CLINICAL EVALUATION OF ESTABLISHED AND NOVEL BIOMARKERS FOR PREDICTION OF POSITIVE BLOOD CULTURES IN SYSTEMIC INFLAMMATORY RESPONSE SYNDROME

M. Hoenigl[1], J. Wagner[1], K. Seeber[1], T. Valentin[1], A. Grisold[2], E. Leitner[2], R. Raggam[1], R. Krause[1]

[1]Department of Internal Medicine. Medical University of Graz, Austria. [2]Institute of Hygiene. Medical University of Graz, Austria.

Objectives: Sensitive biomarkers for early prediction of positive blood cultures in patients with SIRS are urgently needed to provide valuable information for decision-making in the very early onset of the clinical setting. Soluble urokinase plasminogen activator receptor (suPAR) levels reflect inflammation and elevated suPAR levels are found in several infectious diseases. We will evaluate diagnostic potential of suPAR in patients with SIRS and compare results to markers routinely used (PCT, IL-6 and CRP).

Material and method: A total of 132 patients with SIRS were included. In 55 patients blood cultures had resulted positive (Study group 1: causative pathogens, Staphylococcus aureus, Streptococcus spp.; Study group 2, causative pathogens gram-negative bacteria) and 77 patients had negative blood culture results (control group). Simultaneously with blood cultures suPAR, C-reactive protein (CRP), procalcitonin (PCT), interleukin-6 (IL-6) and white blood count (WBC) were determined.

Results: Markedly elevated suPAR levels were found for the SIRS collective (mean 8.0249 (SD ± 3,783) when compared to values previously published for healthy controls (median 3.38; IQR 2.75-4.30 ng/mL). SuPAR values were significantly higher in study group 1 (n = 15, median 8.11; IQR 5.78-15.53; p = 0.006) and study group 2 (n = 40, median 9.62; IQR 6.52-11.74; p < 0.001) when compared with the control group (n = 77, median 5.65; IQR 4.30-7.83). ROC curve analysis revealed an AUC of 0.726 for suPAR in differentiating SIRS patients with septicaemia from those without. The biomarkers PCT (group1, p = 0.001; group2, p = 0.002) and IL-6 (group 1, p < 0.001; group 2, p = 0.017) showed comparable results, while CRP and WBC failed to predict septicaemia.

Discussion: Results may indicate that suPAR, IL-6, and also PCT seem to have a higher potential in predicting bacteremia than CRP and WBC. For PCT and IL-6 this may in particular apply for bacteremia by S. aureus or Streptococcus spp. as both parameters were significantly higher when bacteremia was caused by these organisms. suPAR on the other hand seems to have potential to predict also gram-negative bacteremia, in which suPAR seems to be superior to the comparators.

Conclusions: Preliminary results suggest that suPAR may help predicting bacteremia in clinical routine.

A-28
METABOLIC SYNDROME AS PROGNOSTIC FACTOR IN COMMUNITY-ACQUIRED PNEUMONIA

M. Ramírez[1], M. Falguera[1], A. Gasol[2], A. Ruiz-González[1], I. Chica[1], P. Cabezas[1], M. Vila[3], J. Porcel[1]

[1]Department of Internal Medicine, [2]Department of Oncology, [3]Department of Pulmonology. Hospital Universitari Arnau de Vilanova. Lleida, Spain.

Objectives: The metabolic syndrome has been identified as a multiplex risk factor for cardiovascular disease, associated with

poor prognosis in many pathological processes. To date, the consequences of metabolic syndrome on the outcome of infectious diseases have not been extensively investigated. We aimed to evaluate the impact of metabolic syndrome on the etiology, the mortality and other outcome parameters in patients admitted with community-acquired pneumonia (CAP).

Material and method: This prospective observational study was performed at the University Arnau de Vilanova Hospital in Lleida (Spain) between January 2008 and March 2010 and includes all consecutive non-immunocompromised patients over 18 years old hospitalised for CAP. Risk factors from the National Cholesterol Education Program Adult Treatment Panel III 2001 (NCEP-ATP III) were used to categorize patients as having metabolic syndrome. Other well-recognized prognostic factors were simultaneously collected from patients. Blood, sputum and pleural fluid cultures, antigen detection tests for Streptococcus pneumoniae and Legionella pneumophila and serological tests were used to determine the etiology of cases. Univariate analysis were employed to evaluate the association between metabolic syndrome and outcome, including the following parameters: mortality during admission, mortality at 30 days, global mortality, exacerbation of underlying diseases during admission, development of empyema, admission to the Intensive Care Unit and hospital readmission after discharge. Multivariate analysis, by using the logistic regression model, was employed to evaluate the relation between metabolic syndrome and mortality during admission. Continuous variables were recategorized into binary factors using the most discriminant cut-off point. Results of multivariate analysis were reported as p values and 95% confidence intervals. Statistical significance was set at $p < 0.05$.

Results: A total of 296 cases were enrolled in the study. The mean age of patients was 64 years and 66% of them were males. The prevalence of metabolic syndrome among patients was 38.5%. Univariate analysis showed that metabolic syndrome was significantly associated with the following outcome variables: mortality during admission ($p = 0.001$), global mortality ($p = 0.009$) and exacerbation of underlying diseases during admission ($p = 0.016$). Spectrum of pathogens causing pneumonia did not appear related to the presence of metabolic syndrome, being S. pneumoniae the most common pathogen in both subgroups of patients. The following variables were evaluated in the multivariate analysis as potential prognostic factors for mortality during admission: metabolic syndrome, respiratory rate (> 30 cycles/minute), confusion, septic shock, oxygen saturation (< 88%), $PaCO_2$ (> 50 mmHg) and systolic blood pressure (< 90 mmHg). The metabolic syndrome ($p = 0.010$, 95%CI 2.54-1003.05) was selected as an independent prognostic factor for mortality. Other prognostic factors, identified in this multivariate analysis, were low systolic blood pressure ($p = 0.044$, 95%CI 0.94-0.99), tachypnea ($p = 0.021$, 95%CI 1.39-58.28), low oxygen saturation ($p = 0.035$; 95%CI 1.15-46.36) and confusion ($p = 0.021$, 95%CI 1.44-81.74).

Conclusions: About 40% of patients admitted with CAP had metabolic syndrome. This fact conducted to an increased in-hospital and global mortalities, increased risk of exacerbation of underlying diseases and readmission rate after discharge in univariate analyses; however, no impact was observed on the etiology. Metabolic syndrome remained as an independent risk factor for mortality during admission in the multivariate analysis. In summary, our study suggests that the metabolic syndrome could be a relevant prognostic factor in hospitalised patients with CAP.

HOME INTRAVENOUS ANTIMICROBIAL TREATMENT OF HEALTH-CARE-ASSOCIATED INFECTIONS IN HOSPITAL AT HOME UNITS RESULTS FROM A PROSPECTIVE MULTICENTRIC REGISTRY IN SPAIN

V. González Ramallo[1], M. del Río[2], M. Fernández Miera[3], P. Sanroma[3], O. Estrada[4], M. Mirón[5], B. Massa[6] on behalf of the Group GESTADE

[1]Hospital at Home Unit. Hospital General Universitario Gregorio Marañón, Madrid, Spain. [2]Hospital at Home Unit. Hospital Son Espases. Palma de Mallorca (Illes Balears), Spain. [3]Hospital at Home Unit.Hospital Valdecilla. Santander (Cantabria), Spain. [4]Hospital at Home Unit Hospital Universitari Germans Trias i Pujol. Badalona (Barcelona), Spain. [5]Hospital at Home Unit. Hospital de Torrejón. Torrejón de Ardoz (Madrid), Spain. [6]Hospital at Home Unit.Hospital de La Vila-joiosa. Alicante, Spain.

Objectives: To communicate the characteristics of Health-Care-Associated infections (HCAI) treated in the Hospital at Home Units (HHU) of Spain according to data obtained from the Spanish prospective multicenter TADE Registry. To compare such results with those of community acquired infections included in the same registry.

Material and method: 168 episodes of HCAI treated at HHU included in the prospective multi center TADE registry for an 11 months period (July 2011-May 2012). The location of the infection was analyzed, the causative microorganism, antibiotic sensitivity, the treatment applied and clinical and microbiological outcome. The data were compared with the 510 community acquired infections included in the registry during the same period of time.

Results: The HCAI summed 24.7% of the infections treated at HHU (168/678). Most of the patients admitted in HHU came from a hospital ward (82%), being internal medicine the most frequent origin (45%). The most frequent types of infections being: urinary (26%), skin and soft tissues (17%), respiratory (16%), intra abdominal (15%), and primary bacteremias (14%). The causal agent was identified in 79% of the cases; the most frequently isolated were: Escherichia coli (31; 11 of this with ESBL), Staphylococcus spp. (24; 10 of this methicilin resistant), Pseudomonas spp (21), Enterococcus spp. (19) Klebsiella spp (13) and funghi (10). The most extensively used antimicrobials were: ertapenem (35), piperaciline-tazobactam (25), ceftriaxone (21), daptomycin (12), vancomycin (10) and ceftazidime (9). In 27% of the cases elastomeric devices were used for the infusion and electronic bombs in 24%. In 75% of the cases a peripheral venous catheter was used, in 17% a peripheral insertion central venous catheter and in a 10% central venous accesses of central insertion. The treatment period was 11.8 ± 11.5 days (1-84), being able to complete an 85% of the prescribed treatments. In 86% of the cases healing or improvement was obtained. In 20 cases (12%) readmission to conventional hospitalization was needed, and four (2.3%) patients died at home. The community acquired infections treated at home preferably used ceftriaxone (155, 30%), being the treatment period substantially shorter (10.1 ± 8.2 d) and needing less readmission (5.4%).

Discussion: The HCAI have become a more and more frequent problem meaning an increasing expense due to necessary hospital admissions as well as augmenting isolation problems. The treatment at home of these infections has become frequent in Spain by HHU. In most of the cases the evolution is favorable although the treatment period is longer and the failure rates and readmission are higher than in community acquired infections.

Conclusions: The treatment of HCAI means a fourth part of the intravenous antimicrobial home treatments in Spain. Although the evolution of these is less favorable than that of community acquired infections, the home treatment of these processes is a safe enough measure so as to be recommended in specialized Hospital at Home Units.

A-51
HOME ANTIBIOTIC TREATMENT OF PATIENTS WITH FEBRILE NEUTROPENIA

C. Fehér[1], J. Aibar[2], J. Pericás[1], D. Nicolás[1], S. Fernández[1], N. Seijas[2], C. Hernández[2]

[1]Department of Internal Medicine, [2]Integrated Care Unit, Medical and Nursing Direction. Hospital Clínic. Barcelona, Spain.

Objectives: Patients with febrile neutropenia traditionally require in-hospital intravenous antibiotic treatment because of the risk of serious complications and associated mortality. In a subgroup of these patients who are considered 'low risk', however, treatment in the outpatient setting may be considered. One of such alternatives to hospital admission is the hospital-at-home program (HaH). The aim of this study is to evaluate the efficacy and safety of HaH program in the case of febrile neutropenia and to determine the factors associated to poor prognosis in these patients.

Material and method: 60 cases of patients with febrile neutropenia included in our HaH program between March 2007 and October 2011 were revised. Data were obtained from the data base of the HaH program of the Integrated Care Unit (Medical and Nursing Direction, Hospital Clínic Barcelona) and from clinical history files of each patient. Poor prognosis was defined as a clinical course leading to Emergency Department (ED) visits, hospital readmission or death during the 30 days following HaH discharge. Statistical analyses were performed by means of Fisher's exact test, Student's t test and logistic regression analysis using the software IBM SPSS Statistics version 20.

Results: There were 35 female and 25 male patients included in the study. Their mean age was 59.7 years (SD 10.9). 81.7% were referred to the HaH program by the Onco-Hematology Department and 18.3% were admitted directly from the ED. 20 patients had lung cancer, 22 had breast cancer, 9 had cancer of the urogenital apparatus, 3 had lymphoma and 6 had other miscellaneous conditions. At admission median C-reactive protein (CRP) level was 6.5 mg/dl and mean absolute neutrophil count (ANC) was 581.3 cells/µL (474.7); at discharge these values were 2.7 mg/dl and 5011.9 cells/µL (SD 4996.5) respectively. 91.7% of the patients received intravenous antibiotic, 9.1% of these in form of continuous infusion, being Ceftriaxone and Ertapenem the most frequently used antibiotics. Microbiological evidence of infection was found in 11 cases, being E. coli the most frequent causative organism (5 cases). Median length of HaH stay was 6 days. 14 patients (23.3%) had to visit the ED again and/or needed hospitalization within 30 days after HaH discharge, one of whom died during hospital stay. By logistic regression analysis we found that a higher CRP level at HaH admission is a factor independently associated to this clinical course (OR 1.115 95%CI 1.010 to 1.232).

Discussion: Patients with febrile neutropenia associated to anti-tumor chemotherapy are prone to lack clear infectious focus and to have sterile cultures, hence the indication of broad-spectrum antibiotic therapy. Complications are not uncommon either in this collective. However, HaH has proved to be a valid alternative to hospitalization of selected low-risk patients. Almost a quarter of the patients of this study had to consult a doctor again within 30 days of HaH discharge. High CRP levels indicate more severe infection or increased inflammatory response and are known to be associated to poor outcome in febrile neutropenia episodes. CRP has also proven to be a negative prognostic factor in various malignancies. The relatively low sample size of this study has been a factor limiting the statistical power of the analysis.

Conclusions: Hospital-at-home is a good alternative to hospitalization in the management of cancer patients with low-risk febrile neutropenia. High CRP level at admission was a factor associated to poor prognosis in a 30-day follow-up after HaH discharge.

A-55
STUDY OF COMMUNITY-ACQUIRED BACTEREMIA IN AN EMERGENCY ROOM FROM WHOM TO DRAW BLOOD CULTURES?

M. Torralba, M. de Vicente Collado, A. Costa Cerdá, S. Laínez, B. Martínez, A. Pereira, E. Martín-Echevarría, M. Rodríguez Zapata

Department of Internal Medicine. Hospital Universitario. Guadalajara, Spain.

Objectives: The decision of whom to draw blood cultures from in the Emergency Room (ER) is not resolved. Our objective was to analyze the predictors of bacteremia in the ER and establish a clinical prediction model (CPM) of bacteremia.

Material and method: Cross sectional study with prospective collection of variables and compared against microbiological patterns. Consecutively included patients older than 13 years from whom blood cultures were drawn over a period of 24 months. Clinicians were asked, pre-test, to predict the probability of positive blood culture. CPM has been developed that allowed us to stratify the study population into groups with different risks of bacteremia. The significant variables in univariate analysis were entered into a multiple logistic regression model with stepwise exclusion, using the existence of bacteremia as the dependent variable. After logistic regression to identify independent predictors of bacteremia, a score was assigned to each variable depending on the odds ratio of bacteremia in the multivariate analysis.

Results: We analyzed 693 patients of whom 149 had bacteremias. The variables associated with the presence of bacteremia in the univariate analysis were: diabetes, taking antibiotics before collection of blood culture, the probability pre-test before the extraction of the blood culture, the percentage of neutrophils greater than 80%, systolic blood pressure below 90 mmHg, age, platelets, fibrinogen and C-reactive protein (CRP). In multivariate analysis, the variables independently associated with the diagnosis of bacteremia were: diabetes (OR: 2.17, 95%CI: 1.16-4.07; p = 0.016), taking antibiotics before the blood culture (OR 0.16, 95%CI: 0.08-0.33; p = 0.00001), having more than 80% neutrophils (OR 3.4, 95%CI: 1.88-6.28), p = 0.001), presenting a onco-haematological disease (OR 1.72, 95%CI: 0.98-3.02; p = 0.058), age/10 (OR 1.16, 95%CI: 1.02-1.31; p = 0.023) and increased plasmatic fibrinogen/100 (OR 1.2, 95%CI: 1.08-1.33; p = 0.0005). The model identified four groups with an increased likelihood of bacteremia. A score less than 0 points the prevalence of bacteremia was 7.4%, between 0 and 25 points from 18.9%, between 26 and 35 points from 36.4%, and more than 35 points the prevalence was 48.6%. The ROC curve in our model was 0.75 (95%CI, 0.70 to 0.80). Using a cutoff in the model of -10 points, we obtain a sensitivity of 98.4%, a specificity of 25.8%, negative predictive value of 97.4, positive predictive value of 36% and negative likelihood ratio of 0.062. With this cutoff point 18.6% of blood cultures performed in the ER could be avoided.

Discussion: The ROC curve of our clinical prediction model is not satisfactory. With a cutoff point lower than -10 it is possible to prevent the extraction of blood culture from a significant percentage of patients. The model is especially useful in patients taking antibiotics and attending the ER with suspected bacteremia.

Conclusions: Age, onco-haematological disease, diabetes and taking antibiotics before blood culture extraction, increased fibrinogen and increasing age, behave as clinical and epidemiological variables that independently predict bacteremia. The clinical prediction model would avoid the extraction of blood culture for people with little likelihood of bacteremia.

A-77
OBSERVATIONAL STUDY TO EVALUATE THE NEPHROTOXICITY OF DAPTOMYCIN AND VANCOMYCIN

J. Barberán[1], J. Mensa[2], A. Artero[3], F. Epelde[4], J. Rodríguez[5], J. Ruiz-Morales[6], J. Calleja[7], J. Guerra[8]

[1]Department of Infectious Diseases. Hospital Central de la Defensa Gómez Ulla. Madrid, Spain. [2]Department of Infectious Diseases. Hospital Clínic i Provincial de Barcelona. Barcelona, Spain. [3]Department of Internal Medicine. Hospital Universitario Dr. Peset. Valencia, Spain. [4]Emergency Department. Corporació Sanitaria Parc Taulí. Sabadell (Barcelona), Spain. [5]Department of Neumology. Complejo Hospitalario de Pontevedra. Pontevedra, Spain. [6]Department of Infectious Diseases. Complejo Hospitalario Virgen de la Victoria. Málaga, Spain. [7]Department of Internal Medicine. Hospital Universitario Ramón y Cajal. Madrid, Spain. [8]Department of Internal Medicine. Complejo Asistencial de León. León, Spain.

Objectives: Progressive loss of sensitivity to vancomycin by Staphylococcus aureus (SA) has been related to a significant increase of mortality in Staphylococcal bacteremia, especially when MIC90 values are > 1 ug/ml. In order to avoid this situation, current guidelines recommend higher doses of vancomycin until a valley concentrations in serum of 15-20 mg/dl were achieved. This practice carries an increased risk of nephrotoxicity which in turn worsens prognosis of infection and increases healthcare costs. We present a retrospective study to evaluate the nephrotoxicity of vancomycin compared to daptomycin treatment in patients with Gram-positive cocci infections.

Material and method: Multicenter, retrospective and observational study in a cohort of hospitalized patients with Gram-positive cocci infections treated with vancomycin or daptomycin, according to clinical practice. Patients were compared 1:1 by age, comorbidity, renal function and antibiotic therapy. Data were obtained from medical records. Differences between treatment groups were assessed using the Mann-Whitney U test for continuous variables and the Chi square and Fisher tests for categorical variables. In order to determine the risk factors to develop nephrotoxicity a multiple logistic regression was accomplished.

Results: A total of 133 evaluable patients were included (62 with daptomycin and 71 with vancomycin), 85 (63.9%) males, with a mean (SD) age of 65.8 (15.2) years. The microorganisms more frequently isolated were coagulase-negative staphylococcus (CNS) 43 (32.3%), meticillin-resistant S. aureus (MARSA) 39 (29.3%) and Enterococcus spp 24 (18%). The most common infectious were bacteremia 40 (30%), followed by osteoarticular infections (OAI) 31 (23.3%), skin and soft tissues infections (SSTI) 28 (21.1%) and endocarditis 16 (12%). The OAI, SSTI and endocarditis were more frequent in the daptomycin group. The nephrotoxicity rate was significantly higher in patients treated with vancomycin than daptomycin (p = 0.0058). Vancomycin had to be removed more times than daptomycin due to its nephrotoxicity (p = 0.0072). Vancomycin was an independent predictive factor of nephrotoxicity, along with age and endocarditis as type of infection.

Conclusions: Vancomycin is more nephrotoxic than daptomycin and showed to be an independent predictive factor of nephotoxicity development, which could influence the prognosis and increased hospital stay.

A-93
SYPHILIS IN HIV PATIENTS THINK AGAIN ABOUT AN OLD DISEASE

J. Hergueta González[1], P. Chacón Testor[1], M. Torralba González de Suso[1], A. González Praetorius[2], M. Rodríguez Zapata[1]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital Universitario. Guadalajara, Spain.

Objectives: An increase in the incidence of Syphilis has been detected in HIV patients. Our main goal was to analyze whether the incidence of syphilis has increased among HIV population, as well as an evaluation of these patients' diagnoses through a quality study at our hospital.

Material and method: An ambispective study of cohorts. Phase I Retrospecive (2000-2009). A study has been carried out in every HIV patient for: the number of (luetic serology), the incidence, its treatment and the number of lumbar punctures performed. Furthermore, patients with neurosyphilis were studied together with their progress. Phase II Prospective. (January 2010-December 2011), in which syphilis serologies were requested of every HIV patient treated at our Hospital and lumbar puncture was also performed on HIV patients with late latent lues (those who had not been previously treated) regardless of CD4 cells or RPR status.

Results: Phase I: 564 patients were studied. 73.5% were male with a median age of 38. (IQR: 33-43). The median follow up was 25.0 months (IQR: 6.0-81.9). The median blood samples taken (in which we measured HIV viral load and CD4 lymphocytes) during that period was over 6 (IQR: 2-16). No syphilis serology was performed on 48.9% of the patients. 43.3% of the patients in general had at least one syphilis serology performed on them, whilst 8.0% had two or more /serological tests. The rate of luetic serologies requested was 0.1887 patient/year. Of the 289 patients, who had syphilitic serology data available, 23 patients (8.0%)were positive Lumbar puncture was performed on 9 patients, of whom 5 had neurosyphilis criteria (at least two out of the three criteria: high level of proteins (> 45 mg/dL), cells (> 5 cells/ml) or positive VDRL). Phase II: 251 syphilis serologies were requested of HIV patients, of which 31 were positive (12%). Nineteen of these 31 patients were new syphilis cases, (they had not been previously diagnosed). Of the 19 HIV patients who had been diagnosed, 3 of them had re-infection in the last two years. Lumbar puncture was performed on 8 of the 31 patients with syphilis (23%), one of them fitted neurosyphilis criteria, and other had a doubtful case. The annual incidence of syphilis cases in HIV patients has increased by 6.41 times in the past two years, compared to the incidence during Phase I.

Discussion: We have found an increase in the rate of lues incidence in recent years. Although the incidence has gone up, the rate of syphilis serology performed has been higher in the Phase II period. This could bias our results. We think also that the neurosyphilis criteria are inaccurate and also controversial. In fact only 2 people in both periods had a positive VDRL. Further research has to be carried out to know who needs to undergo a lumbar puncture.

Conclusions: Syphilis prevalence is not negligible in HIV population. In recent years, there has been a remarkable increase in the number of new cases of Syphilis diagnosed of in HIV population, as well as some cases of re-infection. Given the simplicity of the treatment and the serious consequences of misdiagnoses, it is important to insist on performing regular serologies in asymptomatic patients.

A-109
PET-CT WITH 18F-FLUORDESOXYGLUCOSE IN PATIENTS WITH FEVER OF UNKNOWN ORIGIN

A. Fernández[1], J. Deportos[1], E. Francia[2], J. Casademont[2], L. Geraldo[1], V. Camacho[1], J. Duch[1], I. Carrio[2]

[1]Nuclear Medicine Department, [2]Department of Internal Medicine. Hospital de la Santa Creu i Sant Pau. Barcelona, Spain.

Objectives: To evaluate the usefulness of PET-CT in detecting the cause of fever of unknown origin (FUO).

Material and method: We evaluated 27 patients (mean 67y; range 12-88, 15 women, 12 men) in search of focus in the context of prolonged fever (T > 38.3 ºC, no diagnosis after an appropriate

inpatient or outpatient evaluation for 3 weeks, and imaging tests, microbiological and biochemical inconclusive). All patients underwent a whole body PET-CT (Gemini TF hybrid scanner). The diagnostic yield of PET-CT was assessed after other complementary diagnostic examinations or follow-up.

Results: Sixteen patients presented hypermetabolic lesions in PET-CT. In 12 of them the scan guided toward a likely fever outbreak (confirmed to be the cause of fever) in lymph nodes (2 patients with non Hodgkin lymphoma), 2 patients with neoplasms (lung cancer and unknown origin carcinoma), vasculitis (2 patients), pneumonia (3 patients), spondylodiscitis and cholangitis (2 patients). In the remaining 4 patients, PET findings did not confirm the aetiology of FUO showing nonspecific lymphadenopaties. In 11 patients, no abnormal 18F-FDG findings were seen and scans could not guide toward a likely cause of the fever. Six of them had a final diagnosis (2 urinary infections, 1 pneumonia, 1 bacteremia, 1 adult Still disease and 1 Sjögren syndrome). In 5 patients with negative PET either self-limited fever or no other findings were detected in subsequent follow-up after 6 months. Overall results shown a sensibility of 44% (12/27 patients) in detecting the cause of FUO in this series.

Conclusions: PET-CT scans were useful in order to diagnose the cause of FUO in a high percentage of patients. Negative scans had a high negative predictive value (self-limited fever) and allowed to exclude serious pathologies as neoplasms or vasculitis.

ASSOCIATION BETWEEN USE OF BROAD SPECTRUM ANTIBIOTIC AND SUBSEQUENT ISOLATION OF MULTIRESISTANT ACINETOBACTER BAUMANNII: A CASE-CONTROL STUDY IN A HOSPITAL POPULATION

I. Correia[1], A. Gomes[2], A. Fernandes[1], C. Elias[3], V. Nunes[2], F. Aldomiro[1]

[1]Department of Medicine II, [2]Department of Surgery B, [3]Department of Pharmacy. Hospital Prof. Dr. Fernando Fonseca E.P.E. Amadora-Sintra, Portugal.

Objectives: To evaluate broad spectrum antibiotic therapy with meropenem and piperacillin-tazobactam as risk factors for Acinetobacter baumannii infection.

Material and method: Cross-sectional case-control study, with retrospective data collection. We studied all individuals with isolation of multidrug resistant Acinetobacter baumannii (MDRAB) in the Prof. Dr. Fernando Fonseca Hospital (HFF) in 2010. We calculated the incidence of isolates of MDRAB in 2010 per Medical and Surgical wards and Intensive Care Units (ICU) and as a control used a proportional stratified sample per ward for a 1-B = 80% (432 of a total of 39,730 patients admitted were selected for controls) We compared the proportion of patients with MDRAB isolation among patients receiving broad-spectrum antibiotic (AB) therapy with meropenem (MP) and/or piperacillin-tazobactam (PT) in both the overall patient population and per ward. Age, gender, Charlson score, invasive procedures and prior infection were compared among patients with Acinetobacter isolation and the control sample. Statistical significance was defined as a = 0.05 and a CI of 95%.

Results: A total of 112 patients were included: surgical (14%); medical (61%) and ICU (24%). Mean age was 69 (15-99), with 50% male. Global MDRAB incidence was 0.28% (Medical - 0.63%; Surgical - 0.066%; ICU - 6.8% ICU). The incidence of MDRAB was significantly higher amongst patients who recieved MP or PT when compared with other patients: $\chi^2 = 273.5$; df = 1; $p < 0.001$; OR 16.3 (10.53-25.33) for MP and $\chi^2 = 142.0$; df = 1; $p < 0.001$; OR 9.10 (5.91-14.01) for PT. These findings were valid when we analyzed all the groups and when we compared the patient admitted to the surgical ($\chi^2 = 53.45$; df = 1; $p < 0.001$; OR = 9,101 (5.91-14.01) for MP and $\chi^2 = 71.19$; df = 1; $p < 0.001$; OR = 28.2 (9,74-81.58) for PT) and medical wards ($\chi^2 = 63.82$; df = 1; $p < 0.001$; OR = 7.41 (4.25 -12.91) for MP and $\chi^2 = 8.98$; df = 1; $p < 0.003$; OR = 2.61 (1.42-4.79) for PT). For patients admitted to the ICU, the MDRAB isolation was independent of previous MP or PT exposure. When patients treated with MP were compared with those treated with PT, the incidence of MDRAB was significantly higher in the MP group ($\chi^2 = 4.195$; df = 1, p = 0.04. OR = 1.81 IC (1.06-3.09)). There were no statistically significant differences between age, Charlson score, invasive procedures and prior infection between patients with MDRAB isolate and the control group, both in the overall population and by wards.

Discussion: The broad-spectrum AB proved to be a risk factor for MDRAB in our hospital. These results are independent of age, gender, comorbidity measured by Charlson index, invasive procedures and prior infection. This association holds for the medical and surgical patients, not having been found in patients admitted to the ICU, where the incidence of MDRAB is considerably higher. It must therefore be assumed that there are other important factors for the development of infection/colonization by MDRAB amongst these patients. When comparing administration of MP vs PT, therapy with MP was associated with a higher incidence of MDRAB.

Conclusions: Broad-spectrum AB therapy with either meropenem or piperacilin-tazobactan proved to be an independent risk factor for the development of infection/colonization by MDRAB in medical and surgical wards but not in the ICU patients.

CHARACTERISTICS OF THE SKIN AND SOFT TISSUE INFECTIONS WITH POSITIVE CULTURES FOR SPYOGENES

J. Martínez Gómez[1], M. Raya Cruz[1], J. Ferullo[1], M. Arrizabalaga Asenjo[1], A. Nadal Nadal[2], A. Payeras Cifre[1], P. Díaz Antolín[3]

[1]Department of Internal Medicine, [2]Department of Dermatology, [3]Department of Microbiology. Hospital Son Llàtzer. Illes Balears, Spain.

Objectives: To describe epidemiology, clinical characteristics and prognosis of skin and soft tissue infections due to S. pyogenes in our setting.

Material and method: A retrospective review of Hospital Son Llàtzer admitted patients, from 2002 to 2011, with a diagnosis of skin and soft tissue infection (foliculitis, cellulitis, fascitis, abscesses, hidradenitis, furuncle, impetigo, gaseous and Fournier's gangrene) with least a positive isolate of S. pyogenes from local focus or blood cultures. Cases were extracted of the data base of diagnostic codification of Archive's and Clinical Documentation Department of the same Hospital.

Results: From a total of 1105 episodes in 945 patients with diagnosis of skin and soft tissue infections, in 34 (3.6%) cases a positive culture of S. pyogenes was obtained. That episodes were in women in 55.9% cases, with a median age of 51 (range: 1-91) years. In the majority of episodes 27 (79.4%) infection was community acquired. Main clinical presentation was cellulitis/erysipela in 26 (76.5%) cases, followed by abscesses in 6 (17.6%) with only 2 (5.9%) deep infections (miositis), mainly located in lower limbs, 18 (52.9%). Most important comorbidities were: HIV-infection in 7 (20.6%) cases, 10 (29.4%) patients were current drug users, liver disease in 9 (26.4%) and diabetes mellitus in 6 (17.6%). Eleven (32.4%) patients had received antibiotherapy in previous 6 months. In 23 (67.6%) patients a positive culture of the focus was obtained and 19 (55.9%) patients developed bacteremia, Monotherapy, in particular with penicillins or other beta-lactams, was the most used empirical treatment in 18 (52.9%) and 25 (45.4%) cases respectively, followed by clindamycin in 7 (12.7%) episode. Tygeciclin was only used in 1 case of miositis. A Change of treatment was performed in

16 (47.1%) episodes, after microbiological results in 10 (62.5%). As targeted treatment, monotherapy and therapy with 2 antibiotics were equally used in 7 (43.8%) episodes everyone. S. pyogenes was penicillin resistant in 3 (10.7%) cases. In 4 (13.3%) cases there was resistance to clindamycin, one of them was also penicillin resistant. In 11 (32.4%) patients it was necessary surgical debridement and the following complications were observed: severe sepsis in 8 (23.5%) episodes and shock in 7 (20.6%). Six (17.6%) patients died, 3 (8.8%) related to the infection.

Conclusions: In our setting skin and soft tissue infections due to S. pyogenes occur mainly in patients with comorbidities, especially HIV-infection, active drug abuse, liver diseases or diabetes. They are community acquired and cellulitis is the most frequent clinical entity. More than a half of patients developed bacteremia. Penicillins and other beta-lactams in monotherapy were the main antibiotics used as empirical treatment. Surgical debridement was needed in a high percentage of cases and systemic complications were frequently observed.

A-229
INCIDENCE OF STAPHYLOCOCCUS AUREUS BACTEREMIA IN A TERTIARY UNIVERSITY HOSPITAL IN MADRID IS SOMETHING CHANGING?

A. Morales Cartagena[1], L. Sanz Trepiana[1], M. Fernández Ruiz[2], F. Sanz[3], F. Chaves[3], F. López Medrano[2], J.M. Aguado[2]

[1]Department of Internal Medicine, [2]Infectious Diseases Unit, [3]Department of Microbiology. Hospital 12 de Octubre. Madrid, Spain.

Objectives: Staphylococcus aureus blood stream infections (BSI), especially methicillin-resistant (MR) strains, are a cause of high morbidity and mortality in hospitalized patients. Recent studies suggest a downward trend in BSI by these pathogens. The objective of our study was to analyze the changes in the epidemiology of health-care associated *Staphylococcus aureus* BSI in the past years in the different units of our tertiary University Hospital.

Material and method: There are several ongoing initiatives in our hospital to decrease catheter related infections and to emphasize the importance of hands hygiene for both medical and nursing staff (i.e. videos, protocols, courses, use of chlorhexidine instead of iodine, etc.). These initiatives were developed within the scheme called "Zero Bacteremia". We conducted the current study by retrospectively analyzing epidemiological and microbiological data of *S. aureus* BSI episodes registered in our hospital from July 2009 to December 2011. We included information about age, sex, date of episode, hospital unit where the blood culture was extracted and resistance to methicillin, all of which was enclosed in patient clinical reports and the Microbiology Department database. We used SPSS (v19) to analyze our results (Chi square). We calculated the cumulative incidence per semester as cases per 1,000 admissions and as cases per 1,000 in-hospital stays, using Epidat (v4) to compare our results. Statistical significance was set at $p < 0.05$.

Results: The Hospital 12 de Octubre is a tertiary hospital in Madrid with 1370 beds and an average of 42,105.6 admissions per year in the period analyzed (July 2009 to December 2011). There were a total of 272 episodes of *S. aureus* BSI: 85 detected in the Emergency Department, 29 in Intensive Care Units (ICU), 110 in medical wards and 48 in surgical wards. A total of 271 patients were included of which 192 (70.6%) were men, with a median age of 68 y/o. We found 78 (28.7%) cases of MR strains. Grouping our results by semesters, we compared the cumulative incidence obtained depending on where the patient was hospitalized. We have observed a decreasing cumulative incidence for S. aureus BSIs, which was statistically significant in the analysis of the global incidence decrease ($p = 0.042$), and when comparing the incidence drop in medical wards ($p = 0.011$). We observed a proportional decrease of methicillin resistant strains ($p = 0.041$).

Discussion: There seems to be a downward trend in the cumulative incidence of *S. aureus* BSIs in our hospital which is mainly due to the incidence fall in medical wards and ICUs. We could assume that the different strategies to prevent catheter related infections as well as hands hygiene implemented in the past years must have played a fundamental role in what we are observing. In accordance to previous studies we observe a decrease in the proportion of MR *S. aureus*.

Conclusions: The "Zero Bacteremia" plan has had a very positive impact in the decrease of *S. aureus* BSI in the ICUs. However, strategies to promote hands hygiene and peripheral and central lines care in other hospitalization units also seem to have had a relevant impact. These global care campaigns have shown to be effective and very useful to promote health care projects.

A-257
ADMISSION RED CELL DISTRIBUTION WIDTH AS A PROGNOSTIC MARKER IN COMMUNITY ACQUIRED PNEUMONIA

V. Hontañon[1], R. Mayayo[1], A. Fernández-Zamorano[2], C. García-Cerrada[1], F. Montoya-Lozano[1], P. Bravo-Fernández[3], M. Quesada[1], F. Arnalich[1]

[1]Department of Internal Medicine Service, [2]Clinical Biochemistry Service, [3]Archives and Clinical Documentation Service. Hospital Universitario La Paz, IdiPAZ. Madrid, Spain.

Objectives: Red cell distribution width (RDW) reflects variability in size of circulating erythrocytes (anisocytosis). Recent data indicate that increased RDW is an independent predictor for mortality in cardiovascular diseases and pulmonary hypertension. The aim of this study was to evaluate the relation between admission RDW and in-hospital mortality or complicated hospitalization in patients with community acquired pneumonia (CAP).

Material and method: We performed a secondary analysis of prospectively collected data on 184 patients (106 men) diagnosed of CAP throughout 3 years. RDW, blood counts (hemoglobin, mean corpuscular volume, total leukocytes), arterial gasometry, serum glucose and creatinine were measured on admission. Markers of erythropoiesis (serum iron, transferring, ferritin), and nutritional and inflammatory markers (total cholesterol, albumin, C-reactive protein levels) were measured during the first week. Hematologic variables were determined by Cell-Dyn 3500 analyzer, and biochemical laboratory parameters by Roche Integra 800 analyzer. The normal range for RDW is 11.5 to 14.5%. Complicated hospitalization was defined as hospitalization longer than 10 days, which is the standard median length of stay for this condition, or admission to ICU. Binary logistic regression analysis was used for calculation of the odds ratio (OR) in univariate analysis to identify association between patients characteristics and complicated hospitalization or in-hospital mortality. Multivariate forward stepwise analysis was used to determine the independent prognostic factors. Statistical analysis was performed using SPSS 14.0.

Results: The mean age was 65 ± 16 years, the mean follow-up duration was 14 ± 6 days, and 23 patients died. Fifty one patients (27.7%) had complicated hospitalization. Among patients who died, 2 (8.7%) had normal RDW and 21 (91.3%) had RDW higher than 14.5% ($p < 0.001$). Among patients with complicated course, 43 of them (84.3%) had high RDW compared to 15 patients (11.3%) in the non-complicated group ($p < 0.001$). There was a significant positive association between high RDW and serum creatinine and CRP values, and a negative relationship with albumin levels. All variables associated to the combined end point (in-hospital mortality or complicated hospitalization) are shown in Table 1.

Discussion: RDW is a simple laboratory test that has been to be associated with higher mortality and adverse outcome in cardio

pulmonary diseases (1). The results of our study indicate that elevated RDW is also a risk factor for adverse outcome in CAP. The mechanisms underlying this association are poorly known, although RDW may be a surrogate marker for nutritional deficiencies or ongoing inflammation. (1. Patel KV, et al. Red blood cell distribution width and the risk of death in middle-aged and older adults. ArchIntern Med 2009; 169:515-523).

Conclusions: High RDW is a strong independent predictor of complicated hospitalization and mortality in patients with CAP.

Table 1 (A-257). Multivariate analysis for the combined end-point

	Coefficient	Adjusted OR	95% CI	p value
Age > 70 years	1.4	2.5	1.1-5.7	< 0.01
Creatinine > 1.6 mg/dl	1.3	2.3	1.1-5.4	< 0.01
RDW > 14.5	1.7	3.8	1.6-7.2	< 0.01

A-259
EPIDEMIOLOGICAL ANALYSIS OF PNEUMOCYSTIS JIROVECII PNEUMONIA CASES IN A TERCIARY HOSPITAL PRELIMINARY RESULTS

M. Calero Bernal[1], R. Terán Redondo[1], I. Martín Garrido[1], B. Herrero Hueso[1], A. Calzada Valle[1], S. Gutiérrez Rivero[1], M. González Jiménez[1], F. Medrano Ortega[2]

*[1]Department of Internal Medicine. Hospital Virgen del Rocío. Sevilla, Spain. *CIBER Epidemiología y Salud Pública. CIBERESP, Spain.*

Objectives: The introduction of highly active antiretroviral therapy (HAART) has resulted in better immune control to patient with human immunodeficiency virus infection (HIV) and consequently a decrease in both frequency and severity of opportunistic infections, including Pneumocystis jirovecii pneumonia (PcP). On the other hand, in the last few years it has been documented an increase in the cases of PcP in immunosuppressed HIV-negative patients which seen to have a more severe clinical course. The aim of this study was to evaluate the morbility and mortality of PcP in our hospital comparing clinical outcome of HIV-positive and immunosupressed HIV-negative patients.

Material and method: All cases of PcP admitted at Hospital Universitario Virgen del Rocío in Seville between January 2000 and December 2011 were retrospectively reviewed. Episodes were identified through a specific search in the CMBD database. Demographic, clinical and biological data from the clinical charts were recorded in a standardized case report form. Statistical analysis was performed using IBM SPSS Statistics version 19.

Results: A total of 218 cases of PcP were identified during the study period. The present analysis included the evaluation of the first 100 non-selected cases. Of them, 22 were excluded for not meeting criteria for PcP (clinical-radiological pattern compatible with PcP and/or microbiological Pneumocystis confirmation). Of the remaining 78 cases with confirmed PcP, 60 cases were found in HIV-positive patients (76.97%) and 18 (23.03%) in HIV-negative patients. Mortality in the HIV group was 20% (12 cases), but death was directly attributed to PcP in only 5 of these cases (8.33%). Mortality in HIV-negative group was 38.8% (7 cases), but death was directly attributed to PcP in only 4 of these cases (22.2%). The differences in mortality between groups were not statistically significant (p = 0.2313).

Conclusions: The study shows that HIV status remains the most common cause of PcP although 20% of PcP cases were found in HIV-negative patients. There was a trend for higher mortality among HIV-negative patients. The causes of this higher mortality could be the delay in diagnosis and treatment by clinicians that are not aware with PcP in HIV-negative patients or the absence of appropriate prophylaxis in this group of patients.

A-264
COMBINATION OF INTRAVENOUS AND NEBULIZED COLISTIN IN ACINETOBACTER BAUMANNII ERADICATION

J. Furtado[1], E. Carmo[2], I. Gaspar[2], I. Rio Carvalho[2], I. Simões[2], E. Monteiro[2]

[1]Department of Internal Medicine Service II, [2]Intensive Care Unit. Egas Moniz Hospital. Ocidental Lisbon Hospital Centre. Lisbon, Portugal.

Objectives: Ventilator-associated pneumonia (VAP) by multidrug-resistant Acinetobacter baumannii (MRAB) has high mortality. Intravenous (iv) colistin has been related to nephrotoxicity and few studies have shown the efficacy of nebulized administration. This study evaluates the efficacy of combined iv and nebulized colistin compared to conventional iv administration in the eradication of MRAB from bronchial secretions of patients with VAP.

Material and method: Retrospective study of 52 ventilator-associated pneumonia by MRAB cases selected from ICU database, from 2007 to 2008. The control (C) group received iv colistimethate sodium (CMS) 62,000 IU/kg/day and the combined treatment (T) group was given the same protocol added by nebulized CMS 2 million UI bid. Inclusion criteria were diagnosis of VAP and isolation of MRAB on culture and antimicrobial sensitivity tests of bronchial secretions. Patients with other agents or insufficient data were excluded. The endpoints were microbiological eradication or persistence in bronchial secretions. The results were evaluated at days 7, 12, 17 and 21 of treatment, using statistical analysis with Chi^2 or t-Student tests, with 5% of significance, using SPSS software.

Results: After excluding 10 patients due to insufficient data or isolation of other agents, the remaining 42 patients were divided in C group with 28 (60.7%) and T group with 14 (33.3%) patients. 47.6% patients were females and 52.4% were males and the mean age was 72 ± 14 years. No significant differences were found regarding demographic features, admission diagnosis and clinical severity. Mean APACHE II score 31.2 ± 7.0 on ICU admission. At day 7 of treatment, 71.4% patients from T group exhibited MRAB microbiological eradication, compared to 46.4% patients of C group ($p < 0.002$). At day 12, 92.9% patients from T group achieved microbiological eradication. Beyond day 15, mean creatinine clearance 35 ml/min and 59 ml/min of C and T groups were statistically different. There were no serious adverse effects, except for 2 cases of bronchospasm after nebulized CMS, controlled with steroids and not leading to withdrawal. The overall mortality rate was 39.6% and the mean duration of ICU permanence was 36 ± 9 days, with no significant differences among groups.

Discussion: Colistin emerges as first-line drug for the treatment MRAB infections. Few studies used nebulized colistin alone to achieve its eradication. There was a statistically superior eradication rate using combined treatment at day 7 (71.4%), maintained at day 12 (92.9%), suggesting that this regimen allows better responses. Moreover, nebulized colistin may reduce the risk of nephrotoxicity, which was statistically relevant in the control group at 15 days of treatment. Although the duration and dosages of iv colistin did not differ significantly among groups C and T, these findings suggest a relationship between the rate of microbiological eradication and nephrotoxicity. None of the cases of bronchospasm following nebulization led to study withdrawal. Despite good results, effects on prognosis and mortality remain unclear. Other determinants beside APACHE II score, certainly affect clinical outcome, mortality and duration of hospitalization. The absence of clinical variables was a limitation. It is therefore essential to

conduct prospective larger trials in order to establish unequivocally the superiority of combined administration of nebulized and intravenous colistin in the treatment of ventilator-associated pneumonia by A. baumannii MR.

Conclusions: This study confirms that combined nebulized and intravenous colistin regimens are safe and effective treatments to achieve microbiological eradication of MRAB in patients with VAP, reducing nephrotoxicity of intravenous colistin in critically ill patients.

A-266
INFECTIVE ENDOCARDITIS IN INTRAVENOUS DRUG USERS IN RUSSIA: A NEW CHALLENGE IN THE WAY OF DRUG TRAFFICKING

A. Demin, V. Drobysheva

Department of Internal Medicine. Novosibirsk State Medical University. Russia.

Objectives: Infective endocarditis (IE) remains a disease with considerable morbidity and mortality and evolving profile. IE has changed the character during recent decades in Russia. IE of intravenous drug addicts is a new challenge in the way of drug trafficking from Afghanistan to Europe involving Novosibirsk city area. The objective of study was to analyze the recent changes in clinical presentation and treatment of modern IE of drug users.

Material and method: Design: Retrospective observational cohort study conducted from January 2008 through December 2012 at Novosibirsk city among 300 intravenous drug users (morphine, hydromorphone, oxycodone, heroin, meperidine, pentazocine, desomorphine; the average age – 25.2 years) with IE. Clinical, microbiological and echocardiographic characteristics were examined in patients who fulfilled the modified Duke criteria for IE.

Results: The incidence of IE increased 10-fold, reaching 150 cases per 1 mln/year - increasing share of intravenous drug addicts. Early signs of the disease were fever, chills, weakness, sweating, chest pain, shortness of breath, coughing, swelling. All patients had primary form of IE and high activity of the process. Etiologically the change is characterized by a reduction of streptococci and a much higher incidence of staphylococci, gram-negative bacteria and other virulent organisms. Positive blood cultures were in 75% of patients. Causative agents were: S. aureus - in 50%, S. epidermidis - in 18%, S. haemolyticus - in 11%, S. intermedius – in 3%, Enterococcus faecalis - in 4%, E. coli - in 4%, Acinetobacter spp. - in 1%, Pseudomonas aeruginosa - in 2%, Corynebacterium pseudodiphtericum - in 1%, Candida albicans - in 2%, mixed (S. aureus and P. aeruginosa, S. aureus and Candida albicans, E.coli and P. aeruginosa, S. aureus and S. epidermidis) - in 4% of patients. Echocardiographic vegetations were revealed in 86% of patients: the tricuspid valve was affected in 52%, the mitral valve - in 23%, the aortic valve - in 19%, two valves - in 6% of patients. It was observed the lower incidence of classical clinical IE-features which were seen at the end of the last century: fever (50% versus 97%), sweats (57% versus 97%), splenomegaly (15% versus 90%), fingers clubbing (5% versus 35%). In all patients the clinical course of IE was with systemic affection of internal organs of thromboembolic, thrombohemorragic, microvascular and toxic genesis. Thus, anemia, toxic encephalopathy, were observed in 100%, infective hepatitis B and C - 70%, nephritis - in 70%, renal infarction - in 11% of patients, HIV infection and sexually transmitted diseases - in 30%. Lung affection was characterized by development of bilateral pneumonias with severe pulmonary insufficiency in 78%, lung infarctions - in 23%, pleurisies - in 13% of patients. Necrotic vasculitis of the lower extremities developed in 44% of patients. Etiotropic antibacterial chemotherapy often was successful. Chemotherapeutic eradication of staphylococci with vancomycin or daptomycin, 6-10 mg/kg/day for 4 weeks, gram-negative bacteria with ceftazidime and amikacin or meropenem, was obtained in 85% of IE patients. Fungal IE was treated with amphotericin B, fluconasol and valve replacement. Mortality at discharge was 25%, at six months 35%.

Discussion: Russia has become an absolute world market for opiates in the world (20%). From Afghanistan to Russia smuggled at least 12 tons of heroin - a 3 billion (!) single doses. IE is the most serious infection of intravenous drug users. Every day 100 people die from overdoses, 30 thousand/year, which is two times more than a decade of war in Afghanistan.

Conclusions: Drug addiction - it is a civilizational challenge to Russia. IE of intravenous drug users is characterized by primary form, high activity, severe course, multivalvular and polyorganic affection, high mortality rate. Avalanche growth of drug addiction and related diseases makes it necessary to focus health care, government and society to solve this problem.

A-267
PROSPECTIVE STUDY OF BACTERAEMIA DUE TO STAPHYLOCOCCUS AUREUS IN A TERTIARY HOSPITAL

G. Spalter Glicberg[1], G. Ternavasio de la Vega[1], I. García García[2], S. Ragozzino[1], M. Asensio Calle[2], R. Macías Casanova[1], J. García Sánchez[2], M. Marcos Martín[1]

[1]Department of Internal Medicine. Hospital Universitario de Salamanca. Hospital Clínico. Salamanca, Spain. [2]Department of Microbiology. Complejo Asistencial de Salamanca. Salamanca, Spain.

Objectives: To describe the epidemiology, risk factors, clinical characteristics, and influence of appropriate antibiotic therapy on outcomes among patients with S. aureus bacteremia in the University Hospital of Salamanca.

Material and method: We performed a prospective analysis of all episodes of S. aureus bacteremia between June 2010 and March 2012, which were identified through the Microbiology Department. Epidemiological, clinical and microbiological data were recorded during hospitalization and patients were followed-up during admission to assess outcome of infection.

Results: During the study period 65 S. aureus bacteremias were recorded (41.0% men, mean age 76 years [interquartile range: 16-92]). Among them, 36 (55.4%) were community onset (CO) cases, 18 (27.7%) hospital onset (HO), and 11 (16.9%) health care-associated community onset (HACO). Twenty-four (36.9%) bacteremias were detected in Internal Medicine wards and 13 (20%) in the Nephrology Department. Leading comorbidities were chronic kidney disease (21, 32.3%) and chronic heart failure (18, 27.7%). Fifty-four patients (83.0%) had a Charlson index > 2 and 39 (60.0%) > 4. McCabe score was ultimately fatal in 44.6% patients and rapidly fatal in 4.6%. Thirty-five (53.8%) patients had urinary indwelling catheter and 15 (23.1%) had received prior steroid therapy. The focus of bacteremia was unknown in 20 cases (30.8%), respiratory in 16 (24.6%), vascular catheter related in 10 (15.4%), and skin and soft tissue in 4 (6.0%). Twenty (30.8%) of the isolates were resistant to methicillin-resistant S. aureus (MRSA) and the percentage of MRSA was 16.7% for HO bacteremia, 33.3% for CO bacteremia and 45.5% for HACO bacteremia. Eleven patients (16.9%) presented with septic shock and 20 (30.7) died during hospitalization (5 of them had MRSA).

Discussion: Bacteremia due to S. aureus have experienced a sharp increase in frequency in recent years, with significant morbidity and mortality, and there have also been several changes in clinical and epidemiological characteristics. In our series, we describe an elderly population with multiple comorbidities which may explain, at least in part, the high mortality described. Of note, more than half of bacteremia episodes were community-acquired, a worldwide growing trend.

