNAL CLUB DEVELOPED IN THE INTERNAL MEDICINE SERVICE AT TORRECÁRDENAS HOSPITAL

S. Domingo Roa, P. Sánchez López, B. Hernández Sierra, N. Marín Gómez, M. Esteban Moreno, C. Maldonado Úbeda, A. García Peña, G. López Lloret

Department of Internal Medicine. Complejo Hospitalario Torrecárdenas. Almería, Spain.

Objectives: Analyze the issues that were selected in the journal clubs conducted in the Internal Medicine Department of the Hospital of Torrecárdenas for the past 4 years. Also, identify the materials and journals that were of greatest interest in our service.

Material and method: We performed a retrospective study with collection of journals and subjects selected both by senior doctors of Internal Medicine as residents (including rotating through the service) for exhibition in bibliographic sessions held weekly. The period chosen for our study was between to January 2008 to April 2012. After its analysis we report the most interesting topics and the further consulted journals.

Results: During the 4 years analyzed 370 items were exhibited. Of these, 170 (45.9%) belonged to the magazine NEJM (The New England Journal of Medicine), 33 (8.9%) to Clinical Medicine, 24 (6.5%) a Spanish Clinic Journal, 24 (6.5%) at The Lancet, 16 (4.3) at JAMA (Journal of the American Medical Association) and 103 (27.8%) to other diverse. Regarding specific areas: 99 (26.8%) were articles of pharmacotherapy, 265 (71.6%) cardiovascular diseases (4.9% cardiovascular risk factors, 3.5% anticoagulation, 4.1% ischemic heart disease, 3% intervention, 2.7% arrhythmias, heart failure 4.1%, 0.3% valvular diseases and 5.9% others), 57 (15.4%) of infectious subject (2.7% HIV, 3% respiratory infection/tuberculosis, 2.4% bacteremia/sepsis and 3.8% miscellaneous), 30 (8.1%) of neurology (2.4% dementia, 1.9% stroke, epilepsy 0.5%, 3% others), 22 (5.9%) pneumology (3.2% chronic obstructive pulmonary disease, lung neoplasm 1.4%, 1.4% others), 21 (5.7%) of hospital management and 12 (3.2%) of palliative care. Finally, 5 (1.4%) about autoimmune diseases, 12 (3.2%) of digestive and 6 (1.6%) of nephrourology. The articles published in 2010 were the most frequently reviewed (30.8%) in our service. The 80% of the reviewed articles had been published for less than 1 month.

Discussion: The publications raised in the literature of our service sessions were mostly on cardiovascular diseases (71.6%) and pharmacotherapy (26.8%) followed by the infectious theme (15.4%). The magazine further consulted by the medical staff during these sessions was NEJM (170 articles, 45.9%). The items on display are usually very current, since 80% of them had been published for less than 1 month. The year of publication most frequently consulted was 2010.

V-299
BLEEDING EVENTS OF ANTICOAGULANT THERAPY

B. Antequera, C. Castellanos, M. Escrivá, P. Gimeno, L. Pérez, P. Porcar, I. Torres

Hospital de Sagunto. Sagunto. Valencia, Spain.

Material and method: This retrospective study took place in the Department of Internal Medicine at the Hospital of Sagunto. We retrospectively analysed all patients admitted in our department between January 2011 and December 2011 with a clinically bleeding event while receiving anticoagulation therapy. Anticoagulation therapy was defined as oral anticoagulation with vitamin K antagonist (acenocoumarol or warfarin) application of low molecular weight heparin or fractionated heparin. We categorized the events in three subgroups of seriousness, mild, moderate or serious bleeding. Mild bleeding was defined as that with no need of blood transfusion or thorough follow up. Moderate bleeding was defined as that leading to blood transfusion and medical observation. Serious bleeding was defined as that leading to surgical, angiographic intervention, irreversible sequelae or the death of the patient. We also categorized the events in three outcome subgroups, patient alive, death during hospital stay or death in the first twenty four hours of hospital after admission. All statistical analyses were performed using SPSS 19. p-values < 0.05 are considered statistically significant.

Results: During the period of the study there were 49 patients with bleeding complications of anticoagulant treatment. Thirty one events (63.3%) occurred in women and 18 (36.7%) occurred in men. Gender does not correlate with the outcome of the bleeding event. Seventy one per cent of patients were older than 75 years, twenty six per cent of patients were older than sixty five and younger than seventy five and just two per cent of patients were younger than sixty five years at the time of bleeding event. Age does not correlate with the seriousness of the bleeding complication (p = 0.4). Ninety one per cent of the patients were receiving oral anticoagulation with acenocoumarol, four per cent with warfarin and four per cent with low molecular weight heparin. Most events occurred in patients treated for atrial fibrillation (71.4%). Further indications where deep vein thrombosis (6.1%), pulmonary embolism (6.1%) and valvular cardiomyopathy (12.2%). About characteristics of bleeding complication eighty nine per cent of bleedings were spontaneous. Gastrointestinal bleeding was the major bleeding site (59.2%), other bleeding sites were cerebral (26.5%) and muscle skin (14.3%). Eighty five per cent of the bleeding events were moderate or serious bleedings events. Cerebral bleeding resulted in more mortality (61.6%). In 76.9 per cent of severe bleeding events we found the patients took other drugs beside the anticoagulant treatment. Eighty nine per cent of patients with a INR between 1.5 and 2.4 had a moderate or serious bleeding event. Thirty eight per cent of serious bleeding events occurred with INR values > 4.5. Ninety two per cent of cerebral bleedings occurred with INR values > 2.4.

Conclusions: In our study, most of the patients who presented bleeding complications of anticoagulant therapy were over 65 years old. Most of the them received acenocumarol as primary prevention to embolic events in arrhythmias. We have shown that sex is not correlated to the severity of the bleeding s events in patients with anticoagulant therapy. Elevated INR is a firmly established risk factor for haemorrhage. We found a highly significant association between INR greater than 4.5 in serious bleeding events. However most of the bleedings events were gastrointestinal and they did not show significant association with the INR values. Although, an increase of the cerebral bleeding episodes was observed when the INR values were greater than 2.4. As expected cerebral bleedings presented a higher mortality compared to other bleeding sites. There are several studies that have identified the use of multiple medications as a risk factor for bleeding complications and others show no influence on the complication rate. In our study we found a increase of seriousness of the bleeding events in those patients that were taking enhancing medicines of the anticoagulant effect.

V-300
ACUTE FAILURE AS A REASON FOR ADMISSION OF ELDERLY PATIENTS IN THE INTENSIVE CARE UNIT. A 10 YEAR STUDY

E. Massa, E. Mouloudi, S. Papadopoulos, G. Rebelakos, T. Giasnetsova, C. Kydona, N. Gritsi-Gerogianni

Department of Intensive Care. Hospital Hippokratio. Thessaloniki, Greece.

Objectives: Respiratory insufficiency is the most common cause of ICU admission in elderly patients (> 80 years). The aim of this study is the assessment of postoperative respiratory complications in elderly patients requiring intensive care unit (ICU) treatment and their outcome.

Material and method: We studied patients older than 80 years of age with ARF needed treatment in the ICU for more than 24 hours.