Conclusions: MRSA bacteremia is a major problem and is associated with high mortality. Community-acquired bacteremia represents more than half of the cases in our setting.

A-271
ALLOGENEIC BLOOD TRANSFUSION IS A RISK FACTOR FOR DEEP WOUND INFECTION AFTER PRIMARY KNEE ARTHROPLASTY

S. Gómez Lesmes[1], M. Marcos Martín[1], S. García[2], J. Martínez[2], M. Basora[3], J. Sierra[4], J. Mensa[4], A. Soriano[4]

[1]Department of Internal Medicine. Hospital Universitario de Salamanca. Hospital Clínico. Salamanca, Spain. [2]Department of Orthopedic and Traumatology, [3]Department of Anesthesia and Resuscitation, [4]Department of Infectious Diseases. Hospital Clínic of Barcelona. Barcelona, Spain.

Objectives: To analyze preoperative and intraoperative risk factors for deep wound infection in patients with primary knee arthroplasty in the next 90 days after surgery.

Material and method: We reviewed consecutive patients that had undergone primary knee arthroplasty between March 2007 and October 2009 with an established prophylaxis protocol in a tertiary Hospital. Patients were followed up for 90 days after surgery in order to establish the presence of deep prosthetic joint infection. The following clinical and analytical variables were recorded: age, sex, body mass index (BMI), comorbidities, preoperative physical status classification assessed by the American Society of Anaesthesiologist (ASA) score, ischemia time during arthroplasty, postoperative fluid drainage, use of Redon (days), hemoglobin levels before surgery and after surgery, number of packed red cells transfused, C reactive protein and NNIS scale. In univariate analysis categorical variables were analyzed by the Chi-square test and Student's t test or Mann-Whitney U test were used for continuo's variables. A multivariate logistic regression analysis was performed to analyze independent risk factors related with deep wound infection. Variables associated with this outcome with p-value < 0.2 in univariate analysis, were included in the model. Statistical analysis was done with SPSS 19.1 and $p < 0.05$ was considered to be statistically significant.

Results: During the study period, 1331 consecutive patients undergoing primary knee arthroplasty were included. Deep wound infection was diagnosed in 32 (2.4%) patients. Mean age was 70.11 (standard deviation [SD] = 7.47) years and 53% of patients were female. Median (interquartilic range-IQR) time from surgery to infection was 25 (20 to 28) days; NNIS scale 50% was 0, median ASA score 2.25 (SD = 0.51) and BMI 33.58 (SD = 5.72) Kg/m^2. The most frequent isolated microorganism was Staphylococcus aureus (20, 62.5%) followed by coagulase-negative staphylococci (7, 21.9%), Enterococcus faecalis (4, 44.4%) and E. coli (3, 9.4%). After univariate analysis, variables associated with deep wound infection were female sex ($p = 0.021$), presence of diabetes ($p = 0.043$), cirrhosis ($p = 0.046$); American Society of Anaesthesiologists score III or IV ($p = 0.042$); higher BMI ($p = 0.006$), longer duration of limb ischemia ($p = < 0.001$); lower hemoglobin levels on the 4th day after surgery ($p = 0.046$) and need of transfusion ($p < 0.001$). Within each day, the first arthroplasty performed had a lower risk of infection than the others ($p = 0.024$). After multivariable logistic regression analysis, allogeneic blood transfusion was identified as an independent and significant variable associated with higher risk of deep wound infection at 90 days post total knee arthroplasty. Other variables identified as risk factors were, longer time of leg ischemia and BMI. Female sex and being scheduled for the first surgeries of the day were protective factors.

Discussion: Infection is the most devastating and expensive complication of joint arthroplasty and often requires a multidisciplinary approach. Few studies have focused on factors involved in deep wound infection after knee arthroplasty. In our study, allogeneic blood transfusion was identified as an important risk factor for deep wound infection but other studies have reported controversial results.

Conclusions: Allogenic blood transfusion was an important risk factor for deep wound infection within 90 days after primary knee arthroplasty in our setting.

A-274
ADHERENCE TO OPTIMIZATION PROGRAM ON ANTIMICROBIAL PRESCRIBING FOR ADMITTED PATIENTS FOR EMERGENCY DEPARTMENT

L. Benítez[1], M. Fernández-Tomás[1], A. Cuenca[1], E. Muñez[1], T. Álvarez Espejo[1], A. Asensio[2], C. Pérez Velilla[1], A. Ramos[1]

[1]Department of Internal Medicine, Infectious Diseases Unit, [2]Department of Medicine Preventive. Hospital Universitario Puerta de Hierro Majadahonda. Majadahonda (Madrid), Spain.

Objectives: The antimicrobial therapy in infected patients is one of the most effective therapies in medicine. The gradual emergence of bacterial resistance against antimicrobial therapy can reduce this effectiveness. The infections caused by resistant germs are characterized by an increase in mortality. The inappropriate use of antimicrobial therapy is a major risk factor for infections with resistant bacteria. The target of this study is to evaluate the percentage of adherence to recommendations made by a team of experts in antimicrobial therapy (TEAT) after reviewing of the treatment in the third day of hospital admission after transfer from emergency room.

Material and method: Prospective study in a cohort of patients admitted from emergency room. TEAT reviews patients receiving antibiotics for restricted use (linezolid, daptomycin, tigecyclie, imipenem, meropenem, ertapenem or colistin) in third day of hospital admission. The study was carried out for 2 months in the H.U. Puerta de Hierro Majadahonda (November and December of 2011).

Results: One hundred and nine patients were analyzed of which 53.2% were male and 46.4% were women. The median age was 72.4 years and the average age was 76.8 years. Average stay in hospital was 9 days. The patients were admitted more frequently to internal medicine (46.8%), general surgery (13.8%), gastroenterology (10.1%), pneumology (7.3%), urology (7.3%) and oncology (5.5%). One hundred and twenty-seven infectious processes were reviewed (6 patients had 2 infections and 2 patients had 3 infections) of which 40.4% were respiratory, 28.3% were abdominal, 18.3% were urinary and 6.4% were cutaneous. Twenty-six percentage of infections were nosocomial. The antimicrobials for restricted use most frequently administrated were meropenem (63.3%), ertapemen (21.1%) and imipenem (11%). Other antimicrobials had a frequency < 1%. TEAT recommendations performed in 30.3% of cases. These recommendations were accepted in 36.4% of cases. The wards receiving more recommendations were gastroenterology (72.7%), pneumology (62.5%) and urology (50%). The departments that accepted higher percentage of recommendations were internal medicine (41.7%), gastroenterology (16.7%) and pneumology (16.7%).

Discussion: We found a better use of antibiotics from the emergency department, more than other series that considered 30-50% prescriptions in hospital as inadequate. It represented a recommendation in one out three patients admitted. Adhesion to the recommendations was almost in half of cases. The restricted use antibiotics were prescribed to severe ill patients on admission but only 26% of the cases were nosocomial infections. The cohort of patients studied was older (25^{th} percentile = 61 years), which partly justifies the severity of the patients on admission. The percentage of accepted recommendations were lower those reported in the literature but it seems enough to be efficient.

Conclusions: The prescription of antimicrobial therapy in patients admitted from emergency department was correct in a high percentage of patients. The adherence to program of optimization of antimicrobial therapy is moderate. The study of the patients admitted from emergency to a ward by TEAT is a strategy effective in optimizing the use of antibiotics, that could reduce the emergence of bacterial resistant, could reduce mortality associated to infections and also could allow a reduction in pharmaceutical spending. Larger sample sizes are needed to obtain more conclusive data.

A-289
CANDIDA BLOODSTREAM INFECTIONS IN A TERTIARY HOSPITAL CHARACTERISTICS OF PATIENTS IN THE INTERNAL MEDICINE SERVICE

J. Montoro Lara[1], C. Gómez Peñalba[1], G. Lledó Ibáñez[1], B. Orden Martínez[2], C. Maínez Saiz[1], A. Ramos Martínez[1], A. Ángel-Moreno[1], Y. Romero Pizarro[1]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital Universitario Puerta de Hierro Majadahonda. Majadahonda (Madrid), Spain.

Objectives: To analyze clinical aspects of patients with Candida spp bloodstream infections (CBSI) in a tertiary hospital and to identify the relevant aspects of internal medicine patients.

Material and method: We conducted a systematic review of the medical records of patients with an episode of CBSI in a period of two years (May 2010 to April 2012) and compared the characteristics of internal medicine patients with those of patients in other medical and surgical services.

Results: 32 episodes of Candida BSI occurred in our hospital in the study period. The mean age of patients was 77.4 years (11 days-99 years), 50% men. Almost 60% of patients were admitted in medical services (79% in internal medicine, 15 patients); 8 patients (25%) were in surgical services, 3 in the intensive care unit and 2 in pediatrics services. The mean age of internal medicine patients was 83.4 years, significantly higher than that of patients admitted to others medical services (51.5 years) and higher than the median age of surgical patients (71.2 years). All patients had a predisposing factor for CBSI. Highlights the fact that all patients but 3 (90%) had received prior antibiotic treatment in the same admission with an average of 2.7 antibiotics per patient (1.7 in internal medicine and 3.1 in surgical services). Sixty five per cent of these patients received more than one antibiotic and 7 patients (24%) received more than 4 antibiotics. Five patients (15%) had received steroid treatment. In addition, 10 patients had solid organ tumors and 6 had undergone recent surgery. In our series only one patient was a recipient of a solid organ transplant (kidney in this case). In 9 patients (28%), fungemia were considered related to a catheter. In 26 patients a single species was isolated from culture. Candida albicans was the most frequently isolated species, 18 patients; C. guillermondi and C. tropicalis were isolated in 2 patients respectively and C. parapsilosis, C. glabrata and C. lusitaniae in one patient respectively. Six patients had two species of candida, being C. guillermondi the most frequently isolated in these cases (four patients). Twenty-six patients (81%) received empirical antifungal therapy. First-line treatment was fluconazole (57% of treated cases) followed by echinocandins (4 patients anidulafungin, 2 caspofungin and one micafungin). In 2 patients the initial treatment was performed with amphotericin B. Five of the six untreated patients were internal medicine patients: in 3 cases, blood culture results were received after the death of patients; in one case this no-treatment decision was due to patients' baseline situation and the other patient was asymptomatic. Twelve patients (37.5%) died. Mortality in the internal medicine patients was 60% (9 of 15 patients). Four of 9 patients who died in internal medicine did not receive antifungal treatment. Mortality among patients who received no antifungal treatment was twice that mortality of patients who received antifungal therapy (66.6% vs 30.7%).

Discussion: In our series we found a higher number of isolates of Candida guillermondi than usual and we are analyzing whether it is a pseudo-outbreak. The mortality in our hospital is similar to that described in other series.

Conclusions: Internal medicine patients with CBSI were older, more often did not receive antifungal treatment and had higher mortality than surgical and others medical patients.

A-311
OUTPATIENT INTRAVENOUS ANTIBIOTIC TREATMENT IN A HOSPITAL-AT-HOME SERVICE: A SERIES OF 595 CASES

J. Pericás[1], S. Valls[2], J. Aibar[2], S. Fernández[1], C. Fehér[1], D. Nicolás[1], N. Seijas[2], B. Ibáñez[2]

[1]Department of Internal Medicine, [2]Integrated Care Unit. Hospital Clínic. Barcelona, Spain.

Objectives: We investigated the efficacy and safety of patients requiring intravenous antibiotic treatment admitted to hospital at home (HaH) program.

Material and method: 595 episodes of 424 different patients with an active bacterial infection requiring intravenous antibiotic treatment admitted in a hospital at home (HaH) unit between March 2007 and October 2011 were revised. Data were obtained from the database of the Hospital at home Unit of the Hospital Clínic Barcelona and from clinical history files of each patient. The statistical analysis was performed by means of Fisher's exact test, Student's t test and Chi-square analysis using the software IBM SPSS Statistics version 20.

Results: There were 365 male and 230 female patients included in the study, their mean age was 67.8 years (SD: 15.7). Medicine Emergency Department and Oncology were the two most common departments of origin (50.1% and 27.2% of patients, respectively). Mean time of stay in HaH was 6.57 days (R: 1-24). Hospital-readmission during HaH stay was needed in 28 cases (4.7%) and 63 patients (10.6%) were readmitted during the next 30 days after HaH discharge. 30-day mortality after HaH admission was 2.8%. Median Charlson comorbidity index was 4.54. Cardiovascular, pulmonary and metabolic comorbidities were found in 318 (53.4%), 153 (25.7%) and 188 (31.6%) patients, respectively. 262 patients (44%) had a neoplasm and 56 patients (9.4%) presented febrile neutropenia. At admission median C-reactive protein (CRP) level was 13.04 mg/dl and mean absolute leucocyte count was 10,700 cells/µL. Most commonly used antibiotics were: ceftriaxone (63.9%), ertapenem (22.85%), levofloxacin (4.4%) and piperacillin/tazobactam (3.4%). The two most common focus of infection were respiratory (44.2%) and skin/soft tissues (24.5%). Mean duration of antibiotic treatment was 5.16 (SD 2.9). Microbiological evidence of infection was found in 196 (32.9%) and 58 patients (9.7%) presented bacteremia. The most common identified causative agents of infection were: E. coli (71 cases; 36.2%, of which 18 were ESBL), P. aeruginosa (12.2%), S. pneumoniae (10.7%) and Klebsiella spp with 7.6% (20% ESBL). We observed a significant higher mortality in patients referred from Haemato-oncologic department followed by those referred from the Emergency Dpt compared to other departments. Besides, patients with a respiratory focus of infection presented a higher mortality compared to other foci (4.6% vs 1.5%; p = 0.026). According to a satisfaction survey 92.4% of patients would repeat the HaH admission instead of conventional hospitalization.

Discussion: Patients admitted to HaH for and infection requiring intravenous antibiotics showed a high median age and comorbidity,

as well a considerable proportion of multiresistant microorganisms. However, observed rates of mortality and treatment failure are low, so complexity and also a moderate severity can be assumed in HaH. Although only about a third of infections had microbiological confirmation, empirical antibiotic therapy was effective in most patients. The comfortability and easy access to professionals of Integrated Care Unit lead to a high degree of satisfaction among patients.

Conclusions: A wide range of infections requiring intravenous treatment could be referred to the HaH, with a very low rate of mortality and readmission. However, attention must be paid with Haemato-oncologic patients and those presenting a respiratory focus.

A-312
HIGH SUCCESS RATE OF INFECTED VASCULAR PROSTHETIC GRAFTS WITH CONSERVATIVE MANAGEMENT

C. Martínez Vázquez, A. Nodar, M. Pérez Rodríguez, R. Longueira, A. Argibay, D. Portela, B. Sopeña

Infectious Diseases Unit. Complejo Universitario de Vigo. Vigo (Pontevedra), Spain.

Objectives: Appropriate treatment of vascular prosthetic infection has not been clearly defined, nor are there guidelines for its diagnosis and treatment. Therefore, an individualised management is recommended. Many authors following "traditional" or "conventional" criteria recommend removal of the prosthesis, though a growing number of studies report healing of prosthetic infections with conservative methods. We describe our experience with a conservative approach.

Material and method: All patients with confirmed diagnosis of vascular prosthetic graft infection in our center were included in the study between January 2000 and December 2010. Vascular prosthetic infection was defined by the presence of a periprosthetic collection on the CT scan, sings of surgical-site infection, and positive culture of purulent material obtained by puncture-aspiration by Interventional Radiology, surgical drainage or exudates. Similar cases but with negative culture findings were considered as probable infection. The infections were considered as early when diagnosed within two months after the intervention. Inclusion criteria for a conservative management included a functional vascular prosthesis with no anastomotic leak, thrombosis, aortoenteric fistulas or intestinal erosions and a hemodynamically stable patient. Conservative management protocol was: 1) Drainage of periprosthetic abscesses over 3 cm; 2) Intravenous induction antibiotic for at least 4 weeks, according to the pathogen; 3) Oral consolidation antibiotic therapy until clinical, radiological and scintigraphic healing sings are evidenced, with normalization of the acute phase reactants. Once antibiotic has been completed, two years follow-up were needed before considering the patient healed.

Results: A total of 29 cases were diagnosed during the study period. Of these, 7 were excluded: 3 due to aortoenteric fistula, 2 due to intestinal erosion, 1 due to endocarditis and hemodynamic instability, and 1 due to transfer to another center. Of the remaining 22 patients, the location of vascular prosthesis was: 10 femoropopliteal, 4 iliofemoral, 5 aorto-bifemoral and 3 axillo-bifemoral. Eight samples for culture were obtained by surgical drainage, 3 by imaging-guided puncture, and the rest from wound exudates. The most frequently isolated pathogen was methicillin-resistant Staphylococcus epidermidis (45%). Negative culture was obtained in 5 patients. All cases but one were regarded as early infections. Seventeen patients were considered cured and failure of treatment was observed in 5 patients: 3 in the induction phase, 1 in the consolidation phase, and relapse was observed in another case after suspension of the antibiotic. In 4 of these failures surgical removal of vascular prosthesis and revascularization was performed, while in the fifth case a conservative management protocol was employed. The outcome proved favorable in all 5 cases.

Conclusions: In our experience, those patients with vascular prosthetic infection but functional vascular prosthesis can be successfully managed on a conservative therapy.

A-320
PREDICTORS FOR EXTENDED-SPECTRUM BETA-LACTAMASES K PNEUMONIAE BACTERAEMIA

O. Martín[1], C. Villamor[1], L. Téllez[1], M. Monforte[1], F. Valverde[2], A. Delgado-Iribarren[2], J. Losa[1], M. Velasco[1]

[1]Department of Infectious Diseaseas and Internal Medicine, [2]Microbiology Unit. Hospital Universitario Fundación Alcorcón. Alcorcón (Madrid), Spain.

Objectives: Isolation of extended-spectrum beta-lactamases (ESBL) Klebsiella pneumoniae is a new and growing problem in Spain. ESBL E coli is associated with prior antibiotic treatment and living in nursing home, and affects elder and frail patients but epidemiology of ESBL Klebsiella pneumoniae (EKP) is uncertain. To evaluate predictors of bloodstream isolation of EKP we designed this study.

Material and method: We evaluated all patients attended in our hospital during 2011 with bacteraemic Klebsiella pneumoniae infection. Clinical and epidemiological data between patients with or without ESBL were compared. We compared trends in percentage of Klebsiella pneumoniae infection and ESBL production in the last 3 years. Results are expressed as average (SD) or percentage. Independent predictors of EKP bacteremia were evaluated by multivariate logistic regression.

Results: A total of 46 patients were included; mean age 75.5 (2.1) years and 39.1% females. EKP was isolated in 15 patients (32.6%). Trends in E coli bacteremia, ESBL E coli bacteremia and K pneumoniae bacteremia were stable from 2009 to 2011, but EKP increased its percentage almost twice in the year 2011. Patients with EKP bacteremia did not exhibited differences regarding age (70.1 [17.2] vs 78.1 [12.2] years), sex (female 22.2% in EKP vs 39.3%), lived in nursing home (42.9% vs 28.1%), comorbidites such as diabetes and renal chronic disease, nosocomial origin of infection (54.5% vs 25.7%) and presence of shock (22.1% vs 35.1%) or (sepsis 29 vs 40%), $p > 0.05$ for all comparisons. However, patients with EKP bacteremia had more frequently urinary versus other sites of primary infection 50% vs 16%, $p = 0.023$; had received antibiotic in the previous 3 days (57.9 vs 14.8%, $p = 0.004$) and had urinary indwelling device (57.9 vs 14.8%, $p = 0.004$) more frequently; suffered urinary manipulation (52.9 vs 20.7% $p = 0.048$) or UTI in the previous month (66.7 vs 20.6%, $p = 0.009$). In the logistic regression analysis, urinary indwelling device (HR 8.1) and previous antibiotic use (HR 3.2) showed a trend to association but did not reach statistically significance.

Conclusions: Proportion of EKP bacteraemia was very high and exhibited an unexpected increase in the last year in our hospital. Factors associated with this infection seems linked to urinary tract origin and patients are somewhat different to ESBL E coli bacteraemia. Further research is warranted.

Clinical management

G-35
MEDICATION RECONCILIATION AT DISCHARGE IN AN INTERNAL MEDICINE UNIT FOLLOW-UP THROUGH FOUR YEARS AND EFFECT OF INTERVENTION MEASURES

C. Rodríguez Leal[1], B. López Centeno[2], R. Escudero Sánchez[1], C. Crespillo Andújar[1], R. García Caballero[1], M. González Anglada[1], A. Martín de Rosales Cabrera[2], V. Castilla Castellano[1]

[1]Department of Internal Medicine, [2]Hospital Pharmacy. Hospital Universitario Fundación Alcorcón. Alcorcón (Madrid), Spain.

Objectives: Medication reconciliation at discharge is the formal process of obtaining a complete and accurate list of each patient's current home medications including name, dosage, frequency, and route of administration, and comparing discharge medication orders to that list. Reconciliation is done to avoid medication errors. The aim of our study was to analyze the proportion of patients who have had an accurate reconciliation list at discharge within an Internal Medicine Unit and to describe which intervention measures were implemented to improve it.

Material and method: We reviewed discharge reports of Internal Medicine Unit patients during March of 2009, 2010, 2011 and 2012 at Hospital Universitario Fundación Alcorcón (Spain). These reports were collected using our hospital electronic clinical history. Each report was analysed by two different researchers in order to detect whether it was properly reconciled or not. Differences between researchers were argued with a third member in order to obtain an agreement. In February of 2010, 2011 and 2012, we perform an informative presentation to the Unit to report which mistakes were detected during the previous year and to give advice about how to improve the process. To strengthen the message, the most relevant points were also sent by e-mail to the physicians within the Unit. During 2012, a complete list of patient's home medication was also collected and recorded in the electronic history, to facilitate proper medicines reconciliation. Data were collected using ACCESS 2003® database, and they were further analyzed with the SPSS 15.0® software. All patients signed a previous informed consent in order to authorize us to use their data. This study was approved by the ethical committee of the hospital.

Results: We collected a number of 97 consecutive reports in 2009, 198 in 2010, 200 in 2011 and 99 in 2012. The least reconciled type of medicines were: in 2009, antibiotics (21%); in 2010, statins (5.5%). In 2011 and 2012 we did not identify the type of medicine worst reconciled. The most frequent mistake in each year was: 2009 (44.3%) and 2011 (16%), not to detail the end of a treatment; 2010 (9.6%), not to design a treatment that covers all diseases of the patient; and finally, in 2012 (15%), not to detail a treatment that should be continued. The proportion of proper reconciliation for each year was: 36.1% for 2009, 72.7% for 2010, 70% for 2011 and 83.8% for 2012. These data were analyzed with ANOVA, obtaining a significant difference for good reconciliation ($p < 0.001$) between 2009 and the rest of years. There was also a tendency to improve between 2012 and 2011 ($p = 0.057$) and between 2012 and 2010 ($p = 0.179$), although it did not reach statistical significance.

Discussion: In 2009, there was a proportion of good discharge reconciliation of only 36.1%, similar to what is described within literature in other centres. Implementing some cheap and simple interventions, we have improved up to 83.8% in 2012, with a statistically significant difference. Mistakes were changing along the different years; although the physicians work in the Unit remained the same.

Conclusions: Medication reconciliation at discharge is a sign of quality in patients care and reduces adverse events. It is feasible to improve and to keep under adequate control along time using inexpensive interventions like the ones described in our study.

Heart failure

IC-5
OBESITY PARADOX IN HEART FAILURE ELDERLY PATIENTS; CLINICAL MEANING OF OVERWEIGHT AND OBESITY

A. Casas Vara[1], F. Santolaria[2], A. Fernández Bereciartúa[3], E. González Reimers[2], A. García Ochoa[3], A. Martínez Riera[2]

[1]Department of Internal Medicine, [3]Department of Emergencies. Hospital de Campoo. Reinosa (Cantabria), Spain. [2]Department of Internal Medicine. Hospital Universitario de Canarias. San Cristóbal de La Laguna (Santa Cruz de Tenerife), Spain.

Objectives: Obesity paradox holds the improved survival of obese elderly or diseased patients. Obesity paradox has been extensively studied in heart failure. Although, in the last ten years, many studies have shown a better survival related to obesity, the reasons of the paradox are poorly explained. It is not clear why obese heart failure patients have a better survival being overweight a well know vascular risk factor. Moreover, coronary disease is the first cause of heart failure and obesity is a long term risk factor to develop heart failure. Most studies about obesity paradox, even those including multivariate analysis, consider body mass index (BMI) as the only nutritional parameter, and prognosis is controlled by other vascular risk factors. To know if it is fat or other associated beneficial factors, our objective is to analyse the prognostic value of overweight and obesity in elderly heart failure patients, controlling other nutritional data such as mid arm anthropometrics, serum proteins and muscle strength by dynamometry.

Material and method: We included, from January 2005 until July 2008, 244 patients hospitalized with heart failure (diagnosed according to Framingham criteria) at the Internal Medicine unit of a country hospital of Cantabria (Tres Mares Hospital at Reinosa); 115 were men and 129 women with an age range of 55 to 100 years (median age and quartiles of 85 and 79-89 years). Fourteen (5.7%) patients died during hospitalization. All patients were followed up by telephone with a median survival of 984 days.

Results: Patients with a better nutritional status assessed by BMI, subjective score, mid arm anthropometrics, hand grip, serum albumin, prealbumin, lymphocyte count and cholesterol levels showed a better short and long term prognosis. Obese patients with a BMI over 30 kg/m^2 showed a better long term prognosis than those with a BMI 25-30 kg/m^2, than those with a BMI 20-25 kg/m^2 and than those with a BMI under 20 kg/m^2. However, we did not find a relationship between fat excess, triceps skinfold (TSF) over 95th percentile, and survival. Obese and overweighed patients had lesser age and better nutritional status than those with normal or decreased BMI, as shown by anthropometrics, subjective score, handgrip, lymphocyte count, blood haemoglobin and serum albumin, prealbumin and cholesterol. All the nutritional data are closely correlated between each other. NYHA class also correlated with data of status of nutrition: so, as heart failure advances, nutritional status becomes impaired. At multivariate analysis to predict long term survival, neither BMI nor TSF showed an independent predictive value whereas a high mid arm muscle area (MAMA) improved long term survival.

Discussion: The better survival of overweight and obesity suggest us two different hypotheses. The first is that the fat excess, in a primary and specific way, may carry a beneficial condition for survival. In the second, the fat excess, even being not an advantageous condition "per se", would be associated with other factors favouring survival, being a surrogate marker of other protective factors. Our study agrees with the last hypotheses. The obesity is not only a sign of fat excess, but, in heart failure patients, it implies a better status of nutrition with more muscle mass, better strength and immune function, all of which are associated to a

better prognosis. So, the younger age and a better status of nutrition related to a BMI over 30 kg/m^2 may explain the better survival.

Conclusions: Obesity paradox reflects the better status of nutrition (protein mass and function indicators) of high BMI in heart failure patients and the worst of low BMI ones. These differences in the nutritional status may be responsible of differences in survival.

IC-14
VENOUS THROMBOEMBOLISM IN HEART FAILURE HOSPITALIZED PATIENTS

D. Joya[1], A. López de Guzmán[1], S. Nistal[1], I. Perales[1], S. Plaza Canteli[3], A. Zapatero[2], R. Barba[1]

[1]Department of Internal Medicine. Hospital Rey Juan Carlos. Móstoles (Madrid), Spain. [3]Department of Internal Medicine. Hospital Severo Ochoa. Leganés (Madrid), Spain. [2]Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: Patients with heart failure (HF) are at increased risk for venous thromboembolism (VTE). We analyzed a large Spanish database to determine the incidence of VTE in these patients during hospitalization.

Material and method: A retrospective chart review of cohort of consecutive patients admitted with HF as the primary reason for discharge in Spain between January 1st 2006 and December 31st 2007 was performed. For each patient, demographic data, risk factors for VTE and the diagnosis of VTE during hospitalization was recorded.

Results: We analyzed the clinical data of 275,166 adults with HF admitted to the hospital at any public centre in Spain, in 2006 and 2007. We identify 1,360 new diagnosed VTE events among 244,274 HF patients hospitalized more than two days (incidence 0.6%). Women comprised 60.8% of the patients, and the mean age was 76.7 years (SD 11.2). The mean average length of stay was 13.8 days (SD 11.2), and 20.9% died during the hospitalization (OR 2.89 95%CI 2.50-3.27 after adjustment by age and gender). The cost for patients who developed VTE during hospitalization was 4531 € (SD 993), 926€ higher than median cost (3605€). In univariate analysis, gender (women), (0.6% of women suffer a VTE during admission vs 0.5% of men; OR 1.4 95%CI 1.3-1.6) cancer (7.9% vs 5.6%: OR 1.4 95%CI 1.2-1.7), cerebrovascular disease (5.9% vs 4.5% OR 1.3 95%CI 1.1-1.6), concomitant acute infection (23.6% vs 19% OR 1.31 95%CI 1.2-1.5), varicose veins (0.7%vs 0.2% OR 3.1 95%CI 1.6-5.7), malnutrition (1.3% vs 0.7%; OR 2.0 95%CI 1.2-3.2) atrial fibrillation (47.6% vs 41%; OR 1.2 95%CI 1.2-1.4), acute renal failure (8.3% vs 4.2%; OR 2.05 95%CI 1.68-2.48) were significantly associated with VTE during admission. There was a significant reduction in the odds of VTE in patients who had heart failure and diabetes (27.3% vs 32.9%; OR 0.76 95%CI 0.67-0.86). VTE was not significantly associated with obesity, hypertension, acute respiratory failure, chronic renal failure or rheumatic disease. Hospitalized-acquired VTE risk factors were female gender (odds ratio [OR] 1.41; 95%CI 1.64-1.58), neoplasic disease (OR 1.54 95%CI 1.26-1.88), diabetes (OR 0.76 95%CI 0.67-0.85), atrial fibrillation (OR 1.24 95%CI 1.11-1.38) cerebrovascular disease (OR 1.28 95%CI 1.02-1.61), acute infection (OR 1.26 95%CI 1.11-1.43), malnutrition (OR 1.64 95%CI 1.03-2.63) varicose veins (OR 2.75 95%CI 1.47-5.17), acute renal failure (OR 1.98 95%CI 1.63-2.40) and hypertension (OR 0.86 95%CI 0.76-0.97).

Discussion: We examined more than two hundred thousand of consecutive hospitalizations of adult HF patients in Spain, over a 2-year period, and we have seen than almost six patients out of 1000 suffer a VTE during hospitalization. This rate of complication is more than double that the rate demonstrated in the surgical population, based in study which used a similar methodology, where authors observed that 0.24% of hospitalized patients after a surgical procedure suffered a VTE during hospitalization.

Conclusions: VTE appears as a major threat to patients admitted for HF, and pharmacologic prophylaxis should be considered in all high risk situations.

IC-17
HEART RATE VARIABILITY IN PATIENTS WITH AND WITHOUT HEART FAILURE AND VENTRICULAR PREMATURE BEATS

G.S. Gheorghe, A. Cristea, I. Leabu, T. Nanea

Department of Cardiology. Prof Th Burghele Hospital, University of Medicine and Pharmacy Carol Davila. Bucharest, Romania.

Objectives: To assess the change of the heart rate variability (HRV) in patients (pts) with and without heart failure (HeF) in relation to the presence and severity of ventricular premature beats (VPB) and various concomitant clinical conditions.

Material and method: We performed 24 hours Holter ECG monitoring for palpitations in148 pts classified in 2 groups: with (G1) and without (G2) HeF. We noted demographic data, history of arterial hypertension (HP), ischemic heart disease (IHD), old myocardial infarction (OMI), type 2 diabetes mellitus (DM), NYHA class and medication of HeF, VPB Lown class III and IV. We evaluated HRV using time domain methods (ms): standard deviation of normal-to-normal interval over 24 hours (SDNN-24h), standard deviation of the average NN interval index (SDANN); standard deviation of normal-to-normal interval index (SDNNi); frequency domain methods (Hz): very low frequency (VLF), low frequency (LF), high frequency (HF) and LF/HF ratio. Reduced HRV was defined for a SDNN-24h under 100 ms. We compared the results between the 2 groups using EpiInfo 3.5.3 statistical program.

Results: 61 pts where in G1, 75.4% NYHA II, 19.6% NYHA III and 3.2% NYHA IV; 49.2% men; 69.8 ± 10.2 years old. 87 pts were in G2. G1 pts were older than G2 (69.8 ± 10.2 years vs 57.9 ± 15.8 years, $p < 0.0001$), with an increased prevalence of IHD (52.5% vs 23%, $p = 0.0002$), OMI (16.4% vs 3.4%, $p = 0.006$) and DM (26.7% vs 11.5%, $p = 0.01$). 85% G1 pts took beta blockers. 30 (49%) G1 pts and 27 (31%) G2 pts had VPB. VPB Lown III were equal distributed in G1 and G2 (11.5% versus 12.6%, $p = 0.83$) but Lown IV were more frequent in G1 than in G2 (37.7% versus 18.4%, $p = 0.008$). 45.9% pts in G1 versus 26.4% in G2 had reduced HRV ($p = 0.01$). SDNN-24h was 103.7 ± 35.7 ms for G1 vs 124.5 ± 36.2 ms for G2, ($p = 0.0007$) and SDANN was 92.7 ± 35.3 ms for G1 vs 113.5 ± 34.5 ms for G2 ($p = 0.0005$). In G1 group, pts with VPB had lower HRV than pts without VPB (SDNN 24h 94.3 ms, vs 112.9, $p = 0.04$, SDANN index, ms, 82.4 vs 102.6, $p = 0.02$). The prevalence of decreased HRV didn't differ significantly between NYHA classes ($p = 0.72$) and was not associated with the history of HT, OMI, IHD, DM. The presence of DM was associated with the decreased HRV in G2 pts (odds ratio = 5.29 95%CI [1.33;20.93], $p = 0.01$). LF was 396.4 ± 520.3 Hz in G1 and 462.8 ± 334.3 Hz in G2 ($p = 0.008$). LF/HF ratio was 2.64 ± 1.69 in G1 and 3.53 ± 2.49 in G2 ($p = 0.01$).

Discussion: Arrhythmic sudden death can occur in HeF with preserved ejection fraction, proving the need for parameters of arrhythmic susceptibility. HRV, LF and HF components are correlated with arrhythmic risk, demonstrating the imbalance of the cardiac autonomic nervous system. We found a decrease of the HRV in patients with HeF in all NYHA classes, irrespective of the ischemic or non-ischemic etiology, comparing to the pts without HeF. Only in HeF pts the low HRV was associated with the presence of VPBs classes III and IV Lown. The association of DM decreased the HRV in pts without HeF, proving the role of the diabetic autonomic cardiac neuropathy. We did not observe a similar correlation between DM and decreased HRV in HeF pts. In established HeF there are multiple

nervous and hormonal disturbances which can impair the HRV and increase the arrhythmic risk; the role of DM in itself could be less significant. We found a low LF and LF/HF ratio in HeF pts treated with beta-blocker, which can partially explain their antiarhythmic effect.

Conclusions: Pts with HeF had decreased HRV in comparison with pts without HeF. In pts with HeF the decreased HRV was associated with the VPB, irrespective of NYHA class. Pts without HeF and DM had lower HRV comparing with those without DM. The decreased LF and LF/HF ratio in HeF pts might be explained by the high number of pts taking beta blockers.

IC-18
APPLICATION OF SENIORS HEART FAILURE SCORE IN THE RICA HEART FAILURE REGISTRY: AN ASSESSMENT OF VALIDITY AND CLINICAL USEFULNESS

M. Montero Pérez-Barquero[1], L. Manzano[2], F. Formiga[3], C. Grahame[4], J. Pérez Calvo[5], O. Aramburu[6], M. Flather[7] and the RICA (National Spanish Registry of Heart Failure) Investigators[8]

[1]Department of Internal Medicine. Hospital Universitario Reina Sofía. Córdoba, Spain. [2]Department of Internal Medicine. Hospital Universitario Ramón y Cajal. Madrid, Spain. [3]Department of Internal Medicine. Hospital Universitario de Bellvitge. Barcelona, Spain. [4]Department of Cardiology. Norfolk and Norwich University Hospital. Norwich. United Kingdom. [5]Department of Internal Medicine. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain. [6]Department of Internal Medicine. Complejo Hospitalario Regional Virgen Macarena. Sevilla, Spain. [7]Department of Cardiology and Medical School. Norfolk and Norwich University Hospital and University of East Anglia. Norwich. United Kingdom. [8]Work Group. Fundación de la Sociedad Española de Medicina Interna. Madrid, Spain.

Objectives: The objective of this study was to validate the utility of a simple modified SENIORS risk model, in an independent cohort of elderly heart failure patients.

Material and method: The SENIORS risk model was applied to patients in the National Spanish Registry of Heart Failure (RICA) to estimate baseline risk at one year of a) composite outcome of all cause mortality or cardiovascular hospital admission and b) all cause mortality, and to link this to actual event rates in the whole group and subgroups stratified by level of baseline risk. Receiver operating character (ROC) curves were used to determine areas under the curve for prediction of proportion events.

Results: In the RICA registry 580 patients were identified (mean age 77 years, with mean ejection fraction 51%). Rates of death/CV hospitalization were 34% and all cause mortality 17.2% at one year. In the lowest and highest quintiles respectively the expected versus observed risk of death/CV hospitalization were 23.1%/22.4% and 45.8%/45.6% and for death 6.5%/6% and 31.8/36.0%. The risk model provided good separation of Kaplan Meier stratified by tertile of baseline risk, and ROC curves showed a C statistic of 0.61 and 0.68 for agreement between the model applied to the original SENIORS dataset and to the RICA dataset for death/CV hospitalization and all cause mortality respectively.

Discussion: In this cohort of non clinical trial, hospital-based patients with HF, we successfully validated the SENIORS risk at 1 year. If mortality or CV hospitalization to hospital discharge can be reduce with better patient selection. The combination of SENIORS risk, for prediction mortality or cardiovascular hospitalization using the RICA registry, may help to identify appropriate patients that require frequent monitoring. In addition, a method is necessary to identify high risk patients who might benefit from close supervision. Alternatively, patients who poor scores and symptoms refractory to conventional therapy might be select for palliative care.

Conclusions: Our findings show that a simple modified SENIORS risk model performed well when applied to an independent observational cohort of heart failure patients from "the real world" and therefore could be a useful routine clinical tool.

IC-27
PREDICTIVE VALUE OF PLASMA GALECTIN-3 LEVELS IN HEART FAILURE PATIENTS WITH PRESERVED EJECTION FRACTION

I. Páez Rubio[1], F. Carrasco Sánchez[1], L. Galisteo Almeda[2], O. Aramburu Bodas[3], P. Salamanca Bautista[3], J. Morales Rull[4], J. Arias Jiménez[3], J. Pérez Calvo[4]

[1]Department of Internal Medicine, [2]Department of Laboratory. Área Hospitalaria Juan Ramón Jiménez. Huelva, Spain. [3]Department of Internal Medicine. Complejo Hospitalario Regional Virgen Macarena. Sevilla, Spain. [4]Department of Internal Medicine. Hospital Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: Galectin-3 (Gal3) is a novel biomarker involved in fibrosis and inflammation and plays a role in heart failure (HF). However, its usefulness in patients with HF with preserved left ventricular ejection fraction (LVEF) remains sparse and not well-known. We aim to establish the relationship of Gal3 and outcomes in patients with HF with preserved LVEF.

Material and method: We evaluated serum Gal3 levels on admission in 349 consecutive patients with LVEF > 45% hospitalized for HF in three different Spaniard hospitals. LVEF was estimated by the Simpson rule. Renal function was calculated by creatinine and estimation of glomerular filtration rate (GFR) by MDRD-4 equation. We categorize Gal3 into quartiles because normal ranges have not been well established. Primary endpoint was all-cause mortality and/or readmission due to HF during 1-year follow-up. Kaplan-Meier survival plots were performed from baseline to time of primary endpoint. We determined hazard ratio (HR) derived from the stepwise multivariable Cox proportional hazard model to identify predictors of primary endpoint.

Results: During 1-year follow-up period, 109 patients (31.2%) died, and 178 patients (51.0%) were readmitted. Primary endpoint was 53.6% (95%CI; 0.46-0.56). Median of Gal3 was 12.24 ng/ml (9.30-17.63). Gal3 by quartiles was associated at increased risk for adverse events. Kaplan-Meier survival curves only showed increased significantly primary endpoint between first and fourth quartile (Log rank < 0.0001). In univariante model Gal3 above median, anemia, diabetes mellitus, age, hyponatremia, renal failure defined by GFR < 60 ml/min/1.73 m^2 and NT-proBNP levels above median reached statistical significance. After correction for age, anemia, GFR and NT-proBNP levels, serum Gal3 levels above median were at increased adjusted hazard ratio for primary endpoint (HR 1.58; 95%CI 1.17-2.13; p = 0.002). The others variables did not reach significance in multivariable model.

Discussion: Any previous study gave partial information about the relation between HF with preserved LVEF and Gal3. We designed a study to answer specifically this hypothesis. The role of Gal3 in development and progression of HF is also present in patients with preserved LVEF.

Conclusions: Serum Gal3 levels measured on admission in patients with HF and preserved LVEF are strong and independent predictors for unfavourable outcomes.

IC-30
HEMOCONCENTRATION AS A PREDICTOR OF SURVIVAL IN THE YEAR OF DISCHARGE HEART FAILURE

J. Grau Amorós[1], M. Montero[2], F. Formiga[3], A. Serrado[1], A. Armengou[4], A. Conde[5], O. Aramburu[6] and the RICA (National Spanish Registry of Heart Failure) Investigators[7]

[1]Department of Internal Medicine. Hospital Municipal de Badalona. Badalona (Barcelona), Spain. [2]Department of Internal Medicine. Hospital Universitario Reina Sofía. Córdoba, Spain. [3]Department of Internal Medicine. Hospital Universitari de Bellvitge. L'Hospitalet de Llobregat (Barcelona), Spain. [4]Department of Internal Medicine. Hospital Universitari de Girona Dr. Josep Trueta. Girona, Spain. [5]Department of Internal Medicine. Hospital Universitario de Gran Canaria Dr. Negrín. Las Palmas de Gran Canaria (Las Palmas), Spain. [6]Department of Internal Medicine. Hospital Universitario Virgen Macarena. Sevilla, Spain. [7]Work Group. Fundación de la Sociedad Española de Medicina Interna. Madrid, Spain.

Objectives: To determine the prevalence of patients in which we got the hemoconcentration clinic in the three months after a hospital admission for heart failure (HF) and if it is a prognostic factor for re-admission for cardiovascular cause or death during the first year of follow-up.

Material and method: Patients included in the RICA Register who have completed one year of follow-up. We exclude patients treated with iron, erythropoietin or red blood cell transfusion and patients with liver cirrhosis, nephrotic syndrome, or an estimated glomerular filtration < 30 ml/min. We define hemoconcentration as the upper quartile of the distribution of change in the haemoglobin (Hb), expressed in%, the third month following discharge Hb compared with the initial admission. Statistical analysis using the SPSS program using the Student t test, Wilcoxon or the χ^2 according to the category of variables in the univariate analysis; The method of Kaplan-Meier and Cox proportional hazards model to estimate the independent association between hemoconcentration and death. It is considered with statistical significance for all analysis a $p < 0.05$.

Results: 542 patients, mean age 76.9 years (range = 50-96). Mean follow up to the first event of 266.3 days. The group with hemoconcentration showed lower BMI (28.2 ± 5.1 vs 29.4 ± 5.8; p = 0.043); lower value of Hb (11.2 ± 1.5 vs 13.4 ± 1.6; p < 0.001) and received the highest cumulative dose of loop diuretics (57.4 ± 35.2 vs 50.1 ± 29.1; p = 0.023). However, in the three months there were no differences in weight, glomerular filtration and Hb between both groups. We have witnessed 134 deaths (24.7%) and 129 readmissions by cardiovascular causes (23.8%) while the curve of survival of both groups is separated in the first quarter, not reaching statistical significance in the following year (p = 0.167). In the univariate analysis hemoconcentration showed no significance whatsoever to mortality the following year. In the multivariate analysis, were predictors of mortality age (RR 1.05; 95%CI 1.03-1.08), ischemic heart disease (RR 1.6; 95%CI 1.1 -2.32), BMI (RR 0.92; 95%CI 0.89-0.96) and functional class III and IV of the NYHA (RR 3; 95%CI 1.2-7.5 and RR 5.2;95%CI 1.6 -17.3 respectively).

Discussion: The hemoconcentration in patients with HF who have been discharged from a hospital admission has been associated with increased doses of diuretics and further deterioration of renal function; contrary to what we would expect, this reduces the risk of death in the following year. In our cohort of real clinical practice, we found that the persistence of the state of hemoconcentration in the three following months, has no effect on the glomerular filtrate and does not influence the prognosis of the patient.

Conclusions: the hemoconcentration 3 months after admission HF has no character prognosis for readmission or death in the following year, nor does it imply a worsening of the glomerular filtrate.

IC-32
BEDSIDE ULTRASOUND EVALUATION OF THE INFERIOR VENA CAVA AND RISK OF DEATH IN PATIENTS WITH HEART FAILURE

P. Cubo Romano[1], J. Torres Macho[1], J. Casas Rojo[1], A. Rodríguez Almodóvar[2], B. Berzal[2], J. Fernández Alonso[3], G. García-Casasola[1]

[1]Department of Internal Medicine, [2]Department of Cardiology, [3]Department of Laboratory. Hospital Infanta Cristina. Madrid, Spain.

Objectives: We sought to analyze the value of ultrasound assessment of the inferior vena cava (IVC) to identify patients with acute decompensated heart failure (HF) who have high risk of death in the short term.

Material and method: We performed a prospective observational study including patients admitted to a University Hospital and were diagnosed of HF according to the European Society of Cardiology criteria. We excluded patients who were admitted in the intensive care unit, were included in dialysis program or were in agony. Demographic data, functional status, standard medical treatment, comorbidity, etiology of HF, echocardiographic data and analytical parameters were registered. Within the first 24 hours of admission IVC measurement with ultrasound in inspiration and expiration and IVC collapsibility index was assessed. Patient follow-up was performed at 90 days. IVC measurements were performed by an internist with experience in abdominal ultrasonography with a portable ultrasound (Logic e, General Electric).

Results: 43 patients were included (mean age 74 ± 14 years; 60% women). The NYHA average was 2.3 ± 1. The etiology of HF was: significant valvular disease 34.9% (n = 15), hypertensive heart disease 23.3% (n = 10) and ischemic heart disease 16.3% (n = 7). 26 patients (60.5%) had a preserved LVEF and 17 (40%) chronic renal insufficiency. The mean Charlson index was 7.7 ± 3.2). The mean hemoglobin was 12 ± 1.7 mg/dl and mean NT proBNP at income was 6290 ± 5067 pg/ml. Total mortality due to HF at ninety days was 23.3% (n = 10). IVC was visualized in 34 patients (83.7%). Mortality in patients with expiratory IVC diameter < 2.5 cm was 9% (2 of 24), whereas in those with expiratory IVC > 2.5 cm and collapsability index < 50% mortality was 50% (6 of 12) (p = 0.003). The relative risk of death was calculated with the hazard ratio (HR) from Cox regression models. Expiratory IVC > 2.5 cm and collapsability index < 50% was an independent mortality predictor (HR: 8; 95%CI 1.6-12.8; p = 0.01).

Conclusions: Bedside evaluation of the IVC with a hand-carried ultrasound at the time of admission reliably identified patients at risk of death in the short term.

IC-33
CHRONIC SYSTOLIC HEART FAILURE TREATMENT IN SPAIN INFLUENCE OF PATIENT CLINICAL CHARACTERISTICS ON ALDOSTERONE BLOCKERS USE IN INTERNAL MEDICINE SETTINGS

L. Manzano[1], F. Formiga[1], M. Anguita[1], J. Comín Colet[1], M. Crespo Leiro[1], L. Almenar[1], J. Muñiz[1], T. de Frutos[2]

[1]Department of Internal Medicine and Cardiology. VIDA IC Steering Committee, Spain. [2]Medical Department. Pfizer S.L.U., Spain.

Objectives: Chronic heart failure (CHF) has become a cardiovascular epidemic with higher incidence and prevalence. Because of this reason, CHF patients are followed by different specialist and primary care. Previous studies suggest differences in patients characteristics and treatment used between cardiologist and internal medicine (IM) and this differences could be influence in the prognosis. The objective of this study is to compare the systolic CHF management performed

by cardiologist and internal medicine and the influence of clinical characteristics on treatment use by IM.

Material and method: VIDA IC study is a national, prospective registry conducted in 2011 by 115 specialists (cardiologists and internists) across Spain who included consecutive outpatients with CHF and left ventricular ejection fraction (LVEF) < 40%.

Results: A total of 967 patients were evaluated for this analysis. Patients' mean age was 70.6 years, 30% were women and 40% were > 75 years. 37% of these patients were followed by internists and 63% by cardiologists. Patients' mean age was 69 years in Cardiology and 74 years in IM (p < 0.0001); no differences were observed in gender. Patients followed in IM had more hypertension, diabetes, COPD, ictus, significant renal failure, anemia, thyroid dysfunction and atrial fibrillation. CHF severity was similar in both settings. Patients followed by cardiologists received more aldosterone blockers (72 vs 54%, p < 0.001). Within the 353 CHF patients followed by internists, 54% were on aldosterone blocker treatment. There were no differences between patients with and without aldosterone blockers with respect to age, gender, diabetes, hypertension, previous acute myocardial infarction, NYHA class or atrial fibrillation. Serum potassium and creatinine levels were similar in both groups (4.3 ± 0.5 vs 4.3 ± 0.5, p = 0.11 and 1.4 ± 0.9 vs 1.4 ± 0.7, p = 0.58 respectively). Patients on aldosterone blocker treatment had lower systolic blood pressure (132.6 ± 20.4 vs 127.9 ± 18.1, p = 0.024).

Discussion: Considerable differences exist between characteristics of systolic CHF patients followed by internists and cardiologist in Spain. Patients followed by internists were older, had more extracardiac comorbidities, and received less aldosterone blocker treatment. Age and gender did not have influence on aldosterone antagonists prescribed by internists. It is important to note that serum potassium and creatinine levels did not explain the lack of aldosterone blocker treatment in the majority of patients without aldosterone antagonists.

Conclusions: These real world data suggest that there is sub-optimal transfer of clinical trial evidence into clinical practice. Although the percentage of aldosterone blocker treatment in patients with systolic CHF prescribed by internists is relevant, there is still room for improvement the use of this treatment. Further research is needed to evaluate the factors that have an influence on aldosterone antagonist use in Internal Medicine settings.

IC-34
ECHOCARDIOGRAPHIC PREDICTORS OF ADVERSE OUTCOMES IN PATIENTS WITH PULMONARY HYPERTENSION DUE TO LEFT HEART DISEASES

F. Corciova, C. Corciova, C. Arsenescu Georgescu

Department of Cardiology. University of Medicine and Pharmacy "Grigore T. Popa". Iași, Romania.

Objectives: To identify the adverse echocardiographic prognostic factors in patients with pulmonary hypertension due to left heart diseases and their impact on mortality, quality of life, need for hospitalization and complications during hospitalization. *Material and method:* We performed a prospective study that included 370 patients with left heart diseases and pulmonary hypertension. We analyzed a series of echocardiographic parameters (systolic pulmonary artery pressure, the pulmonary acceleration time, left ventricle ejection fraction, dimensions of the right cavities, right ventricle systolic function and presence of the pericardial effusion), and we analyzed their correlation with mortality, WHO functional class, complications and need for hospitalization.

Results: The average systolic pulmonary artery pressure determined by echocardiography (sPAP) was significantly associated with higher mortality (p < 0.001) and shorter survival rates (r 0.52, p < 0.001). Severe pulmonary hypertension, defined as sPAP more than 70 mmHg, was associated with increased number of hospitalisations (p < 0.001), longer duration of hospitalisation (p < 0.001), increased need for mechanical ventilation (p 0.008), higher rates of renal (p 0.01), hepatic (p 0.009) and pericardial (p 0.001) complications. We found no association between sPAP value and need for inotropic support or pleural complications. The pulmonary acceleration time was not statistically associated with mortality (p 0.14) or the survival time (p 0.059). Left ventricle ejection fraction was significantly lower in deceased patients (p 0.03), but we found no correlation between the value of left ventricular ejection fraction and survival time (r 0.0203, p 0.747). Dilatation of right cavities was a major prognostic factor, negatively correlated with mortality. Right ventricular end diastolic diameter and right atrium area (indexed to the body surface area) were closely correlated with the risk of death (p < 0.001). Right ventricular dysfunction was also associated with higher risk of death - average TAPSE in deceased patients was 12.23 ± 4.83 mm and 18.49 ± 5.8 mm in the remaining patients (p < 0.001). Pericardial fluid was associated with a relative risk of death of 3.5 (confidence interval 1.49 to 8.21), p 0.04.

Discussion: There is a lack of consensus on factors that predict mortality and prognosis in patients with pulmonary arterial hypertension. The sPAP, determined by echocardiography, has not classically been seen as a prognostic factor. Yet, recent studies found that severe pulmonary hypertension (defined on echocardiographic criteria) is an independent predictor of mortality, readmission for heart failure or fatal arrhythmia after cardiac surgery in patients with chronic organic mitral regurgitation. In our study, we found that severe pulmonary hypertension (defined as sPAP > 70 mmHg) is closely related to increased mortality, survival duration, number of hospitalizations for clinical worsening and heart failure phenomena and longer hospitalization duration. We also found a statistically higher risk of patients with sPAP > 70 mmHg for mechanical ventilation and renal, hepatic and pericardial complications. Right atrium enlargement, right ventricle dilation and dysfunction and the presence of pericardial fluid correlate in our study both with mortality and functional class.

Conclusions: We identified as main echocardiographic negative prognostic factors: the pulmonary artery systolic pressure value, right cavities dilation, TAPSE and the presence of pericardial effusion. Echocardiography brings very useful tools for assessing prognosis in patients with pulmonary hypertension due to left heart diseases.

IC-35
HEART RATE AS A PROGNOSTIC FACTOR IN PATIENTS WITH HEART FAILURE AND COMORBIDITY

J. Sánchez Gil[1], M. Montero Pérez-Barquero[1], F. Formiga Pérez[2], L. Manzano Espinosa[3], C. Sánchez Sánchez[4], J. Arévalo Lorido[5], M. Carrera Izquierdo[6] and the RICA (National Spanish Registry of Heart Failure) Investigators[7]

[1]Department of Internal Medicine. Hospital Universitario Reina Sofía. Córdoba, Spain. [2]Department of Internal Medicine. Hospital Universitario de Bellvitge. Barcelona, Spain. [3]Department of Internal Medicine. Hospital Ramón y Cajal. Madrid, Spain. [4]Department of Internal Medicine. Hospital Nuestra Señora de Sonsoles. Ávila, Spain. [5]Department of Internal Medicine. Hospital Comarcal de Zafra. Badajoz, Spain. [6]Department of Internal Medicine. Complejo Hospitalario de Soria. Soria, Spain. [7]Work Group. Fundación de la Sociedad Española de Medicina Interna. Madrid, Spain.

Objectives: To know the importance of heart rate in patients with multipathological problems with heart failure (HF) for re-admission for cardiovascular cause or death during the first year of follow-up.

Material and method: Patients included in the RICA Register who have completed one year of follow-up. We include the heart rate to third month following discharge. The heart rate (HR) was distributed

in tertiles (T1 ≤= 70 beats per minute (bpm), T2 70-80 bpm, T3 > 80LPM). Statistical analysis using the SPSS program using the Student t test, χ^2 according to category of variables in the univariate analysis. The methods of Kaplan-Meier and Cox proportional hazards model to estimate the independent association between heart rate and re-admission for cardiovascular cause or death. It is considered with statistical significance for all analysis a $p < 0.05$.

Results: 678 patients with a mean age of 77.1 years (range = 51-96). Mean follow up to the first event of 333 days. After the analysis of the data were obtained Kaplan Meier curves which showed how the lower heart rate at 3 months is a factor of better prognosis for hospital readmission for heart failure and shows a trend toward the statistical significance for re-admission for heart failure or mortality. In the multivariate analysis, were predictors of mortality or re-admission cardiovascular cause, HR-T2 (RR 1.450; 95%CI 1.077-1.953), HR-T3 (1.424; 95%CI 1.036-1.957), age (RR 1.023; 95%CI 1.007-1.038), ischemic heart disease (RR 1.476; 95%CI 1.107-1.969), Beta-Blocker (RR 0.677; 95%CI 0.903-0.507) and functional class III and IV of the NYHA (RR 2.350; 95%CI 1.317-4.194 and RR 4.553; 95%CI 2.079-9.972 respectively).

Discussion: Our analysis confirmed the predictive value of resting heart rate in patients with HF in patients world real, for both the composite outcome of cardiovascular admission or mortality. We should try to get a heart rate less than 70 bpm in patients with heart failure can be beneficial to avoid the re-admission for this cause.

Conclusions: The lowest heart rate is a favourable prognostic factor in patients with heart failure.

IC-38
PREDICTIVE VALUE OF HOMOCYSTEINE IN HEART FAILURE

P. Salamanca Bautista[1], T. Lamas Martínez[1], E. Ramiro Ortega[2], M. Fernández Díaz[2], M. Cano Guzmán[2], J. Jiménez Gallardo[2], O. Aramburu Bodas[2], J. Arias Jiménez[2]

[1]Department of Emergencies, [2]Department of Internal Medicine. Complejo Hospitalario Regional Virgen Macarena. Sevilla, Spain.

Objectives: Hyper-homocysteinemia is an independent novel risk factor for vascular disease. Several studies have also reported that homocysteine (Hcy) could have prognostic value in heart failure. We aim to establish the relationship of Hcy and outcomes in patients with descompensated heart failure.

Material and method: A total of 160 consecutive patients, who had been hospitalized for descompensated heart failure, were enrolled and followed up for one year. Serum Hcy was measured upon admission. The cohort was divided into two subgroups according to normal levels of Hcy in our hospital (15 micromol/L). All-cause death and rehospitalization due to the worsening of HF/death were the primary endpoints.

Results: During 1-year follow-up period, 32 patients (20%) died, and 74 patients (46.5%) were readmitted or died. Across Hcy strata, 44.4% of patients had normal levels of Hcy, and 55.6% had hyper-homocysteinemia. Patients with higher levels of Hcy had a significant increased mortality ($p = 0.03$), but Hcy did not demonstrate to be a predictor of readmission. In univariate model, categorized Hcy reached statistical significance (only for death), but after correction for NT.proBNP levels, GFR, anemia, functional class and other variables, did not reach significance in multivariate model.

Discussion: It is well-known that Hcy is a risk factor for the development of congestive HF and high levels in serum have been associated with adverse cardiac remodeling and reduced pump function. However, the role of Hcy as a predictor of adverse events is not completely established. Future studies should explore this role and whether modification of Hcy levels could improve the clinical outcome in HF patients.

Conclusions: High levels of Hcy are very prevalent in HF patients, irrespective of aetiology or ejection fraction. Further studies, with bigger sample size, could clarify if Hcy play a role as prognostic marker.

IC-44
USEFULNESS OF LUNG ULTRASOUND AND BIOELECTRICAL IMPEDANCE VECTOR ANALYSIS (BIVA) IN DIFFERENTIAL DIAGNOSIS OF DYSPNEA IN PATIENTS WITH COMORBIDITY

P. Bizzotto, G. Bombonato, S. Tonello, A. Verardo, S. Brocco, P. Pesce, M. Bolognesi, D. Sacerdoti

Department of Medicine. Clinica Medica 5. Azienda Ospedaliera Università di Padova. Padova, Italy.

Objectives: Acute dyspnea is a common cause of emergency department (ED) admission. In 2010, patients presenting for dyspnea at the ED of Padua University Hospital were 5% of the total accesses (3,975 cases) and 13% of hospitalizations. Despite new technologies, the diagnosis of dyspnea represents a relevant problem, particularly in elderly patients with comorbidity. Aim: to evaluate the usefulness of lung ultrasound and of bioelectrical impedance vector analysis (BIVA) in the differential diagnosis of dyspnea.

Material and method: We included 37 patients (12 female and 25 male) with a mean age of 78.7 ± 11.4 yr hospitalized in the Medicine Department of Padua University Hospital. The ED admission diagnosis was cardiac (according to the European Society of Cardiology criteria) in 19 patients, infective in 10 (pneumonia or decompensated COPD), mixed (cardiac and infective) in 1 and only descriptive in 7 (respiratory distress or dyspnea). Patients were excluded if they had pulmonary embolism or cancer. All patients underwent lung ultrasound and BIVA on day first, third and before discharge. Lung ultrasound examinations were performed by a single operator, bilaterally scanning the anterior and lateral chest wall, with the patient in supine position. Each scan was considered to be positive when ± 3 close B-lines were visualized (maximum distance between adjacent B-lines of 7 mm). BIVA measurements were obtained with standard tetrapolar bioelectrical impedance electrodes at a frequency of 50 kHz using a phase-sensitive analyzer (Akern 101 Anniversary). The 2 vector components R and Xc were recorded and divided by the subject's height. All BIVA measurements were performed by one operator.

Results: Lung ultrasound modified admission diagnosis in 24 patients (65%; $p < 0.01$), with an increase of mixed dyspnea (from 1 to 13), a decrease in cardiac (from 19 to 17) and infective (from 10 to 7) dyspnea; no patients had a descriptive diagnosis. The number of positive lung scans at admission was not different between patients with heart failure and patients with mixed dyspnea, but was significantly higher in these two groups compared with patients with infective dyspnea (5.0 ± 2.52 and 4.62 ± 2.72 vs 0.57 ± 1.13, $p < 0.01$). Patients with heart failure had a significant reduction in number of positive lung scans at discharge (5 ± 2.52 vs 2.24 ± 2.36, $p < 0.01$) and the reduction was already present three days after admission (5 ± 2.52 vs 2.42 ± 2.71, $p < 0.01$). Also patients with mixed dyspnea had a decrease in positive scans at discharge (4.62 ± 2.72 vs 2.46 ± 1.71, $p < 0.05$), but without any significant difference the third day (4.62 ± 2.72 vs 3.78 ± 2.28, NS). All patients with infective dyspnea had negative lung sonography (less than 3 B-lines for each scan). Regarding BIVA evaluation, R value was not different between subgroups (heart failure 295.13 ± 76 vs mixed dyspnea 290.48 vs 106.07 vs infective 355.3 ± 94.7). Xc value was not different between the three subgroups (heart failure 27.96 ± 17.15 vs mixed 21.15 ± 7.26 vs infective 24.14 ± 6.5). There were no significant differences at discharge.

Conclusions: Lung sonography is a useful tool in differential diagnosis of dyspnea in patients with comorbidity, as it can identify and quantify pulmonary stasis. BIVA is not useful in differential diagnosis of dyspnea and is not suitable to identify pulmonary congestion.

IC-45
EVALUATION OF URINE NEUTROPHIL GELATINASE ASSOCIATED LIPOCALIN TO PREDICT THE FUROSEMIDE DOSE REQUIREMENT AND DEVELOPMENT OF ACUTE KIDNEY INJURY IN ADULT PATIENTS PRESENTING TO THE EMERGENCY DEPARTMENT WITH ACUTE DECOMPENSATED HEART FAILURE

C. Aycan[1], M. Durusu Tanriover[1], M. Arici[1], S. Ascioglu[1], N. Metin Aksu[2]

[1]Department of Internal Medicine, [2]Department of Emergencies. Hacettepe University Faculty of Medicine. Ankara, Turkey.

Objectives: The primary aim of the study was to evaluate the performance of admission urinary neutrophil gelatinase associated lipocalin (NGAL) levels to predict the furosemide dose requirement in the first three days of acute decompensated heart failure patients. The second aim was to evaluate the predictive value of urine NGAL to foresee acute kidney injury (AKI).

Material and method: Patients who were admitted to the Hacettepe University Faculty of Medicine emergency room with acute decompensated heart failure (diagnosed by clinical criteria) between December 2010 and October 2011, and who consented were prospectively enrolled to the study. Patients with chronic renal replacement treatment, congenital heart disease, contrast nephropathy and urinary infection were excluded. Demographic characteristics, chronic diseases, medications, complaints and physical findings, NYHA functional class, daily test and imaging results were recorded. Blood samples for brain natriuretic peptide (BNP) and urine samples for NGAL were obtained on admission.

Results: One hundred patients who presented to the emergency room with decompensated heart failure were enrolled to study. Patients having chronic renal disease developed more AKI when compared to those who have normal basal renal function (38.7% vs 9.6%, respectively) (p = 0.04). Urine NGAL levels were higher in chronic renal disease group (p = 0.02) as well as in AKI group (p = 0.009). On admission more than half of the patients were on furosemide (55%). The per oral furosemide dose at home was less in AKI group (p = 0.01). First day mean furosemide doses were similar between groups (80 mg), however on the second and third days diuretic dose increment was less in AKI group when compared to those who haven't developed AKI. Urine NGAL could not predict the mean diuretic dose in the first, second and third days of heart failure treatment. On ROC analysis urine NGAL above 12 ng/ml cut off value had a sensitivity of 79%, specificity of 67% for predicting AKI. On logistic regression analyses urine NGAL above 12 ng/ml cut off value had an odds ratio of 9 for AKI development.

Discussion: Acute heart failure syndromes can be complicated with cardiorenal syndromes. Acute kidney injury (AKI) is a condition usually confronted in acute and critical patients. Its incidence has been increasing both in inpatients and outpatients. NGAL is one of the promising markers that can differentiate injury and dysfunction and guide in early recognition of AKI. Renal function can decline due to various reasons in patients with heart failure, so sensitive and early markers like NGAL might be used to develop algorithms that will guide in drug treatment. This study showed that those heart failure patients who had high levels of urine NGAL at admission showed a higher rate of AKI. The primary aim of this study was to test the hypothesis that urine NGAL could predict the furosemide dose and guide in the decision to administer diuretics in decompensated heart failure patients. However, we could not demonstrate any association between the NGAL level and the diuretic dose requirement. On the other hand, NGAL was a good marker of AKI which had an odds ratio of 9 for the development of AKI in patients with decompensated heart failure when NGAL was above 12 ng/ml.

Conclusions: Urine NGAL level on admission of a decompensated heart failure patient is a good marker of AKI with an odds ratio of 9 when values above 12 ng/ml are accepted high. However, NGAL level could not predict the furosemide dose requirement in the first three days.

IC-60
PROGNOSTIC VALUE OF ERYTHROPOIETIN AND RELATIONSHIP WITH HEMOGLOBIN AND INFLAMMATORY MARKERS IN PATIENTS WITH HEART FAILURE A NEW EVIDENCE FOR THE HYPOTHESIS OF ERYTHROPOIETIN RESISTANCE

P. Salamanca Bautista[4], J. Santamaría González[1], B. García Casado[2], O. Aramburu Bodas[3], J. Arias Jiménez[3], E. Guisado Espartero[5], A. Barco Sánchez[6], R. Pérez Cano[3]

[1]Department of Internal Medicine. Hospital Nisa Sevilla-Aljarafe. Sevilla, Spain. [2]Department of Internal Medicine. Hospital Comarcal de La Merced. Sevilla, Spain. [3]Department of Internal Medicine, [4]Department of Emergencies, [6]Department of Clinical Biochemistry. Complejo Hospitalario Regional Virgen Macarena. Sevilla, Spain. [5]Department of Internal Medicine. Hospital Comarcal Infanta Margarita. Córdoba, Spain.

Objectives: To determine the prognostic value of erythropoietin(EPO) levels during a year. Correlate erythropoietin with serum hemoglobin levels and circulating inflammatory markers as interleukin 6.

Material and method: We recruited 225 patients admitted in hospital with heart failure diagnosis. They were followed for a period of one year. The group was divided by median in two groups, one with high EPO levels and another with low EPO levels. Differences in mortality by Kaplan-Meier curves were compared. They also were compared using contingency tables. Group was divided in three equal subgroups after (tertiles) (tertile low EPO, medium EPO, and high EPO respectively) and hemoglobin levels intergroup were compared (Anova Test comparing subgroups by Bonferroni substudy). Interleucin 6 levels in the three groups were compared by nonparametric Kruskal-Wallis test (IL6 is not distributed normally). Also we correlated EPO levels and hemoglobin per linear Pearson Correlation.

Results: Kaplan Meier curves shows mortality differences between groups (p = 0.023). Higher mortality in Higher Erythropoietin levels. Similar result was obtained in contingency table (p = 0.040). There were statistically significant differences between EPO and hemoglobin levels (p = 0.00001) and in the intertertil comparison. Our data confirms weak inverse linear relationship (p = 0.001) between EPO and hemoglobin levels. Regarding the relationship between IL6 and EPO tertiles, our data confirms the statistically significant difference in the Kruskal-Wallis test by group (p = 0.028). The trimmed mean 5% of IL6 in each tertile was 3.45, 5.47 and 6.95 for the first, second and third tertile, respectively. This measure of central tendency was used by several outliers in the distribution of IL6.

Discussion: The results we were obtained shows when levels of erythropoietin increases, also increases mortality in these patients. It appears when increasing values of erythropoietin decrease hemoglobin levels. EPO stimulus to the marrow seems don't work to correct the levels of the hemoglobin. That's why in several previous articles was postulated the existence of possible resistance to EPO in the bone marrow related with cytokine-mediated inflammation. Our data support this hypothesis because when process of elevation of EPO is produced, so do the levels of IL6.

Conclusions: 1. Erythropoietin is a known predictor of mortality in one year 2. When levels of erythropoietin increasing, hemoglobin levels falls and vice versa. 3. The increase of erythropoietin and the decrease in hemoglobin is associated with increased serum levels of interleukin 6. 4. Our data support the hypothesis of the likely resistance to erythropoietin in the bone marrow, mediated by inflammatory activity.

IC-61
ROLE OF BIOLOGICAL AND NON BIOLOGICAL FACTORS IN CONGESTIVE HEART FAILURE MORTALITY: PREDICE-SCORE, A CLINICAL PREDICTION RULE

F. Medrano Ortega[1], J. Guerra Vales[2], B. Herrera Hueso[1], E. Andrés Esteban[3], S. Vázquez Fernández del Pozo[3], A. Navarro Puerto[4], I. Marín León[1], A. Gómez de la Cámara[3]

[1]Department of Internal Medicine. Hospital Virgen del Rocío. Sevilla, Spain. [2]Department of Internal Medicine, [3]Department of Clinical Research. Hospital 12 de Octubre. Madrid, Spain. [4]Department of Internal Medicine. Complejo Hospitalario Nuestra Señora de Valme. Sevilla, Spain.

Objectives: Congestive heart failure is a chronic, frequent and disabling condition but with a modifiable course and a large potential for improving. The aim of this project was to develop a clinical prediction model of biological and non biological factors in patients with first diagnosis of heart failure that facilitates the risk-stratification and decision-making process at the point of care.

Material and method: Historical cohort analysis of 600 patients attended at three tertiary hospitals and diagnosed of a first episode of heart failure according Framingham criteria. There were followed one year. We analyzed sociodemographic, clinical and laboratory data with potential prognostic value.

Results: The modelling process concluded into a logistic regression multivariable analysis and a predictive rule: PREDICE SCORE. Age, dependency for daily basic activities, creatinine clearance, sodium levels at admission and systolic dysfunction diagnosis (heart failure with Left Ventricular Ejection Fraction (LVEF < 40%) were the selected variables. PREDICE Score, has range of 22 points to stratifications of 1-year mortality. The model showed a c-statistic of 0.763.

Conclusions: The follow-up of 600 patients hospitalized by a first episode of congestive heart failure, allowed us to obtain a predictive 1 year mortality model from the combination of demographic data, routine biochemistry and easy handling social and functional variables at the point of care. The variables included were non-invasive, undemanding to collect, and widely available. It allows for risk stratification and therapeutical targeting and may help in the clinical decisions process in a sustainable way.

IC-65
DIFFERENTIAL CHARACTERISTICS AMONG PATIENTS WITH IDIOPATHIC (IPAH) AND CONNECTIVE TISSUE DISEASE ASSOCIATED PULMONARY ARTERIAL HYPERTENSION (CDPAH) PULMONARY HYPERTENSION REGISTRY (REHAP) DATA

R. González León[1], M. Egurbide Arberas[2], P. Escribano Subías[3], I. Blanco Vich[4], M. López Meseguer[5], C. Jiménez López-Guarch[3], A. Román Broto[5], M. Castillo Palma[1], and the REHAP Investigators

[1]Department of Internal Medicine. Hospital Virgen del Rocío. Sevilla, Spain. [2]Department of Internal Medicine. Hospital de Cruces. Bilbao (Vizcaya), Spain. [3]Department of Cardiology. Hospital 12 de Octubre. Madrid, Spain. [4]Department of Neumology. Centre Sociosanitari Hospital Clínic i Provincial de Barcelona. Barcelona, Spain. [5]Department of Pneumology. Hospital Universitari General Vall d'Hebron. Barcelona, Spain.

Objectives: Pulmonary arterial hypertension related with connective tissue disease (CDPAH) are said to have a worse prognosis than idiopathic PAH (IPAH). The Spanish registry of pulmonary hypertension (REHAP) was started in 2007 and take in all the PAH forms, including CDPAH. Patients are included from 31 centers but 75% of the pts comes from the 4 larger referee centers of PAH in Spain. Objective: to compare survival, demographic, clinical, treatment and hemodynamic data among patients (pts) with IPAH and CDPAH.

Material and method: Baseline categorical variables are expressed as frequencies and proportions, whereas continuous variables are presented as mean ± SD. Survival rates were calculated using the Kaplan-Meier method and standard life table analyses.

Results: The total number of pts with PAH (diagnosed by means of heart catheterization was) was 634: 402 with IPAH and 232 with CDHAP. CD in the last group were: systemic sclerosis (67%), systemic lupus erythematosus (15%), rheumatoid arthritis (2.6%) and others (15%). Pts of the IPAH group were younger (48 ± 18 vs 57 ± 15 years; $p < 0.001$), with higher male/female ratio (29% vs 12%; $p < 0.001$); at baseline they had a better functional capacity in the 6 minutes walking test (6MWT; 381 ± 115 vs 329 ± 117 meters; $p < 0.001$) and a higher systolic pulmonary arterial pressure (PAPs) measured by echocardiography (82 ± 21 vs 76 ± 23 mmHg; $p < 0.001$) with similar functional class. Hemodynamic differences were detected: IPAH pts had higher median pulmonary arterial pressure (PAPm; 53 ± 15 vs 44 ± 13 mmHg) and pulmonary vascular resistance (PVR 13 ± 6.8 vs 10 ± 5.6 UW; $p < 0.001$) and a greater proportion of responders in the acute vasodilator test (29% vs 17%; $p = 0.004$). CDHAP pts had worse parameters of respiratory functional tests and treatment with endothelin antagonist (ERA) was higher (52% vs 38%; $p < 0.001$) with no other differences in treatment among the 2 groups. IPAP pts had greater survival than CDHAP (1, 2, 3, 4 y 5 years: 90%-84%-78%-74%-69% vs 84%-75%-64%-58%-48%; $p < 0.001$).

Discussion: Pts with CDPAH in REHAP registry, although younger, with better hemodynamic parameters, analogous FC at diagnosis and similar treatment than IPAH pts, have a worse functional capacity (PM6M) and survival.

Conclusions: In the REHAP registry pts with CDPAH have better hemodynamic parameters but a worse survival than IPAH pts. Pts with CDPAH have to be considered of bad prognosis and an early and intensive treatment is mandatory.

IC-71
CHRONIC SYSTOLIC HEART FAILURE TREATMENT IN SPAIN INFLUENCE OF PATIENT CLINICAL CHARACTERISTICS ON BETA BLOCKERS USE IN INTERNAL MEDICINE SETTINGS

L. Manzano[1], F. Formiga[1], M. Anguita[1], J. Comín Colet[1], M. Crespo Leiro[1], L. Almenar[1], J. Muñiz[1], T. de Frutos[2]

[1]Department of Internal Medicine and Cardiology. VIDA IC Steering Committee, Spain. [2]Medical Department. Pfizer S.L.U., Spain.

Objectives: Chronic heart failure (CHF) has become a cardiovascular epidemic with high incidence and prevalence. Previous studies suggest differences in patient's characteristics and treatment used between cardiologist and internists that could have an influence on the prognosis. The objective of this study is to compare the clinical characteristics between systolic CHF patients with and without beta blockers in Internal Medicine settings

Material and method: VIDA IC study is a national, prospective registry conducted in 2011 by 115 specialists (cardiologists and internists) across Spain who included consecutive outpatients with CHF and left ventricular ejection fraction (LVEF) < 40%.

Results: A total of 967 patients were evaluated for this analysis. Patients' mean age was 70.6 years, 30% were women and 40% were > 75 years. 37% of these patients were attended by internists (353) and 63% by cardiologist (614). Patients' mean age was 69 years in Cardiology and 74 years in IM ($p < 0.0001$); no differences were observed in gender. Patients followed by internists had significantly more hypertension, diabetes, COPD, ictus, renal failure, anemia, thyroid dysfunction and atrial fibrillation. CHF severity was similar in both groups. Patients followed by cardiologist received more beta blockers (83 vs 66% ($p < 0.001$). Within the 353 CHF patients followed by internists, 67% were on beta blocker treatment. There were no

differences between patients with and without beta blockers with respect to age, gender, diabetes, hypertension and COPD. Patients on beta blocker treatment had more severe NYHA class (% NYHA III/IV: 41% vs 57.7%, p = 0.0032), acute myocardial infarction (31.1% vs 43.9%, p = 0.019), previous coronary intervention (21.1% vs 41.2% p < 0.001) and atrial fibrillation (44.2% vs 55.3%, p = 0.05). Heart rate and systolic blood pressure were significantly higher in patients without beta blocker treatment (80.1 ± 12.9 vs 73.9 ± 15.2 bpm, p < 0.001 and 134.9 ± 18.8 vs 127.6 ± 19.2 mmHg, p = 0.001, respectively).

Discussion: Considerable differences exist between characteristics of systolic CHF patients followed by internists and cardiologist in Spain. Patients followed by internist were older, had more extracardiac comorbidities, and received less beta blocker treatment. Age, gender, and COPD history did not have influence on beta blocker treatment prescribed by internists. On the other hand, low heart rate or blood pressure did not explain the lack of beta blocker treatment in the majority of patients without beta blockers.

Conclusions: These real world data suggest that there is sub-optimal transfer of clinical trial evidence into clinical practice. Although the percentage of beta blocker treatment in patients with systolic CHF prescribed by internists is relevant, there is still room for improvement the use of this treatment. Further research is needed to evaluate the factors that have an influence on beta blocker use in Internal Medicine settings.

IC-72
INFLUENCE OF ATRIAL FIBRILLATION IN HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH SYSTOLIC CHRONIC HEART FAILURE: REAL WORLD DATA IN SPAIN

L. Manzano[1], F. Formiga[1], J. Comín Colet[1], M. Anguita[1], M. Crespo Leiro[1], L. Almenar[1], J. Chaves[2], T. de Frutos[2]

[1]Department of Internal Medicine and Cardiology. VIDA IC Steering Committee, Spain. [2]Medical Department. Pfizer S.L.U., Spain.

Objectives: It is estimated to be as much as 50% of heart failure (HF) patients may have atrial fibrillation (AF) in its evolution. Furthermore, it is known that HF increases the risk of AF up to six times and AF complicates the clinical curse of HF. Evidence of AF in health-related quality of life (HRQoL) has been demonstrated. This study aimed to describe the HRQoL in ambulatory chronic HF patients and to explore the differences of self-perceived health status according to FA presence.

Material and method: VIDA-IC is a nation-wide, prospective registry conducted by 115 specialist across Spain that included consecutive patients with CHF and LVEF < 40% in 2011. HRQoL was assessed using the Kansas City Cardiomyopathy Questionnaire (KCCQ) and the generic EQ-5D questionnaire that includes the Visual Analogue Scale (VAS). In both questionnaires, higher scores mean better HRQoL.

Results: Clinical characteristics of the 995 patients evaluated were: age 71 ± 11; 70.3% men; mean heart rate 74.1 ± 15.5 lpm; heart rate > or = 70 in 57.9%; LVEF 34 ± 7%; NYHA III-IV class in 44.5%; mean VAS 61.4 ± 19.3; EQ-5D index 0.6 ± 0.3; KCCQ overall summary score 62.3 ± 232. Chronic HF patients had a high prevalence of AF (44.5% had AF: chronic 20.0%, permanent 13.6% and paroxistic 11.1%). Chronic HF patients with AF had worse mean scores of the EQ-5D (0.7 ± 0.2 vs 0.6 ± 0.3, p < 0.0001), VAS (64 ± 19 vs 57.9 ± 19.3, p < 0.0001) and KCCQ overall summary score (65.4 ± 23.1 vs 58.7 ± 22.6, p < 0.0001). For disease-specific evaluation of HRQoL using the KCCQ, chronic HF patients with AF had worse level for all dimensions evaluated except the symptoms stability (59.9 ± 23.1 vs 59.2 ± 23.5, p = 0.6357) and autoefficacy (70.4 ± 22.4 vs 67.9 ± 22.3, p = 0.0926); see the table for the rest of the results.

Discussion: AF affects almost all the dimensions of HRQoL, particularly those related with physical limitations and severity of symptoms.

Conclusions: AF is an important determinant of the HRQoL in patients with systolic chronic HF. It is necessary to evaluate the pathophysiologic mechanism behind the differences observed in HRQoL in patients with chronic HF and AF.

Table 1 (IC-72). Health-related quality of life in patients with systolic chronic heart failure in Spain

KCCQ summary	Without AF	With AF	p-value
Clinical	68.7 ± 26.6	62.3 ± 22.7	< 0.0001
Symptoms	72 ± 22.8	63.3 ± 22.7	0.002
Physical limitations	64.6 ± 27.8	56.5 ± 27.4	< 0.0001
Frequency of symptoms	72.6 ± 22.4	67.1 ± 22.3	0.002
Burden of symptoms	70.2 ± 25.7	63.6 ± 26.2	0.001
Quality of life	57.7 ± 24.1	50.5 ± 23.8	< 0.0001
Social limitation	65 ± 28.8	56.4 ± 29.3	< 0.0001

IC-77
ISCHEMIC CARDIOGENIC SHOCK: PROGNOSTIC FACTORS IN PATIENTS UNDERGOING PRIMARY PERCUTANEOUS CORONARY INTERVENTION

I. López Neyra[1], J. Córdoba Soriano[1], R. Cordero Bernabé[2], M. Bellón Munera[2], D. Melehi[1], O. González Martínez[1], M. Barrionuevo Sánchez[1], F. Salmerón Martínez[1]

[1]Department of Cardiology, [2]Department of Internal Medicine. Hospital General de Albacete. Albacete, Spain.

Objectives: Cardiogenic Shock (CS) is the leading cause of death in patients hospitalized for Acute Coronary Syndrome (ACS). Our aim was to determine which factors were associated with a worse prognosis in a cohort of patients with ischemic CS from a Coronary Care Unit.

Material and method: Prospective study of 99 consecutive patients (P) undergoing primary percutaneous coronary intervention (PCI) due to an ACS complicated with cardiogenic shock. Patients with CS due to mechanic complications or arrhythmias were excluded. Their characteristics were registered and a univariate analysis and multivariate logistic regression analysis were performed to identify risk factors associated with poor prognosis (death in the first 72 hours, in-hospital mortality and long-term mortality).

Results: 99 patients with a mean age of 71 ± 12 years (70% male) were prospectively registered. 50% presented CS at the time of first medical contact. The anterior wall was affected in 40%, CS due to right ventricle affectation was present in 27% and most had multivessel disease with affectation of Left Anterior Descending Artery in 71%. In the management, thrombolysis was performed in 15% and all patients underwent primary PCI (18% multivessel intervention). 19% of PCI were performed at night on call. Intra-aortic balloon counter-pulsation (IABC) was used in 36 patients (9 before PCI and 27 after PCI). Left Ventricular Failure (LVEF < 35%) was found in 42%. Mortality was defined as: Early Mortality (First 72 hours), In-Hospital mortality and Long-term mortality (22%, 40% and 55% in 355 days average follow-up, respectively). In univariate analysis, early mortality was associated with PCI performed at night on call (p: 0.02); Age > 75 years (p: 0.005) and LVEF < 35% (p: 0.001). In-hospital mortality was associated with PCI at night on call (p: 0.02) and LVEF < 35% (p < 0.001). The use of IABC showed a tendency for higher in-hospital mortality (p: 0.06). Long-term mortality was significantly associated with age > 75 years (p: 0.002), LVEF < 35% (0.001) and use of IABC (p: 0.009). In multivariate analysis Early Mortality was associated with PCI at night on call (OR 6.2; 95%CI, 1.5-25) and age > 75 years (OR 5.2; 95%CI, 1.5-17); In-hospital mortality also was associated with the same factors and furthermore with LVEF < 35% (OR 0.004; 95%CI, 1.6-13.6%). Long-

term mortality also was associated with age > 75%, LVEF < 35% and furthermore with use of IABC (OR 2.9; 95%CI, 2.1-7.9%).

Conclusions: CS in patients with ACS is a complication with high mortality. Age is the most important prognosis factor of mortality both early and late in our series. In early mortality it is also important when PCI is performed (on call) and during the hospitalization and in long-term follow-up, left ventricular dysfunction is the most important prognosis factor. In our registry, use of IABC doesn´t improve the prognosis.

IC-79
SERUM OSTEOPROTEGERIN AND MORTALITY IN HEART FAILURE

B. García Casado[1], P. Salamanca Bautista[2], J. Santamaría González[3], E. Guisado Espartero[4], O. Aramburu Bodas[2], J. Arias Jiménez[2], A. Barco Sánchez[5], R. Pérez Cano[2]

[1]Department of Internal Medicine. Hospital Comarcal de La Merced. Sevilla, Spain. [2]Department of Internal Medicine, [5]Department of Laboratory. Complejo Hospitalario Regional Virgen Macarena. Sevilla, Spain. [3]Department of Internal Medicine. Hospital Nisa Sevilla-Aljarafe. Sevilla, Spain. [4]Department of Internal Medicine. Hospital Comarcal Infanta Margarita. Córdoba, Spain.

Objectives: As a follow-up to other research works from our group, the aim of this study is to evaluate serum osteoprotegerin (OPG) and it significance in terms of survival in patients admitted with heart failure.

Material and method: Two hundred sixty patients with descompensated heart failure were enrolled and followed up for one year. Primary end point was all-cause mortality. Admission serum osteoprotegerin levels were determined by ELISA. The study cohort was divided into quartiles and also into two subgroups according to median and an optimal cut-off value determined by ROC analysis. The relationship between groups of osteoprotegerin and mortality was explored using Chi-square test. Statistical analysis was performed using SPSS 18.0.

Results: The mean of age of participants was 75.08 years, and most of the patients were women that had a preserved EF. 32% were in functional class NYHA III-VI prior to admission. After a follow-up of one year, mortality was 28.5%. The cut-off level was established by OPG median (8.05 pmol/l) and according to ROC curve (8.53 pmol/l). The mortality rate was significantly greater in patients with high OPG levels (OR 3.91 95%CI 2.21-7.01). Similarly, the highest OPG quartile (OPG > 11.20 pmol/l) was independently associated with 5-fold increased risk of mortality (OR 5.35 95%CI 2.91-9.81, p < 0.000).

Discussion: Currently, only natriuretic peptides are supported by Clinical Practice Guidelines as biomarkers for routine determination. Osteoprotegerin is a novel inflammatory biomarket in patients with cardiovascular disease such as coronary artery disease, acute coronary syndromes and heart failure post-infarction. Our results are similar to clinical trials, since in these cardiac conditions, OPG is an independent predictor of long-term death. It use could improve risk stratification and follow-up in patients with heart failure.

Conclusions: Serum osteoprotegerin levels on admission predict one-year mortality in patients hospitalized for decompensated heart failure. In addition, osteoprotegerin plays a role in risk stratification, demonstrating a worse prognostic in patients with levels above 11.20 pmol/l.

Inflammation and autoimmune diseases

IF-3
DIAGNOSIS OF LATENT TUBERCULOSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: T SPOT.TB OR TUBERCULIN SKIN TEST?

M. Arenas Miras[1], C. Hidalgo Tenorio[3], P. Jiménez Gámiz[2], J. Sabio Sánchez[1], N. Navarrete Navarrete[1], J. Jiménez Alonso[1]

[1]Department of Internal Medicine, [3]Clinical Infection Disease Unit, [2]Department of Clinical Analysis. Complejo Hospitalario Virgen de las Nieves. Granada, Spain.

Objectives: To analyze in our cohort of patients with systemic lupus erythematosus (SLE) the sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of the T.SPOT.TB in relation with tuberculin skin test (TST) and the concordance between both test for the diagnosis of latent TB. We will develop a diagnosis protocol of the infection in our population.

Material and method: This is a prospective study cohort (August of 2009 to February 2012), where SLE patients were included consecutively, with 4 or more criteria of the ACR, from the Unit of Systemic autoimmune diseases of University Hospital Virgen de las Nieves in Granada. In the first visit we collected epidemiological and clinical dates. We took blood test, urinary test, DNAn antibody, C3 and C4 levels, lymphocyte subpopulations, TST and booster, T. SPOT.TB, chest radiography, SLEDAI (index of activity) and SLICC (index of organ damage). Definition of variables: latent TB infection when positive TST (5 mm as taking treatment immunosuppressive or 10 mm in the rest of patients), T-SPOT-TB positive (according to laboratory technique), immunosuppression: patients in treatment with any immunosuppressive or receiving more than 7.5 mg of prednisone daily.

Results: 92 patients were included, 92.4% were women with an average age of 42.71 and history of risk of acquiring tuberculosis of 9.8% with a percentage of vaccination of the 2.2% (the 18.5% not remembered if they had been vaccinated). 46.7% of the patients were taking immunosuppressive with an average of 1.46 (minimum 1 and maximum of 3) and 19.6% of them with more than 7.5 mg of prednisone/QD. Autoimmune disease that appeared most frequently in our patients was antiphospholipid syndrome (14.3%). In the bivariate analysis: the patients in treatment with immunosuppressive (p = 0.020) and steroids at any dose (p = 0.028) had greater number of negative TST. None of these two variables influenced in the result of the T.SPOT.TB. There is association between the result of T.SPOT. TB Indeterminate and more time for diagnosis of disease (p = 0.012) and index of organ damage SLICC (p = 0.038). Patients in treatment with hydroxychloroquine presented greater agreement in the results of both tests (p = 0.007). In the multivariate study, the high figures of lymphocyte CD8 are associated with a higher discordance between both tests (p = 0.044); on the other hand, the treatment with hydroxychloroquine was related with greater agreement (p = 0.007). The concordance in general (table 3), measured with the Kappa index, between the two tests is low (kappa = 0.324), increasing with the group of patients without therapy IS or steroids (kappa = 0.436) and treatment with hydroxychloroquine (kappa 0.473). Diagnostic accuracy or efficiency of the study was the 92.39%. Finally, based on the results obtained, the diagnosis protocol of latent tuberculosis that we propose for our patients would be making a TST, if TST is positive (and there is no history of vaccination) we would treat them and in the case if it is negative and the patient is in immunosuppressive therapy or steroids, we will do the T.SPOT.TB and decide on the basis of this last test

Discussion: Patients with SLE are considered immnunosuppressed due to treatment and his own disease. This study suggests that the

immunosuppressive medication and corticosteroid treatment are a determinant of anergy.

Conclusions: In patients without immunosuppressive (IS) or steroids therapy, the tuberculin skin test remains a valid technique for the diagnosis of latent in our population group. In the case that the patient is taking IS or steroids at any dose, the T.SPOT.TB would be the alternative for the diagnosis in these cases.

IF-5
CARDIAC INVOLVEMENT IN SYSTEMIC SCLEROSIS: DIFFERENCES IN THE PRESENTATION AND SURVIVAL OF PATIENTS WITH LIMITED, DIFFUSE AND SINE SCLERODERMA SUBSETS

A. Fernández Codina[1], C. Simeón Aznar[1], V. Fonollosa Plà[1], F. Prado Galbarro[2], A. Sarría Santamera[2], A. Guillén Castillo[1], J. Candell Riera[3], M. Vilardell Tarrés[1]

[1]Department of Internal Medicine. Autoimmune Diseases. Hospitals Vall d'Hebron. Barcelona, Spain. [2]Health Technology Assessment Agency. Instituto Carlos III. Madrid, Spain. [3]Department of Cardiology. Hospitals Vall d'Hebron. Barcelona, Spain.

Objectives: To describe the clinical characteristics and survival of a cohort of patients with Systemic Sclerosis (SSc) and cardiac involvement (CI) and compare them between the main SSc subsets (limited lcSSc, diffuse dcSSc and sine ssSSc).

Material and method: Patients with CI and SSc were selected from a reference hospital's database that consists of an overall of 413 patients diagnosed of SSc from April 1980 to July 2011, according to the LeRoy and Medsger's modified classification. We compared the following items: demography, organ involvement, immunological parameters, treatment and survival at 25 years between the 3 SSc subsets. 187patients with CI were included. CI was defined by: clinical manifestations, alterations in echocardiography, stress myocardial perfusion SPECT (Single Photon Emission Tomography), cold-induced myocardial perfusion SPECT, coronary arteries catheterization, chest X-ray and electrocardiogram.

Results: Statistically significant differences in epidemiologic data between the dcSSc and ssSSC were observed in: time since the age at onset until cardiac involvement was diagnosed (13.68 ± 7.81 yrs.; 8.91 ± 5.52 yrs.; p = 0.026), age at diagnosis of SSc (48.46 ± 13.15 yrs.; 57.83 ± 13.21 yrs.; p = 0.015) and age at the moment of death (57.9 ± 12.05 yrs.; 78.5 ± 3.53 yrs.; p = 0.040); statistically significant differences between lcSSc and dcSSc were: mean age at diagnosis of SScc (56.52 ± 12.86 yrs.; 48.46 ± 13.15 yrs.; p = 0.020) and mean age at death (68.48 ± 10.77 yrs.; 57.9 ± 12.05 yrs.; p = 0.020). Global series prevalences of CI variables were: pericardial involvement 2%, ischemic cardiopathy 16%, conduction alterations 16%, cardiomegaly 14%, coronary arteries altered 2%, left ventricle hypertrophy 15%, diastolic dysfunction 15% and left ventricle ejection fraction < 50% 1.4%. Left ventricle hypertrophy was associated with SAH in lcSSc (p = 0.022) but not with the two other SSc subsets. Diastolic dysfunction wasn't associated with AH. No statistically significant differences were found in comparing any CI variable. Average survivals at 10, 15, 20 and 25 years were 94%, 87.1%, 79% and 76.5% in lcSSc; 75.6%, 73%, 53.3% and 49.8% in dcSSc; 95.2% at 10 years and 89.9% for the other 3 periods in ssSSc. Log-Rank test showed significant differences in survival between all 3 SSc subsets.

Discussion: Epidemiological and baseline results matched with the literature. Prevalences of the cardiac involvement variables resulted similar to other published studies, and there was no difference between SSc subsets. No other study had already studied differences among the 3 subsets. Survival was higher in ssSSc group than in the others, and arterial systemic hypertension was not significantly related with left ventricle hipertrophy or diastolic dysfunction in ssSSc and dcSSc, so we consider this alterations to be part of primary SSc CI. lcSSc and arterial systemic hypertension relation was significative probably due to a very long follow up that included the eldest patients.

Conclusions: CI is a common complication of SSc. Main alterations are conduction alterations, ischemic cardiopathy, left ventricle hypertrophy and diastolic dysfunction. There are no statistically significant differences between SSc subsets for cardiologic variables. ssSSc has greater survival rates than lcSSc and dcSSc. Heart disease in this subset might be milder, although larger studies shall be conducted.

IF-10
PULMONARY HYPERTENSION IN SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS OF A STRUCTURED SCREENING PROGRAM

J. Goiri, M. Garmendia, I. Villar, M. Egurbide, C. Aguirre, G. Ruiz-Irastorza

Department of Internal Medicine. Autoimmune Diseases. Hospital Universitario Cruces. Barakaldo (Vizcaya), Spain.

Objectives: To investigate the prevalence and predictors of pulmonary hypertension (PH) in patients with systemic lupus erythematosus (SLE) and to validate a diagnostic strategy.

Material and method: 245 patients with SLE entered a screening program. Possible PH was defined as two consecutive systolic pulmonary arterial pressure (PAP) values > 40 mmHg by echocardiography. The subsequent diagnostic procedure, including right heart catheterization if needed, confirmed or excluded the diagnosis of PH secondary to cardiopulmonary disease or SLE-related pulmonary arterial hypertension (PAH). Independent predictors of PH were identified first by univariant analyses and then by multivariant multiple linear or logistic regression models, including the following independent variables: age, disease duration, sex, lupus nephritis, pleuropulmonary lupus disease, thrombosis, antiphospholipid syndrome, Raynaud´s, arterial hypertension, smoking, antiDNA, antiRo, antiLa, antiRNP, antiphospholipid antibodies, past immunosuppressive treatments, SLICC damage index and SLEDAI. The sensitivity (S), specificity (SP), positive (PPV) and negative predictive values (NPV) were calculated for different screening cutoff values.

Results: 88% patients were women and 99.5% were Caucasians. The mean (SD) age at the time of enrolment was 45 (16) years. 12 cases of PH were detected with a resulting prevalence of 5%. All cases were secondary (cardiomyopathy or valvulopathy = 9, severe pulmonary obstructive disease = 2, shrinking lung syndrome = 1). No cases of PAH were identified. Two consecutive PAP measurements > 40 mmHg performed best as the cutoff point for screening (table). The age at the time of enrolment was the only variable independently associated with PAP values (p = 0.0001), with the SLICC Damage Index score showing a borderline association (p = 0.08). Only the age at the time of enrolment showed an independent association with PH (OR 1.10, 95%CI 1.06-1.17). Specifically, no relationship between SLEDAI scores and PAP or PH was found.

Discussion: Previous studies have found a variable prevalence of PH in lupus. One of the possible reasons is the heterogeneity in the diagnostic process and in the PAP cut-off values. Our study represents the first structured screening program with a PAP definition according to current guidelines. Our results showed a low prevalence of PH with no cases of PAH identified. No specific associations with SLE-related variables were seen. Therefore, we do not recommend screening echocardiograms in lupus patients without a clinical suspicion of PH.

Conclusions: We found a low prevalence of PH and do not recommend screening echocardiograms in asymptomatic lupus

patients. Two consecutive PAP values > 40 mmHg by echocardiogram is the best screening procedure.

Table 1 (IF-10). Sensitivity, specificity, positive and negative predictive values for the different screening definitions of pulmonary hypertension

	Sensitivity	Specificity	Positive predictive value	Negative predictive value
PAP > 30	100	52	10	100
PAP > 40	100	91	38	100
PAP > 40 X2	100	97	70	100

IF-11
CLINICAL SIGNIFICANCE OF AUTOANTIBODIES AGAINST 3-HYDROXY-3-METHYLGLUTARYL-COENZYME A REDUCTASE IN MYOSITIS PATIENTS AND STATIN USERS

A. Selva O'Callaghan[1], E. Balada[1], L. Christopher-Stine[2], X. Mundet[3], M. Farrús[4], J. Grau[5], M. Juanós Iborra[1], A. Mammen[2]

[1]Department of Internal Medicine. Vall d´Hebron General Hospital. Universitat Autònoma de Barcelona. Barcelona, Spain. [2]Department of Medicine and Neurology. Johns Hopkins University School of Medicine. Baltimore, Maryland. United States. [3]Department of Family Medicine. Institut Universitari d'Investigació en Atenció Primària Jordi Gol. Universitat Autònoma de Barcelona. Barcelona, Spain. [4]Department of Family Medicine. Primary Care Center El Carmel. Barcelona, Spain. [5]Department of Internal Medicine. Muscle Research Group. Hospital Clínic Provincial, Institut d'Investigacions Biomédiques August Pi i Sunyer, Universitat de Barcelona. Barcelona, Spain.

Objectives: Statin use has been linked to a specific cause of immune mediated necrotizing myopathy (IMNM), being auto-antibodies against 3-Hydroxy-3-Methylglutaril-Coenzyme A Reductase (anti-HMGCR) a good marker of this condition. Our objective was to determine the presence of anti-HMGCR in myositis patients and statin users in our population and analyse its clinical significance.

Material and method: A historical cohort of patients diagnosed with myositis attending at Vall d'Hebron General Hospital between 1983 and 2012 were analysed for the positivity of anti-HMGCR antibodies. Thirty six (19 female) community patients treated with statins were also studied. Anti-HMGCR autoantibodies were performed by means a enzyme-linked immunosorbent assay. Positivity was considered when values were > 3SD of a control group (healthy blood donors). HLA-class II allele typing was performed by polymerase chain reaction (PCR).

Results: One hundred and eighteen (90 female) patients diagnosed with myositis were included in the study: 60 dermatomyositis, 38 polymyositis [PM], 3 inclusion body myositis and 7 immune-mediated necrotizing myopathy [IMNM] (4 exposed to statins, 2 related to cancer, and one case with anti-SRP). High values of anti-HMGCR were detected in 4 patients, 3 out of 4 with IMNM (75%) exposed to statins, and in 1 patient with PM. HLA-DRB1*11 was detected in 3 out of 4 patients with anti-HMGCR and in 16 out of 135 patients with myositis (75% vs 12%, p = 0.009; OR 21.8 [2.9-165.3]). None of the 36 community patients which were receiving statins were positive for anti-HMGCR autoantibodies.

Discussion: Mammen and Christopher-Stine, described recently an autoimmune myopathy related to statins exposure. Typically, patients presented with muscle weakness after statin exposure, high levels of creatin-phosphokinase values, and high grade of necrosis at muscle biopsy with expression of MHC I in muscle fibers. These "immune-mediated necrotizing myopathy" related to statin exposure appear to improve after immunosuppressive treatment. We also found in our cohort of patients with myositis that anti-HMGCR was a good marker of IMNM due to statin exposure. Moreover, as Mammen and Christopher-Stine have previously reported, our results agree with the idea that the incidence is low and most patients treated with statins even with myalgias or mild levels of creatinphosphokinase were negative; thus, anti-HMGCR seem to target a specific group of statin related myopathy which can benefit of immunosuppressive therapy.

Conclusions: Our data support previous reports which established that some patients probably genetically predisposed (HLA-DRB*11) exposed to statin may develop a specific autoimmune myopathy. Anti-HMGCR autoantibodies seem to be a good marker of this condition.

IF-13
OCCUPATIONAL EXPOSURES AND CLINICAL CHARACTERISTICS IN PATIENTS WITH THE ANTISYNTHETASE SYNDROME

A. Labirua[1], A. Selva O'Callaghan[1], J. Zock[2], R. Orriols[3], X. Martínez Gómez[4], M. Juanós[1], I. Pinal[1], M. Vilardell[1]

[1]Department of Internal Medicine, [4]Department of Preventive Medicine and Epidemiology. Vall d'Hebron General Hospital. Universitat Autònoma de Barcelona. Barcelona, Spain. [2]Centre for Research in Environmental Epidemiology. CREAL. Barcelona, Spain. [3]Department of Pneumology. Vall d'Hebron General Hospital. Barcelona, Spain.

Objectives: Patients with antisynthetase antibodies (aSAb) develop a clinical condition known as antisynthetase syndrome (aSS), which is characterized by interstitial lung disease (ILD), myositis, arthritis, fever, Raynaud's phenomenon and mechanic's hands. Our objective was to evaluate airborne occupational exposure to dust, gases and fumes in a cohort of patients diagnosed with this syndrome and explore associations with clinical characteristics and immunological parameters.