Results: Fourty-three elderly patients were admitted in the ICU during 10 years (1/1/2003-1/6/2012). Twenty-three patients presented respiratory failure requiring ICU admission (15 men and 8 women, with an age of 83.4 ± 2.3 years old and an APACHE II score of 23.7 ± 5.6 on admission). Pre-existing comorbidities were: COPD 4 patients, XNA 7 patients, coronary disease 12 patients and stroke 10 patients. The causes of acute respiratory failure were: pneumonia in 7 patients (30.14%), pulmonary edema in 5 (21.73%), Chronic Obstructive Pulmonary Disease (COPD) exacerbation in 4 (17.3%) and atelectasis in 2 patients (8.6%). The average Length-of-Stay in the ICU was 8, 3 days. The mortality of elderly patients with respiratory complications requiring ICU admission was 52.17%, compared to a 41.9% mortality in elderly patients without ARF on ICU admission.

Conclusions: Pneumonia, Acute Lung Injury (ALI)/Acute Respiratory Distress Syndrome (ARDS) and pulmonary edema are the most common cause for ICU admission in elderly patients. The etiology of respiratory failure might connected to pre-existing comorbidities.

V-301
ACQUIRED HIPOGAMMAGLOBULINEMIA IN ADULT PATIENTS

I. Villaverde Álvarez[1], L. González González[1], R. Lorenzo Castro[1], A. Martínez Vidal[1], S. Cubillo[2], A. Rivera[1], M. Freire[1], B. Sopeña[1]

[1]Department of Thrombosis and Vasculitis. Department of Internal Medicine, [2]Department of Biochemistry. Complejo Universitario de Vigo. Pontevedra, Spain.

Objectives: The aim of this study was to determine the causes of acquired hypogammaglobulinemia and establish the prevalence of CVID in adult patients admitted in a tertiary care hospital.

Material and method: All patients older than 16-years-old with serum immunoglobulin G levels < 500 mg/dl were identified through

the computer file of the Biochemical Department from January, 1, 2010 to December, 31, 2012. The medical records were reviewed to identify the cause of the HGG and to establish if the CVID criteria were present. HGG not studied or ignored by the attending physician were also analyzed.

Results: In this period of time, 90 adult patients with HGG (30% men and 70% women) were identified. The average age at the time of the study was 64 years (rank 21-93). In 24 patients only a single determination of IgG was performed, even the value was clearly pathologic. The cause of the HGG was identified in 78 patients (86.6%). The most frequent causes were: Hematological diseases in 34 patients (38%) (12 multiple myeloma, 16 lymphomas of B cells, 5 chronic lymphocytic leukemia and 1 immunoglobulin light chain (AL) amyloidosis). Drugs in 27 patients (30%): (7 rituximab, 4 by other biological agents (tocilizumab, bortezomib), 3 by cyclofosfamide and 13 by other immunosupressive drugs). 9 patients fulfill CIVD criteria (10%). Nephrotic syndrome was diagnosed in 6 patients (7%). Solid tumors with widespread metastatic disease in 2 patients and 1 case of thymoma. Although, CIVD was the 3 most frequent cause of HGG, only 3/9 patients (33%) had been previously diagnosed and were receiving appropriate treatment. In patients with nephrotic syndrome and patients with hypogammaglobulinemia-induced by drugs recovered the normal levels of immunoglobulins after acute process.

Discussion: Although, the presence of hypogammaglobulinemia (HGG) usually is a relevant analytical data, that may be the clue of severe illness and recurrent infections, it is often overlooked by clinicians and there are few work published about acquired HGG. A large number of conditions are associated with HGG due to either decreased production or increased loss: drugs, malignancy and pre-malignant disorders, systemic illnesses causing bone marrow suppression, nephrotic syndrome, protein-losing enterophaties and others. On the other hand, common variable immunodeficiency (CVID) with an estimated prevalence of 1/20,000 inhabitants remains under diagnosed and with an important diagnostic delay, patients often have been evaluated by several specialist by the time they are diagnosed.

Conclusions: The hematological diseases were the most frequent cause of HGG in this series. New biological agents as rituximab and tocilizumab are frequent cause of hypogammaglobulinemia. Almost 2/3 of patients with common variable immunodeficiency had not been diagnosed by their clinicians.

V-302
A GROUP OF PATIENTS WITH MALT LYMPHOMA DIAGNOSED IN THE "UNIVERSITARIO MARQUÉS DE VALDECILLA" HOSPITAL

E. Cobo García[1], P. Ibarrondo Chamorro[2], M. Lisa Gracia[1], S. Qiu Liu[1], M. Tigera Calderón[1], M. García Hoyos[1], M. Aller Fernández[1], F. Ortiz Flores[1]

[1]Department of Internal Medicine, [2]Department of Haematology. Hospital Valdecilla. Santander. Cantabria, Spain.

Objectives: Review the diagnosed cases of Malt lymphoma (ML) in our hospital, describing the clinical characteristics and their location, as well as the predisposing factors.

Material and method: This is a descriptive study in 16 patients (62.5% women) diagnosed of MALT Lymphoma in the "Universitario Marqués de Valdecilla" Hospital (Santander, Spain). Data regarding the clinical history, age, gender, personal history, clinical manifestations and their location, as well as data coming from the physical exploration, was retrieved. Besides, laboratory data was registered, such as lactate dehydrogenase (LDH > 300 U/l), beta2-microglobuline, uric acid (mg/dl).Information coming from the immunology studies (presence of cryoagglutinins) and bone marrow study were also included. From the image tests (scanner), presence of mediastinal or abdominal lymphadenopathy were obtained. Immunohistochemical study and molecular studies (translocations, clonal rearrangement of immunoglobulin H1) were registered. The clinical stage at the diagnosis, as well as the treatment received, was gathered. The number of relapses was analyzed, the average survival along with the mortality.

Results: The average age at the diagnosis was of 67.63 with a variance of 14 years. The 6.3% of patients were smokers. The 37.5% displayed an infection due to Helicobacter Pylori and a 12.5% showed connective diseases. The more frequent location of MALT Lymphoma was gastric with 62.5%, from which a 50% showed an infection due to H. pylori, followed by the ones located in head and neck with an 18.8%. In regard to the clinical manifestations, only a 6.3% of the cases showed the classic triad (fever, loss of weight, and night sweating), being the most frequent manifestation the loss of weight, present in the 18.8% of the patients. As for the gastric MALT Lymphoma, the most common clinical expression was the gastrointestinal bleeding in the 50% of the cases, followed by the epigastric pain in the 20%. None of the patients showed splenomegaly and only 2 displayed hepatomegaly. The 12.5% presented supraclavicular and inguinal peripheral lymphadenopathy. Regarding the results from the laboratory data collected, the 43.8% of the patients displayed the following results: LDH > 300 U/l, Beta2-microglobuline 3.1 ± 2.7 and uric acid 6.6 ± 1.5 mg/dl. In 5 of the cases, the cryoagglutinins were analyzed and resulted positive in the 18.8%. In the chest and abdominal scanner, lymphadenopathies were observed in 8 of the patients, 25% mediastinal, 16% abdominal and 8.3% in both locations. An immunohistochemical study was carried out in 8 cases, from which a 37.5% was positive for the Bcl2. In 6 cases, the clonal rearrangement of immunoglobulin H1 was studied, turning out positive in the 83.3%. The 75% of the MALT Lymphoma were diagnosed in the earlier stages (I, I1 and I2), having the 62.5% an indolent growth. The 61.5% received chemotherapy treatment, 5 of them were gastric MALT Lymphoma and one located in head and neck. None received radiotherapy treatment. There were no relapses in the follow-up years (6 ± 5 years), although 2 cases did not react to the treatment, ending up in exitus.

Discussion: Patients with MALT Lymphoma in rare cases display systemic manifestations associated with lymphoma, such as the night sweating, fever and loss of weight. Being most frequent the clinical at local level, as it occurs in the gastric Malt Lymphoma with the gastrointestinal bleeding and the epigastric pain. Furthermore, it is shown a high prevalence of infection due to H. pylori in the gastric MALT lymphoma, as it is well-known.