Material and method: Information on lifetime occupational history was obtained using a structured interviewer-led questionnaire from 32 (23 female) out of 60 patients positive to aSAb identified from a cohort of 179 patients with myositis. Cumulative exposure to biological dust, mineral dust and gases/fumes until the onset of disease was determined using a general job-exposure matrix. Myositis-specific and myositis-associated autoantibodies were identified by line immunoassay (Euroimmun, Lübeck, Germany). HLA-class II allele typing was performed by polymerase chain reaction. Serial pulmonary function tests were performed to assess the clinical evolution, and improvement was defined as a > 10% increase in forced vital capacity (FVC) according to the American Thoracic Society. Comparisons between exposed and unexposed patients were performed using the Fisher's exact test and Mann-Whitney test.

Results: The median age of the 32 patients was 42.7 years (IQR: 32.2-52.5). Twenty-six patients tested positive to anti-Jo-1, three to anti-PL-12, and three to anti-PL-7. These patients were classified as having probable or definite PM (9 cases) or DM (15 cases), amiopathic DM (1 case), and the remaining patients (7 cases) had pure ILD without myositis. Twenty-two patients (69%) were carriers of HLA-DRB1*03 haplotype. Sixteen patients (50%) had ever been highly exposed to dust, gases or fumes with a median duration of 8 yrs (IQR: 4-18). ILD tended to be more common in patients with a history of high occupational exposure (94% vs 75%), although it did not reach statistical significance (p = 0.17). No statistically significant associations were found between occupational exposures and the presence of arthritis, mechanic´s hands, fever, Raynaud phenomenon, type of myositis, type of aSAb or positivity to HLA-

DRB1*03. High exposure to dust, gases or fumes was associated with a better prognosis with an improvement observed in 58% of the exposed and 18% of the non- or low-exposed (p = 0.05).

Discussion: Occupational exposure to dusts has been related to the presence of ILD. Fifty per cent of patients diagnosed with aSS were highly exposed to biological dust, mineral dust or gases/fumes, which is higher than 13%, the prevalence reported in a general population samples in our area. Conventional levels of statistical significance were not reached for most of variables analysed, mainly due to the small sample size of the patients studied, because of the rarity of the syndrome. Nevertheless, the relatively better prognosis of patients exposed, argue towards a pathogenic role in some patients; removal of the offending agent could explain this improvement.

Conclusions: A high percentage of patients with aSS had been exposed to dusts, gases or fumes. Removal of the offending agent could explain the improvement observed over time in these patients.

IF-16
PREDNISONE THERAPY IS AN INDEPENDENT CAUSE OF DAMAGE IN SYSTEMIC LUPUS ERYTHEMATOSUS

A. Ugarte, I. Ruiz-Arruza, I. Cabezas, J. Medina, M. Morán, G. Ruiz-Irastorza

Department of Autoimmune Diseases-Internal Medicine. Hospital Universitario Cruces-UPV/EHU. Barakaldo (Vizcaya), Spain.

Objectives: To analyse the association of prednisone therapy with damage at 5 years in an observational cohort of patients with systemic lupus erythematosus (SLE).

Material and method: Demographic and clinical variables were extracted from our database. Prednisone doses were calculated from the medical records. Two prednisone-related variables were constructed for the analysis: the mean daily dose received by the 5th year after the diagnosis and a categorical variable based on the mean daily dose, with the following categories: no prednisone, up to 7.5 mg/d (low dose), up to 30 mg/d (medium dose) and over 30 mg/d (high dose). Damage was calculated at year 5 using the SLICC damage index (SDI). Activity was measured using SLEDAI and recorded as the maximum yearly value.

Results: 249/283 (88%) of patients were women. The mean age (SD) at diagnosis was 36.5 (16) years. 59 (21%) patients had accrued damage within 6 months after the diagnosis of SLE. At year 1, 3 and 5, the frequency of patients with irreversible organ damage was 67/283 (24%), 83/272 (30%) and 91/244 (37%), respectively. The mean (SD) SDI score increased over time: 0.26 (0.59) at 6 months, 0.34 (0.72) at 1 year, 0.52 (0.97) at 3 years and 0.67 (1.05) at 5 years. The most frequent initial damage was at the cardiovascular (13 patients), neuropsychiatric (8 patients), renal (8 patients) and malignancy (7 patients) domains. The mean daily dose of prednisone was significantly higher in patients with any damage at year 5 (10.3 vs 5.8 mg/d, respectively, student t-test, p < 0.001). Likewise, there was a significant association between the mean daily dose of prednisone and the SDI score at year 5 (linear regression, p < 0.001). Analysing new damage accrued after diagnosis, the mean daily dose of prednisone and the SDI variation between year 0 and year 5 were also statistically associated (linear regression, p < 0.001). With regard to the mean daily dose prednisone categories, damage at year 5 was seen in 9/45 (20%) of patients taking no prednisone, 31/104 (30%) of patients taking low doses, 48/90 (53%) of patients taking medium doses and 3/5 (60%) of those receiving high doses (chi-square, p < 0.001). Significant differences in SDI scores and SDI variations between baseline and year 5 were seen in patients taking medium doses vs those taking low doses (ANOVA with Bonferroni, p = 0.018 and 0.021, respectively) and vs those taking no prednisone (ANOVA with Bonferroni, p = 0.003 and 0.005, respectively). However, no differences were seen between patients receiving low doses and those not taking prednisone (ANOVA with Bonferroni, p = 0.77 and 0.89, respectively). The effect of the mean prednisone dose on the absolute SDI score at year 5 persisted after adjusting for gender, age at diagnosis, calendar year of diagnosis, SDI at baseline, mean maximum SLEDAI, class III or IV lupus nephritis and time on antimalarials by year 5 (multiple linear regression, p = 0.003). Likewise, after adjusting for the same variables except for the baseline SDI score, the effect of mean prednisone dose on the SDI score variation between year 0 and 5 also persisted (multiple linear regression, p = 0.002). The results did not change when the categorical prednisone variable was used instead (multiple linear regression, p = 0.009 and p = 0.008).

Discussion: Irreversible organ damage is a major predictor of morbimortality in SLE. The effect of glucocorticoids on increasing organ damage has been suggested in previous studies. This study confirms that prednisone is an independent predictor of damage within 5 years of disease course, including new damage accrued after the diagnosis of SLE. Our results also point to the safety of low prednisone doses (defined as those lower than 7.5 mg/d).

Conclusions: Prednisone causes damage in patients with SLE. Long term doses above 7.5 mg/d should be avoided.

IF-19
SYSTEMIC AUTOIMMUNE DISEASES UNITS (UEAS) IN SPANISH INTERNAL MEDICINE DEPARTMENTS: ANALYSIS OF HEALTH CARE ACTIVITY, PATIENT CARE DEVICES AND FUNCTIONAL STRUCTURE OF 56 UNITS

L. Pallarés[1], R. Pérez Álvarez[2], M. Ramos Casals[3] and the Board of Directors of the Group of Autoimmune Diseases[4]

[1]Department of Internal Medicine. Hospital Son Espases. Palma de Mallorca, Spain. [2]Department of Internal Medicine. Hospital do Meixoeiro. Vigo, Spain. [3]Department of Autoimmune Diseases. Hospital Clínic. Barcelona, Spain. [4]GEAS-SEMI, Spain.

Objectives: To evaluate the structure, health care activity and patient care devices in systemic autoimmune diseases units (UEAS) integrated in Spanish Internal Medicine Departments.

Material and method: Systematic evaluation using a questionnaire containing the main data on patient care, teaching and research in systemic autoimmune diseases (SAD). The questionnaire was sent to all members of the Spanish Group of Autoimmune Diseases (GEAS-SEMI) through the mailing group list in February 2012. UEAS was defined as a functional healthcare structure in which specific circuits have been established to provide targeted care for patients with SAD.

Results: By March 31, 2012, information had been collected from 56 UEAS integrated in Spanish Internal Medicine Departments. Over 50% of UEAS were located in hospitals in Catalonia, Andalusia and Madrid. One third of UEAS have been managing and studying SAD for more than 10 years, and 5 for more than 20 years. In total, 335 healthcare professionals were dedicated to SAD, including 249 physicians, 42 nurses and 44 administrative staff. 75% of UEAS are supported by nurses, 79% have specific administrative support and 98% have a specialized outpatient clinic. Hospitalization was necessary in only 9.5% of patients attended by UEAS, representing a mean of 2.2 beds/month. The hospital beds are shared with the Internal Medicine Department in more than 80% of cases. 91% of UEAS have an outpatient healthcare device to administrate intravenous therapies, 61% have a quick reference device for solving unexpected healthcare problems and 45% have a home care service shared with Internal Medicine. In 2011, UEAS provided health care to 24,700 patients, with a monthly mean of 1,100 first visits and 6,600 follow-up visits.

Conclusions: Comprehensive and specific care for patients with SAD has been developed by Systemic Autoimmune Diseases Units

(UEAS) of the main Spanish Internal Medicine Departments in the last two decades. The key role played by the work of SEMI in creating and strengthening internists' work in clinical areas such as autoimmune diseases has contributed to the consolidation and expansion of this specific targeted healthcare activity through the GEAS group.

IF-25
EFFECT OF ATORVASTATIN ON THE MODULATION OF ARTERIAL STIFFNESS AND BIOLOGICAL MARKERS INVOLVED IN SUBCLINICAL ATHEROSCLEROSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (PRELIMINARY STUDY)

A. Sollet, R. Castejón, L. Benítez, C. Jiménez Ortiz, J. Vargas, M. Yebra Bango

Department of Internal Medicine. Hospital Universitario Puerta de Hierro Majadahonda. Majadahonda (Madrid), Spain.

Objectives: Systemic lupus erythematosus (SLE) is a disease of multifactorial etiology, although it has been suggested the involvement of a dysfunction in the vascular repair which would lead to a premature atherosclerosis. Recently, interesting new data have demonstrated that statins have direct effects on the endothelium, that become them potential candidates in the treatment of SLE, not only for its role in the restoration of endothelial function and prevention of atherosclerosis, but also for its immunomodulatory properties that may reduce disease activity. The aim of this study was to evaluate the effect of treatment with atorvastatin in patients with SLE on classical cardiovascular risk factors, inflammatory markers, clinical parameters of disease activity and markers of subclinical atherosclerosis.

Material and method: Twenty-five women diagnosed with SLE were included in the study, with a median age of 41 years (range 26-63), who received during 8 weeks 20 mg daily of atorvastatin. All patients underwent at baseline (week 0) and at end of treatment (week 8), the determination of classical cardiovascular risk factors, biochemical and immunological markers, factors associated with lupus activity and estimation of biological markers by determining the number of circulating endothelial progenitor cells (EPC) and soluble proteins, as well as a determination of subclinical atherosclerosis by studying pulse wave velocity (PWV).

Results: Atorvastatin therapy was associated with a significant decrease in arterial stiffness measured by PWV (6.93 ± 1.45 vs 6.53 ± 1.06; p = 0.033). Regarding classical cardiovascular risk factors, we observed a significant decrease in total cholesterol levels (171.88 ± 39.36 vs 131.60 ± 34.22; p < 0.001) and LDL cholesterol (99.72 ± 66.5 ± 29.92 vs 29.52; p < 0.001). About factors related to SLE, our results showed a trend towards improvement in the SLEDAI score and an increase in C3 complement values bordering on statistical significance (102.99 ± 25.65 vs 107.54 ± 23.93; p = 0.05). On the study of biological markers, atorvastatin treatment was associated with a significant decrease in the values of soluble VEGF (vascular endothelial growth factor) (321.90 ± 250.27 vs 283.66 ± 223.23; p = 0.003) and a trend towards the reduction of some of the tested cytokines such as tumor necrosis factor (TNF) and interleukin 6 (IL-6). A decrease in the percentage of EPCs that does not reach statistical significance, was also noted (0.50 ± 0.58 vs 0.26 ± 0.16; p = 0.076).

Discussion: Our results suggest that an 8-week period atorvastatin treatment in patients with SLE, improves arterial elasticity measured by PWV. We also observed a trend towards improvement of disease activity and inflammatory activity, probably because there has been an endothelial repair and improvement of arterial elasticity, so it would reduce the demand for endothelial regeneration, migration of EPCs from the bone marrow and the expression of soluble factors.

Conclusions: The present study showed that a short-term treatment with atorvastatin in patients with SLE, could improve arterial elasticity measured by pulse wave velocity These preliminary findings must be confirmed by long-term multicentric studies designed to define the recommendation for statins in SLE patients.

IF-36
WELL-BEING AND QUALITY OF LIFE IN PATIENTS WITH INFLAMMATORY MYOPATHY

I. Armadans[1], A. Selva O'Callaghan[2], B. Visauta[1], I. Pinal[2], M. Juanós Iborra[2], N. Cassá[1], A. Guillén[2], M. Vilardell Tarrés[2]

[1]Department of Social Psychology. Universitat de Barcelona. Barcelona, Spain. [2]Department of Internal Medicine. Vall d´Hebron General Hospital. Universitat Autònoma de Barcelona. Barcelona, Spain.

Objectives: The inflammatory myopathies are chronic systemic connective tissue disorders affecting skeletal muscles and other organs including the skin, joints and lungs. Well-being and quality of life (QOL) are subjective perceptions of vitality (energy) and feeling well that can be described objectively. We measured the well-being and QOL in a large series of patients with inflammatory myopathy attended at our outpatient clinic and seek for clinical and biological correlations.

Material and method: The present study included 63 consecutive adult Caucasian patients diagnosed with idiopathic inflammatory myopathy who were followed regularly at our specialized outpatient clinic in Barcelona, Spain. The diagnosis of dermatomyositis (DM) and polymyositis (PM) was based on the criteria of Bohan and Peter. Characteristic clinical and histological features provided the diagnosis of inclusion body myositis (IBM). The WHO-Five Well-Being Index (1-6) and WHOQOL-BREF quality of life instruments (General QOL, general health, and 4 domains: physical health, psychological, social relationships and environmental, measured by Lickert scoring system which ranged from 1-5) adapted for use in Spanish population were employed. A series of ANOVAs and t-tests were conducted to examine differences between groups in well-being and QOL outcomes.

Results: Over a period of 12 months (January 2011 to January 2012), 63 consecutive patients (52 female), with mean (SD) age 50.7 (16.2) years diagnosed with inflammatory myopathy and followed at our outpatient clinic were prospectively evaluated for well-being and QOL. Patients were classified as having probable or definitive DM (47) or PM (14). Two were diagnosed as IBM. Physical health domain (mean [SD], 3.15 [0.44]), general QOL (3.16 [1.07]) and general health (2.65 [0.96]) had the lower mean values. Statistical significant association was observed between lower mean values in psychological domain and older age (> 60 yrs) (p = 0.03). Patients with DM obtained a significant better mean value in the physical health domain in comparison with the remaining patients (p = 0.048). No statistically significant associations were found between well-being and the mean duration of the disease, type of myopathy (DM vs PM), the presence of myositis-specific (Mi2, SRP, synthetase) or associated (Ro52, PM/Scl, Ku, RNP) autoantibodies, lung involvement or the presence of cancer.

Discussion: Myositis are chronic inflammatory diseases, so it makes sense to analyse the impact of these illness on well-being and QOL. Subjective well-being seems to rely on the personal feelings which go beyond having the disease or not. Our data supports this idea, since no differences have been observed between groups, clinical manifestations or immunological characteristics, nor along the time. Nevertheless, it cannot be discarded that an adaptative phenomenon to the chronicity of the disease occurs in these patients. That DM patients had a better score in the physical health domain, merits a comment. It could be

due to an initial more aggressive immunosuppressive therapy implemented in DM patients, which could achieve an apparent better evolution. Nevertheless, scales to measure activity index (MITAX/MYOACT) or cumulative damage due to myositis (Myositis Damage Index) are necessary weightings in order to a properly interpretation.

Conclusions: Well-being remains stable along the time in patients with inflammatory myopathy regardless the clinical characteristics or biological parameters. Older myositis patients in the psychological domain and patients with DM in the physical healthy domain behave in a different way in comparison with the remaining patients of the series.

IF-38
ANALYSIS OF SYSTEMIC RISK FACTORS IN WOMEN WITH SEVERE PREECLAMPSIA

C. González de Echavarri[1], I. Villar[1], R. Larrieta[2], A. Ugarte[1], R. Ruiz[1], G. Ruiz-Irastorza[1]

[1]Department of Autoimmune Diseases-Internal Medicine. Hospital Universitario Cruces. UPV/EHU. Barakaldo (Vizcaya), Spain. [2]Department of Obstetrics and Gynecology. Hospital Universitario Cruces. Vizcaya, Spain.

Objectives: 1) To analyze the prevalence of risk factors such as antiphospholipid antibodies, congenital thrombophilias, hypertension or hypothyroidism in a cohort of patients with severe preeclampsia. 2) To analyze the association between such risk factors and complicated preeclampsia.

Material and method: 88 women were studied in the Autoimmune Diseases Pregnancy Clinic after delivery following an episode of preeclampsia. Demographic and clinical variables, cardiovascular risk factors and variables associated with maternal complications and pregnancy outcome were analysed. In every woman, antiphospholipid antibodies, congenital thrombophilias (factor V Leiden, prothrombin 20210A mutation, protein C, protein S and antithrombin deficiency) and thyroid dysfunction were screened. Renal Doppler studies were performed in each patient. Complicated preeclampsia was considered in the presence of at least one of the following: thrombocytopenia, high liver enzymes, HELLP syndrome, eclampsia, prematurity or fetal death. A descriptive analysis of the results of the screening program for secondary preeclampsia was carried out. The possible relationship of antiphospholipid antibodies and/or congenital thrombophilias with complicated preeclampsia was analysed.

Results: The mean age (SD) of the patients was 33 (4.5) years. 60 (68%) were in their first pregnancy, 5 (5.7%) had a familiar history of preeclampsia and 45 (51%) had a familiar history of hypertension. 35 (40.2%) presented with at least one vascular risk factor: smoking 23 (26%), dyslipidemia 2 (2.3%), gestational diabetes 8 (9%) and hypertension 3 (3.4%). Complicated preeclampsia presented in 62 women (70.4%). Congenital thrombophilias were found in 10 women (11.3%): protein S deficiency 6 (6.8%); factor V Leiden 3 (3.4%); and prothrombin mutation 1 (1.1%). Positive antiphospholipid antibodies were found in 5 (6%). 8 patients (9.1%) had thyroid dysfunction and only 1 patient had renal artery stenosis. Congenital thrombophilias were not statistically related with complicated preeclampsia: 14.8% of patients with complicated preeclampsia had a congenital thrombophilia, vs 9.5% of those with non complicated preeclampsia, p = 0.71. Likewise, antiphospholipid antibodies were not present in a significantly higher proportion among women with complicated preeclampsia (5% vs 8%, respectively, p = 0.62).

Discussion: Preeclampsia remains a leading cause of maternal morbidity. It is associated with several potential risk factors, however their real impact is not well established. Also, an association between preeclampsia and late cardiovascular disease has been proposed. In this cohort of unselected women with preeclampsia, the prevalence of systemic risk factors was low. A worse prognosis of patients with congenital thrombophilia or antiphospholipid antibodies could not be demonstrated. Given the low prevalence of both conditions, their association with complicated preeclampsia cannot be however excluded. Higher numbers would be needed in order to reach more definitive conclusions.

Conclusions: The prevalence of congenital thrombophilias and antiphospholipid antibodies is low in unselected women with preeclampsia. The association of congenital thrombophilias and antiphospholipid antibodies with complicated preeclampsia could not be proven.

IF-45
CIRCULATING ENDOTHELIAL PROGENITOR CELLS (CEPC), CARDIOVASCULAR RISK FACTOR AND METABOLIC SYNDROME IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) PATIENTS

L. Benítez, S. Valero, A. Ramos, P. García, A. Castañeda, M. Yebra Bango

Autoimmune Diseases Unit. Department of Internal Medicine. Hospital Universitario Puerta de Hierro Majadahonda. Majadahonda (Madrid), Spain.

Objectives: SLE is associated with a stricking increase in the risk of premature cardiovascular due to accelerated atherosclerosis, which significantly contributes to morbidity and mortality in this patients. While traditional risk factors may play a role in this increased propensity, they do not seem to fully account this complication. CEPC play an important role in the repair of vascular damage and it has been suggested that decreased numbers of this population are associated with increased subclinical atherosclerosis. Several studies demonstrate the existence of decreased number of CEPC in patients with cardiovascular risk factors in the general population. The objective of this study is correlate the CEPC with the cardiovascular risk factors and the metabolic syndrome in a population of SLE patients.

Material and method: Forty-six SLE female patients (> 4 ACR 1997 criteria) were included (mean age 45 years). At the time of the patient´s visit cardiovascular risk factors and SLE specific factors were assessed. CEPC were determinated in peripheral blood by flow cytometry with immunomagnetic enriched population of CD34+ cells. CEPC were considered as CD34+/CD133+/KDR+ (immature CEPC) and CD34+/KDR+ (total CEPC). The patients were diagnosed of metabolic syndrome, according the definition by the Adult Treatment Panel III.

Results: At the time of blood sampling 39 patients had inactive disease (SLEDAI < 4), no patient had a damage index (SLICC/ACR) over 6, even 13 patients had SLICC/ACR = 0. Thirteen patients had metabolic syndrome. The smokers, the hypertensive patients, those whit impaired fasting glucose and patients with metabolic syndrome showed a significative decrease of immature or total CEPC percentage subpopulation (Table 1).

Discussion: The association between CEPC and traditional risk factors has been widely studied in the general population of patients with cardiovascular disease. These studies have shown an association between the presence of risk factors and low concentrations CEPC. As for the LES there are few studies on the relationship of CEPC and cardiovascular risk factors with inconclusive results. In our study we observed a significative decrease in the percentage of CEPC in SLE patients with certain risk factors (hypertension, tobacco habit, impaired glucose metabolism) and metabolic syndrome.

Conclusions: Our work shows that CPEC are a new biomarker of cardiovascular risk factors in patients with SLE.

Table 1 (IF-45). Relationship between CEPC and cardiovascular rik factors in SLE patients

Total CEPC	Arterial Hypertension 0.5 ± 0.3	No Arterial Hypertension 1.2 ± 0.7	p 0.03
	Metabolic syndrome 0.79 ± 0.33	No Metabolic syndrome 1.3 ± 0.74	0.01
Immature CEPC	Impaired fasting glucose 0.4 ± 0.2	No Impaired fasting glucose 0.84 ± 0.5	0.02
	Tobacco habit 0.45 ± 0.2	No Tobacco habit 0.84 ± 0.5	0.008
	Metabolic syndrome 0.52 ± 0.25	No Metabolic syndrome 0.88 ± 0.57	0.02

IF-47
CLINICAL OUTCOME OF WOMEN WITH AUTOIMMUNE DISEASES IN A COMBINED MEDICAL-OBSTETRIC CLINIC: THE CRUCES AUTOIMMUNE DISEASES PREGNANCY CLINIC EXPERIENCE

A. Ugarte[1], P. Delgado[2], R. Coto[1], C. Martínez-Caballero[1], M. Cuesta[1], G. Ruiz-Irastorza[1]

[1]Department of Autoimmune Diseases-Internal Medicine. Hospital Universitario Cruces-UPV/EHU. Barakaldo (Vizcaya), Spain. [2]Department of Obstetrics and Gynecology. Hospital Universitario Cruces. Barakaldo (Vizcaya), Spain.

Objectives: To describe the clinical features, pregnancy outcomes and incidence of complications in a cohort of 116 pregnancies in patients diagnosed of autoimmune diseases attended in a combined medical-obstetric clinic.

Material and method: Retrospective review of 116 pregnancies attended at the Autoimmune Diseases Pregnancy Clinic. In this combined medical-obstetric Clinic, running since 2007, women are attended in a coordinated way by an obstetrician specialized in high risk pregnancies and an internist specialized in autoimmune diseases. Women are seen consecutively by both doctors, according to an agreed protocol that establishes the indication and timing for specific tests like placental Doppler studies or fetal echocardiograms. Indications for primary or secondary prophylaxis of preeclampsia or thrombosis have also been set up. Women are followed shortly after delivery and after the puerperium. Patients included in this study met criteria either for systemic autoimmune diseases such as systemic lupus erythematosus (SLE), antiphospholipid syndrome (APS), Sjögren syndrome and systemic sclerosis or were asymptomatic carriers of antinuclear antibodies, antiphospholipid antibodies and anti-Ro antibodies. Data on the previous medical and obstetric history of each woman and concerning the course of current pregnancy (including preconceptional counselling, treatments received, medical complications, such as thrombosis or disease flares, pregnancy outcomes or congenital heart block) were recorded in a database. Statistical descriptors of these variables were generated.

Results: The mean age of the cohort was 33.5 (SD 3.8) years. 35 women (30.2%) had suffered miscarriage in previous pregnancies and 12 (10.3%) reported previous fetal deaths. Preconceptional counselling was accomplished in 67 (57%) of patients. 102 pregnancies (87%) resulted in a live birth whereas 11 pregnancies (10%) ended in miscarriage and 3 (3%) were terminated due to fetal abnormalities. The prematurity rate was 12% and 7 (6.8%) of the newborns were small for gestational age. Preeclampsia occurred in 2 women (1.7%). One pregnancy was complicated with thrombosis. Among the 47 women with SLE (40.5% of the cohort), only one had activity 6 months previous to pregnancy. 9 patients (19%) had a history of nephritis, all in remission by conception. All women took hydroxychloroquine, 24 patients (51%) took low dose prednisone (mean dose 2.8 mg/d) and 8 patients (17%) were treated with azathioprine. This subgroup had a 85% live birth rate, with 15% miscarriages and no fetal deaths. The rate of prematurity was 20%. 11 women (23%) suffered a lupus flare, usually during the 2nd trimester and the puerperium. All but one (a severe vasculitic flare) were mild, mostly at the cutaneous-articular level. One pregnancy was complicated with preeclampsia. No thrombosis was seen. The APS subgroup, with a previous rate of 75% of either miscarriages or fetal deaths, showed a live birth rate of 83%, a miscarriage rate of 16% and a preterm birth rate of 20%. No patients suffered thrombosis and with only 1 case of preeclampsia. No congenital heart blocks were seen in babies born to the 25 anti-Ro positive mothers.

Discussion: The obstetric outcome was greatly improved in the group of women with APS. Preeclampsia, thrombosis and lupus flares were minimised due to adequate pregnancy planning and correct prophylaxis in high risk patients.

Conclusions: The good medical and obstetric outcomes of this cohort of women with autoimmune diseases remark the importance of a coordinated care by specialists in autoimmune diseases and high risk pregnancies. Preconceptional counselling, adequate management of medication, structured obstetric surveillance and close collaboration between specialists are important factors to improve final results.

IF-56
PERIPHERAL ARTERIAL DISEASE IN PATIENTS WITH ANTIPHOSPHOLIPID ANTIBODIES

I. Villar, J. Erdozain, C. González de Echavarri, G. Ruiz-Irastorza

Department of Autoimmune Diseases-Internal Medicine. Hospital Universitario Cruces-UPV/EHU. Barakaldo (Vizcaya), Spain.

Objectives: 1) To analyze the prevalence of peripheral arterial disease (PAD), cardiovascular disease (CVD) and cardiovascular risk factors in a cohort of patients with antiphospholipid antibodies (APL). 2) To identify potential predictors of PAD in patients with APL.

Material and method: 172 patients from the APS-Cruces prospective observational cohort were recruited. This cohort enrolls patients with APS, both primary and secondary to systemic autoimmune diseases, mostly SLE, as well as APL carriers, with and without lupus, but with no previous thrombotic events. The ankle-brachial index (ABI) was determined in every patient, with an ABI < 0.9 having a good correlation with the presence of PAD. A number of variables contained in the cohort database were analysed: demographic (age, sex, race) clinical and immunological (fulfillment of APS criteria, presence of SLE, APL profile, time of follow-up), presence of traditional vascular risks factors, previous cardiovascular events, cardiovascular risk calculated by SCORE and treatments received. A descriptive analysis of the cohort was generated. Potential risk factors for the presence of a low ABI were explored by means of chi-square/Fisher exact test as appropriate.

Results: The study group consisted of 172 patients. 85 patients (49%) fulfilled APS criteria and 87 (51%) were APL carriers without thrombosis. 23 patients (13%) had a SLE-associated APS. 130 patients (76%) were women. The mean age (SD) was 50 years (14) at the time of the study and 41 years (16) at enrolment in the cohort. The mean follow-up (SD) was 9 years (8). 71 (41%) patients had had any thrombosis, with 80 total events. 35 events (44%) were venous and 45 (56%) were arterial thrombosis. 94 patients (72% of the 130 women) had previous pregnancies, with 30 (17%) miscarriages and 18 (10%) fetal deaths. The frequency of

cardiovascular risk factors was as follows: smoking 41 patients (24%), high blood pressure (HBP) 72 patients (42%), diabetes 17 patients (10%), dyslipidemia 86 patients (50%) and family history of cardiovascular events 25 patients (15%). Previous symptomatic arterial disease was present in 52 patients (30%): chronic renal disease 16 patients (9%), stroke 38 patients (22%), ischemic heart disease 7 patients (4%); PAD 4 patients (2%). 34 patients had a low ABI, with a prevalence of 20%. The reported prevalence in the general Spanish population 45 to 55 year old is 1.1% in males and 2.1% in females. Patients with low ABIs had a higher frequency of dyslipidemia (27% vs13%, p = 0.02), more previous PAD (12% vs 0%, p < 0.001), and had smoked more cigarettes (33 vs 19 pack-years, p = 0.011). These patients were treated more frequently with statins (27% vs 13%, p = 0.019). Among patients who fulfilled APS criteria, 15 (18) had a low ABI. In this subgroup, patients with low ABI were more frequently current smokers and previous smokers than never smokers (35%, 16% vs 5%, p = 0.039), had PAD (20% vs 0%, p = 0.005) and miscarriages more frequently (36% vs 10%, p = 0.039) than patients with a normal ABI. Among patients with APL without APS, those with a low ABI (19.22%) were older (58 (16) vs 50 years (15), p = 0.04), had smoked more pack-years (42 vs 19, p = 0.003), had more dyslipidemia (36% vs 13%, p = 0.01) and had been treated with statins more frequently (13% vs 34%, p = 0.021). Patients with APL and a normal ABI had been treated more frequently with antimalarials (36.7% vs 14%, p = 0.015).

Discussion: This study shows evidence of PAD in 1/5 patients with APL. The presence of PAD was mostly related with classical cardiovascular risk factors and was not influenced by the presence of SLE or APS or the APL profile. A protective effect of hydroxychloroquine was evident in patients with APL who did not fulfil criteria for APS.

Conclusions: The prevalence PAD is higher in individuals with APL than in the general population dyslipidemia and smoking were associated with PAD. Hydroxychloroquine was protective in individuals with APL without APS.

IF-57
LIFE-THREATENING CRYOGLOBULINEMIC VASCULITIS ASSOCIATED WITH HEPATITIS C VIRUS INFECTION CLINICAL DESCRIPTION AND OUTCOMES OF 29 CASES FROM A SINGLE CENTER

S. Retamozo[1], C. Díaz-Lagares[1], P. Brito-Zerón[1], M. Gómez[1], X. Bosch[2], A. Bove[1], M. Ramos-Casals[1]

[1]Laboratory Josep Font, Department of Autoimmune Diseases, [2]Department of Internal Medicine, ICMiD. Centre Sociosanitari Hospital Clínic i Provincial de Barcelona. Barcelona, Spain.

Objectives: To analyze the clinical characteristics and outcomes of HCV patients presenting with life-threatening cryoglobulinemic vasculitis.

Material and method: We evaluated 89 patients diagnosed with cryoglobulinemic vasculitis consecutively admitted to our Department between 1995 and 2010. All patients fulfilled the 2010 classification criteria for cryoglobulinemic vasculitis. We reviewed clinical charts of the 181 admissions of these patients searching for life-threatening presentation of cryoglobulinemia. The following organ involvements were considered as potentially life-threatening in HCV patients with cryoglobulinemic vasculitis: cryoglobulinemic, biopsy-proven glomerulonephritis presenting with renal failure, gastrointestinal vasculitis, pulmonary hemorrhage, CNS involvement. We identified 36 patients with 43 admissions due to life-threatening cryoglobulinemia, of whom 29 had HCV-related cryoglobulinemia (the remaining 7 had essential cryoglobulinemia).

Results: A total of 29 patients from our Department fulfilled the inclusion criteria: 20 presented with renal failure, 10 with gastrointestinal vasculitis, 4 with pulmonary hemorrhage and 3 with CNS involvement; 7 patients presented with more than one life-threatening cryoglobulinemic manifestation. There were 14 (48.2%) women and 15 (51.7%) men, with a mean age at diagnosis of cryoglobulinemia of 54.2 years (range, 25 to 82) and a mean age at life-threatening involvement of 57.2 years (range, 25 to 82). In 13 (44.8%) patients, life-threatening involvement was the first clinical manifestation of cryoglobulinemia. Severe involvement appeared a mean of 3.6 years (range 1-30) after the diagnosis of cryoglobulinemic vasculitis. Patients were followed for a mean of 45.5 months (range, 0 to 192) after the diagnosis of life-threatening cryoglobulinemia. Sixteen patients (55%) died. The highest rate of mortality was found in patients presenting with pulmonary hemorrhage (100%), followed by those with gastrointestinal vasculitis (70%), CNS involvement (66%) and renal failure (50%).

Conclusions: HCV-related cryoglobulinaemia may result in progressive (renal involvement) or acute (pulmonary hemorrhage, gastrointestinal ischemia, CNS involvement) life-threatening organ damage. The mortality rate of these manifestations ranges between 50% and 100%. Unfortunately, this may be the first cryoglobulinaemic involvement in almost two-thirds of cases, highlighting the complex management and very elevated mortality of these cases.

IF-58
CHARACTERIZATION OF SYSTEMIC INVOLVEMENT USING THE EUROPEAN 2010 ESSDAI INDEX IN 921 SPANISH PATIENTS WITH PRIMARY SJÖGREN SYNDROME (GEAS-SEMI-SS REGISTRY)

S. Retamozo[1], G. Fraile[2], R. Pérez Álvarez[3], M. Akasbi[4], J. Callejas[5], M. Ripoll[6], B. Pinilla[7], E. Fonseca[8]

[1]Laboratory Josep Font, Department of Autoimmune Diseases. Centre Sociosanitari Hospital Clínic i Provincial de Barcelona. Barcelona, Spain. [2]Department of Internal Medicine. Hospital Ramón y Cajal. Madrid, Spain. [3]Department of Internal Medicine. Hospital do Meixoeiro. Vigo (Pontevedra), Spain. [4]Department of Internal Medicine. Hospital Infanta Leonor. Vallecas (Madrid), Spain. [5]Department of Internal Medicine. Hospital de Especialidades San Cecilio. Granada, Spain. [6]Department of Internal Medicine. Hospital Infanta Sofía. Madrid, Spain. [7]Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain. [8]Department of Internal Medicine. Hospital de Cabueñes. Gijón (Asturias), Spain.

Objectives: To measure systemic activity using the new 2010 European EULAR-SS disease activity index (ESSDAI) in a large cohort of Spanish patients with primary Sjögren syndrome (SS).

Material and method: The GEAS-SS multicenter registry was formed in 2005 with the aim of collecting a large series of Spanish patients with primary SS, and included thirteen Spanish reference centers with substantial experience in the management of SS patients. By March 2012, the database included 921 consecutive patients, recruited since 1994, fulfilling the 2002 classification criteria for primary SS. Systemic involvement was characterized using the definitions included in the European ESSDAI activity index that classify systemic involvement into 12 domains (i.e. organ systems). Each domain is divided in 3-4 levels according to their degree of activity and scored as 0 (no activity), 1 (low activity), 2 (moderate activity) or 3 (high activity). These points are then multiplied by an assigned weight factor, ranging from 1 to 6, with the total score ranging from 0 to 123 points. We retrospectively calculated the following ESSDAI scores analysing the medical charts of all patient.

Results: The mean cumulative ESSDAI score in the cohort was 9.27 ± 0.30, which was of 6.62 ± 0.34 at diagnosis and of 4.16 ± 0.34 before diagnosis (new activity). The percentage of patients who presented activity (score at least 1) at the time of diagnosis in the

different domains ranges between 41% and 82%, with the higher percentages found for the laboratory and glandular domains and the lower for the pulmonary and renal domains. The predominant degree of activity was low in the constitutional, lymphadenopathy, glandular, articular, hematological and biological domains, while a moderate/high degree of activity predominates in the pulmonary, renal, muscular and neurological domains. Higher mean cumulative ESSDAI scores were found in male patients ($p = 0.016$), those with positive salivary gland biopsy ($p = 0.012$), anemia ($p < 0.001$), leukopenia ($p < 0.001$), thrombocytopenia ($p = 0.001$), lymphopenia ($p < 0.001$), ESR > 50 mm/h ($p < 0.001$), anti-Ro/SS-A ($p = 0.014$), anti-La/SS-B ($p < 0.001$), low C3 ($p < 0.001$), low C4 ($p < 0.001$), serum monoclonal band ($p < 0.001$) and cryoglobulins ($p < 0.001$); the mean ESSDAI score at diagnosis was higher in patients with anemia ($p = 0.019$), anti-La/SS-B antibodies ($p = 0.007$), monoclonal band ($p = 0.039$) and cryoglobulins ($p < 0.001$).

Conclusions: The measurement of systemic activity using the new European 2010 EULAR-SS disease activity index (ESSDAI) provides a reliable picture of disease activity (measured organ by organ) in a large cohort of Spanish patients with primary SS.

IF-62
CYSTATIN C AS A MARKER OF CARDIOVASCULAR RISK FACTOR IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

P. García[1], P. Tutor Ureta[1], L. Muñoz[2], R. Castejón[1], R. Silvestre[2], M. Yebra Bango[1]

[1]Department of Internal Medicine, [2]Department of Biochemistry. Hospital Universitario Puerta de Hierro Majadahonda. Majadahonda (Madrid), Spain.

Objectives: Cystatin C (CysC) is a protein with a low molecular weight produced by most cells that has been considered as an excellent marker of glomerular filtration rate (GFR). It is freely filtered at the glomerulus, reabsorbed and catabolized in the proximal renal tubules. Since there is no tubular secretion, CysC is extremely sensitive to small changes in GRF. In addition to its utility as a measure of renal function, it hast been suggested that CysC provides independent prognostic information about cardiovascular (CV) risk. SLE is associated with a striking increase in the risk of premature CV complications due to accelerated atherosclerosis, which significantly contributes to morbidity and mortality in this patient population. The aim of this study was to evaluate the association of CysC serum levels with CV risk factors and subclinical atherosclerosis in SLE patients.

Material and method: We recruit 42 female SLE patients (> 4 ACR 1997 criteria) from outpatient clinics with a median age of 44.2 [19-63]. Patients were selected according to estimated GFR (Crockoft-Gault) ≥ 60 ml/min/1.73 m^2. Data collected included demographics, renal function parameters, SLE activity (SLEDAI index), disease damage (SLICC/ACR index), patient treatment, CV risk factors, inflammatory markers and subclinical atherosclerosis. CysC level was measured using a particle-enhanced immunonephelometric assay. CysC normal level is defined as 0.59-1.01 mg/l. Arterial stiffness, as subrogate of subclinical atherosclerosis, was assessed measuring the carotid-femoral pulse wave velocity (PWV) by Doppler velocimetry.

Results: A positive correlation between CysC values and renal damage parameters was found in the case of creatinine ($p = 0.001$) and microalbumin/creatinine ratio ($p < 0.05$), but not in case of creatinine clearance. Evaluating traditional cardiovascular risk factors, we obtained a significant association ($p < 0.05$) between increased levels of CysC and age, hypertension, hyperlipidemia, metabolic syndrome, body mass index, high homocysteine level and waist circumference. About SLE related factors, a significant association was found between increased CysC levels and the SLICC/ACR score, while no correlation has been shown with patients SLEDAI or any immunosuppressive therapy. However, patients under ACE inhibitors or statins therapy presented a significant increased ($p < 0.05$) in CysC level. In the same way, CysC level correlates with patient arterial stiffness assessed by PWV ($p = 0.015$). A second analysis including only patients without any renal impairment ($n = 30$), defined as GFR ≥ 60 ml/min/1.73 m^2 and normal urinary albumin to creatinine rate, was carried out. No association between CysC levels and any of the CV risk factors, SLE related factors and arterial stiffness was found.

Discussion: Most of the studies associate high serum CysC level as a marker of renal damage, but the relationship as an independent CV risk factor is questionable. In our study, carried out selecting patients with good renal function, CysC correlates with CV risk; but when urinary albumin to creatinine rate is considered as a renal function parameter, CysC lose the association as independent factor of CV risk.

Conclusions: In our SLE patients, serum CysC correlates with renal function but it is not independently associated with cardiovascular risk factor or subclinical atherosclerosis.

IF-65
CLINICAL AND LABORATORY VARIABLES ASSOCIATED WITH DAMAGE AT DIAGNOSIS OF SYSTEMIC LUPUS ERYTHEMATOSUS

M. García Gómez, G. Espinosa, M. Moga, J. Jiménez Alonso, E. Sánchez García, C. Tolosa, M. Micó, M. Herranz

GEAS. Grupo RELES. Vizcaya, Spain.

Objectives: 1. To describe the clinical an immunological characteristics at enrolment of an inception cohort of patients with systemic lupus erythematosus (SLE). 2. To analyse the predictors of damage at diagnosis.

Material and method: Analysis of patients from the multicentric inception cohort RELES who have completed 6 months after the diagnosis of SLE. All patients are enroled at the time of diagnosis. Data are collected prospectively, and introduced in a computerised database with web access via an individual password. Demographic, clinical, laboratory, immunological and therapeutic variables, including the SLICC damage index (SDI) and the Systemic Lupus Activity Disease Activity Index (SLEDAI) are collected at diagnosis and at least once-yearly. In this study we have used the initial SDI, measured 6 months after the diagnosis, as the dependent variable. As independent variables, we used: age, gender, cigarette smoking, arthritis, lymphopenia, active nephritis, ANA (antinuclear antibodies), anti-DNA antibodies, antiphospholipid antibodies and complement levels. Univariate analysis was first performed. All variables with a p value < 0.1 were then introduced in a multivariant multiple linear regression model in order to identify independent predictors of damage.

Results: 83 patients (93%) were women, 77 Caucasian (86%), 25 smokers (28%). The mean age at diagnosis (SD) was 43.75 (16.35) years. 40 patients (45%) met 4 ACR criteria, 38 (43%) met 5 criteria and 11 (12%) met more that5 criteria. At enrolment, 68 patients presented with arthralgia (76%), 40 with arthritis (45%), 46 with photosensivity (52%), 43 with lymphopenia (48%), 14 with lupus nephritis (16%), 13 with pleuritis (15%) and 10 with pericarditis (11%). Thrombosis were present in 12 patients (13%): 4 had venous thrombosis (4%), 2 pulmonary thromboembolism (2%), 3 ischaemic stroke (3%), 1 transient ischaemic attack (1%), 1 myocardial infarction (1%) and 1 small vessel thrombosis at the CNS level (1%). The autoimmunity profile of the studied population was: ANA 87 patients (98%), antiDNA 57 (64%), antiRo 36 (40%), antiLa 13 (15%), antiSm 15 (17%), anti-U1RNP 15 (17%), lupus anticoagulant 17 (19%), IgG anticardiolipin antibodies (aCL) 15 (17%), IgM aCL 13 (14%), IgG antiB2-GP1 9 (10%) and IgM antiB2-GP1 8 patients (9%). 65 patients (73%) had no damage at diagnosis (SDI = 0). Among the remaining

patients, 10 (11%) had a SDI = 1; 9 (10%) had a SDI = 2, 3 patients (3%) a SDI = 3 and one each (1%) had a SDI = 4 and a SDI = 6. In the univariate analysis only the age was associated with the SDI score at diagnosis ($p < 0.0001$). The presence of lupus nephritis showed a borderline significance ($p = 0.069$). In the multiple regression model including these two independent variables, only the age at enrolment showed a significant independent association with damage as measured by SDI.

Discussion: This is the first Spanish multicentric inception cohort of patients with SLE. The clinical profile of patients shows a clear predominance of Caucasian patients with a low incidence of severe organ involvement at enrolment. However, lupus nephritis was present in 16% of patients and thrombosis was seen in a similar proportion. Damage at the time of diagnosis was seen in roughly 1/3 of patients, with a strong predilection for organ domains related to atherothrombotic manifestations. As expected, variables related with disease activity or therapy were not associated with initial damage. Rather, the age at the time of diagnosis was the only independent predictor of the initial SDI score.

Conclusions: The preliminary analysis of the first Spanish multicentric inception cohort of patients with SLE shows a relatively mild disease activity at presentation. Irreversible organ damage was seen at diagnosis in 27% of patients, mainly secondary to atherothrombotic disease. The age at diagnosis was the only predictor of damage.

IF-66
ASSOCIATION BETWEEN LUPUS ACTIVITY, ORGAN DAMAGE AND IMMUNOSUPPRESSIVE THERAPY

M. García Gómez, L. Caminal, J. Canora, M. Rodríguez Carballeira, L. Sáez Comet, A. Castro, L. Pallarés, G. Ruiz-Irastorza

GEAS. Grupo RELES. Vizcaya, Spain.

Objectives: To describe the initial treatment prescribed to recently diagnosed lupus patients and to analyse the relation between global and specific organ activity and the different immunosuppressive drugs.

Material and method: Analysis of patients from the Spanish multicentric inception cohort RELES who have completed 6 months after the diagnosis of SLE. All patients are enroled at the time when 4 ACR classification criteria are met. Data are collected prospectively, and introduced in a computerised database with web access via an individual password. Demographic, clinical, laboratory, immunological and therapeutic variables, including the SLICC damage index (SDI) and the Systemic Lupus Activity Disease Activity Index (SLEDAI) are collected at diagnosis and at least once-yearly. In this study, lupus activity has been classified as low (SLEDAI < 6) or high (SLEDAI ≥ 6). The calculated mean daily prednisone doses in the first 6 months have been divided in low (≤ 7.5 mg/d), medium (> 7.5-30 mg/d) and high (> 30 mg/d). Descriptive statistics were generated. The relation of the different drugs with SLEDAI scores and specific organ involvement were analysed by univariate tests.

Results: 83 patients (93%) were women, 77 Caucasian (86%). The mean age at diagnosis was 43.75 + 16.35 years. 4 patients (4.5%) had a SLEDAI = 0 at enrolment. The remaining 95.5% had a SLEDAI ≥ 1, with a mean (SD) SLEDAI of 8.68 (6.67). 56 patients (62.9%) had a SLEDAI ≥ 6. 79 patients (89%) received antimalarials and 59 (67%) prednisone (with 5 additional patients taking deflazacort). 14 (16%) patients required iv. methyl-prednisolone, 18 (20%) were treated with azathioprine, 8 (9%) with iv. cyclophosphamide, 4 (4%) with methotrexate and 19 (21%) con mycophenolate. 2 patients (2%) were treated with biologic agents. Within the 6 months after enrolment, the mean prednisone dose (SD) was 13.7 mg/d (10.2) with a median dose of 11.22 (range 0.67-45.39). 23 patients (26.4%) received low doses, 32 (36.8%) medium doses and 4 (4.6%) high doses. 18 patients (56.3%) with low activity were not taking corticosteroids, 6 (18.8%) received low doses and 8 (25%) medium doses, with no patients taking high doses of prednisone. In comparison, in the group with high lupus activity, only 10 patients (18.2%) did not receive prednisone, 17 patients (30.9%) received low doses, 24 (43.6%) medium doses and 4 /7.3%) high doses ($p = 0.002$). The mean daily dose of prednisone in the first 6 months was significantly lower in the group with low activity, (median 0 mg/d vs 8.1 mg/d, respectively, $p = 0.001$). A significantly higher dose of prednisone was given to patients with nephritis ($p < 0.001$), anti-DNA antibodies (p 0.01) and low C3 and C4 levels ($p = 0.017$ and $p = 0.033$, respectively). Among the remaining immunosuppressive drugs, only cyclophosphamide and mycophenolate were used more frequently among patients with an SLEDAI ≥ 6 ($p = 0.047$ and $p = 0.018$, respectively). In fact, both drugs had a statistically significant association with the presence of lupus nephritis ($p < 0.001$ for both variables). There was no relation between disease activity and treatment with antimalarials, which were used in roughly 90% of patients in both the high and low activity groups ($p = 1.0$). Likewise, patients with and without lupus nephritis received antimalarials in a similar proportion (85% and 89%, respectively, $p = 1.0$).

Conclusions: Most patients in the RELES cohort received antimalarials as baseline treatment, independently of the degree of disease activity or specific organ involvement. Prolonged treatment with high doses of prednisone is exceptional. However, mean daily doses above 7.5 mg/d were given to more than 1/3 of the cohort within the first 6 months after diagnosis. Prednisone, cyclophosphamide and mycophenolate were used according to SLE activity and the presence of lupus nephritis.

IF-70
CLINICAL AND IMMUNOLOGICAL CHARACTERIZATION OF PRIMARY SJÖGREN SYNDROME IN SPAIN ANALYSIS OF 921 PATIENTS (GEAS-SEMI-SS REGISTRY)

P. Brito-Zerón[1], R. Solans[2], M. Camps[3], A. Casanovas[4], B. Sopeña[5], B. Díaz López[6], F. Rascon[7], R. Qanneta[8]

[1]Laboratory Josep Font, Department of Autoimmune Diseases. Centre Sociosanitari Hospital Clínic i Provincial de Barcelona. Barcelona, Spain. [2]Department of Internal Medicine. Hospitals Vall d'Hebron. Barcelona, Spain. [3]Department of Internal Medicine. Hospital Carlos Haya. Malaga, Spain. [4]Department of Internal Medicine. Hospital Parc Taulí. Sadabell (Barcelona), Spain. [5]Department of Internal Medicine. Complejo Universitario de Vigo. Vigo (Pontevedra), Spain. [6]Department of Internal Medicine. Hospital Universitario Central de Asturias. Oviedo (Asturias), Spain. [7]Department of Internal Medicine. Hospital Son Espases. Palma de Mallorca (Illes Balears), Spain. [8]Department of Internal Medicine. Hospital Universitari Joan XXIII. Tarragona, Spain.

Objectives: To analyse the epidemiological, clinical and immunological characteristics of a large cohort of Spanish patients diagnosed with primary Sjögren syndrome (SS).

Material and method: The GEAS-SS multicenter registry was formed in 2005 with the aim of collecting a large series of Spanish patients with primary SS, and included 21 Spanish reference centers with substantial experience in the management of SS patients. By March 2012, the database included 921 consecutive patients, recruited since 1994, fulfilling the 2002 classification criteria for primary SS.

Results: The cohort included 867 (94%) women and 54 (6%) men (female:male ratio, 16:1), with a mean age at diagnosis of primary SS of 53.81 ± 0.49 years (range, 14-88) and a disease evolution ranging from 6 to 360 months (mean, 74.9 + 4). Eight hundred and eighty two (96%) patients presented xerostomia, 878 (95%) xerophthalmia, 805/863 (93%) had altered ocular diagnostic tests

(Schirmer's test and/or rose Bengal staining), 598/676 (88%) altered parotid scintigraphy and 424/482 (88%) a salivary gland biopsy showing lymphocytic infiltrates grade 3 or 4. Three hundred and nine (34%) patients had cytopenia, including anemia (17%), leukopenia (20%) and thrombocytopenia (8%). The main immunologic features were ANA > 1/80 in 831/919 (90%) patients, anti-Ro/SS-A in 666/917 (73%), RF in 503/890 (57%), anti-La/SS-B in 419/914 (46%), low C3 levels in 80/864 (9%), low C4 levels in 102/863 (12%) and cryoglobulinemia in 81/652 (12%). Systemic involvement included articular involvement (56%), parotid enlargement (34%), respiratory involvement (13%), cutaneous involvement (13%), peripheral nervous system involvement (10%), lymphadenopathy/lymphoma (10%), renal involvement (5%) and central nervous system involvement (3%).

Conclusions: The broad heterogeneity in the clinical and analytical features of primary SS observed in this large cohort of patients suggests that SS should be considered a systemic disease more than a sicca-limited disease. Most of the clinical features and laboratory abnormalities present in primary SS patients are not included in the current 2002 classification criteria.

IF-71
MEASURING DISEASE ACTIVITY OF PRIMARY SJÖGREN SYNDROME USING THE EUROPEAN ESSDAI SCORE: IDENTIFICATION OF PREDICTIVE BASELINE FACTORS (GEAS-SEMI-SS REGISTRY)

P. Brito-Zerón[1], I. Perales Fraile[2], E. Nadal[3], G. de la Red[4], I. Fernández Regal[5], I. Jiménez Heredia[6], B. Kostov[7]

[1]Laboratory Josep Font, Department of Autoimmune Diseases. Centre Sociosanitari Hospital Clínic i Provincial de Barcelona. Barcelona, Spain. [2]Department of Internal Medicine. Hospital Universitario de Fuenlabrada. Madrid, Spain. [3]Department of Internal Medicine. Hospital Universitario de La Ribera. Valencia, Spain. [4]Department of Internal Medicine. Hospital Espíritu Santo. Barcelona, Spain. [5]Department of Internal Medicine. Complejo Hospitalario Universitario Ourense. Ourense, Spain. [6]Department of Internal Medicine. Hospital de Manises. Valencia, Spain. [7]Transverse Group for Research in Primary Care. IDIBAPS, CAP Les Corts. Barcelona, Spain.

Objectives: To evaluate the association between baseline epidemiological, clinical and immunological features and cumulative activity scores in a large cohort of Spanish patients diagnosed with primary Sjögren syndrome (SS).

Material and method: The GEAS-SS multicenter registry was formed in 2005 with the aim of collecting a large series of Spanish patients with primary SS, and included thirteen Spanish reference centers with substantial experience in the management of SS patients. By March 2012, the database included 921 consecutive patients, recruited since 1994, fulfilling the 2002 classification criteria for primary SS. Systemic involvement was characterized using the definitions included in the ESSDAI activity index. Each domain is divided in 3-4 levels according to their degree of activity and scored as 0 (no activity), 1 (low activity), 2 (moderate activity) or 3 (high activity). We retrospectively calculated the following ESSDAI scores analysing the medical charts of all patient.

Results: The cohort consisted of 921 patients, including 867 (94%) women and 54 (6%) men with a mean age at diagnosis of 54 years (range, 14-88). The domains that reached an individual mean ESSDAI score higher than 1 were the articular domain at diagnosis, and the articular, pulmonary, peripheral nervous system and hematological domains in the cumulative ESSDAI score. The variables at diagnosis that showed statistically-significant differences in the mean ESSDAI scores of the greater number of clinical domains were cryoglobulinemia (7 domains), anemia (5 domains), lymphopenia (4 domains) and ESR > 50 mm/h, anti-Ro/SS-A, low complement values and monoclonal band (3 domains). In contrast, other variables were not significantly associated with the mean ESSDAI scores of any clinical domain (leukopenia, neutropenia, ANA and RF).

Conclusions: Cytopenias (anemia and lymphopenia), anti-Ro/SS-A antibodies and cryoglobulinemic-related features (cryoglobulins, hypocomplementemia and monoclonal gammopathy) at diagnosis are key markers of cumulated systemic activity in patients with primary SS. These features are not included in the current 2002 classification criteria, and it may be time to re-evaluate the diagnosis and classification of primary SS according to these findings.

IF-74
USE OF BIOLOGICAL THERAPIES IN 430 PATIENTS WITH SEVERE AND/OR REFRACTORY SYSTEMIC AUTOIMMUNE DISEASES: BIOGEAS REGISTRY

C. Díaz Lagares[1], F. García Hernández[2], E. de Ramón[3], J. Callejas[4], A. Martínez Berriotxoa[5], L. Caminal[6], C. Tolosa[7], L. Sáez[8]

[1]Laboratory of Autoimmune Diseases "Josep Font". Centre Sociosanitari Hospital Clínic i Provincial de Barcelona. Barcelona, Spain. [2]Department of Internal Medicine. Hospital Virgen del Rocío. Sevilla, Spain. [3]Department of Internal Medicine. Hospital Carlos Haya. Málaga, Spain. [4]Department of Internal Medicine. Hospital de Especialidades San Cecilio. Granada, Spain. [5]Department of Internal Medicine. Hospital de Cruces. Barakaldo (Vizcaya), Spain. [6]Department of Internal Medicine. Hospital Central de Asturias. Oviedo (Asturias), Spain. [7]Department of Internal Medicine. Hospital Parc Taulí. Sabadell (Barcelona), Spain. [8]Department of Internal Medicine. Hospital Miguel Servet. Zaragoza, Spain.

Objectives: To analyze the efficacy and safety of biologic therapies in patients with severe and/or refractory systemic autoimmune diseases (SAD).

Material and method: In 2006, the Autoimmune Diseases Study Group (GEAS) of the Spanish Society of Internal Medicine created the BIOGEAS registry, a multicenter study designed to collect data on the use of biological therapies in patients with systemic autoimmune diseases refractory to conventional treatment (failure at least of two immunosuppressants). The information is collected from cases reported by members of GEAS (last updated: 30 June 2012).

Results: 430 patients with SAD treated with biological agents were included in the BIOGEAS registry, 325 (77%) women and 99 (23%) men, with a mean age of 56 years, affected by the following diseases: SLE 172 (40%), inflammatory myopathy 47 (11%), Behçet disease 34 (8%), Wegener granulomatosis, 28 (7%), Sjögren syndrome 26 (6%), uveitis 17 (4%), cryoglobulinemia 16 (4%) PTI 16 (4%), APS 10 (2%), Still disease 9 (2%), scleroderma 7 (2%), sarcoidosis 7 (2%), autoimmune hemolytic anemia 6 (2%), mixed connective tissue disease 5 (2%) and other pathologies 26 (6%). The biological treatment consisted in rituximab in 365 (76%), infliximab in 42 (10%), adalimumab in 31 (7%), etanercept in 22 (5%), anakinra in 4 (1%). In 4 (1%) patients other biological therapies were employed. They were heavily treated patients, who had previously received corticosteroids (410, 97%) and immunosuppressants (357, 84%), including cyclophosphamide (209, 49%), methotrexate (144, 34%), mycophenolate (127, 30%), azathioprine (128, 30%), cyclosporine A (71, 17%), tacrolimus (21, 5%) and leflunomide (7, 2%). Immunoglobulins were employed in 103 (24%) and plasma exchange in 11 (2.6%). Biological therapies were administered in combination with corticosteroids (390, 92%), immunosuppressants (242, 57%), immunoglobulins (16, 4%) and plasma exchange (11, 3%). We could evaluate the response in 398 patients, observing a complete response (CR) in 199 (49%), a partial response (PR) in 114 (28%) and

no response (NR) in 85 (21%). The time of follow-up was 27 months. During the follow-up period 72 patients (17%) relapsed and 85 (20%) suffered any adverse event, consisted in infections (49, 12%), adverse events related to the infusion (18, 4%) and other adverse events (30, 7%). During the follow up 26 patients (6%) died, being the most frequent causes progression of the disease (7 cases), infection (6), cardiovascular disease (5), and neoplasic disease (3).

Conclusions: The off-label use of biologic therapies in patients with SAD and severe or refractory manifestations could be effective and safe, being the use of rituximab in SLE the scenario in which we have more experience.

IF-76
TREATMENT OF SEVERE AND/0R REFRACTORY SYSTEMIC LUPUS ERYTHEMATOSUS WITH RITUXIMAB: ANALYSIS OF 171 PATIENTS

C. Díaz Lagares[1], F. García Hernández[2], M. Camps[3], A. Martínez Berriotxoa[4], N. Ortego[5], L. Sáez[6], L. Caminal[7], L. Pallarés[8]

[1]Laboratory of Autoimmune Diseases "Josep Font". Hospital Clínic i Provincial. Barcelona, Spain. [2]Department of Internal Medicine. Hospital Virgen del Rocío. Sevilla, Spain. [3]Department of Internal Medicine. Hospital Carlos Haya. Málaga, Spain. [4]Department of Internal Medicine. Hospital de Cruces. Barakaldo (Vizcaya), Spain. [5]Department of Internal Medicine. Hospital de Especialidades San Cecilio. Granada, Spain. [6]Department of Internal Medicine. Hospital Miguel Servet. Zaragoza, Spain. [7]Department of Internal Medicine. Hospital Central de Asturias. Oviedo (Asturias), Spain. [8]Department of Internal Medicine. Hospital Son Espases. Palma de Mallorca (Illes Balears), Spain.

Objectives: To evaluate the efficacy and safety of rituximab in patients with systemic lupus erythematosus (SLE) and severe involvement refractory to conventional treatment.

Material and method: In 2006, the Autoimmune Diseases Study Group (GEAS) of the Spanish Society of Internal Medicine created the BIOGEAS registry, a multicenter study designed to collect data on the use of biological therapies in patients with systemic autoimmune diseases refractory to conventional treatment (failure at least of two immunosuppressants). The information is collected from cases reported by members of GEAS (last updated: 30 May 2012).

Results: 171 SLE patients treated with rituximab have been included in the registry (151 women and 19 men, with a mean age of 45 years. The clinical manifestations presented by these patients that motivated the indication were as follows: glomerulonephritis (83 cases, 49%), hematologic involvement (53 cases, 31%), skin involvement (22 cases, 13%), arthritis (17 cases, 10%), pulmonary involvement (14 cases, 8%), serositis and myocarditis (12 cases, 7%), CNS involvement (8 cases, 5%), gastrointestinal involvement (5 cases, 3%). They were heavily treated patients, who had previously received corticosteroids and an average of 2.1 immunosuppressants, including cyclophosphamide (114 cases, 67%), mycophenolate (79, 47%), methotrexate (63, 37%), azathioprine (62, 37%), cyclosporine A (10, 6%), tacrolimus (7, 4%), leflunomide (4, 2%). 44 (26%) received immunoglobulins. In 101 (59%) concomitant immunosuppressive therapy was added to rituximab. We could evaluate the response in 162 patients, of whom 129 (80%) patients had a favorable response to treatment (47% complete response, partial response 33%, 20% no response). The response to treatment by organ was as follows (analyzed those organs with a minimum of 5 cases): kidney (49/77 patients, 77%), hematological (42/50, 84%), skin (13/22, 59%), arthritis (13/15, 86%), lung (12/14, 86%), CNS (6/8, 75%), myocarditis and serositis (9/12, 75%). The time of follow-up was 24 months. 30 patients (17%) suffer a relapse during follow up. 30 (18%) patients suffered an adverse event, including 18 (11%) an infection, 4 (2%) an adverse event related to infusion and 11 (7%) other adverse events. During the follow-up period died 10 (6%) patients, 3 of which died from disease progression and 2 because of infectious complications, 3 patients due to heart failure, 1 to lung embolism and 1 due to unknown cause.

Conclusions: Rituximab may be an effective and safe option for patients with severe SLE refractory to conventional treatment. Renal disease and hematologic disturbances are the manifestations that accumulates more experience in BIOGEAS registry.

IF-77
CLINICAL PATTERNS AND SYSTEMIC CORRELATIONS IN A COHORT OF POSTERIOR UVEITIS AND PANUVEITIS OF PREVIOUSLY UNKNOWN ETIOLOGY

E. Mompean Conesa[1], J. Lozano Herrero[1], M. Herranz Marín[1], A. Sánchez Guirao[1], A. Climent Albadalejo[2], E. Díaz Guía[3], J. Lajara Blesa[3], F. Herrero Huertas[1]

[1]Department of Internal Medicine, [2]Department of Rheumatology, [3]Department of Ophthalmology. Hospital General Universitario José Mª Morales Meseguer. Murcia, Spain.

Objectives: To describe clinical patterns, causes and systemic disease associations in a group of patients with posterior uveitis and panuveitis.

Material and method: Prospective study of 123 consecutive patients with uveitis referred to the Uveitis Unit of our hospital from January 2008 to May 2012. Patients with postoperative or traumatic endophthalmitis were not included. Uveitis were categorized as posterior or panuveitis using the International Uveitis Study Group classification. The causative diagnoses for specific ocular entities or systemic diseases were based on clinical history, ophthalmologic examination, and standard baseline investigations which included blood and urine analyses, VDRL test for syphilis, a chest X-ray and tuberculin skin test. Other specific tests were carried out according with the medical history. Standard diagnostic criteria were employed for all entities of uveitis and systemic diseases related to. Data were analyzed with the statistic pack SPSS 15.0 for windows.

Results: Among the 123 patients included in our study, 37 (30%) had posterior uveitis (22 cases) or panuveitis (15 cases). 59.5% were bilateral, mean ages was 32.6 years (10-68) and 51.4% were women. We achieved a specific diagnosis in 91.9% of the cases: 37.8% were of infectious origin (14 patients), 29.7% were associated with a systemic disease (11 patients) and 18.9% had a specific ocular condition (7 patients). Toxoplasmosis was found to be most common (24.3%, 9 cases), followed by Behçet's disease (6 cases, 16.2%). Idiopathic uveitis was found in 3 patients (8.1%). Infectious uveitis was significantly associated with acute presentation ($p = 0.008$) and absence of extra ocular clinical data ($p = 0.001$). Regarding the treatment, 43.2% (16 patients) received corticosteroids and 37.8% corticosteroid-sparing therapy (14 patients) such as azathioprine (8 patients), cyclosporine (8 patients), methotrexate (4 patients), cyclophosphamide (1 patient) and biologic drugs (4 patients).

Discussion: Uveitis is a major cause of severe visual impairment throughout the world. It comprises a large group of diseases characterized by intraocular inflammation involving not only the uveal tract, but also the retina, optic nerve, and vitreous. Sometimes, ocular inflammation is the initial manifestation of an undiagnosed systemic disease. Thanks to a multidisciplinary work we found a specific etiology in 91.9% of posterior uveitis and panuveitis. The most frequent etiology was infectious disease, and among them, toxoplasmosis, followed by Behçet's disease. Corticosteroid-sparing therapy has an important role in the treatment of these patients.

Conclusions: 1. A very high percentage of posterior uveitis and panuveitis in our series result to have a specific etiology (91'9%). 2.

A stepwise approach is essential while evaluating patients with uveitis: an exhaustive approach comprising a full battery of tests is out of indication. 3. Our results emphasize the usefulness of the collaboration with the internist and/or rheumatologist in the diagnostic and therapeutic management of uveitis.

IF-78
TREATMENT OF REFRACTORY PRIMARY INFLAMMATORY MYOPATHIES WITH BIOLOGICAL THERAPY CLINICAL EXPERIENCE IN 47 PATIENTS: BIOGEAS REGISTRY

C. Díaz Lagares[1], M. Castillo Palma[2], A. Selva O´Callaghan[3], J. Rascón[4], J. Callejas[5], M. Ayala[6], L. Sáez[7], J. Oristrell[8]

[1]Laboratory of Autoimmune Diseases "Josep Font". Hospital Clinic i Provincial. Barcelona, Spain. [2]Department of Internal Medicine. Hospital Virgen del Rocío. Sevilla, Spain. [3]Department of Internal Medicine. Hospital Vall d'Hebron. Barcelona, Spain. [4]Department of Internal Medicine. Hospital Son Espases. Palma de Mallorca (Illes Balears), Spain. [5]Department of Internal Medicine. Hospital de Especialidades San Cecilio. Granada, Spain. [6]Department of Internal Medicine. Hospital Carlos Haya. Málaga, Spain. [7]Department of Internal Medicine. Hospital Miguel Servet. Zaragoza, Spain. [8]Department of Internal Medicine. Hospital Parc Taulí. Sabadell (Barcelona), Spain.

Objectives: To evaluate the efficacy and safety of rituximab in patients with primary inflammatory myopathies and severe involvement refractory to conventional treatment.

Material and method: In 2006, the Autoimmune Diseases Study Group (GEAS) of the Spanish Society of Internal Medicine created the BIOGEAS registry, a multicenter study designed to collect data on the use of biological therapies in patients with systemic autoimmune diseases refractory to conventional treatment (failure at least of two immunosuppressants). The information is collected from cases reported by members of GEAS (last updated: 30 May 2012).

Results: 47 patients treated with primary inflammatory myopathies treated with biological agents have been included in the registry (34 women and 8 men, with a mean age of 49 years) are included in the BIOGEAS registry, of which 31 (66%) suffered dermatomyositis, 15 (32%) polymyositis and 1 (2%) inclusion body myositis. In 9 (18%) an antisynthetase syndrome was observed. They were heavily treated patients, who had previously received corticosteroids and an average of 2.1 immunosuppressants, including cyclophosphamide (26 cases, 58%), methotrexate in 18 (40%), azathioprine in 16 (36%), cyclosporine in 15 (33%), mycophenolate in 14 (31%), tacrolimus 5 (11%) and leflunomide 1 (2%). 44 (26%) received immunoglobulins. Clinical manifestations that prompted the use of rituximab were: myositis in 35 (80%), skin involvement in 15 (34%), interstitial lung disease in 11 (25%) and arthritis in 4 (10%). The biological therapy rituximab was used in 36 (77%) and 11 (23%) anti-TNF (7 etanercept, 3 infliximab and 1 adalimumab). In 37 (82%) concomitant immunosuppressive therapy was added to biological therapies, immunoglobulins in 8 (18%) and PE in 1 (2%). Response could be assessed in 41 patients, including a complete response (CR) in 18 (44%), partial response (PR) in 14 (34%) and no response (NR) in 9 (22%). The response was greater in patients treated with rituximab (CR 52%, PR 42% and 7% NR) than in those treated with anti-TNF (CR 20%, PR 10% and 70% NR), $p < 0.0001$. We observed the following response in the main affected organs: muscle (RC: 50%, PR: 29%, NR: 21%), skin (CR: 58%, PR: 33%, NR: 8%) and lung (CR: 53%, PR: 13%, NR: 33%). Follow-up time was 24 months. During this time 11 (23%) relapsed and 5 (12%) developed any adverse event: 4 (8%) infection and 1 (2%) adverse event related to the infusion. Four (9%) patients died during follow-up, one due to disease progression, one to colonic neoplasia, one to biliar sepsis and one of unknown cause.

Conclusions: Despite not having approved indication, biological therapies could be effective and safe in the treatment of refractory inflammatory myopathies, with the response obtained with rituximab higher than with anti-TNF.

IF-80
TUBERCULIN SKIN TESTING IN UVEITIS PATIENTS

A. Sánchez Guirao[1], E. Mompeán Conesa[1], M. Herranz Marín[1], J. Lozano Herrero[1], E. Díaz Guía[2], A. Climent Albadalejo[3], I. Vigueras Campuzano[1], F. Herrero Huertas[1]

[1]Department of Internal Medicine, [2]Department of Ophthalmology, [3]Department of Rheumatology. Hospital General Universitario José Mª Morales Meseguer. Murcia, Spain.

Objectives: To evaluate the results of tuberculin skin test (TST) in patients with uveitis, to identify the clinical ocular signs of presumed intraocular tuberculosis (TB) in our cohort and to assess the outcome of specific treatment.

Material and method: Retrospective interventional case series of 121 new consecutive patients with uveitis presenting to the Uveitis Unit of our hospital from January 2008 to March 2012. All patients underwent a full systemic review, ocular examination, and standard baseline investigations which included: blood and urine analyses, VDRL test for syphilis, a chest X-ray and TST using the standard Mantoux method. The diagnosis of presumed intraocular TB was made when intraocular findings were consistent, the TST was positive and no other cause of uveitis was found. We considered suggestive clinical signs of TB associated uveitis the presence of granulomatous inflammation, broad-based posterior synechiae, retinal vasculitis with or without choroiditis, and serpiginous-like choroiditis. Data were analyzed with the statistic pack SPSS 15.0 for windows.

Results: 15 of the 121 patients (12.2%) had a positive TST result: 8 were anterior, 2 intermediate, 4 posterior uveitis and 1 panuveitis. Mean age was 44.27 years (22-68) and 66.6% women. The predominant ocular clinical findings were granulomatous inflammation (33.3%) synechiae (33.3%), retinal vasculitis-periphlebitis (33.3%), intraocular hypertension (26.6%) and choroiditis (13.3%), including one case with serpiginous-like choroiditis. Only one patient had evidence of extraocular disease (pulmonary). There was no significant association between positive TST and age, sex or location of uveitis. We found significant association between anterior or intermediate granulomatous uveitis and positive TST ($p = 0.03$). Six patients (40%) were considered to have presumed or definitive intraocular TB disease and received ATT, 4 of them together with a tapered course of oral corticosteroids. Other 2 patients received TB isoniazid chemoprophylactic therapy because of concomitant immunosuppression for the treatment of the underlying uveitis. The clinical outcome of these patients is analyzed.

Discussion: TB can have a variety of ocular manifestations, and consequently may mimic a number of ocular inflammatory diseases. As the absence of pulmonary disease does not rule out the diagnosis of ocular TB, a high index of suspicion should be maintained in uveitis patients. Recently proposed guidelines for the diagnosis of TB uveitis include exclusion of other known etiologies of uveitis, suggestive clinical history and signs, supportive investigations such as positive TST or interferon-gamma release testing, chest X-ray findings, response to empiric antituberculosis treatment (ATT) and, in some, evidence of M. tuberculosis or its DNA in ocular fluids/tissues. Important considerations with TST include anergy and false-positives from prior BCG vaccination. Interferon-gamma release assays (IGRA) is a specific test of detecting TB without the problem of cross-reaction in patients with prior BCG vaccination, but its chief limitations are limited availability and increased expense.

Both TST and IGRA may be negative or indeterminate in immunosuppressed states. Until tests with greater proven specificity and sensitivity are developed, tuberculin skin test should remain an integral part of systemic work-up for uveitis patients.

Conclusions: 1. About 12% of patients referred to our Uveitis Unit for systemic evaluation had positive tuberculin skintesting (mantoux), and 40% of them were considered to have presumed or definitive intraocular tuberculosis. 2. The presence of granulomatous inflammation is significantly associated with positive tuberculin skin testing. 3. Tuberculin skin testing remains as a useful diagnostic test for TB-uveitis in areas where immunological methods such us interferon-gamma release assays (IGRA) are not available.

IF-81
UVEITIS DIAGNOSIS AND TREATMENT IN A COMBINED MEDICAL-OPHTHALMOLOGICAL CLINIC

A. Martínez Berriotxoa[1], J. Artaraz[2], A. Fonollosa[2], S. Eguiluz[1]

[1]Department of Internal Medicine, [2]Department of Ophthalmology. Hospital Universitario Cruces. Barakaldo (Vizcaya), Spain.

Objectives: To report the experience of an interdisciplinary uveitis clinic developed by the Services of Ophthalmology and Internal Medicine of Cruces University Hospital (Barakaldo, Spain).

Material and method: Prospective observational cohort of 122 uveitis patients. All patients with uveitis (2008-2012) were evaluated by an ophthalmologist, who established the pattern of uveitis by location, clinical course and laterality. 122 patients in which a systemic disease was suspected and/or systemic treatment was required were evaluated by an internist, who arranged the diagnostic tests depending on uveitis pattern and extraocular symptoms and signs.

Results: Uveitis pattern and diagnosis: anterior uveitis (AU): 51 (41.8%) patients: 1) Acute recurrent and nonrecurrent unilateral AU: Behçet's disease (9), idiopathic no-HLA B27 (8), idiopathic HLA B27 (7), spondyloarthropathy (5), psoriasis (1), ulcerative colitis (1), sarcoidosis (1), herpes zoster (1), temporal arteritis (1). 2) Acute bilateral AU: Idiopathic no-HLA B27 (5), psoriasis (1). 3) Chronic AU: Idiopathic no-HLA B27 (6), Fuch's heterochromic ciclitis (2), ulcerative colitis (1), psoriasis (1), breast carcinoma (1). Intermediate uveitis (IU): 17 patients (13.9%): Idiopathic intermediate uveitis/pars planitis (12), probable sarcoidosis (3), probable tuberculosis (1), probable lymphoma (1). Posterior uveitis (PU): 23 patients (18.9%): 1) Unilateral chorioretinitis: Toxoplasmosis and HIV infection (1), progressive subretinal fibrosis syndrome (1), idiopathic neuroretinitis (1), idiopathic multifocal choroiditis (1), ampiginous choroiditis (1), tuberculous serpiginous-like choroiditis (1), vasoproliferative retinal tumor (1). 2) Bilateral chorioretinitis: Serpiginous choroiditis (3), tuberculous serpiginous-like choroiditis (1), leptospirosis (1), birdshot choroidopathy (1), punctate inner choroidopathy (1), unclassified idiopathic chorioretinitis (1). 3) Retinal vasculitis: Behçet's disease (3), idiopathic retinal vasculitis (3), probable tuberculosis (1), Eales disease (1). Panuveitis: 31 patients (25.4%): 1) Chorioretinitis panuveitis: Chronic Vogt-Koyanagi-Harada (VKH) disease (4), Lyme disease (1), sympathetic ophthalmia (1). 2) Vitritis panuveitis: Sarcoidosis (3), idiopathic (4). 3) Retinal vasculitis panuveitis: Behçet's disease (1), idiopathic (1). 4) Exudative retinal detachment panuveitis: VKH disease (5), syphilis (1). 5) Unclassified panuveitis: Idiopathic (6), tuberculosis (2), sarcoidosis (1), ankylosing spondylitis (1). Treatments: 12 patients were referred to other specialists for treatment and one discontinued follow-up. 109 patients were treated in the uveitis clinic; systemic corticosteroids were required in 65 (59.6%) and immunosuppressive therapy in 52 (47.7%), 18 (16.5%) of which were treated with more than one immunosuppressant. Drugs employed were methotrexate (29 patients, 26.6%), azathioprine (22, 20.2%), cyclosporine (17, 15.6%) and cyclophosphamide (3, 2.8%). Anti-TNF agents were used in 11 (10.1%) patients, in all cases after failure of at least one first line immunosuppressive drug.

Discussion: Uveitis is a major manifestation of several diseases and differential diagnosis is often complex. In our experience, identification of the pattern of uveitis is a very helpful tool to guide the initial diagnostic plan. Systemic disease (infectious, inflammatory-autoimmune or neoplastic) was diagnosed in 53 (43.4%) of the 122 patients evaluated, and 52 (47.7%) of the 109 patients treated required immunosuppressive therapy. These results reflect the two main roles of the internists in an interdisciplinary uveitis clinic: diagnosis of extraocular diseases and immunotherapy management.

Conclusions: Diagnosis, management and follow-up of patients with uveitis requires close cooperation between ophthalmologists and internists. Diagnosis of systemic diseases and immunosuppressive therapy management are the internist's major roles in an interdisciplinary uveitis clinic.

IF-82
POLYMYOSITIS AS A SYNDROME RATHER THAN A DISEASE

J. Milisenda[1], V. Vilela[1], S. Prieto González[1], C. Cardozo Espínola[1], P. Moreno Lozano[1], A. Selva O´Callaghan[2], J. Grau[1]

[1]Muscle Research Unit. Department of Internal Medicine. CIBERER. Centre Sociosanitari Hosp. Clínic i Provincial de Barcelona. Barcelona, Spain. [2]Department of Internal Medicine. Hospital Universitari General Vall d'Hebron. Barcelona, Spain.

Objectives: The objective of the present study is to explore if true pure PM exists.

Material and method: A longitudinal retrospective and prospective search for all muscle biopsy reported as "polymyositis pattern" was performed in a database of all muscle biopsies performed at our institution from January 1997 to May 2012. The medical charts of all the included patients were revised and data regarding clinical muscle involvement, previous medical conditions, initial and final diagnosis were also collected. In addition we evaluated if the patient's final diagnosis changed over time.

Results: Forty six muscle biopsies among 1,290 fulfilled the inclusion criteria. All the muscle biopsies were evaluated by the same expert pathologist in the field of muscle pathology. The diagnoses at initial evaluation based on clinical, laboratory, and histopathological criteria wereas follows: pure PM, 10 (21.7%); inclusion body myositis (IBM), 9 (19.5%); connective tissue diseases, 15 (32.6%); cancer related myositis, 4 (8.7%); drug-induced myositis, 4 (8.7%); chronic viral infection related myositis, 2 (4.3%); muscle dystrophy, 1 (2.1%); graft versus host disease, 1 (2.1%). At follow-up evaluation, only one patient remained with a diagnosis of pure polymyositis since four diagnoses changed to IBM, three to necrotizing autoimmune myositis and two to mixed connective tissue disease. The patients with paraneoplastic, viral, drug toxicity, muscle dystrophy and graft versus host disease remained with the same diagnosis. The more frequent underlying diseases of myositis in our study were systemic sclerosis and IBM.

Discussion: Polymyositis (PM) is considered as a rare disease (code ICD 10 M33.2). Although it was originally classified as a separate entity among inflammatory myopathies, nowadays is considered as an exclusion diagnosis and was compared even to mythological beasts. It is known that infectious agents, drugs, congenital dystrophies, endocrine and systemic diseases are associated with the histological findings of the PM pattern. Although a clinical and pathological pattern for PM is worldwide admitted, no

systematic study that effectively rules out other conditions and reduces the risk of misdiagnosis has been published. In order to clarify these controversies, we decided to perform a study focusing only in patients with a muscle histopathological pattern of PM. Out of the 46 biopsies analyzed ten (21.7%) where initially identified as pure PM. After a complete evaluation and follow-up only one remained with such diagnosis, while the other nine cases where reclassified as other diseases.

Conclusions: True polymyositis apparently doesn't exist as a disease but rather seems to be a syndrome. Therefore, patients with clinical and pathological picture resembling a PM should in fact be investigated for other causes of myositis.

IF-85
SUBCLINICAL ATHEROSCLEROSIS AND MINERAL METABOLISM IN SYSTEMIC LUPUS ERITEMATOUS (SLE) PATIENTS

C. López Robles[1], R. Ríos Fernández[2], E. Moreno Escobar[3], J. Callejas Rubio[2], N. Ortego Centeno[2]

[1]Department of Internal Medicine. Hospital General de Antequera. Antequera (Málaga), Spain. [2]Department of Systemic Autoimmune Diseases, [3]Cardiology Unit. Hospital de Especialidades San Cecilio. Granada, Spain.

Objectives: Subclinical atherosclerosis is an emerging problem in Lupus patients. These patients have a higher prevalence of osteoporosis and, therefore, an accelerated bone mineral metabolism, than general population. Several authors highlight the possible relationship between the parameters of resorption/bone remodeling with inflammation and vascular calcification, which determines subclinical atherosclerosis. Different parameters have been used to find out this possible relationship. The aim of our study is to determine the correlation between bone mineral metabolism parameters (Ostase-BAP, osteocalcin, osteoprotegerin) and those related to subclinical atherosclerosis (brachial artery reactivity, carotid intima-media thickness, carotid plaques, Ankle Brachial Index (ABI)).

Material and method: We undertake a cross-sectional descriptive study in a group of SLE patients. We collected demographic and clinical data from medical records. Ostase®-BAP (Bone-specific Alkaline Phosphatase), osteoprotegerin, osteocalcin, PTH, calcium and phosphorus serum levels were determined. Cardiovascular involvement was assessed trough ankle-brachial index (ABI), carotid doppler and brachial artery reactivity. Statistical analysis was performed using SPSS 15.0.

Results: We studied 54 patients (47 women, 88.1%) with a median age of 45.5 years. Demographic and clinical characteristic are shown in Table 1. Ostase®-BAP, osteoprotegerin, osteocalcin, PTH, calcium and phosphorus serum levels are shown in Table 2. Ostase®-BAP serum levels significantly correlates with intima-media thickness ($r = 0.292$, $p < 0.47$) but not with other parameters of subclinical atherosclerosis or the ABI. No correlation was found between the levels of other bone mineral metabolism parameters and subclinical atherosclerosis or the ABI. Only 7 patients of the entire sample had carotid plaques.

Discussion: Ostase-BAP is a bone remodeling marker that has been useful as a biochemical marker of bone metabolism in diseases such as osteoporosis or Paget's disease. In both diseases this parameter increases. In turn, the intima-media thickness has been extensively studied in the last decade as a marker of atherosclerosis, in such a way that when larger, higher risk of atherosclerosis. According to our data, higher levels of Ostase-BAP (increases remodeling), are associated with an increased intima-media thickness (and cardiovascular risk), which is consistent with other studies published so far.

Conclusions: Our results suggest that high levels of BAP-Ostase could be a useful parameter in order to establish an intima-media thickness alteration. However, more studies with larger numbers of patients are needed. Prospective studies could be also useful in order to confirm this.

Table 1 (IF-85). Demographic and clinical characteristic

Variable	Mean ± SD/n (%)
Age (years)	45.85 ± 13.1
Sex (Female/Male)	47/7 (87/13)
Smoking (Yes/No)	16/38 (29.6/70.4)
HTA (Yes/No)	14/40 (25.9/74.1)

IF-93
EARLY VERSUS LATE ONSET SYSTEMIC SCLEROSIS: ANALYSIS OF 1037 PATIENTS FROM RESCLE REGISTRY

M. Alba[1], J. Mejía[1], G. Espinosa[1], M. Egurbide[2], C. Tolosa[3], L. Trapiella[4], C. Simeón[5], V. Fonollosa[5] and the RESCLE Investigators

[1]Department of Autoimmune Diseases. Centre Sociosanitari Hospital Clínic i Provincial de Barcelona. Barcelona, Spain. [2]Department of Internal Medicine. Hospital de Cruces. Barakaldo (Vizcaya), Spain. [3]Department of Internal Medicine. Corporación Sanitaria Universitaria Parc Taulí. Sabadell (Barcelona), Spain. [4]Department of Internal Medicine. Hospital Universitario Central de Asturias. Oviedo (Asturias), Spain. [5]Department of Internal Medicine. Hospitals Vall d'Hebron. Barcelona, Spain.

Objectives: To determine if the age at disease onset may modulate the clinical characteristics and evolution of patients with SSc.

Material and method: The Spanish Network for Systemic Sclerosis recruited 1037 patients with a mean follow-up of 5.2 ± 6.8 years. Based on the mean ± 1SD of age at disease onset (45 ± 16 years), patients were classified in 3 groups; Group 1: age equal or below 30 years (early onset); Group 2: age between 31 and 58 years, and Group 3: age equal or older than 59 years (late onset). We compared the initial clinical presentation, capillaroscopy pattern, immunological features, cumulative clinical manifestations and death rates between the three groups.

Results: One hundred and ninety five patients belonged to group 1, 651 to group 2 and 191 to group 3. Female distribution was similar between the three groups (91%, 86%, and 88%). Interestingly, time from disease onset to diagnosis was significantly higher in patients with early onset (group 1) (12 ± 13, 5.8 ± 6.7, and 2.4 ± 3.6 years; $p < 0.001$). Raynaud's phenomenon was the most frequent initial manifestation without differences between the three groups (88%, 84%, and 78%; $p = 0.134$). Patients with early onset SSc had higher prevalence of myositis (11%, 7.2%, and 2.9%; $p = 0.009$), esophageal involvement (72%, 67%, and 56%; $p = 0.004$) and lower prevalence of centromeric antibodies (33%, 46%, and 47%; $p = 0.007$). In contrast, patients with late onset SSc was characterized by lower prevalence of digital ulcers (54%, 41%, and 34%; $p < 0.001$) but higher rates of heart conduction system alterations (8.7%, 13%, and 21%; $p = 0.004$), and pulmonary hypertension (12%, 19%, and 25%; $p = 0.048$). Mortality tended to be higher in late onset patients (9.7%, 15%, and 18%; $p = 0.053$) and the Kaplan-Meier survival curves were significantly different ($p < 0.0001$) for the three groups of patients.

Conclusions: Age at disease onset is associated with differences in clinical presentation and outcome in patients with SSc.

IF-138
DIAGNOSTIC FEATURES AND MORTALITY CAUSES IN A LARGE COHORT OF SPANISH PATIENTS WITH ANCA-ASSOCIATED VASCULITIDES (REVAS STUDY)

R. Solans[1], L. Caminal[2], G. Fraile[3], L. Sáez[4], J. Ríos[5], M. Zamora[6], X. Solanich[7], M. Rodríguez[8] and REVAS Study Members from Spain

[1]Department of Internal Medicine. Hospital Universitario Valle de Hebron. Barcelona, Spain. [2]Department of Internal Medicine. Hospital Universitario Central de Asturias. Asturias, Spain. [3]Department of Internal Medicine. Hospital Universitario Ramón y Cajal. Madrid, Spain. [4]Department of Internal Medicine. Hospital Universitario Miguel Servet. Zaragoza, Spain. [5]Department of Internal Medicine. Hospital Universitario La Paz. Madrid, Spain. [6]Department of Internal Medicine. Hospital Universitario Virgen de las Nieves. Granada, Spain. [7]Department of Internal Medicine. Hospital Universitario Bellvitge. Barcelona, Spain. [8]Department of Internal Medicine. Hospital Mutua de Terrasa. Barcelona, Spain.

Objectives: To describe the clinical features present at ANCA-associated vasculitides (AAV) diagnosis and to investigate the causes of mortality in a large cohort of patients from Spain.

Material and method: We analyzed the demographic, clinical and laboratory features of all patients diagnosed with AAV in 15 different Hospitals from Spain, between January 1995 and December 2011. The statistical analysis was performed using the SPSS vs 15.0.

Results: 276 patients were included: 118 with GPA, 107 with MPA and 51 with EGPA. ANCA were positive in 85.9% of cases: 33.8% C-ANCA and 51.8% P-ANCA. The mean age at diagnosis was 55.8 ± 17.4 years. The mean follow-up was 80.6 ± 74.33 months. The most frequent features at diagnosis were fever (51.8%), constitutional symptoms (43.8%), arthralgia (56.2%), hemoptisis (21%) and purpura (20.3%). Renal failure was present in 47.5% of patients, lung involvement in 45.5%, and pulmonary-renal syndrome in 14.5%. Sensory peripheral neuropathy was detected in 26.1% of cases and ENT in 35.1%. Renal failure, alveolar haemorrhage and pulmonary-renal syndrome were significantly most frequent in MPA ($p = 0.000$, $p = 0.016$ and $p = 0.032$, respectively), and ENT involvement in GPA ($p = 0.000$). Lung infiltrates and mononeuritis multiplex were more frequent in EGPA ($p = 0.002$). All patients were treated with oral corticoids (CS) and 48.2% also received intravenous CS pulses. CYC was given to 82.2% of patients (37.7% intravenously and 44.6% orally). Dialysis was required in 16.7% of cases and plasma exchange in 6.5%. During the follow-up 34.8% of patients suffered bacterial infections, 12.7% opportunistic infections, and 4.7% neoplasm. Bacterial infections were most frequent in patients with leukopenia ($p = 0.000$), CS pulses ($p = 0.030$), oral CYC ($p = 0.004$), and dialysis ($p = 0.005$). Opportunistic infections were also most frequent in patients with renal failure ($p = 0.008$), CS pulses ($p = 0.001$), and leukopenia ($p = 0.000$). Fifty-five (19.9%) patients died: 33 with MPA, 15 with GPA, and 3 with EGPA. Mortality was significantly related to renal failure ($p < 0.000$), nephrotic syndrome ($p = 0.024$), myocarditis ($p = 0.014$), urinary tract infections ($p = 0.017$), opportunistic infections ($p = 0.001$), neoplasm development ($p = 0.012$), MPA ($p = 0.005$), and age older than 65 years at diagnosis ($p = 0.001$).

Discussion: AAV are chronic and relapsing diseases characterized by inflammatory cell infiltration and necrosis of small blood vessel walls. Fever, arthralgia, constitutional syndrome, renal failure and lung involvement are the most frequent diagnostic features. Severe renal and cardiac involvement, infections, and neoplasm are the most frequent causes of death. Infections are more frequent in patients treated with oral CYC and high doses of CS. Immunosuppressant drugs less toxic than CYC, and biological therapies are increasingly used in order to reduce the conventional treatment toxicity and the mortality related to infections.

Conclusions: In spite of therapy, AAV are still related to a high mortality and morbidity. The illness severity and infections related to treatment, are the most frequent causes of death. New therapies should be investigated in order to reduce the treatment toxicity and the mortality related to infections.

Osteoporosis

O-1
INFLUENCES OF BLOOD PRESSURE LOWERING ON BONE TURNOVER AND OPG/RANKL/RANK SYSTEM IN NEWLY DIAGNOSED HYPERTENSIVE ADULTS

M. Naharci[1], M. Karaman[2], S. Ay[2], S. Tapan[3], I. Tasci[1], U. Safer[1], N. Karadurmus[2], E. Bozoglu[1]

[1]Department of Geriatrics, [2]Department of Internal Medicine, [3]Department of Medical Biochemistry. Gulhane Medical Faculty Training Hospital. Ankara, Turkey.

Objectives: Blood pressure lowering has been reported display favorable effects on bone turnover in subjects with hypertension. Moreover, renin angiotensin aldosterone system blockage was shown to exert beneficial effect on parenchymal bone cells. The present pilot study was conducted to search for the effects of antihypertensive medication on circulating bone remodeling.

Material and method: Forty subjects with newly diagnosed and never treated hypertension who were free of any other metabolic/chronic disease or medication were included in the study ($n = 40$, mean age 54.9 ± 10.6 years). Patients were randomly divided into two groups and received monotherapy with amlodipine 5 mg or valsartan 80 mg, with a double dose after two weeks in uncontrolled hypertensive subjects. Blood bone turnover markers and osteoprotegerin (OPG)/RANKL/RANK system were measured before and after a 12-week treatment.

Results: Both treatment arms resulted in significant and equal levels of systolic and diastolic blood pressure lowering. Treatment of individuals either with amlodipin or valsartan did not result any change in serum osteocalcin or serum C-telopeptide of type I collagen (CTX) level (Table). However, amlodipin caused some reduction in CTX blood level compared to valsartan but the difference between the two was not significant (9.5% versus 1.0%, $p = 0.421$). Antihypertensive treatment reduced circulating soluble RANKL (sRANKL) level significantly ($p = 0.004$), however this was evident only in the amlodipin treated subjects ($p < 0.001$) (Table). Although blood OPG concentration did not show any difference after the treatment, sRANKL/OPG ratio decreased significantly by the end of 12th weeks ($p < 0.001$). The decrease in blood sRANKL level correlated negatively to circulating vitamin D concentration ($r = 0.420$, $p = 0.023$).

Discussion: To our knowledge, this is the first human study searching for the association of antihypertensive drug use and bone remodeling markers.

Conclusions: Antihypertensive treatment did not affect circulating bone turnover markers in the present study. Amlodipin resulted in some decrease in blood sRANKL level, suggesting that it may be a better option than valsartan to prevent of bone loss in hypertensive adults.

Table 1 (O-1). Effects of antihypertensive therapy on bone remodeling markers

	Amlodipin (n = 20) Before	Amlodipin (n = 20) After	Valsartan (n = 20) Before	Valsartan (n = 20) After	p1 (A vs V before)	p2 (A before vs after)	p3 (V before vs after)
Osteocalcin (ng/mL)	8.01 ± 3.03	8.46 ± 3.88	8.47 ± 4.28	9.35 ± 3.28	0.697	0.505	0.160
CTX (ng/mL)	18.2-617.3	16.7-560.9	23.4-544.2	25.6-598.8	0.340	0.263	0.881

sRANKL (pmol/L)	97.9-2290.1	58.6-1113.4	60.4-331.2	103.3-320.2	0.127	< 0.001	0.502

O-3
OSTEOPOROTIC HIP FRACTURES IN A TERTIARY HOSPITAL IN CANTABRIA, SPAIN

M. Fernández García[1], L. Velasco Arjona[2], J. Martínez[3], J. Olmos Martínez[1], J. González Macías[1], J. Hernández Hernández[1]

[1]Department of Internal Medicine. Hospital Valdecilla. Santander (Cantabria), Spain. [2]Department of Internal Medicine. Hospital Sierrallana. Torrelavega (Cantabria), Spain. [3]Department of Clinical Biochemistry. Hospital Comarcal de Laredo. Laredo (Cantabria), Spain.

Objectives: To analyze the epidemiological features of hip fracture in an urban tertiary hospital in a region of Northern Spain.

Material and method: We have reviewed retrospectively all the clinical charts of patients, aged 50 years or more, admitted to our hospital from January 2010 to December 2010, with a diagnosis of hip fracture. Patients who had suffered a high-impact trauma or underlying pathological condition, such as bone cyst, cancer, Paget disease of bone, etc. were excluded. Data were obtained through the informatized database of the "Clinical Documentation and Admission Department". Codes used on our search were 820.0–820.9 according to the international classification of diseases, ninth edition (ICD-9-CM).

Results: We have included 289 patients (63 men –21.8%- and 226 women). Mean age was 83.1 (range, 54-99). Seventy-two percent of patients (n = 210) lived in urban areas. Fall was at home in 89.2% of the cases (n = 239). Seventeen subjects (6.3%) had sustained a previous hip fracture. Fourteen patients were on antiosteoporotic drugs (71.4% bisphosphonates) and 26 did receive oral calcium and/or vitamin D (61.5% calcium and vitamin D). Forty five per cent patients (n = 130) had a cervical fracture and 159 a trochanteric one. Fracture was on the left side in 52.9% of the cases (n = 153). Ninety-six percent of patient underwent surgery (n = 166 osteosynthesis and n = 108 prostheses). Postsurgical complications occurred in 74 patients (27%), the most frequent being respiratory infection (n = 9), cardiac failure (n = 5) and sixteen per cent presented prosthesis-related complications (n = 3 mobilization or fracture and n = 9 infection). Mortality was 20.4% (n = 57). Only three patients died during the first month after admission and the rest in the first year after discharge.

Discussion: In our cohort, hip fracture occurred mainly in patients 80 or older, living in urban areas who sustained a fall at home. The female-male ratio was 3.5. Trochanteric fractures, mainly perthrocanteric, were the more frequent type, in both sexes. Surgery remains the mainstay in the treatment of hip fracture according to published data with a high incidence of post-surgical complications increasing consequently the duration of hospital stay and health burden of osteoporotic fractures. Mortality was about 20% in our series, affecting main way older patients with greater comorbidity. Almost all fractured patients in our study, did not receive any antiosteoporotic drug (bisphosphonates, PTH) or supplementation with calcium, associated or not to vitamin D, prior to the event.

Conclusions: Despite having an easily accessible health service and appropriate diagnostic and therapeutic instruments, hip fracture is today a prevalent complication of osteoporosis with a non-negligible morbidity and mortality. Detection of patients at risk for this condition and the implementation of early and proper therapy when needed, could prevent, to a greater extent this type of fracture.

O-4
OSTEOPOROTIC HIP FRACTURES IN A SECONDARY HOSPITAL IN CANTABRIA, SPAIN

L. Velasco Arjona[1], M. Fernández García[2], J. Martínez[3], J. Olmos Martínez[2], J. González Macías[2], J. Hernández Hernández[2]

[1]Department of Internal Medicine. Hospital Sierrallana. Torrelavega (Cantabria), Spain. [2]Department of Internal Medicine. Hospital Valdecilla. Santander (Cantabria), Spain. [3]Department of Clinical Biochemistry. Hospital Comarcal de Laredo. Laredo (Cantabria), Spain.

Objectives: To analyze the epidemiological features of hip fracture in a secondary hospital in a region of Northern Spain.

Material and method: We have studied retrospectively all the clinical charts of patients aged 50 years or more, and admitted to our hospital from January 2010 to December 2010, because of hip fracture. Subjects with fractures due to a high-impact trauma, or to an underlying pathological condition, such as bone cyst, cancer, Paget disease of bone, etc., were excluded. Data were obtained through the informatized database of the "Clinical Documentation and Admission Department. Codes used on our search were 820.0–820.9 according to the international classification of diseases, ninth edition (ICD-9-CM).

Results: We have included 186 patients (50 men –27%- and 136 women). Mean age was 84.9 (range, 50-101). Seventy-two percent of patients lived in rural areas. Nineteen subjects (10%) had sustained a previous hip fracture. Only two patients were on antiosteoporotic drugs (calcitonin and teriparatide), and 8 did receive oral calcium and/or vitamin D. Fall was at home in 85% of the cases (n = 161). Eighty-six patients (46%) had a cervical fracture and 100 a trochanteric one. Fracture was on the right side in 57% of the cases. Ninety-eight percent of patient underwent surgery (osteosynthesis or prostheses). Postsurgical complications occurred in 31 patients (17%), the most frequent being respiratory infection, cardiac failure and prosthesis-related complications (movilization or infection). Mortality was 9.7% (n = 18). Seven died during the first month after fracture, and 11 in the first year.

Discussion: In our study, hip fracture occurred mainly in the elderly, in patients living in rural areas, and who sustained a fall at home. Trochanteric fractures were more frequent than cervical ones. Surgery remains the mainstay in the treatment of hip fracture, but post-surgical complications can occur. Mortality was about 10% in our series. Moreover, we have observed that, almost all fractured patients in our study, did not receive antiosteoporotic drugs.

Conclusions: Hip fracture is a prevalent complication of osteoporosis with a high morbidity and mortality. Detection of

patients at risk for this condition and a proper therapy when needed, could prevent, to a greater extent this type of fracture.

O-5
ASSESSMENT OF VERTEBRAL DEFORMITY IN WARFARIN-TREATED WOMEN

L. Briongos Figuero, T. Gómez Traveso, L. Hernanz Román, A. Gutiérrez García, V. de la Cruz Palomero, S. Rizzo Raza, E. Izquierdo Delgado, L. Inglada Galiana

Department of Internal Medicine. Hospital Universitario Río Hortega. Valladolid, Spain.

Objectives: Osteoporosis is the most common bone disease and lot of drugs can cause bone loss. Warfarin inhibits the gamma-carboxylation of osteocalcin and may adversely affect skeletal health. Our aim was to determine if warfarin-treated women have more vertebral fractures than non-warfarin treated ones.

Material and method: Retrospective study in elderly women taking warfarin. We included 105 cases (women with atrial fibrillation taking warfarin) and 78 controls (women hospitalized in the Internal Medicine ward not taking anticoagulant treatment). Presence of vertebral deformity was valuated using Genant semi-quantitative method on lateral chest radiography. Data were analyzed using SPSS v15.0 (statistical significance: $p \leq 0.05$) and expressed as mean ± standard deviation, frequencies and percentages, and chi-square test for associations between variables.

Results: 105 warfarin-treated women were identified. Mean age was 80 ± 7 years and 60% were aged ≥ 80 years. Of the 105 patients, 82% arterial hypertension, 41% had heart failure, 34% stroke, 25% diabetes mellitus, 18% vascular disease, 16% kidney failure, 16% dementia and 18% previous fall. Warfarin users and non-users had similar age (79 ± 7, 51% aged ≥ 80 years) and similar prevalence of diabetes mellitus (25% vs 23%). Compared to non-users, warfarin-treated patients had more arterial hypertension (82% vs 52%, $p < 0.001$), more heart failure (41% vs 15.4%, $p < 0.001$), more stroke (34% vs 1.3%, $p < 0.001$) and more kidney failure (16% vs 5%, $p < 0.001$). Warfarin non users had no previous fallen, dementia neither vascular disease. Regarding vertebral deformity rate, 28.6% (n = 30) of warfarin taking patients had vertebral fracture on lateral chest radiography and 29.5% (n = 23) of non-warfarin-treated patients had vertebral deformity, without significant differences between both groups.

Discussion: Contrary to our expectations, we found no association between use of warfarin and vertebral deformity rate in this cohort of older women. Clinical relevance of these observations is uncertain due to contradictory data in scientific literature. Some studies have found that patients taking warfarin has lower bone density than control patients related with long-term exposure to this drug (Philip et al. QJM. 1995;88:635; Caraballo et al. Arch Intern Med. 1999;159:1750). However, other studies reflect that warfarin had no adverse effect on bone density, bone loss or fracture rate (Rosen et al. Am J Med. 1993;94:62; Jamal et al. Ann Intern Med. 1998;128:829) like in our investigation. Differences found in our series regarding chronic disease are logic and had no relevance to the main aim of our study.

Conclusions: Since warfarin inhibits gamma-carboxyglutamate formation, it is suspected that warfarin use accelerates bone loss and increases fracture risk. Despite our study had several limitations due to lack data in clinical records and retrospective design, our series provides data not before reported in our Health Care Area. More extensive studies are necessary to confirm these data.