Conclusions: The MALT Lymphoma is a low aggressivity and indolent growth type of lymphoma with a good response to treatment, but it should be suspected when having local symptoms even when missing systemic clinic.

V-303
DIAGNOSTIC YIELD AND ASSOCIATION OF SCALE EPWORTH SLEEPINESS IN OSAHS: CROSS-SECTION

D. Gutierrez Bejarano[1], S. Martín[2], E. Eguia Ángeles[1], C. Camero Zavaleta[1]

[1]Teaching Unit of Family and Community Medicine. Primary Care Management of Segovia. Segovia, Spain [2]Department of Internal Medicine. Hospital General. Segovia, Spain.

Objectives: To identify the diagnostic yield of the Epworth Sleepiness Scale (ESS) in a patient population of Segovia (Castilla and Leon, Spain) with clinical suspicion of apnea/obstructive sleep hypopnea (OSAHS) and establish the relationship between the result of the ESE and the Polygraph diagnosis of OSAHS.

Material and method: This is a cross sectional study which included all patients (188) Service of Neumology of the General

Hospital of Segovia, who had undergone a sleep study (Ambulatory Polygraph) in the period between January 2011 and March 2012 and who were referred to this service by a clinical suspicion of OSAHS. As sources of information for data collection were used Polygraphs Register of Service of Neumology and the charts of patients enrolled in the study. Statistical analysis was performed using SPSS V.18.0 and applied Logistic Regression test.

Results: We included in the study population 188 patients with a mean age of 56.16 years (95%CI 54.35 to 57.96). Of these, 83.5% (157) were male and 16.5% (31) women. The results obtained in the ESE were compared with the results of the Polygraph through a Contingency Table, where we find that for the study population, the ESS had a sensitivity of 82.7%, a specificity of 24.3%, a Positive Predictive Value of 85% and a Negative Predictive Value of 20.7%. Additionally, our data and through a logistic regression model, we found statistical significance to claim that the probability of having an abnormal polygraphic diagnosis (OSAHS) is greater in patients with pathological ESE (OR: 4,078, 95%CI: 2.87-6.33, $p < 0.05$).

Discussion: Several authors have documented in their research, such as sleepiness is a cardinal symptom of marked diagnostic value in the management of OSAHS. The ESE is built from this symptom and it becomes a very useful screening tool in primary care to detect patients with this condition. In recent years, has also documented its utility for optimizing the use of more expensive tests such as the Polygraph. The data obtained in our study, show a sensitivity to the ESE and a positive predictive value similar to those obtained in previous studies. However, considering the low negative predictive value is necessary to consider other tests and/or scales in patients with high clinical suspicion and a negative ESE. The positive predictive value observed in our series, it's consistent with the results obtained in the logistic regression model where we found an odds ratio with statistical significance to claim that in our series, the probability of having a diagnosis compatible with OSAHS polygraph is greater if is part of an abnormal ESE. These findings should be interpreted with caution, considering the sample size and source of patient recruitment (Specialty Care).

Conclusions: In our area, the Sensitivity and Positive Predictive Value obtained for the ESE, mean that this test is maintained as a scale with acceptable performance in screening patients with clinical suspicion of OSAHS. Its low cost, easy implementation and positive predictive value make it a useful tool in the field of primary care. Additionally, with our data, we found a statistically significant association between an abnormal ESE and polygraphic diagnosis of OSAHS, a finding that should be considered in clinical practice at the time of making decisions in referring patients to Care (Neumology).

V-307
DIAGNOSIS OF NEOPLASIA IN AN INTERNAL MEDICINE SERVICE OF A GENERAL HOSPITAL

C. Maldonado Úbeda, G. Parra García, G. López Lloret, A. García Peña, B. Hernández Sierra, M. Esteban Moreno, F. Laynez Bretones, F. Díez García

Department of Internal Medicine. Complejo Hospitalario Torrecárdenas. Almería, Spain.

Objectives: To analyze the patients diagnosed of malignancy who were admitted for any reason in an Internal Medicine Service of a general hospital (Spain) in the last 5 years.

Material and method: We performed a retrospective study in patients admitted in an Internal Medicine Service for the last 5 years (January 2007-December 2011). During this period we recruited 4,468 patients, 211 of them were diagnosed at discharge from a neoplasm not previously known. We analyzed the basic epidemiological variables and the type of tumor that most often was described in these patients. Data were analyzed in SPSS database 17.

Results: Of a total of 4,468 patients, 211 cases were diagnosed some class of malignant neoplasm (4.7%) and 80 patients of them (37.9%) had metastasis at the diagnosis. Regarding gender, 135 (64%) were male and 76 (36%) were female, the mean age registered were 76 years old (± 16 years). There were 68.7% of cases older than 65 years old, 20.3% were between 65 and 50 years old and 11% were younger than 50 years of age. The most common malignancy diagnosis was the haematological one with 69 cases (32.7%): 47 (22.3%) lymphomas and 22 (10.4%) myelomas. Secondly was the lung cancer with 42 cases (19.9%). These were followed by: colon 17 (8.1%), bladder 15 (7.1%), kidney 9 (4.3%), breast 8 (3.8%), stomach 6 (2.8%), gynaecological cancers 6 (2.8%), liver 5 (2.4%), prostate 3 (1.4), pancreas 1 (0.5) and miscellaneous 19 (9%). Eleven cases (5.2%) were diagnosed of an occult malignancy and 36 patients (17.1%) had a second primary tumor.

Conclusions: In an Internal Medicine Service a total of 211 patients (4.7%) were diagnosed of malignant neoplasm during a 5 years period. Haematological malignancies (32.7%) were the most frequently (lymphomas and myeloma) followed closely by lung cancer (19.9%). There were predominantly males over 65 years old. We emphasize that the diagnosis was often made at an advanced stage and that the diagnosis of second tumors was relatively frequent.

V-308
INTERNAL MEDICINE/PSYCHIATRY DEPARTMENTS, AN EFFICIENT PARTNERSHIP

I. Mejías Real[1], L. Montero Rivas[1], R. Tirado Miranda[1], A. Ortegón Gallego[1], M. Pinillos Villatoro[1], A. Moreno Campos[2], E. Guisado Espartero[1], C. Aranda Valle[1]

[1]Department of Internal Medicine, [2]Department of Psychiatry. Hospital Comarcal Infanta Margarita. Córdoba, Spain.

Objectives: A Psychiatry Consultation (PC) is considered a tool that allows the clinicians requested collaboration between different medical specialties and Psychiatry. In our hospital Psychiatry department (PD) has been opened recently for the management of patients with psychiatric pathology subsidiary of hospital admission. The objective of this study was to analyze the impact this new DP in the management of inpatients admitted in the Internal Medicine Department (January 2011-May 2012).

Material and method: A retrospective and descriptive analysis of the PC made by clinicians specialists in Internal Medicine. We analyze demographic data, character of the consultation, reason for consultation and diagnostic.

Results: We analyze one hundred and eighty-five PC. Ninety-nine (50.85%) were women; the age range was between thirty-one and ninety years old. Most of the PC (68.64%) were performed with normal character and only sixteen (8.69%) required an urgent response. The most common reason for that was for adjustment the treatment and assessment of psychiatrist pathology known previously. Psychiatry pathology did not identify in only three patients.

Conclusions: PC allows us to analyze the work done by several specialties. The opening of the PD in our hospital has allowed us a more appropriate management of patients with previously known psychiatric disorders admitted to our hospital for organic disease. It results in a higher quality care; guard against discontinuation of psychotropic drugs treatment during hospitalization and avoid the possible psychiatry complications. All of them improve patient safety.