O-6
OSTEOPOROSIS IN DOWN SYNDROME

R. Costa Segovia, C. García Martínez, R. de Miguel Buckley, F. Moldenhauer Díaz

Department of Internal Medicine. Hospital Universitario de la Princesa. Madrid, Spain.

Objectives: Down syndrome (DS) is the most frequent chromosome abnormality in newborns and also the most frequent cause of intellectual disability. However, the life expectancy in this group has increased and many now survive more than 45-50 years, and therefore it is mandatory to pursue research not only in paediatric but also in adult age. It has been demonstrated that patients with DS have a lower bone mineral density (BMD), independent of their age and sex, compared with people not affected by this syndrome. We present a descriptive study of the bone mass of our DS patients, and different epidemiologic and clinical features that may affect it.

Material and method: A descriptive retrospective study of BMD, nutritional and hormonal parameters of 104 DS outpatients, obtained via standard blood analysis and dual energy X-ray absorptiometry (DXA). Osteoporosis was defined by T score equal or under -2.5. Osteopenia as T score between -1 and -2.5.

Results: There was an equal sex distribution with 50% males and 50% females, a mean age of 32.7 years (range 15-62), 61.3 kg of mean weight (39-95.5 kg) and 148.4 cm of mean height (range 128-177 cm). From our group of patients, of which 29.8% were obese, 30.7% overweight and 39.4% normal weight, the mean Body Mass Index (BMI) was 27.95 kg/m^2. 25% of patients were over 40 years, of which 14 (53.8%) were women, 8 (57%) of them post-menopausal. Vitamin D average levels were 25.44 ng/ml, a 35.6% insufficiency (< 30 ng/ml) and 36.5% deficiency (< 20 ng/ml) of vitamin D was observed. Secondary hyperparathyroidism was observed in 5.8% of patients. Betacrosslaps levels were increased in 32.5% of patients whereas 99% presented normal alkaline phosphatase. It was found that 10.6% of women had low oestrogen levels. Compared with BMD of same age and sex, 93% of patients had an appropriate femoral mineral density but only a 63% presented normal lumbar spine bone density. When compared to healthy 30 -year old patients (T score), DS patients presented 2.9% of femoral osteoporosis and 35% of femoral osteopenia, while if we refer to lumbar spine osteoporosis we can objectify a 48.1% of osteopenia, and 22.1% of osteoporosis. As expected, age and bone disease are associated and a statistically significant association was established between having lumbar spine and femoral bone affected ($p < 0.001$). Lumbar (p 0.023) and femoral (p 0.038) osteopenia and osteoporosis were also statistically significantly associated to low oestrogen levels. No statistically significant association was established in our study between Vitamin D levels, betacrosslaps, weight or gender with BMD measured with DXA. There was a tendency for males to have more bone disease, but no statistically significant association was found.

Discussion: As previous studies have suggested, our DS patients presented more frequently an altered BMD, which allows us to compare their osteoporosis/osteopenia prevalence to that of Spanish women between 60-69 years of age. However this was not associated with higher bone resorption or low Vitamin D levels. Our data reveals that males with DS have a higher tendency for osteoporosis, although no relationship with hypoandrogenism was established.

Conclusions: Down syndrome patients present altered DXA with higher frequency than population non affected by the syndrome, albeit with some specific characteristics. Therefore it would be necessary to perform further studies in search of biomechanic, genetic and hormonal factors that may interfere in their bone alterations and differentiate them from those of the general population.

O-8
FACTORS THAT INFLUENCE FRACTURE TYPE, MORTALITY AND FUNCTIONAL RECOVERY IN OLD PATIENTS WITH OSTEOPOROTIC HIP FRACTURE

A. Contra Carne[1], A. Montero Sáez[1], C. Gómez-Vaquero[2], I. Martín-Esteve[2], M. Aparicio[2], L. Boix Palop[1], F. Formiga[1], R. Pujol Farriols[1]

[1]Department of Internal Medicine. Hospital Universitari de Bellvitge. L'Hospitalet de Llobregat (Barcelona), Spain. [2]Department of Rheumatology. Hospital Universitari de Bellvitge. L'Hospitalet de Llobregat (Barcelona), Spain.

Objectives: To analyze patients (pats) admitted for hip fracture (Fx) secondary to a low impact trauma and to investigate determinants of morbimortality and presence of determining factors on the type of Fx.

Material and method: From March 1, 2009 to December 31, 2010, all pats admitted with osteoporotic hip Fx in a university hospital, were visited in a prospectively and formalized way. Sociodemographical, clinical and analytical data were collected. Data referred to the patient's status before the Fx, complications arising during admission and at discharge. Phone follow-up were performed after 3 months and after one year of hospital discharge. We analyzed which variables were associated with cognitive and functional recovery and mortality. We assumed that there would be functional recovery if one of these premises were met: positive opinion from the pat or family, no significant decline of the Barthel index (BI) (lower than 20 points) and maintenance of walking ability (self moving ability, a support, walker or wheelchair). We assumed there was cognitive recovery when the opinion of the pat or the family was positive and showed no deterioration in the Pfeiffer test (PT).

Results: 425 pats were included with a mean age 83 ± 8 years. Women (72%) were older than men (84 ± 8 versus 81 ± 8 years, $p < 0.01$). On admission, the body mass index (BMI) was 25.7 ± 4.8 Kg/m^2. The Charlson comorbidity index (CI) medium was 1.7 ± 2.0 and BI, 76 ± 29 points. Pats were categorized according to mistakes in the PT: The median ± SD was 1.82 ± 1.09. 15.9% of pats, 14.3% and 12.8% showed mild, moderate or severe deterioration, respectively. Dementia was present in 69 pats (17.64%). The mean number of currently taken drugs was 6 ± 5. Regarding laboratory parameters, mean haemoglobin was 11.8 ± 1.9 g/dL, serum creatinine, 98 ± 72 mmol/L (normal renal function in 65% of patients, estimated by the MDRD-creatinine clearance rate), albumin levels were 31.4 ± 4.3 g/L. With respect to bone metabolism, a calcidiol serum level of 29.2 ± 24.7 nM/L stands out. The majority of Fx was either pertrochanteric (45%) or subcapital (43%). The most frequent surgical procedure was placement of osteosynthesis material (59%). Subcapital Fx were associated with a lower previous status estimated by the BI (71 ± 33 vs 79 ± 24; $p < 0.01$) and PT (55% vs 45% of the pats with some degree of deterioration; $p < 0.05$). None of the other analyzed variables was related with the type of hip Fx. Seven% of the pats died during hospitalization, 9% before the 3 months and 9% during the first year. Statistically significant factors associated with higher mortality were: male gender, older age, lower BMI, worse CI, IB and PT, higher drugs use, hypovitaminosis D, worse renal function and lower concentrations of serum albumin and haemoglobin. The type of Fx or surgical intervention was not associated with mortality. In surviving pats, the frequency of functional recovery after 3 months and after one year was 63% and 61% respectively (p not significant). Cognitive recovery was 35% and 36% respectively (p not significant). Statistically significant variables that determined the absence of functional recovery were older age and lower calcidiol and serum albumin. A lower cognitive recovery was determined by older age, worse IB and worse PT.

Conclusions: Pats with hip Fx present a high mortality. On admission, predictors of morbidity and mortality were male gender, older age, lower BMI, worse CI, IB and PT, higher drugs use, hypovitaminosis D, worse renal function and lower concentrations of serum albumin and haemoglobin. In pats with hip Fx, a more evident deterioration in functional status and a poorer previous cognitive state determines a larger frequency of subcapital Fx.

O-9
THERAPIES WITH CALCIUM SUPPLEMENTS OR ANTIRESORTIVES IN OLD PATIENTS BEFORE AND AFTER OSTEOPOROTIC HIP FRACTURE

L. Boix Palop[1], A. Montero Sáez[1], C. Gómez-Vaquero[2], M. Aparicio[2], I. Martín Esteve[2], A. Contra Carne[1], F. Formiga[1], R. Pujol Farriols[1]

[1]Department of Internal Medicine, [2]Department of Rheumatology. Hospital Universitari de Bellvitge. L'Hospitalet de Llobregat (Barcelona), Spain.

Objectives: To investigate phospho-calcium metabolism in patients (pats) with hip fracture (Fx), with special emphasis on the serum concentration of calcidiol and response to supplements of calcium (Ca) and vitamin D (vitD). Another aim was to analyze the osteoporotic Fx prevention in these pats before and after the Fx.

Material and method: From March 1, 2009 to December 31, 2010, all pats admitted with osteoporotic hip Fx in an university hospital, were visited in a prospectively and formalized way. Sociodemographical, clinical and analytical data were collected. Data referred to the patient's status before the Fx, complications arising during admission and at hospital discharge. Analytical parameters of phospho-calcium metabolism were identified in peripheral blood. Pats were inquired about administration of Ca and/or vitD supplements. With regard to phospho-calcium metabolism, pats with a glomerular filtrate < 30 ml/min were excluded (n: 101). Deficiency of vitD was defined as the serum concentration of calcidiol < 25 nM/L and insufficiency as < 50 nM/L.

Results: We included 425 pats with a mean age 83 ± 8 years. Women (72%) were older than men (84 ± 8 versus 81 ± 8 years, $p < 0.01$). On admission, the Barthel index was 76 ± 29 points. Pats were categorized according to mistakes in the Pfeiffer's test: The median ± standard deviation was 1.82 ± 1.09. 15.9% of patients, 14.3% and 12.8% showed mild, moderate or severe deterioration, respectively. Dementia was present in 69 pats (17.64%). Regarding laboratory parameters, mean haemoglobin was 11.8 ± 1.9 g/dL, serum creatinine, 98 ± 72 mmol/L (normal renal function in 65% of pats, estimated by the MDRD-creatinine clearance rate), albumin levels were 31.4 ± 4,3 g/L and calcidiol serum level was 29.2 ± 24.7 nM/L. With regard to phospho-Ca metabolism, we included finally 324 pats (83 ± 8 years, 71% women). 58% of pats had vitD deficiency. The monthly distribution of the average concentrations of calcidiol showed a statistically significant increase in the summer months. Pats receiving Ca and vitD supplements had a higher mean serum concentration of calcidiol (47.6 ± 43.4 nM/L vs 25.2 ± 11.2 nM/L; $p < 0.001$), a lower vitD deficiency (24% vs 60%; $p < 0.001$) and insufficiency (71% vs 96%; $p < 0.001$) than those who did not receive them. 77 pats (18%) reported to have been diagnosed osteoporosis. 144 (39%) had had an osteoporotic Fx. 39 (11%) had undergone to a bone densitometry. 88 pats (23%) had been treated with Ca and vitD. 60 pats (19%) had received antiresorptive or anabolic treatments (AAT), 56 (14%) were taking some AAT at the time of admission (bisphosphonates [BisP]: 80%, strontium ranelate [SRa]: 14%; calcitonin: 6%). 30% of pats with prior Fx were receiving AAT as opposed to 14% of non-fractured ($p < 0.001$), 84% of pats with a previous hip Fx were not receiving AAT. AAT administration was not related to age or cognitive or functional previous status. At discharge, AAT was prescribed to 244 pats (63%): BisP: 88%, SRa: 11%; teriparatide: 1%. Three months after hospital discharge, 155 pats (48%) continued receiving AAT: BisP: 85%, SRa: 13%, raloxifene: 2%, teriparatide: 1%. One year after discharge, 139 (47%) were

receiving AAT: BisP: 85%, SRa: 9%, raloxifene: 3%, teriparatide: 3%, calcitonin: 1%.

Conclusions: In hospitalized patients with hip Fx, there is a high prevalence of hypovitaminosis D which did not achieve a satisfactory decrease in the subgroup that received vitD supplements. In a high Fx risk population, the frequency of treatment for the prevention of Fx is very low, regardless of age and of the previous cognitive and functional status. The treatment adherence decreases after hospital discharge but it is higher than what has been reported in previous studies.

O-14
LOW BONE MINERAL DENSITY IN A COHORT OF FEMALES WITH SYSTEMIC LUPUS ERYTHEMATOSUS

P. Flors Villaverde, A. Aljibe Aguilar, R. González Mazario, L. Micó Giner, J. Calabuig Alborch

Department of Internal Medicine. Hospital Universitario La Fe. Valencia, Spain.

Objectives: Assess the prevalence of low bone mineral density (BMD) in a cohort of patients with Systemic Lupus Erythematosus (SLE) and identify risk factors associated with it.

Material and method: Retrospective and descriptive analysis of 77 female patients with SLE (ACR criteria 1997), recorded in a database on the Internet (www.registroles.es). BMD was estimated in all patients by calcaneal peripheral densitometry (densitometer PIXI-Lunar®) and was considered pathological with a T-score < -0.6 (osteopenia T < -0.6, osteoporosis T < -1.6). Risk factors assessed were age, body mass index (BMI), smoking, sedentary lifestyle, whether patients had reached menopause and its age of onset, duration of SLE, the number of outbreaks, treatment with pulses of intravenous corticosteroids, disease activity index (SLEDAI) and SLICC damage index. The data were processed using SPSS 20.0.

Results: The mean age of patients was 39.2 ± 1.4 years, with an average disease duration of 120.4 ± 11.1 months and 4.6 ± 0.8 disease outbreaks. The mean SLEDAI and SLICC damage index at the time of registration were 4.9 ± 0.5 and 1.7 ± 0.2, respectively. The average BMI was 24.7 ± 0.5. 71.4% of patients were premenopausal, 39% smokers and 66.2% had a sedentary lifestyle. Only 10.4% had received pulses of intravenous steroids. BMD was pathological in 28 of the patients (36.4%), of which 19 had osteopenia (24.6%) and 9 osteoporosis (11.7%). Comparing both groups with normal and pathological bone densitometry, the only variables with statistical significance were menopause, disease duration and menopause.

Conclusions: 1. These patients were mostly young and of reproductive age. They had a long disease duration, moderateactivity and low chronicity. 2. There was a high prevalence of potentially modifiable risk factors (smoking and physical inactivity). Only one tenth of the patients had received intravenous steroids. 3. More than a third of the patients had low BMD. More than a tenth had osteoporosis. 4. Association between low BMD and age, menopause and duration of SLE was statistically significant.

O-15
RELATIONSHIP BETWEEN OSTEOPOROSIS, OBESITY AND THE INSULIN RESISTANCE INDEX IN A POPULATION OF PRE AND POSTMENOPAUSAL WOMEN

J. Gil Domínguez, Á. Ruiz de Temiño de la Peña, A. Beltrán Sánchez, L. Hernánz Román, T. Gómez Traveso, L. Briongos Figuero, Á. Silva Vázquez, J. Pérez Castrillón

Department of Internal Medicine. Hospital Universitario Río Hortega. Valladolid, Spain.

Objectives: In our study we hope to find a possible association between obesity and insulin resistance with osteoporosis.

Material and method: We performed a prospective study of cases and controls in the Valladolid hospital, Rio Hortega, that included 286 pre and postmenopausal women between the ages of 38 and 85. We collected data including comorbidity, treatments, weight and height. We classified the degree of obesity according to the WHO. We measured the levels of vitamin D and plasma insulin, and calculated the insulin resistance index according to the HOMA test. Densitometry was performed at the lumbar spine and the hip, considering osteoporosis to be a bone mineral density lower than 2.5 standard deviations below the peak bone mass in young adults (T-score ≤ -2.5).

Results: We found a correlation between the insulin resistance index and obesity in the overall study population, the HOMA test increasing as the body mass index increased (HOMA average cases of grade II obesity 8.3 ± 9.4 versus 2.4 ± 2.6 in those of normal weight). Upon stratifying by osteoporosis, this relationship is lost and there exists a greater insulin resistance among patients of normal weight than among obese. In addition, we observed a lower percentage of osteoporosis among obese (obesity grade I 7.3%, overweight 38.7%) than in patients of normal weight (54%), with a statistically significant difference (p = 0.029). Excluding women under treatment for diabetes mellitus, we found no significant differences in HOMA or the percentage of osteoporosis.

Discussion: Osteoporosis and obesity maintain an inverse relationship, bone mineral density rising as body weight and body mass index also rise. This has been demonstrated in numerous studies as well as being in agreement with our own study, in which we have found a lower percentage of osteoporosis among patients with greater obesity. One possible explanation would be the mechanical effect that occurs in obesity, which could have a protective effect on the bone. Furthermore, the adipose tissue may have an influence due to the production of hormones and adipokines such as leptin, adiponectin, resistin and interleukins. In postmenopausal women, body fat mass and bone mineral density are positively associated, possibly due to the androgen's aromatization of the estrogens through the adipose tissue, accompanied by the hormone transporter of sex hormones. However, there is some controversy over whether the body fat has a protective effect for osteoporosis, as there are studies which have shown there exists an increased risk of osteoporosis with an increase in the proportion of body fat. Furthermore, there may be a participation of the hormones secreted at the pancreatic level, such as insulin, amylin and preptin. Hiperinsulinemia secondary to insulin resistance has been suggested as a possible explanation for the relationship between obesity and bone mineral density. The insulin would have a mitogenic effect on the osteoblasts, stimulating their function. However, in some studies this association has not been found, which could points towards the existence of other responsible hormonal factors. In our study we found a greater insulin resistance index among obese. But on the other hand, upon comparing cases of osteoporosis against those without osteoporosis, this relationship was lost. This could indicate that insulin resistance is not one of the mechanisms involved in the relationship between obesity and osteoporosis.

Conclusions: In our study we have not been able to demonstrate a relationship between insulin resistance and osteoporosis, which disagrees with the facts obtained in the latest publications. For this reason, we believe that it is necessary to carry out more studies analyzing this possible association.

O-16
PATIENTS ADMITTED WITH HIP FRACTURE HAVE A HIGHER INCIDENCE OF PREVIOUS FRACTURES THAT PATIENTS ADMITTED IN THE HOSPITAL BY OTHER DISEASES: A CASE-CONTROL STUDY OSTEOPOROSIS WORKING GROUP OF THE SPANISH SOCIETY OF INTERNAL MEDICINE (GTO-SEMI)

J. Blázquez[1], A. Navarro[1], M. Martín[2], M. Arias[3], M. Moro[4], B. de Escalante[5], M. Galindo[6], J. P. Castrillón[7]

[1]Department of Internal Medicine. Complejo Hospitalario Universitario de Albacete. Albacete, Spain. [2]Department of Internal Medicine. Complejo Hospitalario Regional Virgen del Rocío. Sevilla, Spain. [3]Department of Internal Medicine. Complejo Asistencial de Zamora. Zamora, Spain. [4]Department of Internal Medicine. Hospital Central de la Cruz Roja San José y Santa Adela. Madrid, Spain. [5]Department of Internal Medicine. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain. [6]Department of Internal Medicine. Complejo Hospitalario La Mancha Centro. Alcázar de San Juan (Ciudad Real), Spain. [7]Department of Internal Medicine. Hospital Universitario del Río Hortega. Valladolid, Spain.

Objectives: 1) To know data on the types of hip fracture. 2) To study the incidence of previous fractures, the incidence of family history of hip fracture, and to make a comparative analysis with a group of patients admitted for another condition.

Material and method: This is a prospective multicenter cooperative study case-control Osteoporosis Working Group of the Spanish Society of Internal Medicine (GTO-SEMI). in which cases are patients admitted for hip fracture and controls, patients of the same age, admitted to internal medicine without current hip fracture either upon. It is a descriptive analysis of data on hip fractures in the group of cases and a comparative analysis of family history, personal history of fracture and history of falls between cases and controls. Statistical analysis: chi-square test.

Results: We collected 890 patients, 443 cases and 447 controls, for 17 hospitals. General epidemiological data. In the case group, there were 332 women (74.9%) and 111 males (25.1%), with a ratio female/male 3/1. Age: 50-103 yrs, mean 82.3 ± 8.5 yrs, with differences between women (83.0 ± 8.2 yrs) and males (80.1 ± 8.9 yrs): $p < 0.05$. In the control group, there were 308 women (68.9%) and 139 males (31.1%), with a ratio female/male of 2.2/1. Age: 53-102 yrs, mean 80.4 ± 8.3 yrs, with differences between women (81.7 ± 7.8 yrs) and males (77.5 ± 8.8 yrs), $p < 0.05$.Data related to fractures. Types of hip fractures: cervical, 171 (38.6%); trochanteric, 198 (44.7%); subtrochanteric, 58 (13.1%); other, 12 (2.7%); unspecified, 4 (0.9%). Side of fracture: the right, 222 (50.1%); left, 218 (49.2%), unspecified, 3 (0.7%). 23 patients (5.2%) had other fractures coincide with hip fracture: wrist, 10 (2.25%); humerus, 7 (1.6%); another, 6 (1.4%). Family history of fractures: cases, 71 (16%); controls, 51 (11.4%); $p = 0.051$. Personal history of fractures were 123 patients (27.8%) in the case group (wrist fracture, 34; humerus fracture, 17; vertebral fracture, 15; other fractures 58) and 50 patients (11.2%) in the control group (wrist fracture, 16; humerus fracture, 10; vertebral fracture, 9; other fractures, 20), $p < 0.001$. They had falls in the last year 189 patients (42.7%) in the case group, median 2, and 124 (27.7%) patients in the control group, median 2, $p < 0.001$.

Conclusions: 1. About 30% of patients with hip fracture had already had a previous fracture. 2. Compared with controls, patients with hip fracture had a higher incidence of previous fractures and falls. 3. Also had a higher proportion of patients with a family history of hip fracture in the case group than in controls, close to statistical significance. 4. These data reinforce the need to identify patients most at risk and implement preventive measures to prevent hip fracture.

O-19
UTILITY OF MARKERS OF BONE RESORPTION AND FORMATION IN PATIENTS WITH CHRONIC CORTICOSTEROID TREATMENT

M. Ruiz Campuzano[1], M. Esteban Moreno[2], M. Ortego Jurado[3], M. García Morales[3], R. González Ferrer[3], N. Ortego Centeno[3], J. Callejas Rubio[3], R. Ríos Fernández[3]

[1]Department of Internal Medicine. Hospital General Universitario Rafael Méndez. Lorca (Murcia), Spain. [2]Department of Internal Medicine. Complejo Hospitalario de Especialidades Torrecárdenas. Almería, Spain. [3]Department of Internal Medicine. Hospital de Especialidades San Cecilio. Granada, Spain.

Objectives: Bone markers are products of bone cells, or its action on bone, which can be measured in blood and urine and report on the state of bone remodeling. With other clinical data they can be used to evaluate patients with osteoporosis (OP), and to determine adherence to treatment and response. Its usefulness in the management of osteoporosis induced by glucocorticoids (GC) is still questioned. The aim of our study is to establish the usefulness of these markers as predictors of bone loss in patients with chronic steroid therapy.

Material and method: Prospective observational study in a cohort of patients diagnosed with any autoimmune diseases treated with GC, for more than 3 months. As formation markers, osteocalcin (BGP) and bone alkaline phosphatase (Ostase) were measured; and as resorption markers: Beta CrossLaps (CTX) and tartrate-resistant acid fofatasa (TRAP). Also measured osteoprotegerin (OPG), a protein involved coupling in the formation/resorption. We performed a statistical analysis to determinate the degree of correlation between the percentage of increase in bone mass and the various markers of bone resorption and formation.

Results: We analyzed a total of 141 patients (76.6% women), mean age: 56 ± 15 years; mean dose of prednisone: 5.19 ± 3.5 mg/day.

Conclusions: In our study no statistically significant relationship between percentage of bone loss and markers of bone formation or resorption were found. Thus, these markers do not show utility as predictors of bone loss in patients with chronic steroid therapy.

O-22
OSTEOMED: A PROJECT OF OSTEOPOROSIS WORKING GROUP OF THE SPANISH SOCIETY OF INTERNAL MEDICINE ANALYSIS OF THE FIRST 500 CASES

J. Blázquez[1], M. D. Curiel[2], J. Olmos[3], J. P. Castrillón[4], F. Rodero[5], A. Navarro[1], I. G. Valle[1], P. S. Molini[6]

[1]Department of Internal Medicine. Complejo Hospitalario Universitario de Albacete. Albacete, Spain. [2]Department of Internal Medicine. Fundación Jiménez Díaz. Madrid, Spain. [3]Department of Internal Medicine. Hospital Valdecilla. Santander (Cantabria), Spain. [4]Department of Internal Medicine. Hospital Universitario del Río Hortega. Valladolid, Spain. [5]Department of Internal Medicine. Hospital de la Defensa. Zaragoza, Spain. [6]Department of Internal Medicine. Hospital Universitario de la Princesa. Madrid, Spain.

Objectives: To develop a database of patients with osteoporosis of Internal Medicine consultation centers in Spain.

Material and method: The Osteoporosis Working Group of the Spanish Society of Internal Medicine (GTO-SEMI) has developed a medical history available on the Web. Inclusion criteria. There are eligible patients with osteoporosis, osteopenia and fragility fractures (irrespective of bone mass) that can be studied and followed according to clinical practice. We made an descriptive analysis of the first 500 cases.

Results: General epidemiological and clinical data. We collected 500 patients, 432 women (86.4%), aged 66.8 ± 11.2 yr and 111 men (13.6%), aged 63.9 ± 12.8 yr. 264 (52.8%) are naïve patients and 236 (47.2%) are patients in treatment.. Anthropometric data: height, 156.08 ± 8.02 cm; weight 65.1 ± 11.2 K, BMI, 28.7 ± 4.2 K/m^2. Here are the most relevant data about risk fracture factors, fractures and treatments: 142 (28.4) patients with a family history of fractures or osteoporosis. 47 (9.8%) patients were smokers and 48 (9.2%) are ex-smokers. The median daily intake of dairy calcium is 556 mg. Most common diseases associated with effects on bone metabolism are nephrolithiasis (55 pts, 11%), hypothyroidism (45 pts, 9%), and hypercalciuria (27 pts, 5.4%). 125 (25%) patients had a history of vertebral fracture and 75 patients (15%), history of nonvertebral fracture. The mean lumbar spine T score was -2.74. The mean T-score at the femoral neck was -2. The distribution bycategory of T-score was as follows: at the lumbar spine < -2.5, 278 patients; -1 to -2.5, 103 patients, > -1 patients, 18. At the femoral neck was < -2.5, 140 patients; -1 to -2.5, 235 patients; > -1 patients, 68. Treatment. Number of patients with each drug: Calcium 369, Vitamin D 401, Risedronate 112 Alendronate 91, Ibandronate 31, Zoledronic 11, Raloxifene 10, Strontium Ranelate 58, Teriparatide 34, PTH 1-84 27, Denosumab 4.

Conclusions: 1. At this moment, we have included 500 patients, half naive and half treated. 2. About 80% of the patients are women with a mean age of 65-70 years. 3. About 30% of patients have family history of major fractures or osteoporosis, while the sum of patients with vertebral and non-vertebral fracture is 40%. 4. 55% of patients had osteoporosis criteria in lumbar spine and femoral neck 28%. 5. Almost all patients treated, take calcium and vitamin D. Of the patients with active treatment, most are taking bisphosphonates.

[3]Department of Biostatistics. Boston University. Boston, Massachusetts, United States of America. [4]National Heart, Lung and Blood Institute´s Framingham Study. Harvard Medical School. Boston, Massachusetts, United States of America. [6]Cardiovascular Health Research Unit. University of Washington. Seattle, Washington, United States of America.

Objectives: It is not known whether common beta cell–associated single nucleotide polymorphisms (SNPs) interact with hypertension or hypertension treatments in their associations with change over time in fasting glucose (FG) or incident type 2 diabetes mellitus (T2DM).

Material and method: In the Framingham Offspring Study, we pooled data from 3,471 participants into 6 ~4-yr periods (15,852 person-exams; mean age 52 years, 54% women). We defined three hypertension exposures: 1) hypertension vs no-hypertension; 2) treated vs untreated hypertension; 3) five mutually exclusive anti-hypertension drug categories (beta-blockers, thiazides, renin-angiotensin system agents, combinations, others) vs untreated hypertension; and two genetic exposures reflecting total beta-cell genetic risk burden: 16 FG-SNP and 33 T2DM-SNP additive genetic scores. We tested ~4-year mean change in FG or odds of T2DM by hypertension category and per-risk allele change in genetic scores. We sought hypertension-by-genetic-score significant ($p < 0.05$) interaction in joint models including hypertension categories and the genetic risk scores.

Results: Versus no hypertension, hypertension conferred higher change in FG (2.6 vs 1.7 mg/dl; $p < 0.0001$) and T2DM risk (OR = 2.9; 95%CI 2.8-3.0; $p < 0.0001$). Versus untreated hypertension, treated hypertension conferred higher change in FG (3.4 vs 3.0 mg/dl; $p < 0.0001$) and T2DM risk (OR = 1.4; 95%CI 1.3-1.5; $p = 0.02$). Beta-blockers (OR = 1.6; 1.1-2.4), combination treatment (OR = 1.6; 1.1-2.5) and others (OR = 2.0; 1.4-2.9) increased T2DM risk (all $p < 0.02$). Genetic scores increased ~4-yr change in FG (0.6 mg/dl; $p = 8.9E-16$) and T2DM risk (~17%; $p = 2.1E-7$), per risk allele. In joint models including interaction terms, all hypertension category-by-genetic score interaction terms were $p > 0.05$. In joint models without interaction, hypertension ($p < 0.0001$) and FG-SNP or T2DM-SNP genetic scores independently increased change in FG or T2DM risk (both $p < 0.001$).

Discussion: We found that hypertension, hypertension treatment, and genetic scores derived from FG- and T2DM-associated SNPs conferred higher ~4-year change in FG and risk of incident T2DM in non-diabetic subjects in Framingham. We detected no interaction effect for any hypertension-treatment category-by-genetic score, although hypertension and genetic scores were independently associated with glycemic outcomes. The influence that hypertension or its treatment exerted on change in FG and T2DM risk was homogeneous irrespectively of the genetic susceptibility conferred by fasting glucose- or T2DM-associated common genetic variation. Reciprocally, the effect of fasting glucose- and T2DM-associated common genetic variation on change in FG and T2DM risk was not greater in the presence of hypertension or its treatments.

Conclusions: Hypertension, hypertension treatment and common FG- and T2DM-SNP genetic scores independently predicted change in FG and T2DM incidence, but did not modify each other's association with change in FG or T2DM risk in our population.

RV-7
EFFECTS OF MODERATE-TO-HIGH INTENSITY ENDURANCE EXERCISE AND DIFFERENT DIETARY MODELS ON CIRCULATING ENDOTHELIAL PROGENITOR CELLS IN METABOLIC SYNDROME PATIENTS

M. Pérez Porras, J. Fernández, L. Landaeta Díaz, D. Rosado Álvarez, I. Túnez Fiñana, J. López Miranda, F. Pérez Jiménez, F. Fuentes Jiménez

Department of Internal Medicine. Hospital Universitario Reina Sofía. Córdoba, Spain.

Objectives: To determine the influence of different dietary models combined or not with a moderate-to-high intensity exercise program on endothelial progenitor cells (EPCs) levels; microvascular endothelial function; cardiovascular risk factors (CVRF) and changes on oxidative state in metabolic syndrome patients.

Material and method: 60 metabolic syndrome patients (50-70y) were randomized in 4 groups with 12 weeks of treatment: group A only with hipocaloric Mediterranean diet (MeD); group B with Mediterranean diet + exercise (MeDE), group C with low fat and high carbohydrates diet (LoF), and group D with low fat diet + exercise (LoFE). The exercise consisted of 3 weekly sessions of 30 minutes of aerobic exercise; 2 were supervising on a cycle-ergometer and arm-ergometer and one was unsupervised consisting of 30-minute walk. Circulating level of EPCs (CD34+KDR+), reactive

Table (RV-7). HRP in groups LoF, MeD, LoFE and MEDE

Variable LoF	LoF	LoFE	LoFE	MeD	MeD	MeDE	MeDE
Week S-0	S-12	S-0	S-12	S-0	S-12	S-0	S-12
PORHmax 150.1 ± 24.9	142.4 ± 22.4	145.8 ± 27.8	187.5 ± 18.5	149.6 ± 10.6	144.3 ± 24.9	144.5 ± 24.9	195.1 ± 24.9
iAUC 277.6 ± 29.0	178.9 ± 34.9*	239.9 ± 27.7	344.1 ± 56.2*	249.6 ± 33.1	220.1 ± 36.1	252.0 ± 50.1	253.3 ± 71.1

ischemic hiperaemia (RIH) measured by post-ischemia reactive hyperemia test (HRP), determining PORHmax and IAUc, and CVRF were determined at the beginning and at the end of each intervention. Effect of different interventions (independent variables) on EPCs level and HRP (dependent variables), was determined through an ANOVA with repeated measures (4 groups × 2 times).

Results: MeDE improved significantly more the EPCs levels and oxidative state after intervention than MeD, LoF and LoFE. LoFE significantly increased EPCs vs MeD and LoF. On the other hand, MeDE and LoFE improved RIH (PORHmax and IAUc) vs MeD and LoF, without difference between these treatments (table). LoFE was more effective than Mediterranean diet in reducing abdominal fat and others measured CVRF, with equal effectiveness in the loss of body weight. LPO was reduced and GPx was increased after intervention in MeDE.

Discussion: A reduced number of EPCs correlates with the CVRF score and to predict future cardiac events. In this sense, improving the oxidative status and measured CVRF has been associated with a better endothelial function.

Conclusions: A hypocaloric Mediterranean diet plus endurance exercise of moderate-to-high intensity increases EPCs levels and improves oxidative status more effectively than a low fat diet plus exercise; both models improves microvascular endothelial reactivity in patients with metabolic syndrome.

RV-10
CLINICAL VALIDITY OF FRAMINGHAM CARDIOVASCULAR RISK SCALE IN PATIENTS BEING TREATED IN A VASCULAR RISK CONSULTATION ACCORDING TO SUBCLINICAL ATHEROSCLEROSIS

R. Romero Sevilla[1], R. Velasco Romero[2], L. Crespo Rincón[2], A. Costo Campoamor[2], I. Casado-Naranjo[1], J. Muñoz-Torrero[2]

[1]Department of Neurology, [2]Department of Internal Medicine. Complejo Hospitalario de Cáceres. Cáceres, Spain.

Objectives: To determine the clinical validity of the Framingham score in patients from Cáceres being treated in a vascular risk consultation by assessing subclinical atherosclerosis using carotid ultrasound High Resolution (CUHR).

Material and method: Prospective, observational study of 450 consecutive patients seen in a vascular risk consultation at the Hospital San Pedro de Alcántara in Caceres, from June 2009 to June 2011, which were stratified into new categories of Framingham according to findings based on the intima-media thickness (IMT) and plaque score (PS) by carotid ultrasound High Resolution.

Results: Of the 450 patients, 267 were men (59.33%) and 183 women (40.66%). The mean IMT of the entire sample was 0.7808 (by gender: M = 0.7983, W = 0.7554). The mean IMT and Plaque score was significantly higher in men over 65 years (0.9257, 7.76 ± 5.21) and with a history of hypertension (0.84 ± 0.13, 4.93 ± 5.00) DM (0.86 ± 0.13, 5.65 ± 3.01) and previous stroke (0.87 ± 0.13, 5.44 ± 4.01). Regarding the diagnostic value of the Framingham score to identify patients at high cardiovascular risk found a sensitivity (S) of 50.33% and a specificity (E) of 79.60%, positive predictive value (PPV) of 82.87% and negative predictive value (NPV) of 44.98%. In Man (S) was 58%, (E) of 76%, PPV of 86% and a NPV of 42%. For women, the (S) was 37%, (E) of 83%, PPV of 75% and a NPV of 48%. According to the Framingham score, 25% of patients (n = 114) were assigned to the category of low risk, 35% (n = 156) and 40% (n = 180) included in the intermediate and high risk respectively. According to the findings in the CUHR 15% (n = 66) were assigned to the category of low risk, 19% (n = 86) and 66% (n = 298) classified as intermediate and high risk respectively. Thus 47.4% of patients were stratified with respect to the CURH correctly, while 32.7% were reclassified to high risk category and only 6.6% were reclassified from the category of high risk to bottom.

Discussion: The results of our study indicate that the carotid mean IMT was significantly associated with age and sex. The mean carotid IMT highest among men over 65 years and this leads to an increase in direct proportion with age, being these results consistent with several studies which establish that age is the main factor that influences the IMT progression. These findings confirm other published that relate the IMT with cardiovascular risk factors (CVRF) because the carotid mean IMT in our patients was higher in those who had a history of hypertension, diabetes, and stroke, a figure expected since the increase in IMT is the result of effects of CVRF on the vascular wall. In our study we found that the sensitivity of the scale of Framingham to detect patients at high cardiovascular risk was 50% in the entire series, a percentage that drops to 37% in women, leaving much of the population considered at high CVR unidentified and therefore without intervention therapeutic measures. CURH utilization allows the clinician to re stratify the patient in a more proper CVR group, thereby improving the sensitivity of the test while maintaining their specificity. Our results show a clear tendency to decrease considerably the group of patients at intermediate risk from 35% (n = 156) according Framingham, to 19% (n = 86) according to CURH. Also increases by about 26% the number of patients considered at high risk in which no doubt would start aggressive treatment.

Conclusions: The carotid ultrasound High Resolution is a useful method for the proper classification of cardiovascular risk in those patients in whom the Framingham scale has a low sensitivity and NPV.

RV-48
KNOWLEDGE ON STROKE WARNING SYMPTOMS AND ACTION IN RESPONSE TO STROKE IN SPAIN. A NATIONWIDE POPULATION-BASED STUDY

K. Lundelin[1], A. Graciani[1], J. García Puig[2], P. Guallar-Castillón[1], F. Rodríguez-Artalejo[1], J. Banegas[1]

[1]Department of Preventive Medicine and Public Health. Universidad Autónoma de Madrid- IdiPAZ-CIBER in Epidemiology and Public Health (CIBERESP). Madrid, Spain. [2]Department of Cardiometabolic. Hospital Universitario La Paz. Madrid, Spain.

Objectives: Worldwide thrombolysis rates remain suboptimal. Ambulance transfer is associated with greater use of this time-dependent treatment. Information on public awareness of stroke symptoms is important for planning effective education programs to promote calling of emergency services for suspected stroke. However, there is a paucity of data on this subject in European countries. Our objectives were to explore the recognition of stroke symptoms, awareness of the need to activate the emergency medical services for acute stroke events, and the association between knowledge of warning symptoms and intent to call for an

ambulance among a sample representative of the adult population of Spain. This is the largest study on this subject to date in Europe.

Material and method: The data were taken from the Study on Nutrition and Cardiovascular Risk in Spain, a cross-sectional study conducted in a sample representative of the Spanish non-institutionalized population aged 18 years or older in 2008-2010. Study participants were selected by multistage clustered random sampling. The households within each section were selected by random telephone dialing using the landline telephone directory as the sampling frame. Subjects in the households were selected proportionally to the distribution of the population of Spain by sex and age. The study included a computer-assisted telephone interview on stroke symptom knowledge and the first action to perform in a stroke event, based on the American Heart Association and American Stroke Association recommendations, and two home visits to perform a physical examination and to obtain blood samples.

Results: Among 11,827 adults, 7,711 (65.2%; 95%CI, 64.1-66.3) identified four to six stroke warning symptoms, considered as adequate knowledge. A total of 1,348 (11.4%) were unable to classify any of the symptoms correctly. In the multivariate analysis higher education was significantly associated with better knowledge of symptoms, and age 65 years or older, fair/poor self-rated health, history of obesity and known diabetes were significantly associated with less knowledge of stroke symptoms. One in 5 individuals indicated they would do something other than calling for an ambulance if they thought someone was having a stroke. The number of specific stroke warning symptoms known was directly associated with the intent to call an ambulance in a stroke event (OR adjusted for sociodemographic and clinical variables, 1.06 per symptom, 95%CI 1.03-1.09; $p < 0.001$).

Conclusions: In this population-based study stroke symptom knowledge was suboptimal and only modestly associated with the intent to call for an ambulance. Educational interventions are needed to link stroke recognition more strongly to an immediate need to call for an ambulance in order to increase stroke patients' access to thrombolysis.

RV-61
CLINICAL EFFECTS OF THE PROSTACYCLIN ANALOGUE ILOPROST IN PATIENTS WITH IIB-STAGE PERIPHERAL ARTERIAL DISEASE. RESULTS FROM A RANDOMIZED STUDY BY THE SCIENTIFIC SOCIETY FADOI

G. Gussoni[1], A. Valerio[1], A. Fontanella[2], L. Steidl[3], F. Capelli[4], A. Puzzo[5], C. Nozzoli[6], A. Mazzone[4]

[1]Department of Research. FADOI Foundation. Milan [2] Department of Internal Medicine. Hospital Fatebenefratelli. Naples, Italy. [3]Department of Internal Medicine. Hospital Circolo e Fondazione Macchi. Varese, Italy. [4]Department of Internal Medicine. Hospital Civile. Legnano, Italy. [5]Department of Vascular Surgery. Hospital Galliera. Genova, Italy. [6]Department of Internal Medicine. Hospital Careggi. Florence, Italy.

Objectives: Patients with peripheral arterial disease (PAD) at stage IIb, and pain-free walking distance (PFWD) less than 100 metres, have both impaired quality of life and severe clinical outcome. The prostacyclin analogue iloprost is indicated in patients with more advanced PAD (critical limb ischemia). The objective of this study was to evaluate the efficacy of iloprost, added to standard therapy, in patients with IIb stage and PFWD less than 100 metres, and non-eligible for surgical revascularization.

Material and method: Patients enrolled were randomized to receive standard medical therapy (Group A) or standard therapy plus iloprost (Group B), for 1 year. Standard therapy was chosen by the attending physician and tailored for the individual patient, and it may include lifestyle measures and pharmacologic treatments such as anti-aggregating agents, heparin, hemorheologic/vasodilators. Iloprost was administered for ten days every three months (continuous intravenous infusion of 0.5-2.0 ng/kg/min for 6 hours/day). Treadmill test to assess PFWD was performed every three months, before starting the ten-day iloprost cycle (Group B).

Results: A total of 101 patients (50 in Group A and 51 in Group B) were enrolled. At baseline, the two study groups were similar as for mean age (71.9 ± 7.5 vs 68.5 ± 11.2), concomitant diabetes (44% vs 41%), ankle-brachial index (right 0.59/left 0.63 vs 0.64/0.60), and standard therapy. Figure 1 shows the values of PFWD during the study period. By considering the last observation carried forward, PFWD was significantly higher in patients treated with iloprost (87.4 ± 65.5 vs 127.3 ± 70.3, $p < 0.01$). Six patients in the Group A (12%) vs no patients in the iloprost group had a worsening of PAD towards critical limb ischemia. Major cardiovascular events occurred in 30% and 5.8% of patients in Group A and Group B, respectively ($p < 0.001$). Five patients in Group A died, vs none in Group B. No serious unexpected adverse reactions occurred in patients receiving iloprost.

Discussion: Patients with PAD at stage IIb and non-eligible for surgery, even though treated according to best medical practice, have severe short-/medium-term outcome. In these patients there is therefore a stringent medical need, and an anticipated use of iloprost could be a very interesting treatment option. Up to our knowledge, this is the first prospective randomized study designed to evaluate the effects of iloprost in this setting.

Conclusions: In patients with PAD at stage IIb and non-eligible for surgery, iloprost in addition to standard therapy significantly increases exercise capacity. Of particular interest, the percentage of patients who died or experienced major cardiovascular events was significantly lower in patients receiving iloprost. Future, larger and longer-term studies should focus on the effects on this therapy on clinical outcome.

RV-110
THROMBOLYSIS IN STROKE VICTIMS: FRIEND OR FOE?

D. Miranda[1], C. Rozeira[1], T. Gregório[1], L. Paredes[1], P. Carneiro[2], M. Veloso[2], D. Pinheiro[1], V. Paixão Dias[1]

[1]Department of Internal Medicine, [2]Department of Neurology. Centro Hospitalar Vila Nova de Gaia /Espinho. Vila Nova de Gaia, Portugal.

Objectives: Cerebrovascular events are associated with high mortality and morbidity. A regular follow-up and monitoring after the acute event and the control of cardiovascular risk-factors tend to decrease the risk of recurrence. The objective of this study was the portrayal of ischemic stroke victims after the event and compare the functional recovery of patients whom underwent thrombolysis and patients with standard antiplatelet treatment.

Material and method: Retrospective descriptive study with outpatients observed in 2011 after hospitalization in a stroke unit. Demograhic data was analised and an measurement of functional recovery was performed using Barthel scale. Disability was assessed with Rankin scale, considering a Rankin scale of ≤ 2 as a non-disabled person. Evaluation of both scales was performed at the 3rd, 6th and 12th month after clinical discharge.

Results: A total of 382 patients with ischaemic stroke were observed as outpatiens during follow-up after hospitalization in a stroke unit (median age of 67 years; 55% male), 43 (11.3%) of whom underwent thrombolysis. The percentage of patients with no disability at the 3rd, 6th and 12th month with thrombolysis treatment was respectively 78.2%, 79% and 76.3%, compared 75.5%, 81.6% and 92.3% in patients with standard antiplatelet treatment. Median Barthel score in thrombolysis patients at the same

evaluations was 81.7; 77.1 and 82, while standard antiplatelet treated patients presented a median Barthel score of 79.8; 82.6 and 87.5.

Discussion: Patients with thrombolysis treatment presented initially a lower disability rate than the group with antiplatelet treatment, but seemed to stagnate with functional recovery. At the 6th and 12th month patients with standard antiplatelet treatment were less disabled than thrombolysis patients.

Conclusions: While thrombolysis treatment seems to limit the extend of functional disability at short terms, this study didn´t show benefits at medium terms.

RV-130
INCIDENCE AND PROGNOSTIC IMPLICATIONS OF ANEMIA IN PATIENTS ADMITTED WITH ACUTE CORONARY SYNDROME

L. García Serrano, J. Nogales Asensio, P. García García, C. Aranda López, P. Mellado Delgado, C. García Corrales, J. López Mínguez, A. Merchán Herrera

Department of Cardiology. Complejo Hospital Universitario de Badajoz. Badajoz, Spain.

Objectives: Between hospitalized patients with acute coronary syndrome (ACS), anemia is an usual finding. The aim of our study was to analyze the incidence of anemia at admission and during hospitalization, related variables, and the influence of the admission hemoglobin level (Hb) and post-admission fall in Hb on short-term prognosis in these patients.

Material and method: We performed a retrospective cohort study that included 804 consecutive patients admitted with ACS diagnosis: 414 (51.5%) without ST segment elevation (-NSTE) and 390 (48.5%) with ST segment elevation (-STE). Anemia was defined as hemoglobin < 13 g/dl in men and < 12 g/dl in women. The fall in Hb was calculated as the difference between admission Hb and the lowest Hb recorded during hospitalization.

Results: At admission, anemia was present in 21.8% of patients. Among patients without anemia at admission, 25.8% developed anemia during hospitalization. The prevalence of anemia at admission, anemization during hospitalization and the fall of Hb over several baseline characteristics are shown in the table. Female gender, age, diabetes (DM), renal insufficiency (RI) at admission and antiaggregant therapy (AT) before admission were associated with a higher prevalence of anemia. Patients with anemia had a worse risk profile (GRACE score: 144.1 ± 42.7 vs 120.9 ± 33.7 points; p < 0.001). Anemia at admission was associated with a higher incidence of heart failure (HF) and a conservative therapeutic strategy (CTS), with lower rates of percutaneous coronary intervention (PCI), during hospitalization. Fall of Hb was associated with a higher in-hospital mortality (OR = 1.3; p = 0.03). Age (p = 0.01), presence of HF (p < 0.001) and fall of Hb (p = 0.05) were related with in-hospital mortality in multivariate analysis.

Conclusions: There is a high prevalence of anemia at admission in patients admitted with ACS. This prevalence is higher between some subgroup of patients such as women, elderly and patients with RI or DM. Anemia and fall of hemoglobin levels during hospitalization are associated with a worse prognosis and also with a more conservative therapeutic strategy. In view of this, our data indicate that both parameters should be incorporated in the prognostic stratification of patients with ACS.

RV-133
SITAGLIPTIN PRETREATMENT IN DIABETES PATIENTS PRESENTING WITH ACUTE CORONARY SYNDROME: RESULTS FROM THE ACUTE CORONARY SYNDROME ISRAELI SURVEY (ACSIS)

D. Gavish[1], E. Leibovitz[1], I. Goldberg[2], L. Bubyr[2], S. Matetzky[2], S. Gottlieb[3]

[1]Department of Medicine A. Wolfson Hospital. Tel Aviv University. Holon, Israel. [2]Neufeld Cardiac Research Institute. Sheba Medical Center. Ramat Gan, Israel. [3]Department of Cardiology. Bikur Holim Hospital. Jerusalem, Israel.

Objectives: We studied the association between treatment with oral hypoglyemic medications and the clinical presentation of diabetes patients with acute coronary syndromes (ACS).

Material and method: Multivariate logistic regression analysis was used to evaluate the risk of in-hospital complications among 445 diabetic patients with acute coronary syndromes enrolled in the Acute Coronary Syndrome Israeli Survey (ACSIS) 2010. Patients were categorized into 3 groups according to medications at time of admission: 1) DPP 4 inhibitors (as monotherapy or in combination DPP4i), 2) Metformin (monotherapy or in combination, excluding DPP-4i) and 3) other oral hypoglycemics.

Results: Patients in the DPP4i group displayed similar baseline clinical characteristics to the other 2 groups, with the exception of a younger age and a lower frequency of prior CHD and CRF. Medical therapy with DPP4i was associated with a significantly lower rate of in-hospital complications (post MI angina, re-infarction, pulmonary edema, infections, acute renal failure and lower KILLIP score) and a shorter duration of in-hospital stay as compared with treatment with metformin or other oral antiglycemic drugs. Consistently, multivariate logistic regression modeling showed that treatment with DPP-4i was associated with a lower risk (OR = 0.13; p = 0.01) of in-hospital complications compared with other oral hypoglycaemic therapy.

Discussion: Our retrospective analysis showed a beneficial association between pre-treatment with DPP4i and cardiovascular outcomes among patients admitted with acute coronary syndromes. Alongside the history of CHF and age, chronic treatment with Sitagliptin, the only DPP4i given in our study population, was associated with improved KILLIP class on admission, reduced rate of in-hospital complications (most notably infections and acute renal failure) and reduced rate of 30-day major cardiovascular events.

Conclusions: We conclude that pre-treatment with DPP4i is associated with reduced tate of in hospital complications and 30-day MACE of patients presenting with acute coronary syndrome.

Table (RV-130). Prevalence of anemia at admission, anemization and fall of hemoglobin levels during hospitalization

RV-142
THE PHOENIX: HDL-CHOLESTEROL REBORNS FROM ITS OWN ASHES AS THE MOST DETERMINANT METABOLIC FACTOR OF CAROTID INTIMA MEDIA THICKNESS

C. Martínez Ruiz[1], E. Tutor Pellicer[1], M. Fabregate Fuente[1], R. Fabregate Fuente[1], A. Rodríguez Guerrero[1], A. Cruz Culebras[3], E. Marín Manzano[2], J. Sabán Ruiz[1]

[1]Department of Endothelial Pathology. Department of Internal Medicine, [3]Department of Neurology, [2]Department of Vascular Surgery. Ramón y Cajal Hospital. Madrid, Spain.

Objectives: 1. To evaluate the role of HDL-C and Apo-A1 in bilateral Carotid Intima-Media Thickness (CIMT) in patients with moderate-high cardiovascular risk under treatment. 2. To evaluate if haemodynamic, inflammatory and other metabolic factors impact on CIMT in this population.

Material and method: N = 171 patients with moderate-high cardiovascular risk, treated for LDL-C, hemoglobin A1c and blood pressure targets according to 2011 ESC/EAS guidelines. Age: 57.6 (15.1) years. n = 108 (63.2%) hypertensives; n = 111 (64.9%) with hyperglycemia; n = 88 (51.5%) with hypercholesterolemia; n = 32 (18.7%) smokers. Blood pressure by OMRON MI 10IT. Glucose, HDL-C, Triglycerides (TG): Hitachi. LDL-C calculated if TG < 400 mg/ml. ApoA-I, ApoB: Nephelometry. A1c: % (DCCT). high–sensitivity C-Reactive Protein (hs-CRP): Nephelometry. CIMT was assessed on the posterior wall of right and left common carotid arteries using a 5-12 MHz multi-frequency linear array ultrasonic transducer (Vivid S5, GE Healthcare). Statistical Analysis: Continuous variables as mean (standard deviation-SD). Paired t-test. Evaluation of agreement by Bland-Altman plot, with limits at mean ± 1.96*SD of the difference. Pearson's correlation. Multivariate linear regression models (B: non-standardized coefficient; Bs: standardized coefficient; R^2: model coefficient of determination), backwards method. SPSS, v15.0.

Results: 1- No significant differences were observed between paired right and left CIMT: 0.687 (0.158) vs 0.686 (0.156). Both CIMTs showed a positive correlation (r = 0.496, p < 0.001). The agreement was assessed by Bland-Altman-plot: only 6 subjects (3.5%) were out of limits of agreement for right-left difference [0.0016 ± 0.3089], with no association between difference and mean. 2- Both right and left CIMTs became thicker with age: right-CIMT: r = 0.560; p < 0.001; left-CIMT: r = 0.491; p < 0.001. 3- Assuming the higher CIMT value (left or right) as representative of patient´s risk, both HDL-C and ApoA-I were inversely correlated to CIMT after adjustment for sex and age. HDL-C: Bs = -0.158; p = 0.027; R2 = 0.376. ApoA-I: Bs = -0.146; p = 0.024; R2 = 0.372. 4- In our population, CIMT did not show a significant association with LDL-C, ApoB, apoB/ApoA-I ratio, TG, chronic hyperglycemia, A1c, office blood pressure, hypertensive status, hs-CRP or smoking.

Discussion: The increase of CIMT has been related to cardiovascular risk factors (CVRF) and proven Coronary Artery Disease. Although left CIMT is usually considered as the gold-standard, there are not enough studies to support this laterality. Low levels of HDL-C and ApoA-1 have shown their consistency as CVRF in Framingham, PROCAM and INTERHEART studies, as well as their contribution to the so-called "residual risk" of subjects under treatment with statins. However, the role of HDL-C has been over and over again questioned, even branded it a "fallen-angel" (Medscape, May-2012). Our results give a breath of fresh air in the high density lipoproteins scene, throwing cold water on the intentions of their critics.

Conclusions: 1. Right and left CIMT are in close agreement with each other. 2. After adjustment for sex and age, HDL-C and ApoA-I were the most determinant factors of CIMT in subjects treated for A1c and LDL-C targets. 3. Casting doubt upon the important role of HDL-C in atherothrombotic disease seems to be a fruitless job, only surpassed by the fact of questioning the aspirin.

RV-144
CAROTID ATHEROSCLEROSIS IN 147 PATIENTS WITH PRIMARY SJÖGREN SYNDROME: THE ROLE OF TRADITIONAL AND AUTOIMMUNE-RELATED FACTORS

[1]Sjögren Syndrome Research Group (AGAUR), Laboratory of Autoi, [2]Department of Hypertension (AC), Department of Internal Medicine, ICM. Centre Sociosanitari Hospital Clínic i Provincial de Barcelona. Barcelona, Spain. [4]Primary Care Research Group, IDIBAPS, Centre d'Assistència P. GESCLINIC. Barcelona, Spain. [3]Department of Internal Medicine. Hospital do Meixoeiro. Vigo (Pontevedra), Spain.

Objectives: We evaluate the prevalence and clinical significance of carotid plaques measured by ultrasonography in a large series of patients with primary Sjögren syndrome (SS), focusing on the possible association with clinical and immunological SS features, the therapies administered and the impact on cardiovascular disease.

Material and method: The study cohort included 147 patients with primary SS consecutively evaluated and followed in our department between 2005 and 2011. Carotid ultrasound was performed and the intima-media wall thickness and presence of plaque was investigated in all patients. Traditional vascular risk factors and autoimmune-disease and treatment related factors were also analysed.

Results: The cohort included 141 (96%) women and 6 (4%) men, with a mean age at diagnosis of primary SS of 55.38 ± 1.09 years and a mean disease evolution of 96.63 + 4.81 months. Eighty nine (61%) patients presented carotid plaques in the ultrasound study; in 53 (36%) patients, plaques were bilateral. Analysis of epidemiological and autoimmune features showed that patients with primary SS and carotid plaques showed a higher mean age at diagnosis of SS (58.97 vs 49.88 years, p < 0.001), a higher frequency of IgG anticardiolipin antibodies (11% vs 0%, p = 0.054) and a lower frequency of antibodies against Ro60 (36% vs 67%, p = 0.01) in comparison with patients without carotid atherosclerosis. No statistical association was found between carotid plaque and previous/current therapy with antimalarials, corticosteroids or immunosuppressive agents. With respect to traditional cardiovascular risk factors, patients with carotid plaques showed a higher frequency of hypertension (42% vs 24%, p = 0.034), hypercholesterolemia (49% vs 29%, p = 0.017) and diabetes mellitus (33% vs 19%, p = 0.051); the percentage of patients with at least one vascular risk factor was also higher in comparison with those without carotid plaques (86% vs 64%, p = 0.002). The frequency of cardiovascular events developed by patients with carotid plaques was higher (14% vs 7% in patients without plaques) although the difference was not statistically significant. The age-sex adjusted multivariate analysis showed that SS patients with carotid plaques had a higher mean age at SS diagnosis (p = 0.004) and a lower frequency of antiRo60 antibodies (p = 0.48).

Conclusions: Nearly two thirds of patients with primary SS had carotid plaques detected by ultrasound. Age and anti-Ro60 antibodies were independently associated with carotid atherosclerosis, while corticosteroid use was not associated with plaques. These results suggest that cardiovascular risk factors should be taken into account in the management of patients with primary SS and show the importance of recognizing and controlling both traditional and SS-related cardiovascular risk factors.

RV-153
AMBULATORY BLOOD PRESSURE (BP) MONITORING IN DIABETICS WITH POORLY-CONTROLLED HYPERTENSION AT THE CLINIC FREQUENCY AND FACTORS ASSOCIATED WITH NORMAL AMBULATORY 24-H BP MONITORING

M. Martínez[1], P. Loeches[2], M. de Francisco[3], C. Mateo[4], M. Pereda[5], F. Palau[6], A. Sánchez[7], J. García Puig[7]

[1]Department of Internal Medicine. Hospital Infanta Sofía. Madrid, Spain. [2]Department of Primary Care, [3]Nurse. Centro de Salud Dr. Tamames. Coslada (Madrid), Spain. [4]Department of Primary Care. Centro de Salud Fuencarral. Madrid, Spain. [5]Department of Metabolic and Vascular - Department of Internal Medicine. Hospital La Paz. Madrid, Spain. [6]Department of Primary Care. Centro de Salud El Escorial. El Escorial (Madrid), Spain. [7]MAPA Working Group. Monitorización Ambulatoria de la Presión Arterial. Madrid, Spain.

Objectives: The APD study (Automedición de la Presión A RTERIALen Diabéticos), currently ongoing, is a 2-year clinical trial designed to compare 2 follow-up strategies in type 2 diabetics with poorly controlled hypertension at the office: 1) a home blood pressure (hBP)-based follow-up, and 2) a clinic BP(cBP)-based follow-up. The main outcome variable is the percentage of subjects with normal 24 h ambulatory BP at the final follow-up visit. In this report we analyze the baseline BP results and characteristics of the first 168 randomized patients. Objective: to estimate the frequency of patients with normal 24-h mean ambulatory BP (< 130/80 mmHg) and its correlates in patients with poorly-controlled hypertension at the clinic

Material and method: Non-institutionalised type 2 diabetics attending either at 14 primary-care clinics or at a hospital setting were eligible. The main inclusion criteria was a cBP ≥ 140/90 mmHg (mean of 3 measurements). The main exclusion factor was renal insufficiency (serum creatinine equal or higher than 2 mg/dL) or proteinuria. Patients underwent a clinical interview, physical exam, cBP measurement, 24-h ambulatory BP monitoring, standard biochemical serum analysis and microalbuminuria in 3 early-morning samples

Results: One hundred and sixty-eight subjects (65% males, aged 65.4 ± 8.1 years) were randomized either to hBP or cBP-based follow-up. Mean duration of hypertension and diabetes were 9.1 ± 8.5 and 10.1 ± 7.4 years, respectively. Mean cBP systolic and diastolic were 151 ± 12 mmHg and 81 ± 12 mmHg, respectively. Around a quarter of the subjects (25.8%, 95%CI 18.1-33.5%) had 24-h ambulatory Bp < 130/80 mmHg. We did not find significant differences between this group of patients and those with higher ambulatory BP values with respect to demographic variables, educational status, duration of hypertension or diabetes, subclinical target organ disease, macrovascular disease, body mass index, physical exercise, smoking, or antidiabetic treatment. Patients with 24h Bp < 130/80 mmHg had lower HbA1c values than those with higher values (6.1 ± 1.4 vs 7.3 ± 1.1%, p < 0.001). Patients with systolic cBP > 160 mmHg had a significantly lower likelihood of 24h Bp < 130/80 mmHg that those with lower systolic cBP values (12% vs 34%, respectively; p = 0.03).

Discussion: Our data support previous reports that show that a substantial proportion of diabetic with poorly-controlled hypertension at the clinic have normal BP values when measured by ambulatory monitoring. Thus, this technique may help identify those patients with a normal BP out of the clinic who do not need to have their antihipertensive treatment intensified. We did not find any demographic or clinical characteristics associated with a normal ambulatory BP. Interestingly, we found a significant inverse association with HbA1c.

Conclusions: One quarter of adult diabetic patients with poorly-controlled arterial hypertension had normal 24 h mean ambulatory BP. Patients with higher cBP were more likely to show elevated 24h BP and worse glycaemic control than the remaining subjects.

RV-157
IMPACT OF DIABETES AFTER MYOCARDIAL INFARCTION WITH ST ELEVATION AS DIASTOLIC DYSFUNCTION

E. Cambronero Cortinas, M. Corbi Pascual, J. García López, M. Barambio Ruiz, M. Fernández Anguita, I. López Neyra, C. Llanos Guerrero, J. Navarro Cuartero

Department of Cardiology. Hospital General de Albacete. Albacete, Spain.

Objectives: Diabetes are associated with diastolic dysfunction. In recent years, it has been increasingly apparent that LV diastolic dysfunction contributes to increased mortality rates in patients with acute coronary syndrome independent of systolic function. Different ventricular filling patterns are associated with different prognoses. Objectives: the aim is to investigate the prognostic value of diabetics patients (p) admitted with a myocardial infarction with ST elevation (STEMI) according to their diastolic function, classified into four types of LV filling patterns: Normal (1), impaired relaxation (2), "pseudonormalization" (3), and restrictive (4).

Material and method: Are realized a prospectively analysis 87 diabetic p with STEMI undergoing primary angioplasty. Analyzing the incidence of cardiovascular events defined as death, recurrent ischemia, revascularization and stroke.

Results: 21.8% were women, 25.3% were active smokers, 11.2% with previous history of Coronary Artery Disease (CAD), 69% had hypertension, 46% were dyslipemic and 13.8% nephropathy. The mean age was 70 ± 12.5 years. Based on the filling pattern: 11.5% showed pattern (1), 44.8% pattern (2), 32.2% pattern (3) and 11.5% pattern (4). Baseline characteristics were similar in all groups. There were no significant differences in treatment. Cardiogenic shock rate was higher with restrictive filled (0%, 5.6%, 3.6%, 12.5%, respectively, p = 0.0001). Restrictive pattern was associated with more total events (10%, 38.5%, 11.1%, 50% p = 0.007), higher admission rate of cardiac causes (0%, 7.7%, 3.6%, 37.5%, p = 0.024) and total mortality (0%, 5.1%, 0.1%, 25%, p = 0.0001). In survival analysis found that in the first 300 days 100% of patients with restrictive pattern had events, compared to 10% of patients with other types of patterns (log Rank: 43.966, p = 0.0001).

Conclusions: Diabetic patients with restrictive diastolic function have a poor outcome, with a high incidence of mortality and cardiovascular events.

RV-158
EFFECT OF DIFFERENT DEGREES OF GLUCOSE METABOLISM ALTERATIONS ON THE CD36 EXPRESSION IN MONOCYTES OF PATIENTS WITH ATHEROSCLEROSIS

M. López Carmona[1], M. Bernal López[1], F. Calleja[2], S. Santamaría Fernández[1], F. Tinahones Madueño[3], R. Gómez Huelgas[1]

[1]Department of Internal Medicine, [2]Department of Cardiovascular Surgery. Hospital General de Málaga. Málaga, Spain. [3]Department of Endocrinology. Complejo Hospitalario Virgen de la Victoria. Málaga, Spain.

Objectives: Atherosclerosis is particularly severe among the diabetic population. In pre-diabetic stage there is an excess of disease that is not attributable to other cardiovascular risk factors. The CD36 is a monocytic scavenger receptor that captures primarily oxidized LDL. Aim: To determine the expression of CD36 levels, both mRNA and protein (glycated and not glycated) in the initial stages of diabetes.

Material and method: Experiments "in vitro" with monocytes from atherosclerotic patients (n = 22) were carried out. The monocytes were cultured, in different times, during 48h as maxim, in extreme hyperglycemia (HG) conditions and in normoglycaemia (NG). Subjects with fasting glucose ≥ 126 mg/dl were excluded. The

atherosclerotic patients were divided into into three subgroups: 5 subjects with NG, 7 subjects with pre-diabetes (preDM) and 10 subjects with diabetes (DM).Also, these assays were realized with healthy subjects (n = 8) as control subjects.

Results: In the assays with HG, a very early expression peak of mRNA (4h) and another lower one after (24h) were obtained, indicating that influence of hyperglycemia on CD36 expression is fluctuating. In the group with NG, there was no difference of expression compared with control group, after 48h of culture. The expression peak appeared at the end of the experiment. Non glycated protein showed peaks of expression in two groups but, it was earlier in higher glucose concentrations (HG: 16h/NG: 48h). Like in glycated protein levels, the glucose inhibited receptor expression but at different times (HG: 8h/NG: 48h). In the experiment with patients, CD36 mRNA expression was decreased in NG subjects respect to preDM subjects and from them respect to DM subjects. Non glycated protein levels were not altered in either group. Glycated protein progressively increased from the NG subjects respect to preDM subjects and from them respect to DM subjects (p = 0.03). The diabetes development should be result of an increment of CD36 glycated expression, due, maybe, to the increment in the receptor recycling.

Conclusions: Acute HG is an important modulator of the expression of CD36 in vitro, with an increment in the synthesis of mRNA and a decrement in the expression of the protein in monocyte surface. In patients with atherosclerosis the development of abnormal glucose metabolism causes a progressive increment in CD36 receptor expression, maybe, due a posttranslational stimulus that could, partly, explain the excess of atherosclerotic disease in patients with disglycemia.

RV-159
EFFECTS OF CONTINUOUS POSITIVE AIRWAY PRESSURE (CPAP) ON PATIENTS WITH OBSTRUCTIVE SLEEP APNEA SYNDROME (OSAS) AND METABOLIC SYNDROME

E. Nadal, E. Rovira, M. Abdilla, R. Julve, I. Ezquerra, S. Ferrandis, J. Esteve

Department of Internal Medicine. Hospital Universitario de la Ribera. Valencia, Spain.

Objectives: The aim of the present study was to evaluate the long term effects of continuous positive airway pressure (CPAP) on metabolic and hemodynamic components of metabolic syndrome in patients with obstructive sleep apnea syndrome (OSAS) treated with CPAP.

Material and method: 158 patients recently diagnosed of OSAS without CPAP therapy, with apnea-hypopnea index (AHI) > 5 events/h and with CPAP treatment criteria were recruited for a longitudinal prospective study. 21 patients were excluded: 8 patients with a mild OSAS and 13 patients refused their inclusion on this study. 137 patients were included. 46 patients were non-compliant with the CPAP therapy and 91 patients fulfilled CPAP treatment for > 4h/night (CPAP compliance group). The patients were studied at 0 and 6 months after starting CPAP therapy. Blood pressure (BP) analysis with clinical BP and ambulatory blood pressure monitoring (office BP, diurnal BP, nocturnal BP); anthropometric variables (weight, body mass index (BMI) and waist circumference), and biochemical variables (glucose, HbA1c, insulin, HDL cholesterol, LDL cholesterol, triglycerides and fibrinogen) were studied. The results before and after CPAP therapy were compared using Student-t for continuous variables and chi-squared test for categorical ones. T-test was used to analyze inter and intra group differences.

Results: There were no statistically significant differences between groups in the basal analysis. During the follow up of non-compliant CPAP group, significant increases in blood pressure values were observed in office systolic BP (133 ± 15 vs 147 ± 21; p = 0.001) and office diastolic BP (80 ± 8 vs 85 ± 10; p = 0.020), systolic BP 24 hours (124 ± 14 vs 129 ± 12; p = 0.001), diurnal systolic BP (127 ± 11 vs 134 ± 13; p = 0.001), and diurnal diastolic BP (78 ± 8 vs 81 ± 7; p = 0.001) without significant changes in metabolic and anthropometric variables. In the compliant CPAP group, decreases were obtained in all BP parameters. Statistically significant differences were detected in office systolic BP (144 ± 16 vs 138 ± 14 mmHg; p = 0.037), office diastolic BP (87 ± 8 vs 83 ± 8; p = 0.003), systolic BP 24 hours (129 ± 13 vs 126 ± 11 mmHg; p = 0.049) and diurnal diastolic BP (81 ± 9 vs 78 ± 8 mmHg; p = 0.005). In biochemical variables, significant decreases in fibrinogen levels were detected and decrease in glucose, HbA1c, and insulin levels with borderline significance. Significant decrease was observed at 6 months for both groups in all BP measures (with the exception of diastolic BP 24 hours and nocturnal diastolic BP) and non significant decrease in glucose and total cholesterol levels.

Discussion: 6 months of CPAP therapy reduced the blood pressure levels in patients with OSA and concurrent metabolic syndrome. Patients who used CPAP for > 4h/night had reductions in glucose, HbA1c, and insulin. A poor metabolic control may be associated with fibrinogen levels and glucose metabolism. Further follow-up, will probably show the beneficial effects on metabolic syndrome variables and a decrease on cardiovascular risk.

Conclusions: The reduction of AHI after CPAP therapy was positively correlated with BP and probably produces favourable changes in lipid concentrations and glucose metabolism. CPAP therapy compliance is essential especially in patients with cardiovascular risk factors. A longer follow-up period is necessary to assess the total metabolic effects of CPAP therapy.

RV-169
NEW APPLICATIONS OF PPAR-GAMMA-ACTIVATION IN TREATMENT OF ARTERIAL HYPERTENSION WITH METABOLIC DISTURBANCES

A. Demin

Department of Internal Medicine. Novosibirsk State Medical University. Novosibirsk, Russia.

Objectives: The genetic basis of insulin resistance are the mutations of the nuclear intercellular hormone regulator (or the peroxisome proliferator-activated receptor-PPAR-gamma) which plays an important role in carbohydrate and lipid metabolism. Angiotensin receptor blocker (ARB) II telmisartan promotes PPAR-gamma, and, thus, may affect insulin resistance, lipid profile and target organ damage in arterial hypertension (AH). To estimate efficiency and tolerability of PPAR-gamma-activating ARB II telmisartan and standard ACE inhibitor enalapril in AH with metabolic disturbances of carbohydrate metabolism, lipid profile and renal dysfunction was the study objective.

Material and method: 80 patients with mild-to-moderate AH, mean 150/92 mmHg (primary or AH after chronic kidney disease), were randomized to telmisartan, 40-80 mg daily (n = 40) or enalapril, 10-20 mg daily (n = 40) for 8 weeks, according to a prospective, randomized, open-label, parallel-group design. Randomization was performed by a computer generated list of random numbers. At the end of 2-week washout period and after 8 weeks of active treatment, systolic and diastolic blood pressure (SBP and DBP), 24-h noninvasive mean BP monitoring was performed, fasting plasma glucose (FPG), HOMA-IR, HBA1c, lipid profile and renal function were evaluated.

Results: After 8 weeks' treatment according to the ABPM, telmisartan is more pronounced than enalapril reduced mean daily blood pressure in hypertensive patients (-17.5 mm vs -10.8 mm), including the last 8 h dosing (-18.2 mm vs 7.2 mm) - * p < 0.05. During the treatment, telmisartan reduces (p < 0.05) FGP rates by

7%, HOMO-IR by 21% and HbA1c by 8%, whereas enalapril had no effect on these parameters. Telmisartan, unlike enalapril, significantly improved the lipid profile: TCh (-17%), LDL cholesterol (-13%), p < 0.01, and triglycerides (-25%, p < 0.05). Proteinuria decreased by 35% in the telmisartan group (p < 0.01) and only 10% for enalapril, creatinine clearance and serum potassium levels have stabilized, and in the enalapril group noted further deterioration in these indicators. As can be seen with renal hypertension ARB telmisartan had a greater renoprotective effect than ACE inhibitor enalapril. There were no of clinically significant changes in laboratory parameters compared with baseline, including liver function tests. The frequency of side effects (dizziness, headache, cough) was lower in the telmisartan group (10% vs 35%, p < 0.01) in the absence of cough (0% vs 15%). Thus, the use of telmisartan compared with enalapril was characterized by a better tolerability and safety.

Discussion: As these studies alter our understanding of the AH treatment? A partial agonist of PPAR-gamma telmisartan, the only ARB that can positively influence the metabolic disturbances (visceral obesity, insulin resistance, particular, impaired glucose tolerance, dyslipidemia, proteinuria). Telmisartan, 80 mg/day, reduces proteinuria in patients with nephrogenic AH, can be used as a renoprotective agent in the treatment of chronic kidney disease. The use of telmisartan in patients with AH effectively in terms of not only the correction of blood pressure and organ protection, but also the impact on certain links in cardiometabolic continuum and the prevention of metabolic disturbances progression. The prospect of further research is to develop a new ARB, in addition to influencing blood pressure in insulin resistance and dyslipidemia, which will more effectively prevent the organ damage and cardiovascular complications in patients with AH, diabetes, and a combination of these diseases.

Conclusions: As well as providing superior 24-hour BP monitoring including the last 8 h of the dosing interval control, a highly selective angiotensin type-1 receptor blocker telmisartan unlike enalapril, improved insulin sensitivity and lipid profile in hypertensive patients with metabolic disturbances, which may be explained by its partial PPAR-gamma activity.

RV-184
IMPACT OF HDL-CHOLESTEROL AND HYPERGLYCEMIC STATUS ON MICROVASCULAR ENDOTHELIAL DYSFUNCTION

M. Fabregate Fuente, R. Fabregate Fuente, O. Sánchez Sánchez, S. Tello Blasco, C. Martínez Ruiz, E. Marín Manzano, A. Rodríguez Guerrero, J. Sabán Ruiz

Department of Endothelial Patology. Hospital Universitario Ramón y Cajal. Madrid, Spain.

Objectives: To assess the haemodynamic and metabolic factors implicated in microvascular endothelial dysfunction (ED).

Material and method: N = 117 patients: 61.1 (12.4) years. 59.8% males. 74.4% hypertensives. 70.1% with chronic hyperglycemia, 46 with type 2 Diabetes mellitus (T2DM). 17.1% Smokers. 49.6% with metabolic syndrome (2005 ATP-III criteria). Type 1 DM and LADA were previously excluded. Serum biochemistry by HITACHI autoanalyzer. Blood pressure by OMRON M10-IT, A1C (%): DCCT; C-reactive protein hsCRP (mg/L) and ApoA1 (mg/dl) by nephelometry.

Pulse amplitude and augmentation index measured with Endo-PAT2000 (Itamar Medical). Response to hyperemia according to Hamburg et al (2008): PAT ratio = ln[(Xh/Xh0)/(Xc/Xc0)], 90-120 seconds after deflation. Cut-off point for endothelial dysfunction: PAT ratio < 0.4, according to Rubinshtein et al (2010). Statistical analysis: Mean (standard deviation). Comparations by t-test or Mann-Whitney's test. Squared-Chi test. Odds ratio [95% confidence interval]. Multivariate linear regression, age and gender as covariates, standardized beta (s-B) and model R^2. p < 0.05. SPSS v15.0 (SPSS Inc).

Results: 1. The prevalence of ED (PAT-ratio < 0.4) was 59.0%. No differences were observed in age between ED and non-ED subjects: 61.7 (11.9) vs 59.9 (13.1). 2. ED was more frequent in males (68.6% vs 44.7%, p = 0.013), odds ratio 2.701 [1.257; 5.805]. 3. In age- and sex-adjusted models, PAT ratio was significantly related to: HDL-C: s-B = 0.205, p = 0.033, R^2 = 0.125 and apoA1: s-B = 0.233, p = 0.027, R2 = 0.140. 4. Among the different combinations assessed for hyperglycaemic status, T2DM+IGT showed the strongest association with ED: s-B = -0.211, p = 0.032, R2 = 0.125. 5. Abdominal obesity reached a borderline significance: s-B = -0.177, p = 0.062, R2 = 0.117. Moreover, patients with ED had a higher waist-to-hip ratio: 0.98(0.09) vs 0.91(0.09), p < 0.001. 6. In our study, neither hsCRP, augmentation index, office blood pressure, hypertensive status nor smoking showed a significant impact on microvascular function.

Discussion: Endothelial dysfunction is a key component of atherogenesis and contributes to the development of cardiovascular disease. Measurement of peripheral vasodilator response is an useful method for assessing microvascular function. According to Framingham Study, male sex, body mass index, ratio of total to HDL-C, T2DM, smoking, and lipid-lowering treatment were associated with lower pulse amplitude hyperemic response. T2DM + IGT showed the strongest association with ED, in agreement with the results of the Paris Prospective Study. With regard to T2DM, the FIELD Study showed that fenofibrates prevent the development of retinopathy, although the explanation remains an enigma. The role of HDL-C in microvascular function, as deduced from our results, could help to solve it.

Conclusions: 1. In contrast to macrovascular ED studies, age is not a determinant factor of microvascular ED.2. Our results confirm that microvascular ED is more prevalent in males.3. Regarding ED, T2DM and IGT go hand in hand.4. With the demonstrated implication of HDL-C in the microvascular function, we have taken a step in solving the riddle of the FIELD study.

RV-200
RELATIONSHIP BETWEEN ENDOTHELIAL AND CARDIAC DYSFUNCTION IN HYPERTENSIVE DIABETIC PATIENTS

A. Vintila, I. Bruckner

Coltea Clinical Hospital, Internal Medicine and Cardiology. Carol Davila University of Medicine and Pharmacy. Bucharest, Romania.

Objectives: Endothelial dysfunction is a key element in the pathogenesis of arterial hypertension and diabetes mellitus. Along with oxidative stress, it is highly responsible for target organ damage. On the other hand, cardiac involvement in hypertension and diabetes is very prevalent, even in patients without clinical manifestations of heart disease. Left ventricular diastolic dysfunction is frequently seen with possible progression to overt heart failure. The early diagnosis of cardiac involvement is essential in preventing cardiovascular morbidity and mortality in these patients. We hypothesized that endothelial dysfunction in hypertensive and diabetes mellitus patients may be correlated with left ventricular diastolic dysfunction, so that markers of endothelial dysfunction could predict subclinical cardiac involvement.

Material and method: Prospective study of 60 hypertensive patients, with or without type 2 diabetes mellitus, aged 58.55 ± 9.13 years, without evidence of coronary artery disease and without clinical signs of heart failure. Patients were assessed by complete case history, clinical examination, 12-lead ECG, ECG stress test, flow mediated vasodilation (FMD) and transthoracic echocardiography. Serum levels of total cholesterol, LDL-, HDL-cholesterol, triglycerides, creatinine, uric acid, glycated hemoglobin (HbA1c), C-reactive protein, von Willebrand factor and

NT-proBNP were analyzed. Left ventricular (LV) diastolic function was assessed using standard echocardiographic evaluation (two-dimensional, M-mode, color M-mode), spectral Doppler of transmitral flow and tissue Doppler imaging at the level of mitral annulus. All patients were in sinus rhythm and with normal left ventricular ejection fraction. Patients with comorbidities known to damage endothelial function were excluded.

Results: Impaired flow mediated vasodilation was found more frequently in patients with diabetes mellitus (5.87 ± 3.10% vs 9.72 ± 3.62%, p < 0.001), as well as high values of von Willebrand factor (167.62 ± 56.07% vs 137.01 ± 41.80%, p = 0.036). FMD was inversely correlated with plasma levels of von Willebrand factor (r = -0.458, p < 0.001) and with the duration of hypertensive disease (r = -0.531, p < 0.001). Statistically significant correlations have been found between parameters of left ventricular diastolic dysfunction and impairment of endothelial function. FMD values were correlated with A wave velocity (r = -0.624, p < 0.001), E/A ratio (r = 0.620, p < 0.001) and E' velocity calculated as the mean value of E' measured at lateral, septal, anterior and inferior mitral annulus (r = 0.492, p < 0.001). Diabetic patients had lower values of E/A ratio (0.88 ± 0.24 vs 1.08 ± 0.22, p = 0.002), longer EDT (223.33 ± 41.66 vs 194.67 ± 29.75 ms, p = 0.007), lower values of E' (0.08 ± 0.02 vs 0.10 ± 0.02 m/s, p = 0.001) and higher values of E/E' ratio (9.69 ± 2.25 vs 7.25 ± 1.53, p < 0.001).

Conclusions: Both endothelial dysfunction and left ventricular diastolic dysfunction are highly prevalent in patients with arterial hypertension and diabetes mellitus. FMD is a marker of endothelial dysfunction in both hypertensive and diabetes patients. We assume the bidirectional relationship between vascular dysfunction and cardiac diastolic dysfunction.

CLINICAL CHARACTERISTICS OF VTE PATIENTS WITH D-DIMER LEVELS DETERMINED AT THE END OF ANTICOAGULATION

J. Sahuquillo[1], M. Martín[2], M. Monreal[3], P. Marchena[4], M. Durán[5], J. Villalta[6], V. Rosa[7] and the RIETE Investigators

[1]Department of Internal Medicine. Hospital Municipal de Badalona. Badalona (Barcelona), Spain. [2]Department of Internal Medicine. Hospital Infanta Sofía. San Sebastián de los Reyes (Madrid), Spain. [3]Department of Internal Medicine. Hospital Universitari Germans Trias i Pujol. Badalona (Barcelona), Spain. [4]Department of Internal Medicine. Hospital de Sant Boi. Barcelona, Spain. [5]Department of Internal Medicine. Hospital Vall d'Hebron. Barcelona, Spain. [6]Department of Internal Medicine. Hospital Clínic. Barcelona, Spain. [7]Department of Internal Medicine. Hospital Virgen de la Arrixaca. Murcia, Spain.

Objectives: To analyze the characteristics of patients with VTE to which d-dimer was determined at the end of anticoagulant treatment.

Material and method: Prospective registry (R.I.E.T.E.) of the clinical, epidemiological and procedure in over 2,500 patients with VTE to which d-dimer was determined at the end of treatment.

Results: An average of 33% of our patients had positive d-dimer at the end of treatment, depending on the technique of determination. Age, renal failure, COPD, underlying neoplasm, or the use of LMWH in the maintenance therapy showed a statistically significant relationship with a positive d-dimer after cessation of treatment (p < 0.001) and had low statistical power of patients with heart failure (p = 0.021) or proximal DVT (p = 0.016). Moreover estrogen therapy, distal DVT and the use of VKA as therapy were great statistical power with normal d-dimer at the end of treatment (p < 0.001) and pregnancy (p = 0.003), male gender (p = 0.005) and immobility greater than 3 days (p = 0.090) with a lower statistical power. The duration of anticoagulation was similar in both groups, about 9 months, and the time of determination of the d-dimer was later in the positive cases (p = 0.061). Moreover the recurrence rate was 9.4% in the group with positive d-dimer and 6.2% in the group with normal d-dimer (p = 0.004). The average Sensitivity and PPV of the different techniques used d-dimer determination were 56.2% and 6.9% respectively, being higher with the techniques such as Auto Dimer-d test, VIDAS d-dimer or IL test D-dimer. The mean Specificity was 67.3%. The NPV was high for all techniques (97.2%).

Discussion: The rate of positive d-dimer at the end of therapy in our registry was lower (33%) than the average found in the literature (45-48%). The rate of relapses with positive d-dimer is lower too (9.4%) than that reported to date (about 17%), both events possibly due to the heterogeneity of the determination techniques used in the registry and highest average duration of anticoagulant therapy (about 9 months). The clinical and epidemiological factors associated with higher percentage of positive d-dimer were similar to those in the literature. The sensitivity of the techniques of determination and PPV were low, except for some technical such us VIDAS, Autodimer test or IL test. The specificity was moderate while the NPV of all of them was high.

Conclusions: The d-dimer levels at end of treatment are influenced by different characteristics of patients with VTE, including age, risk factors for VTE, comorbidity, clinical presentation and treatment and probably the time of determination. These factors should be considered when interpreting the results. The d-dimer levels at the end of anticoagulant therapy influence the rate of recurrent VTE, but possibly not the only factor involved. Quantitative techniques for determining the d-dimer have a high negative predictive value for recurrence, but have low sensitivity and PPV in general, except some of them like VIDAS, Autodimer test, and IL test.

T-6
PREVALENCE AND RISK OF VENOUS THROMBOEMBOLISM (VTE) IN ACUTELY ILL HOSPITALIZED MEDICAL PATIENTS (MEDITROM STUDY)

J. Nieto[1], I. Camacho[2], and Meditrom Study Investigators

[1]Department of Internal Medicine. Hospital Virgen de la Luz. Cuenca, Spain. [2]Department of Biometrics. Phidea Marvin. Madrid, Spain.

Objectives: The aim of the ongoing MEDITROM study is to analyze the prevalence of VTE, associated risk factors and prophylaxis use in consecutive patients admitted to hospital for acute medical illnesses. This interim analysis reports on the population characteristics and main outcomes of patients included until May-2012.

Material and method: Multicentre retrospective study. Discharge lists were reviewed in participating centres to select the first consecutive 20 patients, aged ≥ 40 years and admitted ≥ 4 days to a medical unit. Exclusion criteria were: admission for diagnostic procedures, VTE or surgical illness, or management provided by the local investigator.

Results: Discharge reports from 1.646 medical patients (48 centres) were evaluated; 690 patients did not meet the inclusion

criteria or were excluded; Data from 957 (58.1%) patients were analyzed. The median age was 78 years (range, 40-101 years) and 49% were females. The median hospital stay was 8 days (range, 4-59 days). Admission diagnoses were cardiovascular diseases 25.5%, respiratory diseases 31.5%, neurologic diseases 14.7%, infections 16.8%, gastrointestinal diseases 12.2%, neoplasia 6.37%, other 39.8% (35% of the patients had 2 o more admission diagnosis). Complete immobilization (patient confined to bed or chair) affected to 41.3% of the patients, and decreased mobility (rest on bed or chair more than 50% of the time during the day and bathroom privileges) to 53.7%. During hospitalization, 6.62% of the patients died, 2.95% developed symptomatic VTE and 6.61% bleeding episodes. Most (76%) of symptomatic VTE episodes occurred in patients receiving appropriate prophylaxis. Overall, 59% of the patients were at risk of VTE according to the Pretemed Guide (score ≥ 4), 62.1% of the patients received VTE prophylaxis (pharmacologic, 98.3%; mechanical, 1.5%) and 64.7% had at least one risk factor for bleeding. The proportion of patients at VTE risk (Pretemed score ≥ 4) and no risk factors for bleeding that did not receive prophylaxis was 24.3%.

Conclusions: The population characteristics and main outcomes portray real-life medical practice. Nearly 24% of hospitalized acute medical patients at risk of VTE and with low risk for bleeding didn't receive the recommended prophylaxis.

T-20
VENOUS TROMBOEMBOLIC DISEASE RELATED WITH HORMONAL CONTRACEPTIVES IN WOMEN WITH THROMBOPHILIA. FINDINGS FROM THE RIETE REGISTRY

B. García Olid[1], Á. Blanco Molina[1], J. Trujillo[2], J. Ogea[3], E. Rodríguez[4], M. Morales[5], M. Monreal[6] and the RIETE Investigators

[1]Department of Internal Medicine. Hospital Universitario Reina Sofía. Instituto Maimónides de Investigación Biomédica (IMIBIC) de Córdoba. Universidad de Córdoba. Córdoba, Spain. [2]Department of Internal Medicine. Complejo Hospitalario Universitario de Cartagena. Cartagena (Murcia), Spain. [3]Department of Internal Medicine. Hospital Universitario Reina Sofía. Córdoba, Spain. [4]Department of Internal Medicine. Hospital Nuestra Señora de Sonsoles. Ávila, Spain. [5]Department of Internal Medicine. Hospital del Tajo. Aranjuez (Madrid), Spain. [6]Department of Internal Medicine. Hospital Universitari Germans Trias i Pujol. Badalona (Barcelona), Spain.

Objectives: The use of hormonal contraception increases the risk of venous thromboembolism. This risk is greater among women with thrombogenic mutations. In this study we investigate the possible influence of genetic thrombophilia in the characteristic clinics, the additional risk factors associated and the outcome during the first 3 months of venous thromboembolism related with hormonal contraceptives.

Material and method: RIETE is an ongoing registry of consecutive patients with objectively confirmed, symptomatic acute VTE. The clinical manifestations, the presence of risk factor and outcome were investigate in all enrolled women using hormonal contraceptive with Factor V Leiden, prothrombin G20210A mutation, strong thrombophilia (antithrombina III, protein C and S deficiency) and no thrombophilia marker.

Results: As of November 2011, 38,668 patients had been enrolled, of whom 822 (2%) were women using hormonal contraceptive. Three hundred sixty-three were studied for genetic thrombophilia test. One hundred thirty-six were positive for thrombophilia and were compared with the negative thrombophilia women (N = 227). The prevalence of FV Leiden, FIIG20010A and strong thrombophilia was 45.6%, 34.6% and 19.8%, respectively. The thrombophilia positive women were not younger than negative thrombophilia women. There was no difference in additional risk factor as immobility, postoperative period, varicose veins, prior prolonged travel, or prior venous thromboembolism between thrombophilia positive and negative women. The duration of hormonal therapy before the presentation of venous thrombosis was similar in the four groups. No differences in the clinical manifestations, as such deep venous thrombosis (DVT) or pulmonary embolism (PE), was found between the groups. During the 3-month study period, one woman with FII20210 mutation died (fatal PE) and three thrombophilia negative women had a VTE recurrence (2 DVT and 1 PE). No hemorrhagic events were observed in any of the groups.

Discussion: Previously it has been described that carriers of prothrombin G20210A have an increase risk of developing isolated PE. Our data obtained in thrombophilia- positive woman users of hormonal contraceptive do not support this difference in clinical presentation of venous thromboembolism.

Conclusions: The thrombogenic mutations have no influence in the characteristic clinics, the risk factors associated or on the outcome of venous thromboembolism related with hormonal contraceptives.

T-21
RISK SCALES AND RISK ASSESSMENT CRITERIA TO PREVENT VENOUS THROMBOEMBOLISM IN HOSPITALIZED MEDICAL PATIENTS

M. Artero[1], G. Tornel[1], S. Herrera[1], J. Trujillo[1], M. Torralba[2], I. Puche[2], M. Ruiz[2], V. Rosa[3]

[1]Department of Internal Medicine. Hospital Santa Lucía. Cartagena (Murcia), Spain. [2]Department of Internal Medicine. Hospital Morales Meseguer. Murcia, Spain. [3]Department of Internal Medicine. Hospital Virgen de la Arrixaca. Murcia, Spain.

Objectives: To evaluate the concordance of 3 methods of venous thromboembolic risk assessment (Pretemed and Padua scales, and clinical criteria of the Medenox study) in medical patients admitted to hospital.

Material and method: Observational study of patients admitted to Internal Medicine service. The first 5 consecutive patients who did not need anticoagulant therapy were collected daily and the Pretemed and Padua scales, and inclusion criteria of Medenox study was considered. The following hospitals from the Region de Murcia participated in the study: Hospital Santa Lucía (Cartagena) and Hospitals Morales Meseguer and Virgen de la Arrixaca (Murcia).

Results: Three hundred and thirty-four patients were valued with Pretemed risk scale and inclusion criteria of Medenox study. Overall agreement was 61% (95%CI: 56%-66%) although kappa index value was 0.23 (0.12-0.33). Global agreement between Pretemed and Padua risk scales was 54% (49%-59%) with a kappa index of 0.12 (0.04-0.19). Overall agreement between Padua scales and Medenox criteria was 53% (48%-59%) with a kappa index of 0.08 (0-0.16).

Discussion: Although each of these risk scales and clinical criteria for pharmacologic thromboprophylaxis of hospitalized medical patients have been validated and have been found useful to indicate thromboprophylaxis, the correlation between them in order to classificate high-risk patients as venous thromboembolism, and thus making pharmacological thromboprophylaxis, is low.

Conclusions: Concordance between the classification of patients with Pretemed and Padua risk scales and Medenox study criteria in order to identify medical patient in high-risk of venous thromboembolism is no more than of low-grade. Therefore, results of one risk scale should not be extrapolated to another. Only prospective studies comparing the 3 "risk scales" of venous thromboembolic events in medical inpatients may indicate the most useful classification criteria.

Table 1 (T-21)

p < 0.001	Medenox "high risk"	Medenox "No risk"
Pretemed "High risk"	61 (36%)	96 (59%)
Pretemed "low risk"	109 (64%)	68 (42%)

Table 2 (T-21)

p = 0.057	Pretemed "high risk"	Pretemed "low risk"
Padua "high risk"	16 (29%)	141 (51%)
Padua "low risk"	40 (71%)	137 (49%)

Table 3 (T-21)

p = 0.002	Medenox "high risk"	Medenox "low risk"
Padua "high risk"	21 (38%)	143 (51%)
Padua "low risk"	35 (62%)	135 (49%)

T-30
ECONOMIC BURDEN OF VENOUS THROMBOEMBOLISM AND ANTITHROMBOTIC PROPHYLAXIS IN MEDICAL INPATIENTS. A REAL-WORLD ANALYSIS BY THE SCIENTIFIC SOCIETY FADOI

G. Gussoni[1], S. Frasson[1], E. Foglia[2], M. Campanini[3], M. Bonfanti[2], G. Vescovo[4], A. Mazzone[5], on behalf of the FADOI Permanent Study Group for Clinical Governance[6]

[1]Department of Research. FADOI Foundation. Milan. Italy. [2]Center for Research in Health Economy and Management (CREMS). University L. Cattaneo. Castellanza. Italy. [3]Department of Internal Medicine. Hospital Maggiore della Carità. Novara. Italy. [4]Department of Internal Medicine. Hospital S. Bortolo. Vicenza. Italy. [5]Department of Internal Medicine. Hospital Civile. Legnano. Italy. [6]Department of Research. FADOI Scientific Society. Rome. Italy.

Objectives: Venous thromboembolism (VTE) is a significant cause of morbidity and mortality in medical patients. In addition, the economic burden of this disease is plausibly relevant as well, due to management of acute episodes and to the costs of long-term complications. However, few real-world data are available on this topic, since information mainly comes from post-hoc analyses of randomized clinical trials. Aim of our study was to assess the in-hospital costs of VTE management and antithrombotic prophylaxis in patients hospitalized in Internal Medicine (IM) departments.

Material and method: To assess the costs of VTE and of prophylaxis, each investigator collected data from five hospitalized consecutive patients diagnosed with VTE (VTE group). Within the same time frame, the medical reports of five patients who received prophylaxis and who did not develop VTE, were reviewed by each investigator (NO-VTE group). Patients in the NO-VTE group were those hospitalized immediately before the corresponding VTE patients (casual selection). The economic analysis was undertaken by applying a process analysis, the initial phase of the more comprehensive Activity Based Costing technique. Accordingly to this approach, only information closely linked to VTE or its prevention was registered.

Results: The in-hospital paths of 160 patients with VTE and 160 patients receiving prophylaxis and without VTE were evaluated, from 26 IM units in Italy. The total median costs for VTE management were around four-times higher than those for prophylaxis (€ 1,348.68 vs € 373,03). This difference was particularly sustained in the phase of hospital stay, and partially by the time of admission to the hospital. Similar results were obtained by considering the costs for VTE management in the subgroup of patients without signs of VTE at hospital admission. Human resources were the most important cost-driver (55.5% and 65.7% in the VTE and NO-VTE groups), followed by instrumental (24.6% in VTE and 15.5% in NO-VTE) and haematologic tests (12.6% in VTE patients and 13.3% in controls). In the NO-VTE group the direct costs for prophylaxis accounted for 4.5% of total.

Discussion: Available analyses on the costs of VTE management and/or antithrombotic prophylaxis rely on data from large administrative or hospital databases or from randomized clinical trials. In the former, there is a difficulty in isolating health costs related to VTE, whereas in the latter, strict inclusion criteria, standardized prophylaxis and diagnostic work-up may significantly affect economic results. In this perspective, the experimental design (with a medium-size data collection) and the 'real-world' approach are strengths of our study, making the results reliable and of value.

Conclusions: The real-world data of this study confirm the economic burden of in-hospital treatment of VTE, and the relatively low costs of thromboprophylaxis. An extended follow-up would have plausibly added consistency to these results. A greater adherence to evidence-based protocols for VTE prevention could probably reduce the current financial burden of VTE on healthcare systems.

T-36
INITIAL THERAPY FOR ACUTE VENOUS THROMBOEMBOLISM WITH RENAL INSUFFICIENCY: LOW MOLECULAR WEIGHT HEPARIN (LMWH) VS UNFRACTIONATED HEPARIN (UFH)

C. Falgà[1], J. Trujillo[2], S. Schellong[3], V. Zorrilla[4], P. Gallego[5], M. Barrón[6], M. Monreal[7] and the RIETE Investigators

[1]Department of Internal Medicine. Hospital de Mataró. Mataró (Barcelona), Spain. [2]Department of Internal Medicine. Hospital Universitario de Santa Lucía. Cartagena (Murcia), Spain. [3]Department of Medical Clinic II. Municipal Hospital of Dresden Friedrichstadt. Dresden. Germany. [4]Department of Pneumonology. Hospital Txagorritxu. Vitoria (Álava), Spain. [5]Department of Internal Medicine. Hospital SAS de Jerez. Jerez de la Frontera (Cádiz), Spain. [6]Department of Pneumonology. Complejo Hospitalario San Millán y San Pedro. Logroño (La Rioja), Spain. [7]Department of Internal Medicine. Hospital Universitari Germans Trias i Pujol. Badalona (Barcelona), Spain.

Objectives: 1. To study if there are major differences between LMWH or UFH for initial therapy of VTE in patients with or without renal insufficiency. 2. To compare the incidence of fatal PE, fatal bleeding and all-cause mortality in patients treated with LMWH vs UFH.

Material and method: We studied 38,531 patients with VTE included in the RIETE Registry and we evaluated the outcomes at 15 days. We used propensity score-matching to compare patients treated with UFH vs those with LMWH, in groups stratified by creatinine clearance (CrCl): > 60 ml/min, 30-60 ml/min or < 30 ml/min.

Results: 38,531 patients with acute VTE were included in RIETE. The inclusion criteria were symptomatic acute deep venous thrombosis (DVT) or pulmonary embolism (PE) confirmed by objective tests. The patients were classified in three groups according to their CrCl: CrCl > 60 ml/min (82%), CrCl 30-60 ml/min (12%) and CrCl < 30 ml/min (5.8%). In all, 90% received initial treatment with LMWH, 5.6% with UFH, 1.3% with fondaparinux and 1.2% with thrombolytics. The majority of

patients in all subgroups were initially treated with LMWH (90%) and mean daily doses of LMWH slightly decreased with worsening of renal function. The patients treated initially with UFH more likely had chronic heart failure, recent bleeding or anemia, were younger and weigher more compared wiht those treated with LMHW in all 3 subgroups. We used propensity score-matched groups of patients with Cr Cl > 60 ml/min (1,598 matched pairs), 30-60 ml/min (277 matched pairs) and < 30 ml/min (210 matched pairs). In the three groups of patients was observed and increased incidence of fatal PE when we compared UFH vs LMWH (2.8% vs 1.2% p 0.001; 3.2% vs 2.5% p NS and 5.7% vs 2.4% p 0.023) respectively. No differences in the incidence of fatal bleeding were found in all groups (0.3% vs 0.3%; 0.7% vs 0.7% and 0.5% vs 0.0% respectively). Neither was observed differences in major bleeding or recurrent PE in the three groups. Multivariate analysis confirmed that patients treated with UFH were at an increased risk for fatal PE (OR 2.3; 95%CI: 1.5-3.6) and all mortality (OR 1.8; 95%CI: 1.3-2.4).

Discussion: The findings in this study show that majority of patients with severe renal failure in RIETE was treated initially with LMWH. This study found that the risk of fatal PE was two times higher in VTE patients initially treated with UFH than in those receiving LMWH. The better outcome also in patients with severe renal failure is an unexpected finding. This could be explained because these patients were more sick but any difference in baseline characteristics disappeared after propensity score matching. Are necessary more additional studies with longer follow-up.

Conclusions: This study show that initial therapy with UFH vs LMWH was associated with two-fold higher incidence of fatal PE during the first 15 days of therapy irrespectively of renal function with no differences in fatal bleeding.

T-56
PREDICTION OF QTHROMBOSIS RISK SCORE WITH PADUA RISK SCORES FOR MEDICAL INPATIENTS

M. Artero, G. Tornel, C. Smilg, S. Herrera, J. Trujillo

Department of Internal Medicine. Hospital Universitario Santa Lucía. Cartagena (Murcia), Spain.

Objectives: To evaluate whether the prediction of QThrombosis risk with a risk scale for medical inpatients (Padua risk score) could be considered.

Material and method: Observational study of patients admitted to Internal Medicine service (Hospital Santa Lucía, Cartagena (Spain)). The first 5 consecutive patients who did not need anticoagulant therapy were daily gathered during a month and Padua risk score and QThrombosis risk were calculated.

Results: Ninety-four patients were valued with Padua risk score and QThrombosis risk score at 1-year (www.qthrombosis.org). Padua risk scoring was considered as a continuous variable. Patients with a high-risk scoring in Padua score had a prediction of VTE with QThrombosis calculator of 0.85 (SD = 0.64) and 0.25 (SD = 0.37) in patients with a low-risk Padua risk scoring ($p < 0.001$). An equation was calculated with a lineal regression analysis: QThrombosis risk scoring = 0.164 * Padua scoring (95%CI: 0.142-0.186). Determination coefficient was r2 = 0.70, so 70% QThrombosis scoring was determinated by Padua risk scoring.

Discussion: A scale for predicting risk of venous thromboembolism (Padua risk score) during admission the patient could predict not only the risk of an episode of VTE during it but up to 1 year after admission (QThrombosis risk).

Conclusions: A simple risk assessment scale (Padua risk score) could not only predict the risk of the patient of venous thromboembolism during admission but also up to one year after treatment.

T-75
PULMONARY EMBOLISM AND 3-MONTH OUTCOMES IN 4,036 PATIENTS WITH VENOUS THROMBOEMBOLISM AND CHRONIC OBSTRUCTIVE PULMONARY DISEASE. DATA FROM THE RIETE REGISTRY

L. Bertoletti[1], S. Quenet[1], R. Sánchez[2], S. Soler[3], A. Riera Mestre[4], J. Sahuquillo[5], J. López Sáez[6], F. del Molino[7] and the RIETE Investigators

[1]Thrombosis Research Group. University Hospital of Saint-Etienne. St-Etienne. France. [2]Department of Internal Medicine. Hospital General Universitario de Alicante. Alicante, Spain. [3]Department of Internal Medicine. Hospital de Sant Jaume. Olot (Girona), Spain. [4]Department of Internal Medicine. Hospital Universitario de Bellvitge. L'Hospitalet de Llobregat (Barcelona), Spain. [5]Department of Internal Medicine. Hospital Municipal de Badalona (Barcelona), Spain. [6]Department of Internal Medicine. Hospital Universitario Puerto Real. Cadiz, Spain. [7]Department of Internal Medicine. Hospital General de Catalunya. Barcelona, Spain.