V-311
RHABDOMYOLISIS: ONLY ELEVATION OF MUSCLE ENZYMES?

A. Castro, M. Fernández, I. Navas, L. Horrillo, C. Tojo, B. Matía, J. Canora, A. Zapatero

Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: Rhabdomyolisis is defined as an entity that results from acute and severe destruction of skeletal muscle tissue, causing the release of the intramiothitic substances that results in nonspecific myalgia and urinary disorders whose main complication is the deterioration of the renal function secondary the deposition of myoglobine in the renal tubules, It´s usually secondary to predisposing conditions such as toxic intake and injuries, sometimes it´s secondary to muscle primary and endocrine disorders or genetic diseases. Nowaday, elevation of COK still is the most sensitive serum marker and should therefore always be measured when we suspect the diagnosis.

Material and method: Retrospective descriptive study including all cases of rhabdomyolisis reported in the Internal Medicine Department of Fuenlabrada University Hospital between June 2004 and April 2012. In all cases, patients required hospitalization due to this entity. We describe epidemiological, clinical and laboratory outcomes.

Results: There were 20 cases of rhabdomyolisis over the 8 years reviewed, 2 of which were excluded for primary genetic myopathy (McArdle's disease). There was a clear predominance of women among the patients (55%), with a widely varying age range between 21 and 85 years, with an average of 52.4 years. Both variables (sex and age) appear to have a close relationship with the intense physical exercise; on the other hand, it presented as etiological agent in 55% of the cases. There are also other predisposing factors, such as trauma with secondary immobilization, group of elder people with cognitive impairment (22%), the group taking statin drugs (22%) and antipsychotics (11%) or febrile diseases (11%). Analytically, the CPK elevation was seen in 100% of the cases, with values between 590 and 66,057 with a mean of 16,779.06. There are other findings such as myoglobinuria (55%)l, mild hypokalemia (16.6%) and disorders of the urinary sediment (57%). The deterioration of renal function was evident in 27.7%, with a maximum value of creatinine of 2.04 mg/dl, showing all good evolution in response to prescribed treatment (except 1 case with a previous diagnosis of chronic kidney disease). 100% of the patients received supportive care with fluid therapy, to which was added alkalinization of the urine in 4 patients (22%).

Conclusions: Rhabdomyolisis is a benign entity that envolves favorably in most cases where there use ir appropriate. In the vast majority of the patients plenty of hydration and alkalinization of urine should be sufficient measures to prevent their passage through dialysis. Clinical manifestations in a proper epidemiological context, led by the traumatic pathology and intense physical activity, greatly facilitates the diagnosis, without forgetting that there are some exceptional cases where this condition may mask underlying primary pathology with variable prognosis.

V-314
DESCRIPTIVE STUDY OF PATIENTS ADMITTED WITH DIAGNOSIS OF ACUTE PANCREATITIS IN A REGIONAL HOSPITAL

I. Machuca Sánchez, J. Manchón Castilla, D. Navarro Moreno, T. Pérez Pino, M. Camilo Hache, P. Ruiz Sanjuan, M. Nieto Riesco, L. Pozo Rosado

Department of Internal Medicine. Hospital Virgen del Puerto. Plasencia (Cáceres), Spain.

Objectives: Describing and relating the clinical and epidemiological features, analytical and etiology of patients admitted to our hospital with the diagnosis of acute pancreatitis.

Material and method: Retrospective study was performed of all patients hospitalized with a diagnosis of acute pancreatitis in the period of time from 1st January 2011 to 1st January 2012. Statistical analysis was performed using the SPSS program.

Results: We collected a total of 79 patients classified by etiology into 4 groups: gallstone (39.2%), alcoholic (22.8%), idiopathic (22.8%) and other causes (15.2%), that includes drug-induced pancreatitis, hypertriglyceridemia, posttraumatic, post-ERCP and others. About patients, 44 were male (55.7%) and 35 were female (44.3%). The average age was 60 years. The average value of amylase on admission was 1506.32 U/L. The hospital average stay was 8 days. Only 3 (3.8%) patients required ICU admission, presenting D (2.5%) and E levels (1.3%) according to severity level of acute pancreatitis Balthazar´s classification. Mortality was not found in none of our patients. In the stratification by etiology and gender, the alcoholic etiology was more frequent in males and the idiopathic etiology was more frequent in females. In the stratification by etiology and age, the alcoholic etiology was more frequent in fewer than 50 years old patients. In the other hand, the acute gallstone pancreatitis and acute idiopathic pancreatitis were more frequent in older 50 years old patients.

Discussion: Acute pancreatitis is an acute inflammatory process of the pancreas that causes abdominal pain and elevated blood levels of pancreatic enzymes. The incidence is higher in men (55.7%). The acute gallstone pancreatitis is the most common cause of acute pancreatitis in our environment. According to alcoholic etiology, this is more frequent in males; in the other way, the idiopathic etiology is more frequent in females; but there is no corresponds with the results obtained in the literature. Early cholecystectomy in acute gallstone pancreatitis could prevent repeat episodes for this cause.

Conclusions: Acute pancreatitis is a clinical entity potentially serious and even fatal at times. Although the exact mechanism that triggers of disease is unknown; we know the etiological agents that trigger the acute pancreatitis, emphasizing the gallstone etiology and chronic high intake of alcohol. The acute pancreatitis is currently responsible for 1% of hospital mortality, so is very important to make early diagnosis and treatment to reduce morbidity and mortality in the middle-long time.

V-315
DEVELOPMENT OF CONSUMPTION OF OPIOID DRUGS FOR FIVE YEARS IN A PALLIATIVE CARE UNIT

M. López Fernández, M. del Cañizo Gómez, M. Budiño Sánchez, A. Antolí Royo, M. Garcinuño Jiménez, E. Barroso, D. Sánchez Fuentes, J. Barragán Casas

Department of Internal Medicine. Complejo Asistencial de Ávila. Ávila, Spain.

Objectives: Identify and evaluate the evolution of consumption of opioid drugs in our palliative care unit of Avila Medical Complex.

Material and method: Patients admitted to the Palliative Care Unit of the Complex Care of Avila. Study period: 2007-2011. Was assessed using the Anatomical Therapeutic Chemical Classification/ Daily Definite Dose (ATC/DDD). We evaluated the opioid that were available in the Hospital Pharmacy.

Results: Opioid use has been classified by the active ingredient, the various presentations and number of stays per year. The results are presented in Table 1 and the total of the drugs according to the route of administration is presented in Table 2. The significant variations in the consumption of oral morphine and fentanyl transmucosal, are due to two specific cases with high demand for analgesia.

Table 1 (V-315). DDD/year for each active ingredient

	2007	2008	2009	2010	2011
Oral morphine	110.8	26.2	11.7	107.7	37.2
Parenteral morphine	1,155.7	1,113.7	1,156.0	1,005.3	1,187.0
Transdermal fentanyl	2,362.5	1,851.0	1,312.5	1,435.5	1,492.5
Sublingual/buccal fentanyl	0	0	0	74.7	60.0
Transmucosal fentanyl	162.7	17.7	14.0	17.0	135.0
Oral oxycodone	0	0	149.3	104.9	353.1
Parenteral oxycodone	0	0	0	0	256.3
Oral tramadol	22.2	18.0	45.0	112.0	68.3
Parenteral tramadol	25.3	23.3	10.0	68.3	54.0
All	3,839.1	3,049.9	2,698.5	2,925.5	3,643.4

Table 2 (V-315). DDD/100/stays for each route of administration

Route of administration	2007	2008	2009	2010	2011
Oral	5.4	2.1	9.6	16.0	24.1
Parenteral	47.9	54.0	54.5	53.0	78.7
Sublingual/buccal	0	0	0	3.7	3.2
Transmucosal	6.6	0.8	0.7	0.8	7.1
Transdermal	95.8	88.0	61,4	70.9	78.4
All	155.7	145.0	126.2	144.5	191.5

Conclusions: Transdermal fentanyl is the mainstay of analgesic therapy. Oxycodone has been used regularly since its introduction. There are significant variations in consumption of morphine and fentanyl transmucosal, which are related to two specific cases.

V-316
ANTICOAGULATION AND ANEMIA IN PATIENTS ADMITTED TO A SERVICE OF INTERNAL MEDICINE

H. Gómez Rodríguez, A. Martínez Zapico, C. Suárez Cuervo, C. Costas Sueiras, M. Fernández Almira, I. Piñero de Paz, S. de la Villa Martínez

Department of Internal Medicine. Hospital Universitario Central de Asturias. Oviedo (Asturias), Spain.

Objectives: To determine the epidemiology of anemia in patients admitted to our hospital and evaluate the possible relationship between lower hemoglobin levels and the presence of anticoagulant medication.

Material and method: Review of medical records of all patients admitted to internal medicine department in a period of six months, from November 1, 2011 to April 30, 2012, with hemoglobin levels below 10 g/dl. We excluded patients who died within 24 hours after admission.

Results: We reviewed 96 patients with hemoglobin below 10 mg/dl. We found 48 men and 48 women. The median age was 75.2 in men and 79.3 for women. 33.3% of patients smoked. 21.9% of patients recognized harmful use of alcohol. 64% were hypertensive. 29.2% were diabetic. 41.1% had heart disease, being Hypertensive Cardiomyopathy the most frequent. 19.8% had chronic renal failure. 7% had COPD. 21.9% of patients with atrial fibrillation, of which 85.7% were taking anticoagulants (all with Warfarin/Aldocumar). The INR of anticoagulated patients was above the therapeutic range in 31.6% of cases. Mean hemoglobin in anticoagulated patients was 7.6 g/dl and 7.66 g/dl in those with anticoagulation over range, while that of non-anticoagulated was 7.43 g/dl. On the other hand, 37.5% of patients were taking antiplatelet agents.

Conclusions: Patients admitted with anemia have a high average age, with large numbers of comorbidities. Among them is frequent the presence of atrial fibrillation, so a significant number of patients are receiving anticoagulant medication, being frequently overdosed. However, neither anticoagulation or overdosage of it was associated with lower hemoglobin levels.

V-317
ANALYSIS OF THE EPIDEMIOLOGICAL AND CLINICAL CHARACTERISTICS OF PATIENTS WITH SPINAL METASTASES

L. Vela Manzano[1], S. Sánchez de las Matas Pena[2], E. Sifuentes Díaz[1], A. Fernández Rodríguez[1], C. Cano Gómez[2], F. Brun Romero[2]

[1]Department of Internal Medicine, [2]Department of Orthopedic Surgery. Hospital Universitario Puerta del Mar. Cádiz, Spain.

Objectives: To analyze the epidemiological and clinical characteristics of patients diagnosed with spinal metastases at our hospital, and to evaluate the therapeutic procedure performed on the basis of the recommendations of the current prognostic scales.

Material and method: A retrospective study of patients diagnosed with spinal metastases between 2006 and 2010 in our hospital (with a minimum of one year follow up after diagnosis). The study variables were: mean age, sex, Karnofsky performance status, number of vertebral metastases, number of extraspinal bone metastases, number of metastases in internal organs, metastases to major organs (brain, lung, liver, kidney), type of primary tumor, presence of neurological damage at the time of diagnosis, presence of pathologic fracture, type of treatment, survival from diagnosis, and in the case of patients who received surgery or radiotherapy, improvement or no pain and the index Karnofsky after them. Was applied to all patients Tokuhashi scale for spinal metastases and found adhesion and forecast consistency of the scale (certainty of the survival indicated by scale). We excluded those cases in which clinical data were incomplete for analysis or in which follow-up was lost.

Results: 279 cases were analyzed. The mean age was 65 years (SD ± 13), being 60% (n = 168) males. At the time of diagnosis,

55.6% of patients performed normal life without restriction (Karnofsky index 80-100), 33.7%, maintained some functionality but required assistance from a caregiver (Karnofsky index 50-70), and 10.7% needed to be bedridden (Karnofsky index 10-40). 75.5% of cases had two or more spinal metastases. 80.4% of patients had bone lesions extraspinals. The internal organ involvement was less common, being found in 58.7% of patients. 47.2% of patients had no metastases in major organs, presenting 17.4% in liver metastases, 15.9% in more than one major organ and 13.8% in lung, brain and kidney were less frequent. The most frequent primary tumors were lung 26.1% of cases (n = 73), breast 21.8% (n = 61) and prostate cancer to 10.7% (n = 30). 16% had spinal cord injury (30 cases incomplete and 17 complete), and only 10.2% of all patients with pathological fracture debuted, introducing the 82.8% bone pain as an initial symptom and the rest more than one symptom. As for treatment, 30 patients underwent surgery (10.7%), 9 with curative intent and 21 with palliative intent. In the remaining patients conservative treatment was undertaken, with the symptomatic treatment the most used drug (33.3%) followed by radiotherapy (17.9%), chemotherapy (16.3%) and radio-chemotherapy (11.7%). Among the patients treated up to 26.6% developed complications after surgery, with surgical wound infection the most frequent (25%). The improvement in pain and Karnofsky index of operated patients occurred in 76.2% and 71.4% of cases respectively and in patients who received radiation therapy occurred in 65.2% and 51.4% respectively. In 64.8% of cases, the criteria Tokuhashi scale for therapeutic decision making, with a 71.6% consistency prognosis. Exitus rate was 92.3%, with a median survival of 12.8 months, with less than 6 months in 53% of patients.

Conclusions: In our setting, the primary tumors with vertebral metastases more frequent, as described in the literature, are lung, breast and prostate. Patients undergoing surgery had a greater improvement in pain and functionality that patients treated with radiotherapy. This seems more related to the baseline of the patient with the type of treatment itself. Note that in 64.8% followed the recommendations of the Tokuhashi scale, low percentage for a scale with a prognostic high consistency as described in the literature.

V-318
ANALYSIS OF PATIENTS WITH PERCUTANEOUS ENDOSCOPIC GASTROSTOMY

C. Fernández Méndez, N. Pazos Otero, M. Blanco, L. Amador Barciela

H.A.D.O. Complejo Universitario de Vigo. Vigo (Pontevedra), Spain.

Objectives: Investigation of the characteristics of patients who received percutaneous endoscopic gastrostomy (PEG) feeding, indications of placement, and complications of the procedure.

Material and method: Design: A retrospective analysis was undertaken of patients who had a PEG tube replacement between January and February 2011. The data of the subjects were collected from the Hospital at Home Service follow-up registers. In the sanitary area of the C.H.U.V.I. (Complejo Hospitalario Universitario de Vigo (Galicia, Spain); University Hospital Complex of Vigo), the nurses in the Hospital at Home Service (HADO) are responsible for the replacement of PEG tubes once they have been inserted at hospital. The patients' clinical features were collected from the computer application that stores the clinical records of the patients in Galician hospitals (IANUS). The following parameters were analysed: age, gender, indication and timing of PEG tube insertion, and complications of the procedure. Setting: HADO Service (Hospital at Home) patients, sanitary area of CHUVI. Subjects: 40 patients who had PEG tube replacement during the time of study.

Results: The average age of the patients was 75,725 (range 34-100). Most of them were women, 25 patients (62, 5%). The commonest reason for PEG tube placement was dementia (65% of the cases). Other reasons were acute stroke (8 cases, 20%), neurodegenerative disease (2 cases, 5%), neoplasias of the upper gastrointestinal tract and the respiratory upper tract (4 cases, 10%). The complications of the procedure were long-term complications in almost all the cases. Only one of the patients in the study group had a short-term complication, namely, pneumoperitoneum related to PEG insertion. Aspiration pneumonia was the commonest long-term complication; 23 patients were admitted to hospital because of it (57% of the study group). The average number of admissions for each of the patients with aspiration pneumonia was 2.56 (range 1-10). There were other long term complications: PEG tube fell out (11 patients; 27, 5%), blocked PEG tube (7 patients; 17.5 %), PEG tube snapped (9 patients; 22, 5%), PEG site infection (3 patients; 7.5%).

Conclusions: PEG feeding is the preferred method of long-term enteral feeding. Dementia is the most common diagnosis in the patients who undergo a PEG tube placement. Most of the patients who need a PEG tube placement are ancient women. The procedure implies almost no short-term complications (1 out of 40 subjects in our study). Aspiration pneumonia is the commonest long term complication (57, 5% patients in the study group, who required an average of 2.56 hospital admissions since the PEG tube was placed).

V-321
STUDY OF DIARRHEA IN THE YEAR 2011 IN A REGIONAL HOSPITAL

D. Navarro Moreno, P. Ruiz Sanjuán, I. Machuca Sánchez, M. Camilo Haché, J. Arrebola Benítez, J. Manchón Castilla, M. Koussa Madroñal, M. Nieto Riesco

Department of Internal Medicine. Hospital Virgen del Puerto. Plasencia (Cáceres), Spain.

Objectives: Knowing the characteristics of diarrhea admitted to our hospital in Internal Medicine and Geriatrics. Estimating the frequency of the different variables considered in the patient's history, debut, diagnostic tests, diagnoses and type of treatment required. Knowing the most common mechanisms producing infectious diarrhea.

Material and method: We performed a data collection of all patients admitted to the Internal Medicine and Geriatrics in 2011 due to diarrhea, corresponding 52 cases (32% of diarrhea admitted to our hospital this year). It comes with a frequency analysis of various variables: entered service (Internal Medicine or Geriatrics), age, sex, duration (acute, persistent and chronic), characteristics (with or without pathological products, abdominal pain, vomiting, wasting syndrome, fever), immunosuppression, after taking antibiotics, diagnostic tests (stool, parasites, Clostridium difficile, blood) and imaging (CT, endoscopy), diagnosis (nonspecific diarrhea, bacterial, virus, parasites/fungi, organic, other causes), treatment required (nothing or fluid replacement, antibiotic therapy or surgery). Descriptive study of the different micro-organisms.

Results: The N is 52 study patients, corresponding to 31.9% of diarrhea admitted to the Hospital Virgen del Puerto in 2011. The frequency of the different variables is: Income in Internal Medicine 63.4% and Geriatrics 36.6%. Age: mean age of 66.8 years, 73% aged over 65 years and 27% lower. Gender: 61.5% were female and 38.5% men. Personal history: immunosuppression in 27% of cases (chronic kidney disease, kidney cancer and were taking steroids 33.3% and

66% prostate, uterus or digestive cancer and cohabiting in a residence) and taking antibiotics previously 21.1% of patients. Duration: 65% acute, persistent 19.2% and chronic 15.3%. Features: with pathological products 21.2%, fever 13.4%, 32.6% abdominal pain, vomiting 46% and 21.1% wasting syndrome. Diagnosis: stool cultures positive at 9.6%, 13.5% negative parasites and toxin of C. difficile present 9.6%. No positive blood culture. There were 15.6% CT and 21.5% colonoscopies. Regarding diagnosis, 54.9% were non-specific, 19.6% bacterial (40% with previous shot of antibiotics and Clostridium difficile more common by 45%, 36% followed by Salmonella 36%, E. coli 9% and C. jejuni 9%), 1.9% viral (rotavirus) and 23.5% for other reasons (intolerance to oral iron, treatment with duloxetine, inflammatory bowel disease or with no clear etiology). We found no cases with parasites, fungi or associated with neoplasia. Most were treated with fluid replacement 54.9% and 45% with antibiotics.

Discussion: Diarrhoea is usually a benign and self-limiting, in which most patients require only symptomatic treatment and sometimes with antibiotics. The most common infectious cause is bacterial. Colonic neoplasia is little cause of diarrhea there is to limit the use of tests such as colonoscopy.

Conclusions: Factors such as immunosuppression and the use of antibiotics are associated with increased likelihood of diarrhea, and especially that caused by Clostridium difficile. We found rare causes of diarrhea, as can be related to SSRIs (duloxetine) or intolerance to oral iron, demonstrating the importance of history in the medical record.

V-322
INSERTABLE LOOP RECORDER: EXPERIENCE IN OUR HOSPITAL

M. Iguzquiza Pellejero[1], T. Matajira Chia[2], P. Artero Bello[2], P. Revilla Martí[2], L. Castro Figueroa[2], A. Sánchez Val[2]

[1]Department of Internal Medicine, [2]Department of Cardiology. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: The aim of our study was evaluate the profile of the patient who is implanted an insertable loop recorder and determine the diagnostic performance of this device in our Hospital.

Material and method: Study Observational, descriptive, retrospective of insertable loop recorder performed at our institution from 1998 to March 2012.Clinical, epidemiological data were collected. All devices were programmed to trigger automatic or manual. It was studied at the time of explant or at one year.

Results: There were 74 patients, mean age 65.12 (11-85), 37 males (50%). The main indication for implantation was 83% recurrent syncope (62 cases), among other indications were palpitations 1 case (1.4%), monitoring of patients with atrial fibrillation, ablation 1 case (1.4%). In 43 cases, 58.1% showed no pathological findings. It provides evidence of a cause of syncope based on the following findings: 7 cases of complete AV block (9.5%)%), 3 cases 2:1 AV block (4.1%), 4 cases of sick sinus syndrome (5.4%), 2 cases slow atrial fibrillation (2.7%), 1 case of non-sustained ventricular tachycardia (1.4%), 2 cases of bradycardia syndrome-tachycardia (2.7%). In 5 cases (6.8%) was confirmed vasovagal syncope profile and 2 cases (2.7%) was confirmed neurological etiology. As a complication 2 devices were removed due to infection. According to the findings in insertable loop recorder was implanted 15 pacemaker and 1 DAI.

Conclusions: The profile of the patient who is holter loop insertable is a patient in the sixth decade of life presenting syncope of unknown etiology. The Holter loop insertable helped to show an etiology of syncope from vasovagal pathology confirmation to the indication of ICD implantation. Becoming a useful tool in selected cases of syncope in clinical practice.

V-323
MANAGEMENT OF DIPLOPIA CASES IN A REGIONAL HOSPITAL

M. Gómez Hernández[1], A. Vergara Díaz[1], M. Romero Rivero[1], R. de la Rosa Morales[1], R. Espinosa Calleja[1], S. Vidal Serrano[1], S. Andrades Segura[2]

[1]Department of Internal Medicine, [2]Department of Community and Family Medicine. Hospital San Juan de Dios de El Aljarafe. Sevilla, Spain.

Objectives: The aim is to conduct a descriptive assessment of the Management of the diplopia cases assessed in a regional hospital.

Material and method: We conducted a retrospective descriptive study of a series of clinical cases assessed by diplopia, first in the Emergency Department and subsequently monitored in the Internal Medicine or the Ophthalmology Areas. This study took place between 1st of January 2009 and the 31st of December 2011. Several variables were analyzed, such as: sex, age, type of diplopia, description of affected cranial nerve type, first contact service, cranial CT scan carrying out, period of time between the debut and the first medical assistance at Ophthalmology or Internal Medicine and etiology of the diplopia.

Results: The sample consists on 56 patients, 26 women (46.4%) and 30 men (53.5%). The mean age is 58.5 years old (89-23). The type of diplopia stated on the clinical report was horizontal on the debut for the 38% of the cases, non-specified for the 16% and vertical for the 2%. The affected cranial nerve type was undefined for the 27% of the cases, showed variability in its determination by 16% of the patients and VI PC predominated (23%) followed by III PC (23%) and IV (12%) amongst the cases where it was defined. Emergency was the service which established the first contact with the clinical case in the majority of the situations (54%); the rest were first assessed in the Ophthalmology or the Internal Medicine Areas. A cranial CT scan was carried out in 59% of the cases. The mean period of time between the debut and the first medical assistance at Internal Medicine was 8 days (from 0 up to 52 days). The classification of etilogies is: microangiopathic (DM) 48% idiopathic 17%, tiroid orbitopathy 5%, neuromuscular pathology: miastenia gravis, area ORL pathology, orbitary pseudotumor, ophtalmoplegic migraine, tumoral (neurinoma-meningioma), sd. Tolosa Hunt.

Discussion: The diplopia of non-ophtalmic etiology is a severe clinic entity and has a very broad spectrum of presentation. We work in a regional hospital, where the medical specialty of Neurology or the sub- specialty of Neuro-ophthalmology do not exist. It is therefore established a protocol in the process of diagnosis, monitoring and treatment of diplopies involving several areas: Emergency, Internal Medicine and Ophthalmology. The importance of this study lies in the absence of clinical practice guidelines in the existing literature, partly due to the existence of multiple etiologies responsible for the development of diplopia.

Conclusions: Diabetic microangiopathy was the most common etiology of diplopies. The collaboration between the areas of Ophthalmology and Internal Medicine has sped up the global assessment of patients with diplopia. The possibility of carrying out an initial assessment followed by a detailed diagnosis of the neuromuscular dysfunction at the Ophthalmology Service appears to be an interesting area for future improvement.

V-325
RENAL HISTOPATHOLOGICAL FINDINGS IN PATIENTS WITH 2,8- DYHYDROXYADENINURIA

H. Runólfsdóttir[1], V. Edvardsson[1,2], S. Hardarson[2], R. Palsson[1,2]

[1]Faculty of Medicine. University of Iceland. Reykjavik, Iceland. [2]Landspitali – The National University Hospital of Iceland. Reykjavik, Iceland.

Objectives: Adenine phosphoribosyltransferase (APRT) deficiency is an autosomal recessive disorder of purine metabolism that leads to excessive urinary excretion of the poorly soluble 2.8-dihydroxyadenine (DHA), causing kidney stones and chronic kidney disease (CKD). Lack of awareness among clinicians and pathologists may contribute to the low number of reported cases worldwide. The aim of this study was to characterize the renal histopathological findings in Icelandic patients with 2.8-dihydroxyadeninuria.

Material and method: The medical records of 32 Icelandic patients listed in the APRT Deficiency Registry of the Rare Kidney Stone Consortium were reviewed. Patients who had undergone a native kidney biopsy procedure or nephrectomy were identified. All renal biopsies and nephrectomy specimens were reviewed by an experienced renal pathologist.

Results: Three of the 32 patients had undergone a kidney biopsy and one had undergone nephrectomy. Patient 1 was a 55 year old woman with severe acute kidney injury superimposed upon mild CKD but no past history of stone disease. Patient 2 was a 42 year old woman with past history of recurrent kidney stones presumed to be composed of uric acid and stage 4 CKD. Patient 3 was a 42 year old man with acute kidney injury superimposed on advanced CKD and history of recurrent kidney stones since childhood. Patient 4 presented at the age of 14 months with oliguric acute kidney injury due to bilateral stone impaction, requiring unilateral nephrectomy. Histologic examination revealed extensive DHA crystal deposits and variable degree of renal scarring, chronic interstitial inflammation and glomerulosclerosis in all 4 cases. Polarized light greatly facilitated the detection of renal crystals. Distribution of the DHA crystals in the kidney are summarized in the Table.

Discussion: Renal histopathological findings in patients with APRT deficiency include extensive DHA crystal deposits which appear to cause significant tubulointerstitial scarring and inflammation. DHA crystals appear to be primarily located in the renal cortex, most commonly within tubular lumens.

Conclusions: APRT deficiency causes crystalline nephropathy with characteristic histopathological features. Care must be taken not to confuse 2.8-dihydroxyadeninuria with other forms of crystalline nephropathies.

PATIENTS UNDER TREATMENT WITH VITAMIN K ANTAGONIST AND NONVALVULAR ATRIAL FIBRILLATION: ANALYSIS OF ADVERSE EVENTS AND HOSPITALIZATION DUE TO THIS ISSUE

R. Pérez Temprano, R. Cortés Peláez, E. García Sánchez, J. Jiménez Gallardo, M. Colmenero, R. Pérez Cano

Department of Internal Medicine. Complejo Hospitalario Regional Virgen Macarena. Sevilla, Spain.

Objectives: Although vitamin K antagonist reduce the stroke risk in atrial fibrillation by as much as 60%, and guidelines recommend them for reduction of stroke risk in AF patients at moderate to high risk of stroke, they are contraindicated in many patients and often underutilized even in eligible patients for whom they are indicated. This antagonist has numerous food and drug interactions, a relatively narrow therapeutic window, increased risk of bleeding, and the requirement for frequent monitoring and dose adjustments. For all these reasons we wanted to know the characteristics of adverse events hospitalizations due to these problems.

Material and method: We analyzed the episodes of adverse events in a one year period, that required hospitalization due to vitamin K antagonist treatment, in patients with nonvavular atrial fibrillation, in a third level hospital, covering a population of 500,000 people, in Spain. Descriptive study has been made from medical reports out of the hospital data base.

Results: A total of 46 subjects were included, 20 females (43.5%) and 26 males (56.5%) with a mean age of 76 ± 8.9. Most of the patients were hospitalized in Internal Medicine (73.9%). Three patients (6.5%) died during hospitalization and eighteen (39.1%) required blood transfusion. CHADS-VASC of 3 or more points were observed in 76% of patients, and 5 or more in 34.7%. HASBLED index PRE-episode, 3 points or more in 17.4% of patients and 5 or more in 2.2%. HASBLED POST-episode, 3 or more in 65.2%, and 5 or more in 6.5%. Previous hospitalization for this issue, sixteen (34.8%). A total of thirty five (76%) continued with vitamin K antagonist after the episode. Most frequent adverse events were, haematoma of the rectus sheath and soft tissues (21.7%), hematuria (18%), upper gastrointestinal bleeds (17%), high INR and anemia (17%), low gastrointestinal bleeds (11%) and haemoptysis (6.5%).

Conclusions: We have observed a clearly increased on the HASBLED index after the adverse episode, and some patients had a previous hospitalization for this matter. This supposes an increase one year bleed, justifying more regular reviews, that in some cases does not really happen. We should consider in these cases a change on our therapeutic approach considering the new anticoagulant agents.

Table 1 (V-325)

Patients	Location of crystals			
	Tubular lumen	Inside tubular cells	Interstitium	Cortex/medulla
1	3+	3+	1+	3+/1+
2	2+	2+	1+	3+/1+
3	3+	3+	1+	No medulla in biopsy
4	1+	1+	1+/0	Mostly in cortex

ISCHEMIC COLITIS: A PREVALENT BENIGN ILLNESS IN OLD PEOPLE

S. García Martínez[1], M. Pérez Panizo[1], R. García Díez[1], S. Rodríguez García[1], C. Ruíz Bayón[1], E. Castelar Delgado[1], P. Dios Díez[1], A. Domínguez Carbajo[2]

[1]Department of Internal Medicine, [2]Department of Gastroenterology and Hepatology. Complejo Asistencial de León. León, Spain.

Objectives: Ischemic colitis (IC) is the most frequent form of mesenteric ischemia, affecting mostly elderly with cardiovascular risk factors (CVRF). The aim of this study is to review the clinical presentation of IC in a tertiary hospital.

Material and method: Retrospective study of IC presented during 2011 at Complejo Asistencial Universitario de León. Diagnostic criteria for IC were: 1. High clinical suspicion: patient ≥ 60 years old + ≥ 1CVRF. 2. Diagnostic colonoscopy (either by macro or microscopic findings). 3. Diagnostic laparoscopy or laparotomy. 4. Mild clinical suspicion + suggestive Ultrasound Scan (US) or abdominal CT. Exclusion criteria: Colonic ischemia due not to arteriosclerosis, but mechanical process.

Results: We analyzed 66 patients with mean age of 76 years (range 49-94) and similar gender distribution (55% females). The main risk factors showed were: previous ischemia event (34%) [coronary (15%), ictus (17%), intermittent claudication (2%), IC (8%)]; smoking (26%), alcoholism (12%), obesity (9%), hypertension (74%), diabetes mellitus (32%), dyslipemia (35%), NSAIDs (14%), COPD (6%), previous abdominal (26%) or vascular(8%) surgery. The main symptoms at diagnosis were: abdominal pain (83%), vomiting (9%), diarrhea (51%), rectorrhagia (74%), fever (17%) and hemodinamic instability (22%). Colonoscopy was performed in the 83% of the cases, with a compatible histology in the 80%. Antibiotics were used in the 91%: ciprofloxacin + metronidazole in the 63%. IC was reason for admission in the 88% of the cases, and in the remaining 12% it was a diagnosis in patients hospitalized for other causes. About the outcome, surgery was necessary in 4 patients (6%), complications appeared in the 23%, and the 9% of the patients died during admission.

Conclusions: IC is present in old subjects with CVRF and evidence of arteriosclerosis (previous ischemic event). The classic clinical presentation consists of abdominal pain and rectorrhagia. Although outcome is generally good, some patients experienced severe forms and poor prognosis.

A RARE CASE OF HEPATITIS C NEGATIVE MIXED TYPE (TYPE 2) CRYOGLOBULINEMIA

J. Schilders, H. Van Zaanen, A. Brouwers

Department of Internal Medicine. Sint Franciscus Gasthuis. Rotterdam, Netherlands.

Objectives: Cryoglobulinemia is defined as one or more immunoglobulins in the serum which precipitate at temperatures below 37C and dissolve again on rewarming. Criteria for the classification of cryoglobulinemia patients are based on serologic, pathologic and clinical findings. We present a patient with hepatitis C negative mixed type cryoglobulinemia.

Results: Case report: a 58-year old Caucasian man was admitted to the Intensive Care because of an arterial occlusion and was treated with urokinase and stenting. During admission he was successfully treated with clarythromycin because of pneumonia. One month after discharge the patient returned with hypoxemia with massive hemoptysis. He was readmitted to the Intensive Care for intubation and mechanical ventilation. Physical examination showed erythematous lesions on his lower extremities, biopsy showed a leukocytoclastic vasculitis. We found an increased level of creatinine with dysmorphic erythrocytes in the urinanalysis, suggesting glomerulonephritis. Decreased levels of C3, C4 and an elevated C1q-bindingtest suggested activation of the immune system. Over time the patient developed progressive renal failure, all tests for auto-immune diseases (ANA, ENA, ANCA, anti-CCP) were negative except for a positive IgM rheumatoid factor. Also viral tests including hepatitis C RNA were negative. Because of a possible seronegative Wegener granulomatosis he started with prednisone, cyclophosphamide and plasmapheresis, with poor result. Additionally a monoclonal IgM-kappa paraprotein and cryoglobulins were present in the serum. Bone marrow biopsy (performed after initial treatment) showed 1% plasma cells and 15% B-lymphocytes with an increased kappa/lambda ratio of 47, the ratio of kappa/lambda free light chains in the serum was also increased (ratio 23). We concluded that the patient had a hepatitis C virus negative mixed cryoglobulinemia (type 2) with diffuse alveolar haemorrhage, leukocytoclastic vasculitis of the skin and glomerulonephritis. He was treated with prednisone 1 mg/kg daily and rituximab 375 mg/m^2 weekly for 4 weeks. Currently he is doing well and is treated with prednisone (tapering scheme) and rituximab every three months (for 2 years according to non Hodgkin lymphoma protocols). Kappa/lambda ratios, IgM, complement levels etc. are normalised and cryoglobulins can not be detected anymore.

Conclusions: Cryoglobulinemia mixed type 2 is an immune complex-mediated systemic vasculitis. In a majority of cases it is induced by B-cell activation by the hepatitis C virus, therefore HCV-negative cryoglobulinemia is very rare. It is unknown what the causative factors are involving HCV-negative cryoglobulinemia mixed type 2, but this diagnosis should always be considered in HCV-negative patients.

SMALL BOWEL ANGIOEDEMA DUE TO ACQUIRED C1 INHIBITOR DEFICIENCY

T. Oostergo[1], G. Prins[1], Y. Schrama[2], I. Leeuwenburgh[3]

[1]Department of Internal Medicine, [2]Department of Nephrology, [3]Department of Gastroenterology and Hepatology. Sint Franciscus Gasthuis. Rotterdam, Netherlands.

Objectives: Acquired angioedema (AAE) is a rare disorder due to an acquired deficiency of C1 inhibitor. It is characterized by nonpitting, nonpruritic subcutaneous or submucosal edema of the skin, respiratory of gastrointestinal tract. When localized in the gastrointestinal tract it can cause severe abdominal pain, mimicking an acute surgical abdomen, or chronic recurrent pain of moderate intensity. The disorder is associated with B cell lymphoproliferative disorders and autoimmune diseases.

Results: We report a case of a 48-year old man presenting with recurrent episodes of hypotension and abdominal pain. Computed tomography of the abdomen showed edema of the small bowel. The first determinations of C1 inhibitor level and activity, determined in a symptom free period, were normal. Repetition of the test in the acute phase however, showed low C1 inhibitor level. Further diagnostic work-up revealed an acquired C1 inhibitor deficiency possibly due to a monoclonal gammapathy. This man was treated with tranexamic acid as prophylaxis for his frequent attacks and till now on he is free of symptoms.

Conclusions: The diagnosis of acquired C1 inhibitor deficiency is based on the medical history and on plasma C4, C1q and C1 inhibitor level and activity. In case of high suspicion and a normal C1 inhibitor activity, it is recommended to repeat this test during an angioedema attack. Early diagnosis is important for treatment of severe, potentially life-threatening attacks and to start prophylactic treatment in patients with frequent or severe angioedema attacks.