Objectives: We recently found that patients with chronic obstructive pulmonary disease (COPD) present more frequently with pulmonary embolism (PE) than deep venous thrombosis (DVT) (Bertoletti et al. Eur Respir J. 2011).

(. They also suffer from higher rate of death, bleeding or PE as the first venous thromboembolism (VTE) recurrences than non-COPD patients. The main objective of this study was to compare the 3-month evolution of patients with COPD and acute VTE, according to their initial clinical presentation (PE or DVT), in the RIETE registry.

Material and method: In the RIETE registry, a prospective cohort study VTE patients, demographic data, characteristics of PE and DVT, and known risk factors were recorded in addition to events (death, bleeding, VTE recurrence) occurring within a 3-month follow-up. Adjusted hazard ratios (HR) and 95% confidence intervals (CI) for initial VTE presentation as a potential predictor for overall death, fatal PE, first recurrent VTE as PE and major bleeding were calculated in COPD patients whom require antithrombotic therapy for VTE.

Results: By June 2011, 4,036 (11%) of the 37,090 patients included in the RIETE registry had COPD (67% men, median age: 75 years). The initial VTE presentation was PE in 2,452 (60%). Under treatment, three-month cumulative incidence of overall death (including fatal PE), first recurrent VTE as PE and major bleeding were: 11% (Fatal PE: 2%), 2% and 2.5%, respectively. During the three month follow-up period, risk of fatal PE (HR = 8.21, 95%CI: 3.57-18.87), recurrent VTE as PE (3.87, 2.31-6.49) and death (1.46, 1.2-1.8) were significantly higher in COPD patients presenting with PE than in COPD patients presenting with DVT. There was a trend towards an increased risk of major bleeding (1.47, 0.96-2.24).

Discussion: The main limitations of the study were possible underestimations of recurrent PE and fatal PE in our group of patients with persistent respiratory symptoms, as the absence of functional respiratory data.

Conclusions: During the first three months of VTE treatment, the risk of death, fatal PE and recurrent VTE as PE were significantly increased for COPD patients presenting with PE compared to COPD patients presenting with DVT.

T-81
VENOUS THROMBO-EMBOLISM (VTE) RISK REASSESSMENT PATIENT SAFETY PROJECT

T. Chang Kwok, P. Vasdev, L. Elling, S. Stinchcombe

Department of Internal Medicine. Kings Mill Hospital. Nottinghamshire. United Kingdom.

Objectives: 40% of adult medical and major surgical inpatients are not receiving effective thrombo-embolism prophylaxis. This resulted in 25,000 deaths annually in England (Donaldson L. Annual Report of the Chief Medical Officer 2007). Apart from initial VTE risk assessment, National Institute for Health and Clinical Excellence stresses the importance of VTE risk reassessment after 24 hours of admission and whenever clinical condition changes (National Institute for Health and Clinical Excellence. Venous Thromboembolism. 2010). VTE risk has never been properly reassessed in our trust. This carries a significant patient safety risk. Aim: The aim of the project was to improve VTE risk reassessment in our hospital. Our target was to achieve 90% compliance in 1 ward in terms of VTE risk reassessment as per NICE guideline.

Material and method: A prospective 2-week-audit in a 24-bedded ward was performed. A sticker was then introduced in the drug chart to prompt doctors to reassess the VTE risk. This was coupled with education of all healthcare professionals in the ward. We then completed two further audit cycles. We assessed whether appropriate action has been taken if the patient's VTE risk has changed since admission. This was taken as our gold standard outcome clinical measure.

Results: Prior to the intervention, the percentage of patient having documented reassessment of VTE risk after 24 hours of admission has improved from 15% to 32% after two audit cycles. Our gold standard outcome also showed improvement from 53% to 75% after 2 audit cycles. We found that the low outcome measure initially was due to the failure in picking up error made in assessing the initial VTE risk on admission unless a significant clinical event occurs.

Discussion: Despite not achieving our target, we have noted improvement objectively from feedback received from the ward as well as subjectively as shown in the results. Further audit cycles and innovative ideas are being carried out to improve our outcome measures. We are also trying to incorporated VTE reassessment into e-prescribing which is being rolled out in our hospital.

Conclusions: VTE risk reassessment should be incorporated in our daily assessment of patients.

Others

V-3
THE EFFECTS OF PIOGLITAZONE AND METFORMIN ON PLASMA ASYMMETRIC DIMETHYLARGININE LEVELS IN PATIENTS WITH TYPE 2 DIABETES

U. Safer[1], V. Binay Safer[4], A. Sonmez[2], S. Tapan[3], I. Tasci[1], I. Naharci[1], E. Bozoglu[1], T. Dogru[1]

[1]Department of Geriatric, [2]Department of Endocrinology, [3]Department of Medical Biochemistry. Gulhane Medical Faculty Training Hospital. Ankara, Turkey. [4]Department of Physical Medicine. Ankara Physical Medicine and Rehabilitation Education and Research Hospital. Ankara, Turkey.

Objectives: Type 2 diabetes has become an epidemic disease in recent years. Patients with type 2 diabetes mellitus have higher risk for cardiovascular diseases than the normal population. Prospective clinical studies of the last years demonstrate the increased importance of Asymmetric dimethylarginine as a novel cardiovascular risk factor. We evaluated the effects of two insulin-sensitizing hypoglycemic agents on plasma Asymmetric dimethylarginine levels in patients with newly diagnosed and untreated type 2 diabetes mellitus.

Material and method: Forty-six patients with type 2 diabetes mellitus were randomized to treatment either with pioglitazone (15-30 mg/day) or metformin (1,000-2,000 mg/day). Plasma Asymmetric dimethylarginine (ADMA) levels and homeostasis model assessment of insulin resistance scores were determined at baseline and at 12th week of treatment.

Results: By the end of the 12th week, fasting plasma glucose, HbA1c, HOMA-IR scores and waist circumferences improved equally in both treatment arms. HDL cholesterol increased only in the pioglitazone group ($p = 0.01$). On the other hand, metformin treatment had additional regulatory effects on BMI, blood pressure and total and LDL-cholesterol levels ($p = 0.01$, $p = 0.01$, $p < 0.001$ ve $p < 0.001$, respectively). Pioglitazone and metformin lowered ADMA concentration but not displayed a significant effect.

Discussion: Neighter pioglitazone nor metformin displayed a significant effect on circulating ADMA concentration.

Conclusions: The results of the present study imply that two different oral antidiabetic agents which are commonly used in the treatment of type 2 diabetes mellitus have similar effects on endothelial functions.

Table 1 (V-3). The comparison of the results at baseline with pioglitazone or metformin

	Pioglitazon n = 23	Metformin n = 23	p
Gender (M/F)	13/8	14/9	
Age (years)	55.5 ± 8.0	55.0 ± 9.4	0.81
Waist circumfe (cm)	103.5 ± 8.3	102.4 ± 7.8	0.58
BMI (kg/m2)	30.4 ± 4.2	31.4 ± 3.8	0.44
SBP (mmHg)	129.8 ± 9.3	131.3 ± 9.0	0.50
DBP (mmHg)	82.0 ± 4.6	83.0 ± 6.1	0.47
HbA1c (%)	6.4 ± 1.1	6.9 ± 1.8	0.20

V-9
PHARMACOLOGICAL TREATMENT WITH TETRAHYDROBIOPTERIN IN PULMONARY HYPERTENSION

B. Francis, M. Wilkins, L. Zhao

Department of Pharmacology and Therapeutics. Imperial College London. London, United Kingdom.

Objectives: Pulmonary hypertension (PH) is a complex and multifactorial disease. It is characterized by endothelial cell dysfunction leading to pulmonary arterial vasoconstriction, vascular remodelling, inflammation and thrombosis in situ. Endothelial nitric oxide synthase (eNOS) is a cornerstone in endothelial cell and cardiac function and its activity is regulated by tetrahydrobiopterin (BH4). When BH4 bioavailability is limited, eNOS becomes uncoupled, i.e. dysfunctional, and generates superoxide rather than nitric oxide (NO), leading to the development of PH. Thus, the main objectives of this study are: 1) to clarify the role of endothelial BH4-eNOS-NO-Superoxide pathway in the pathophysiology of PH; 2) to evaluate the effect of pharmacological supplementation with BH4 in animal models of PH.

Material and method: Isolated perfused lung studies where used to explore the acute pharmacological effect of BH4 and its mechanism in regulating pulmonary vascular tone. In vivo studies were used to evaluate the effects of chronic BH4 treatment in PH models (hypoxia and monocrotaline- induced PH) and biochemical

and histological studies aimed to clarify the molecular mechanism of BH4 as a potential therapy for PH.

Results: In isolated perfused lungs, BH4 inhibited hypoxic pulmonary vasoconstriction and increased NO metabolites. In a Langendorff heart preparation, BH4 increased right ventricular systolic pressure (RVSP) in the hypertrophied right ventricle (RVH) compared to control as well as contractility. BH4 prevented the development of PH in MCT model. In a dose of 10 and 100 mg/kg, it reduced pulmonary artery pressure (PAP) (29.3 ± 5.2 to 21.7 ± 3.6 and 21.5 ± 2.3 mmHg, $p < 0.05$), attenuated RVH (10 mg/kg) and prevented it (100 mg/kg). BH4 (10 and 100 mg/kg) ameliorated vascular muscularization in a dose dependent manner (78 ± 4% and 64 ± 4% vs 95 ± 4% respectively, $p < 0.01$). eNOS protein levels in lung homogenates were maintained and cGMP was increased. BH4 rescue therapy attenuated further development of PH in MCT model. RVSP was reduced (46.2 ± 8.4, 43.6 ± 6.6 mmHg (10 and 100 mg/kg) vs 58.1 ± 16.0, $p < 0.01$) and RVH was attenuated (0.45 ± 0.1, 0.43 ± 0.1 (10 and 100 mg/kg) vs 0.53 ± 0.1, $p < 0.05$). BH4 attenuated pulmonary vascular muscularization. BH4 (10 mg/kg) reduced RV myocyte diameter compared to placebo while BH4 (100 mg/kg) reversed to control levels. BH4 maintained normal levels of eNOS protein and enhanced lung tissue levels of BH4, cGMP and NO. In hypoxia model, BH4 (100 mg/kg) reversed RVSP over 7 days (radiotelemetry, from 63 ± 4 to 44.5 ± 4 mmHg). At two weeks, BH4 (100 mg/kg) partially reversed RVH compared to placebo and BH4 (10 mg/kg) (0.50 ± 0.02, 0.58 ± 0.03 and 0.57 ± 0.1 respectively, $p < 0.05$). BH4 (100 mg/kg) induced partial reversal in vascular muscularization compared to placebo and BH4 (10 mg/kg) (65.2 ± 6%, 81.4 ± 9% and 74.3 ± 10% respectively, $p < 0.01$). BH4 (100 mg/kg) increased eNOS enzymatic activity in lung homogenates (but not protein levels). BH4 moderately increased cGMP ($p > 0.05$) and significantly reduced superoxide levels.

Discussion: BH4 increases NO and H_2O_2 production and has direct antioxidant action, all leading to pulmonary vasodilation and enhanced cardiac contractility. BH4 was a safe and tolerant therapy. BH4 was effective in prevention and amelioration of PH in MCT model. BH4 partially reverses PH in hypoxia model. The mechanisms of BH4 therapy involve the following: Improvement of pulmonary & cardiac hemodynamics, attenuation/reversal of cardiac hypertrophy, amelioration/reversal of lung vascular muscularization and improving endothelial cell dysfunction.

Conclusions: BH4 is a potential therapy which addresses the vasoconstrictive, hyperproliferative and hypertrophic nature of PH and warrants further investigation.

V-23
GENETIC ANALYSIS OF 373 SNPS IN OBSTRUCTIVE SLEEP APNEA (OSA)

E. Sánchez Ruiz-Granados[1], M. Romero Jiménez[1], M. Sáez Goñi[2], A. Grilo Reina[2], J. Domínguez[1]

[1]Department of Internal Medicine. Hospital Infanta Elena. Huelva, Spain. [2]Department of Internal Medicine. Complejo Hospitalario Nuestra Señora de Valme. Sevilla, Spain.

Objectives: To study the genetics components of the Obstructive Sleep apnea.

Material and method: We performed a genetic association analysis of 373 polymorphism (SNPs) wiith OSA. These SNPs were selected in a previous genome wide association analysis (GWAS) for metabolic syndrome (MS) related phenotypes. The genetic association study of OSA includes 387 subjects retrospectively assessed at the Internal Medicine Unit of the "Virgen de Valme" University Hospital (Seville, Spain). All of them are hypertensive patients. All participants gave their written consent to participate. To increase the power of our study we used data from the Framingham sleep study on OSA. The diagnostic of obstructive sleep apnea was done through polisomnography. OSA was defined as an IAH of 5 or more. We used a stepwise logistic regression model to select de independent determinants of OSA. The traits associated with $p < 0.05$ in this model, were used as covariables for the genetic association study of OSA We performed independent analyses in both population and a joint analysis controlling by population effect (included as a covariable in the model).

Results: The Spanish population consists on 225 men and 161 women between 15 and 96 years old. The prevalence of OSA is 90.7%, 80% has MS (ATP3 definition) and 81.9% are obese (BMI > 30). The Framingham population consists on 183 men and 185 women between 40-81 years old. The prevalence of OSA is 65.8%, 35% has MS and 34% are obese. In the independent analysis in each population, we didn't identify any SNP associated with OSA with $p < 10^{-4}$ as determined by the Bonferroni correction ($p = 0.05/373, < 10^{-4}$). None but the rs11211631 polymorphism is associated with OSA with $p < 0.5$ in both populations with the same direction of effect. In the joint analysis, this SNP is associated with OSA with $p = 7.21 \times 10\text{-}4$, which is in the range of Bonferroni correction. At this locus, the presence of the A allele reduces the risk of OSA presentation with an estimated OR of 0.57 (0.42-0.79).

Discussion: In the pathogenesis of OSA, genetic factors play an important role, explaining up to 40% of the variance of (AHI). Nevertheless, there is little data regarding specific genes associated with OSA. Some genes have been related to OSA: genes affecting upper airway and ventilator control (such the serotonin receptor type 2A (5HTR2A) or the transcription factor (Phox2b) and, in genes related to metabolic syndrome components. In our study the only SNP consistently associated with OSA syndrome in the whole population is the rs11211631 polymorphism. We have investigated if the presence of hypertension in our population, a well known risk factor for OSA, was acting as a confounding factor in our study. The Breslow-Day test performed in the Framingham population based sample did not show evidence of heterogeneity affecting our results ($p = 0.5019$ for the 11211631 polymorphism).

Conclusions: As a whole, or study does not support that OAS and MS share major genetic determinants. Only the SNP rs11211631 seems to be associated with the occurrence of OSA but this result must be validated in independent studies.

V-25
LOWER LIMIT NORMALITY (LLN) FOR COPD DIAGNOSIS

S. Araújo Fernández, S. Rodríguez Pecci, H. Enríquez Gómez, L. Novoa Llamazares, A. Arca Blanco, M. Rodríguez Arias, J. Álvarez Otero, J. de la Fuente

Department of Internal Medicine. Hospital Povisa. Vigo (Pontevedra), Spain.

Objectives: To compare the differences emerging in a cohort of patients with COPD diagnosed by GOLD criteria using the lower limit of normality (LLN) to define COPD.

Material and method: Prospective cross-sectional study carried out in the Internal Medicine Department of Povisa hospital, that included patients with COPD diagnosis based on GOLD criteria, consecutively admitted for different reasons from September 2008 to March 2010. The following variables were recorded: age, sex, smoking status, COPD severity, evolution of the disease, cardiovascular risk factors, comorbidity and reasons for admission. The LLN criteria for defining COPD were based on lower limit of normal of FEV1/FVC obtained by the formula of the CECA. Finally, there were 2 groups: patients who met the criteria for COPD diagnosis using the LLN and patients who didn't it.

Results: Two hundred forty six patients were included and 51 (20.7%) were women. By using the LLN criteria 53 patients of those diagnosed by GOLD criteria were excluded (21.5%), 3 of them were women. COPD patients diagnosed by LLN criteria were more frequent

actively smokers than excluded patients (26.4% vs 11.3% p = 0.02, OR = 2.8, CI 1.1-6.9). Patients excluded by LLN criteria had more prevalence of previous smoking (73.6% vs 53.4%, p = 0.008, OR 0.4, CI 0.2 to 0.8), hypertension (77.4% vs 51.8%, p = 0.001, OR 0.3, CI 0.1 -0.8), CV events (47.2% vs 20.7%, p < 0.001, OR 0.2, CI 0.1 to 0.5), intermittent claudication (24.5% vs 9.8%, p = 0.005, OR 0.3, CI 0.1 to 0.7) and higher mean age (76 ± 9.3 vs 69 ± 11.1, p < 0.001) with a less severity of disease (higher VEF1 and FEV/FVC) (60 ± 14 vs 48 ± 14.4 and 0.68 ± 0.02 vs 0.55 ± 0.08, p < 0.001). When we compare the causes of hospitalization between the two groups, the patients with COPD diagnosed by criteria LLN had a higher prevalence of COPD exacerbation (80.8% vs 56.6%, p = 0,005), whereas those excluded by LLN had a higher percentage of hospitalizations for heart failure (15.1% vs 3.6%, p = 0.005). There were no differences in the other variables studied. There were no differences according to gender in the LLN criteria group COPD with respect to the analysis in the original population defined by GOLD criteria (p = 0.6).

Discussion: The definition of airway obstruction from a fixed ratio may inappropriately classify the presence of obstruction in extreme ages and the overdiagnosis is especially relevant in olders than 70 years due to physiological changes that occur over the years. The use of LLN to diagnose obstruction can avoid the mentioned limitations as it considers the values based on age and sex. In our series, although the mean age was advanced, the highest percentage of patients had severe or very severe illness with respiratory symptoms in the most cases. In this situation the over diagnosis is less likely so with the use of LLN criteria, a small percentage of older patients with milder disease but with more comorbidities were excluded.

Conclusions: By using the LLN criteria for the diagnosis of COPD compared to GOLD criteria, a population of older age, with less deterioration of lung function but with greater number of comorbidities were excluded. The use of LLN criterion may be useful to avoid over diagnosis of COPD in older people because these population may have criteria in spirometry due to the changes in lung function over the years without symptoms or history to justify the disease. In those cases in which the symptoms of COPD are clear, the use of LLN criterion does not provide additional benefits to the GOLD criteria.

V-35
METABOLIC SYNDROME EPIDEMIOLOGY

M. Popoviciu

Department of Internal Medicine. University of Oradea, Faculty of Medicine. Oradea, Romania.

Objectives: Metabolic syndrome defines the presence of a group of metabolic factors at the same individual, with various clinical manifestation proportions and intensities, being associated with an increased risk of developing cardiovascular disease and type 2 diabetes. The main objective of this paper is to determine the prevalence of Metabolic Syndrome according to different parameters in patients with type 2 diabetes.

Material and method: A group study of 290 patients with type 2 diabetes hospitalized in the Diabetes Clinic of Oradea from January 2011- March 2012.For every patient was made a study sheet in which was noted: sex, age, duration diagnosed with diabetes, type of diabetic treatment, family history, complications of diabetes mellitus, type of diet and physical activity weight and abdominal circumference, metabolic control, lipid profile (total cholesterol, HDL-cholesterol, LDL-cholesterol, triglycerides),inflammatory status (fibrinogen, C-reactive protein), blood pressure and electrocardiographic examination.

Results: Metabolic Syndrome was found in 167 of the patients, resulting in a prevalence of 57.6%. MS prevalence was higher in men than women, but without significant difference (p > 0.05). Prevalence was maximum at the ages between 41-60 (67.7%), followed by the patients with ages over 60 (50.0%) and was 1.2 times higher in patients living in the urban area compared to the rural area (64.5% vs 52.7%). The greatest prevalence of MS was registered at the patients treated with ADO (70.9%), 1.3 times greater than those who are insulin dependent (p < 0.05). Obese patients have the prevelence over 80%, significantly higher than that in overweight patients (33.0%) or normal weight patients (3.3%) (p < 0.001). The risk of MS is 26 times higher in obese compared to normal weight patients (RR = 26.09), and 2.6 times higher in obese compared to overweight patients. Significant differences exist in the lipid profile of patients with and those without MS (p < 0.001). Fibrinogen and CRP have values above the normal limits, with significantly higher percentages in patients with MS compared to those without it (22.8% vs 15.5%, respectively 27.0% vs 22.0%) (p < 0.05).

Discussion: There are no significant differences in glycaemia between patients with or those without MS. Prevalence of diabetic complications is higher in those with MS compared to those without it (92.2% vs 87.8%) (p < 0.05). ECG modifications were 1.6 times higher in those with MS as compared to those without it (63.5% vs 39.8%) (p = 0.023). Significantly high differences were observed in dysmetabolic cardiomyopathy (52.2% vs 19.6%) (p < 0.001).

Conclusions: 1. Prevalence of metabolic syndrome was higher in men than in women, but no significant differences (p > 0.05) between the ages of 41-60 years (67.7%) and urban area (64.5%). 2. Metabolic syndrome risk is 1.7 times higher in patients with positive family history compared to those without positive family history of metabolic and/or cardiovascular disease (RR = 1.74). Also the risk in postmenopausal women is 2.6 higher than in premenopausal women (RR = 2.63). 3. Metabolic syndrome risk is 1.7 times higher in patients that have a hyper-caloric diet and/or hyper-lipidic diet compared to those with healthy eating habits (RR = 1.69). 4. The risk of metabolic syndrome in patients without physical activity is 1.3 times higher than for those with physical activity (weekly or daily) (RR = 1.26). 5. The risk of metabolic syndrome is 26 times higher in obese than in normal weight individuals (RR = 26.09), and 2.6 times higher in obese compared to overweight individuals (RR = 2.61). 6. In regard to lipid profile there is a significant difference between patients with metabolic syndrome and those without metabolic syndrome (p < 0.001).

V-38
CLINICAL FEATURES AND PREDICTIVE RISK FACTORS FOR RECURRENT UPPER GASTROINTESTINAL BLEEDING IN AN EMERGENCY ROOM

C. Blas Carracedo[1], I. Portero[2], R. González González[2], J. Agud Aparicio[1]

[1]Department of Internal Medicine, [2]Department of Emergency. Hospital Universitario Severo Ochoa. Leganés (Madrid), Spain.

Objectives: To describe the clinical characteristics of patients with recurrent UGIB and the variables related to rebleeding risk in our population.

Material and method: Prospective observational case series. We studied consecutive patients attending to the emergency room (ER) of the Hospital Severo Ochoa, Leganés, Madrid, with a diagnosis of UGB during one year (from 1-april-2010 to 31-march-2011). In this report we present data on patients suffering recurrent UGIB. The investigators obtained written approval by the Institutional Ethics Committee prior to patient inclusion. Patients signed an informed consent before inclusion. Statistical analysis was performed with SPSS 15.0 for windows.

Results: During the observation period 206 patients were admitted in the ER with the diagnosis of UGIB; 66.5% were males. Mean age was 63.25 (SD ± 18.43). The prevalence of recurrent bleeding in this population was 6.8%, with a mean age of 64.4

(slightly older than non-rebleeders). Fifty percent or rebleeding episodes appeared in the first 48 hours. Rebleeders had more frequent history of digestive complaints; the most frequent were dyspepsia, gastrointestinal surgery and gastrointestinal neoplasia. The prevalence of gastrointestinal neoplasia in patients with rebleeding was statistically significant (OR = 2.5, p = 0.003); early rebleeding was frequent in this group. A clinical presentation as hematemesis was significantly associated with rebleeding risk (OR = 11; p = 0.005. Active bleeding (OR = 7 and p = 0.022) and recent hemorrhage through a nasogastric tube (0R = 5.3, p = 0.065 were also related with higher risk of recurrence. Forrest classification was available in 53.5% of all patients and in 32.6% of those with recurrent bleeding (the remainders were unclassifiable lesions). Rebleeders didn't have worse Forrest scores than non-rebleeders. Nevertheless, early rebleeders did have higher mean scores in the clinical risk scales (Rockall and Blatchford), this difference was not present in patients with later recurrences.

Discussion: An important goal in the management of upper gastrointestinal bleeding (UGIB) is defining a group with high risk of recurrent bleeding, to provide adequate diagnostic and therapeutic measures. We provide guidance on some clinical parameters that could impact on the risk of rebleeding. The basic tool was to establish the profile of rebleeders: sixth decade, often male and alcohol abuse. Early rebleeders tend to be older, have history of peptic ulcer, gastrointestinal malignancy or gastrointestinal surgery and the most common presentation is hematemesis. Late rebleeders are usually younger and often have liver disease with portal hypertension. Also, this study shows a relationship between the presence of cancer and the risk of rebleeding that is important for the adoption of special measures of care for these patients. Note that in this study, endoscopic Forrest classification, had little value, probably due to the low number of cases and also, because most illnesses were not classifiable by this scale. Limitations: low number of cases in our population so it is necessary to perform multicenter studies with sample size calculated based on the recurrence of rebleeding in UGIB.

Conclusions: 1) We found a 6.8% prevalence of rebleeding in UGIB. 2) Half of the recurrences were found in the first 48 hours. 3) Dyspepsia, gastrointestinal surgery or the presence of gastrointestinal neoplasia were the most frequent antecedents. 4) Rebleeding patients had more frequently neoplasia, especially early rebleeders (they had 2.5 probability of recurrent hemorrhage). 5) Presentation with hematemesis had 11 times more probability of rebleeding. 6) Active bleeding and recent bleeding upon nasogastric tube insertion were associated with increased risk of rebleeding. 7) Given the low frequency of rebleeding, for the proper assessment of the clinical characteristics of patients suffering recurrent UGIB, and accurate prediction of risk, more powerful studies are needed (with greater samples or multicentric recruitment).

V-41
CONSTITUTIONAL SYMPTOMS, STUDY OF A SERIES OF 100 PATIENTS

F. Sauchelli, I. Novo Veleiro, G. Ternavasio de la Vega, L. Moralejo Alonso, S. Inés Revuelta, A. Fuertes Martín

Department of Internal Medicine. Hospital Clínico Universitario de Salamanca. Salamanca, Spain.

Objectives: First, to determine the frequency of constitutional symptoms (unintentional weight loss, asthenia and anorexia in the last 6 months) as reason for referral to our unit; second, to know the spectrum of diseases responsible of the constitutional symptoms in our setting and third, to analyze the association between relative variables and the final diagnosis.

Material and method: Retrospective cohort study of 100 patients studied on the UCAI-MI (Unidad de Consulta y Atención Inmediata-Medicina Interna) from 2008 to 2012 in a tertiary-care level teaching hospital in Spain, including only those whose reason for referral to our unit was the triad of unintentional weight loss, asthenia and anorexia. A descriptive study was performed, analyzing epidemiological and analytical values, clinical characteristics as well as the number of studies needed and its association with final diagnosis, especially with cancer. Quantitative variables comparison was performed using the Student´s t test or the ANOVA test when more than two groups were compared. Qualitative variables comparison was performed by the χ^2 test, using Fisher's exact test when expected frequency was less than 5. SPSS statistical program version 18 was used.

Results: During the study period, 2,489 patients were derived to UCAI-MI (mainly from emergency department and primary care centres). Of these, 230 patients had constitutionals symptoms, but only 100 met the 3 symptoms. Of these, 57% were males, the median age was 76 years-old (27-93). The median days of study till diagnosis were 19 days (1-150). The average number of tests needed to reach the diagnosis was 3.57 (SD = 1.58). The most frequent diagnostic groups were cancer (37%), not-cancer digestive disease (13%), autoimmune diseases (8%), infectious diseases (7%), dementia (3%), and other diseases (23%). Remarkably, only 3% of mood disorders were diagnosed. The most common aetiologies of cancer were colorectal (9 cases), gastric (6), lung (5) and pancreas (5). A comparative study based on age was performed, no patients under the age of forty-five years had cancer, 32% of patients between forty-six and seventy-five years old had cancer, and 50% of patients over 76 years old had cancer, this difference is statistically significant ($p < 0.05$). The most relevant variables related with cancer were age over 75 years old ($p = 0.008$), symptoms such as bone pain, dyspnoea, abdominal pain ($p = 0.01$), analytical values including anaemia, high CRP, high ESR ($p < 0.005$). The single serum tumour marker statistically associated with the presence of oncologic disease was Cyfra 21.1 ($p = 0.049$).

Discussion: Over 10% of patients seen in our unit refer constitutional symptoms, which represents a significant healthcare burden. We found differences with other studies in the prevalence of most common diseases related with constitutional symptoms, probably due to the different patient profile attending our unit (exclusively outpatients). Age of patients, analytical variables (CRP, ESR, haemoglobin), and specific symptoms are better predictors of cancer disease than tumour markers at initial diagnosis.

Conclusions: The presence of constitutional symptoms is a matter of concern for physicians who are at the door of the health system. These patients are referred quickly to rule out serious disease like cancer. In this context, as expected, the risk of cancer increases with age, occurring in half of patients over 75 years. Patients with a higher CRP, ESR or anaemia as well as those who have specific symptoms are more likely to have cancer. Notably, even in the presence of constitutional symptoms, there was no oncologic disease in patients younger than 45-years, so other causes should be sought in this subgroup.

V-57
BIOMARKERS IN FABRY DISEASE (FD)

S. Olivera González[1], M. Torralba Cabeza[2], J. Pérez Calvo[2], B. Amores Arriaga[2], D. Hughes[3], G. Pastores[4], R. Nuviala Mateo[5]

[1]Department of Internal Medicine. Hospital de Denia. Denia (Alicante), Spain. [2]Department of Internal Medicine, [5]Department of Biochemistry. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain. [3]Department of Academic Haematology. Royal Free. London, United Kingdom. [4]Department of Neurogenetics and Neurology. NYU School of Medicine. New York, United States of America.

Objectives: Cystatin C (CsC) is a useful biomarker in early renal and cardiac damage. NT-proBNP has a negative predictive value in

heart failure. We have studied the relationship between these two biomarkers and Mainz Severity Score Index (MSSI) in FD.

Material and method: We performed a descriptive study including 89 FD patients, and a corresponding number of matched healthy controls. Statistical analysis was performed with SPSS 18.0.

Results: MSSI was calculated by gender (Table 1). In studies of correlation (Spearman rho) we found a statistically significant relationship ($p < 0.01$) between CsC and renal score, with a strong correlation (r 0.644, $p < 0.001$, 95%CI 0.497-0.776), and between NT-proBNP and cardiovascular score (r 0.656, $p < 0.001$, 95% 0.515-0.758). Stratified by gender Spearman rho was 0.601 in women ($p < 0.001$) and 0.642 in men ($p < 0.001$). As for the ratio of NT-proBNP and cardiovascular score is 0.457 in men ($p < 0.001$) and 0.747 women ($p < 0.001$). To assess organ involvement, we performed the correlation coefficient between CsC and GFR being 0.713 ($p < 0.001$) and stratified by gender was 0.685 in women ($p < 0.001$) and 0.409 in men ($p < 0.001$). Relating NT-proBNP and GFR, the coefficient was 0.557 ($p < 0.001$) (0.478 in women and 0.240 in men, both $p < 0.001$).

Discussion: In FD it's not available biomarkers to assess disease progression, needing of initiate ERT, or response to it. Our study found a strong correlation between CsC and renal failure, being higher in the case of women, in which the clinical presentation due to lyonization phenomenon is more variable. We have also found a strong correlation between NT-proBNP and cardiovascular impairment, much higher in women. This is a very interesting result, because in women, the variability in clinical presentation is greater, so it can be very useful CsC in early renal involvement, and NT-proBNP in early cardiovascular damage. There are many unknowns about when to start ERT or if it's being effective. The data obtained in our study have significant validity from the standpoint of clinical and prognosis and to speculate about the use of CsC and NT-proBNP as biomarkers in FD, with the MSSI, and they will bring to this one more dynamic in terms of patient assessment.

Conclusions: CsC is a good prognostic marker in early FD to determine the renal and/or heart failure. NT-proBNP is elevated in patients with FD and cardiac damage, so it's a good marker for the detection of suchinvolvement. CsC and NT-proBNP are good biomarkers in early renal and cardiovascular damage in women. CsC could be a good biomarker in the FD in the future, after further studies with serial measurements inpatients on ERT, thus underpinning earlier intervention in cases of poor outcome.

Table (V-57)

MSSI	Total	General	Neurological	Cardiovascular	Renal
Female	17.35	4.8	4.47	5.08	2.93
Male	28.13	6.19	6.02	10.64	5.11

V-64
SERUM VITAMIN A, E, B3, B6, B12, C AND FOLIC ACID LEVELS AND BRAIN ATROPHY AMONG ALCOHOLICS

C. Fernández Rodríguez, M. Martín González, E. González Reimers, J. Viña Rodríguez, M. García-Valdecasas Campelo, A. Martínez Riera, M. Durán Castellón, F. Santolaria Fernández

Department of Internal Medicine. Hospital Universitario de Canarias. San Cristóbal de La Laguna (Tenerife), Spain.

Objectives: Alcoholics are often malnourished, and deficiency in micronutrients are frequently observed among them. Some vitamins, such as vitamin E, B1, A, among others, may be involved in brain alterations suffered by these patients. We analysed the relation between serum vitamin A, E, B6, B3, D, B12, C and folic acid and brain atrophy, cognitive impairment, nutritional status, and liver function impairment among cirrhotics and non-cirrhotic alcoholics.

Material and method: 75 alcoholics (10 women) admitted to our unit due to withdrawal syndrome, subjected to brain computed tomography (CT) scan, in which Evans, Huckmann, ventricular, and cella indices were quantitatively assessed, as well as frontal atrophy and cerebellar atrophy; liver function, minimental test, and nutritional status both by anthropometry (body mass index (BMI)), whole body densitometry (total fat mass and total lean mass), and subjective evaluation.

Results: Mean age was 51 ± 12 years. Marked differences were observed among cirrhotics and non-cirrhotics regarding Vitamin A and E (lower in cirrhotics, $t = 3.16$ and $t = 3.11$, respectively; $p < 0.003$) and B12 (higher in cirrhotics, $t = 2.74$; $p = 0.008$). Vitamin E showed a significant correlation with ventricular index (= 0.44; $p = 0.007$); vitamin B6 was significantly lower among those with cerebellar atrophy ($t = 2.33$; $p = 0.027$) and a trend was observed between cerebellar atrophy and vitamin E ($t = 1.90$; $p < 0.07$). In addition vitamin A, vitamin E and vitamin B6 levels were significantly related with liver function impairment (assessed by prothrombin, albumin, and bilirubin), and an inverse, significant trend (inverse correlations with albumin and prothrombin activity and direct one with bilirtubin) was observed for vitamin B12.

Conclusions: Among alcoholics, liver function impairment leads to altered serum vitamin levels, which are o related with brain alterations. No relation was observed with BMI, lean or fat mass, or subjective nutritional evaluation.

V-67
ANALYSIS OF THE EXPRESSION OF PEROXISOME PROLIFERATOR-ACTIVATED RECEPTORS GAMMA (PPAR GAMMA) IN OBESE PATIENTS

J. Torres Triana[1], E. Bernardo[2], L. Hernández[3], L. Manzanedo Bueno[1], A. Verdugo[2], O. Rozo[3], G. Sabio[2], M. Marcos[1]

[1]Department of Internal Medicine, [3]Department of Surgery. Hospital Clínico Universitario de Salamanca. Salamanca, Spain. [2]Department of Vascular Biology and Inflammation. Centro Nacional de Investigaciones Cardiovasculares Carlos III. Madrid, Spain.

Objectives: Chronic disorders, such as obesity, diabetes, inflammation, non-alcoholic fatty liver disease and atherosclerosis, are related to alterations in lipid and glucose metabolism, in which peroxisome proliferator-activated receptors (PPAR) alfa, PPARbeta/delta and PPARgamma are involved. Our objective was to analyze the expression of PPAR gamma in obese patients and lean controls.

Material and method: Prospective observational case-control study comparing obese adult patients (at least 18 years of age) with body mass index (BMI) greater than 35 who underwent elective bariatric surgery at the University Hospital of Salamanca between November 2010 and November 2011 versus healthy volunteer controls with BMI lower than twenty-five. Before surgery, fasting venous blood samples were collected. Serum was obtained after centrifugation and was stored at -80 ºC and human whole blood was collected in PAXgene Blood RNA Tubes and stored at -20 ºC until RNA was extracted. The expression of mRNA was examined by quantitative PCR analysis using a 7900 Fast Real-Time PCR machine. The relative mRNA expression was normalized by measurement of the amount of GAPDH mRNA. Statistical significance was calculated by using Student's t-test.

Results: A total of 28 subjects, 17 patients and 11 controls were included in this case–control study. Of these patients, 12 were female and 5 were male. The mean age was 45 years, the mean preoperative weight was 132.16 Kg, with a BMI of 49 kg/m^2. After RNA extraction and PCR analysis, we observed that obese patients had significantly decreased blood PPAR-gamma expression when compared with lean controls ($p < 0.05$).

Discussion: Obesity acts as a stress signal that induces multiple inflammatory responses in tissue, which play an important role in the pathogenesis of cardiovascular disease, metabolic syndrome, non-alcoholic fatty liver disease and hepatocellular carcinoma (HCC). The PPARgamma is a nuclear receptor that regulates adiposity differentiation, insulin sensitivity and lipid metabolism. Recent studies in mice have determined that PPARgamma overexpression might be a protective factor for the development of hepatic steatosis and HCC. In our study, obese patients had lower levels of PPARgamma in blood, so it is important to conduct further studies to determine its correlation with a possible increased risk of developing non-alcoholic fatty liver disease (NAFLD) and/or HCC.

Conclusions: There are differences in the expression of PPARgamma blood between obese patients and healthy controls, so more studies are needed to determine whether evidence of low levels of PPARgamma in obese patients correlates with increased development of NAFLD and/or HCC.

V-72
ULTRA-LONG-ACTING INSULIN DEGLUDEC HAS A FLAT AND STABLE GLUCOSE-LOWERING EFFECT

R. Gómez Huelgas[1], L. Nosek[2], T. Heise[2], S. Bottcher[3], H. Hastrup[4], H. Haahr[4]

[1]Department of Internal Medicine. Hospital Regional Universitario Carlos Haya. Málaga, Spain. [2]Department of Clinical Science. Profil Institut fur Stoffwechselforschung, Science. Neuss, Germany. [3]Global Development. Novo Nordisk. Alborg, Denmark. [4]Global Development. Novo Nordisk. Soborg, Denmark.

Objectives: To evaluate the dose-response relationship of IDeg at steady state (SS) in people with type 2 diabetes.

Material and method: In this double-blind, two-period, crossover trial, the dose response relationship of three doses of IDeg (0.4, 0.6 and 0.8 U/kg) was evaluated at steady state. Participants were given IDeg once-daily for 6 days, with a washout period of 13–21 days between treatments (starting after the last dosing on Day 6). Following dosing on Day 6, subjects underwent a euglycaemic glucose clamp (Biostator; clamp blood glucose level: 5 mmol/L). Pharmacokinetic samples were taken up to 120 h after the last injection of IDeg.

Results: Forty nine insulin-treated people with type 2 diabetes without concomitant oral anti-diabetic agents were included (mean: age, 58.7 years; BMI, 29.6 kg/m^2; HbA1c, 7.6%; duration of diabetes, 14.1 years). For all dose levels, mean 24-h glucose infusion rate (GIR) profiles were flat and stable. Total glucose-lowering effect (AUCGIR, total, SS) increased linearly with increasing dose. Over 24 h, the glucose-lowering effect of IDeg was evenly distributed between the first and second 12 h for all 3 dose levels (AUCGIR,0–12h,SS/AUCGIR, total, SS = 0.5). The blood glucose levels of all participants stayed very close to the clamp level until the end of the experiment (mean blood glucose levels in the last 10 min of a 24-h dosing interval were 5.0–5.1 mmol/L for all IDeg doses). Total serum exposure of IDeg (AUCIDeg, total, SS) increased proportionally with increasing dose with an estimated log-dose slope of 0.93 [95%CI: 0.82; 1.03]. The terminal half-life estimated across the three dose levels after the last dose was 25.1 hours. IDeg was well tolerated and no safety concerns were identified.

Discussion: Insulin degludec (IDeg) is a new-generation, ultra-long-acting basal insulin that forms soluble multi-hexamers upon subcutaneous injection, resulting in a depot from which IDeg is continuously and slowly absorbed into the circulation. These pharmacological properties provide a stable blood glucose-lowering effect which lasts beyond 24 hours in people with type 2 diabetes.

Conclusions: IDeg has a flat and stable blood glucose-lowering effect, and a duration of action beyond 24 hours in people with type 2 diabetes.

V-86
INTRAVENOUS THROMBOLYSIS IN ACUTE ISCHEMIC STROKE. FACTORS INVOLVED

M. Menduiña Guillén[2], P. Alaminos García[1], P. Navarrete Navarro[1], F. Guerrero López[2], M. Monteiro da Pina[2]

[1]Department of Intensive Care. Complejo Hospitalario Regional Virgen de las Nieves. Granada, Spain. [2]Department of Internal Medicine. Hospital de Especialidades San Cecilio. Granada, Spain.

Objectives: To evaluate medical practice and results of intravenous thrombolytic therapy (IVT) with rTPA in acute ischemic stroke and factors associated.

Material and method: Prospective cohort study. Data were obtained using UCI neurocritical patient database from 2002 to 2010, inclusive. We included all patients with acute ischemic stroke treated with IVT. Independent variables were defined as age and sex, time first symptoms-emergency admission (T1), emergency admission-CT (T2) and CT-IVT administration (T3), and CT findings, including the presence of ischemic penumbra. Quantification of initial neurological deficit was assessed by NIHSS at admission and 24 h of IVT, the degree of disability for daily activities at 3 months by the modified Rankin Scale (MRS). Symptomatic cerebral hemorrhage (SCH) and malignant infarction of middle cerebral artery were considered complications. Quantitative variables were expressed as mean ± SD and qualitative variables are expressed as percentages. We used the chi^2 test and t Student.

Results: We analyzed 166 patients, age = 65.7 ± 11.6 years, 57.8% males. The neurological deficit of 14.9 ± 5.6 points admission NIHSS decreased to 10.1 ± 7.1 ($p < 0.001$) 24 hours after IVT. The times were: T1: 91.5 ± 67.8 minutes, T2: 124.9 ± 68.9 minutes, and T3: 175.3 ± 83.8 minutes. The rate of SCH was 9.6%, and was correlated with higher admission NIHSS score 17.7 ± 4.6 vs 14.6 ± 5.7 ($p < 0.04$) and male sex, 57.8% vs 42.1 ($p < 0.05$) The rate of malignant infarction of the middle cerebral artery was 6.5% and was associated with a 62.5% mortality. The degree of freedom from dependence/disability at 3 months (MRS 1 and 2) correlated only with the admission NIHSS score, 16.4 ± 4.8 vs 13.3 ± 6.4 ($p < 0.005$) and female gender, 59 vs 41% ($p < 0.005$).

Conclusions: The IVT is secure and efficient treatment in ischemic stroke. This analysis allows us to identify the variables associated with complications and functional status of patients.

V-93
INSULIN DEGLUDEC IMPROVES LONG-TERM GLYCAEMIC CONTROL WITH A LOWER RATE OF HYPOGLYCAEMIA VS INSULIN GLARGINE IN TYPE 2 DIABETES

J. Gómez Cerezo[1], P. Hollander[2], A. King[3], A. Francisco[4], L. Endahl[4], A. Garber[5]

[1]Department of Internal Medicine. Hospital Infanta Sofía. San Sebastián de los Reyes (Madrid), Spain. [2]Department of Internal Medicine. Baylor Endocrine Center. Dallas, Texas, United States of America. [3]Department of Endocrinology. Diabetes Care Center. Salinas, California, United States of America. [4]Global Development. Novo Nordisk. Soborg, Denmark. [5]Department of Medicine Molecular and Cellular Biology. Baylor College of Medicine. Houston, Texas, United States of America.

Objectives: To compare the efficacy and safety of IDeg with insulin glargine (IGlar), both treatments administered once daily with mealtime insulin aspart ± metformin ± pioglitazone as part of a basal–bolus treatment regimen.

Material and method: This was a 1-yr, open-label, treat-to-target trial. Subjects with type 2 diabetes and HbA1c 7–10% after at least 3 months of any insulin regimen ± OAD(s) were randomised (3:1) to IDeg or IGlar. Basal and bolus insulin were titrated weekly

throughout the study using structured algorithms. The target glucose for basal insulin was a FPG < 5 mmol/L.

Results: A total of 992 subjects were included (mean: age 58.9 years, diabetes duration 13.5 years, HbA1c 8.3%, FPG 9.2 mmol/L) A similar proportion of subjects completed the trial with IDeg (83%) and IGlar (85%). After 1 year, 50% of the subjects in both groups achieved a target HbA1c < 7% (p = NS) and HbA1c levels decreased 1.2%-points and 1.3%-points for IDeg and IGlar, respectively (estimated treatment difference [ETD] IDeg-IGlar: 0.08%-points [95%CI: –0.05; 0.21]). FPG was reduced by 2.4 mmol/L with IDeg and by 2.1 mmol/L with IGlar (ETD: –0.3 mmol/L [95%CI: –0.65; 0.06], p = NS). The rate of confirmed hypoglycaemia (defined as either a PG < 3.1 mmol/L or a severe episode requiring assistance according to ADA definition) was significantly lower with IDeg than IGlar (11.1 vs 13.6 episodes/patient-year; estimated rate ratio [ERR] IDeg/IGlar: 0.82 [95%CI: 0.69; 0.99], p = 0.0359). The rate of nocturnal confirmed hypoglycaemia (confirmed hypoglycaemia occurring between 00:01–05:59) was 25% lower with IDeg compared to IGlar (1.4 vs 1.8 episodes/patient yr; ERR: 0.75 [95%CI: 0.58; 0.99]; p = 0.0399). Rates of severe hypoglycaemia were low for both IDeg and IGlar (0.06 and 0.05 episodes/patient yr, respectively). IDeg was well tolerated; the rates of adverse events were similar between IDeg and IGlar groups, with no treatment-specific effects. Total mean daily insulin doses were 1.46 U/kg and 1.42 U/kg at 1-yr in the IDeg and IGlar groups, with ~50:50 relative contributions of the basal and bolus components.

Discussion: The ultra-long action profile of insulin degludec (IDeg), a new basal insulin, is due to soluble multi-hexamer formation upon subcutaneous injection. This long-acting profile may provide similar effectiveness as other basal insulin, while reducing the risk of hypoglycaemia, as observed in this trial.

Conclusions: Insulin degludec, given as basal–bolus treatment with insulin aspart improves long-term glycaemic control with a significantly lower risk of overall and nocturnal hypoglycaemia compared with insulin glargine for patients with type 2 diabetes.

V-111
ADRENOCORTICAL CARCINOMA: LOW INCIDENCE HIGH MORTALITY

C. Casas, L. González, L. Valle, M. Rodríguez, J. Bermúdez, W. Zabaleta, J. de la Fuente

Department of Internal Medicine. Povisa. Vigo (Pontevedra), Spain.

Objectives: Adrenocortical carcinoma is a rare tumor originated in the adrenal cortex, with an incidence of 1-2 per million population annually with characterized by a 5-year survival of less than 50%. Early diagnosis is uncommon; when diagnosed, AC are usually on advanced stages of National Cancer Institute (NCI). Complete surgical resection is the only potentially curative treatment for patients on localized tumors. OBJECTIVES: To analyze all the cases of adrenocortical carcinoma (AC) diagnosed in POVISA Hospital during the period included from january 2000 to march 2012.

Material and method: Retrospective study designed to describe all the cases of adrenocortical carcinoma in the period previously described. All the patients with clinical symptoms and signs, tests with suggestive findings and confirmed pathological anatomy of adrenocortical carcinoma were included. We describe the main presentation, clinical findings, treatment received and evolution.

Results: There were diagnosed 6 patients (4 females, 2 males) with a mean age of 65 years.All of them were diagnosed on stage IV of National Cancer Institute (NCI). Personal history of hypertension (50%), smoking habit (17%), previous cancer (17%). Regarding to the symptoms we found Cushing syndrome (83%), steroid myopathy (67%), arterial hypertension (50%), hyperandrogenism (17%), abdominal symptoms (17%), general repercussion (17%). Imaging studies and blood tests showed elevated cortisol plasma level (100%), adrenocortical tumor > 6 cm in tomography (83%), hipokalemya (66%), hyperglucemia (66%), alteration in coagulation (66%), erythrocyte sedimentation rate (50%), hyperaldosteronism (33%). All of them received treatment: symptomatic with adrenolitic drugs (66%), adjuvant Mitotane treatment (50%), chemotherapy with different protocols (50%) and surgery with nefrectomy and supradrenalectomy (33%).With respect to evolution they had a survivor rate of 5,5 months after diagnose, 83% died and only 17% are alive.

Conclusions: Adrenocortical carcinoma is a rarely cancer but with a high mortality. Although it can be potentially cured on early stages, unfortunately is often diagnosed in advanced stages of NCI. Cushing syndrome and steroid myopathy are the most frequent symptoms and signs we found and regarding to imaging a blood studies elevated cortisol level, hipokalemya, hyperglucemia and supradrenal tumor > 6 cm. On the stage all our patients were diagnosed there was no possible curative treatment. We must suspect this pathology when we have this symptoms and signs in order to do an early diagnosis.

V-112
INFLUENCE OF OBESITY AND MALNUTRITION ON RESPIRATORY DISEASE ADMISSIONS

R. Martin[1], M. Yebra[2], A. López de Guzmán[2], D. Velasquez[1], J. Canora[1], A. Zapatero[1], C. González de Villaumbrosia[2], R. Barba[2]

[1]Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain. [2]Department of Internal Medicine. Hospital Rey Juan Carlos. Móstoles (Madrid), Spain.

Objectives: Obesity is a risk factor in other conditions, like high blood pressure, heart disease and type-2 diabetes. However, recent studies have shown that obese people with chronic diseases have a better chance of survival than normal-weight individuals do. This finding has been called the "obesity paradox". Malnutrition is a common problem in patients with chronic or serious diseases, there are a lot of studies that have repeatedly demonstrated how clinical malnutrition negatively affects the recovery from a disease, trauma or surgery, and it is generally associated with an increase in morbidity and mortality both in acute and chronic patients. Our aim is to analyze the influence of obesity and malnutrition on in-hospital mortality and re-admittance 30 days after discharge in patients admitted for respiratory disease.

Material and method: Data from the Minimum Basic Data Set (MBDS) from all patients discharge from all the Departments of Internal Medicine (IM) of the Spanish National Health hospitals between the years 2005-2009 were analyze. We analyzed those patients with a Major Diagnostic Category (MDC) equal to 4 –Respiratory Disease-. The Major Diagnostic Categories (MDC) are formed by dividing all possible principal diagnoses (from ICD-9-CM) into 25 mutually exclusive diagnosis areas. Patients with a diagnosis of obesity (ICD-9: 278.00-278.09) or malnutrition (ICD-9: 260-263.9) were also identified. The mortality indexes of obese and malnourished patients were compared against the subpopulation without theses diagnosis.

Results: 833,091 respiratory disease admittances were analyzed, with 65,099 (7.9%) diagnosis of obesity and 13217 (1.6%) of malnutrition. In-hospital global mortality reached 11%, 5.1% in obese patients and 11.5% in non-obese; p < 0.001. Obese patients showed a lower in-hospital mortality risk (OR 0.45 95%CI 0.43-0.46) than non-obese after adjusting for possible confusing factors (age,

sex, Charlson index, acute respiratory failure). Mortality in malnourished patients was 20.5%, vs 10.5% in non-malnourished; p < 0.001. Malnourished patients had a much higher risk of dying while in hospital (OR 1.93 95%CI 1.85-2.02) even after adjusting for possible confusing factors.

Discussion: Overweight or obese status is typically, although not always, seen with chronic bronchitis, whereas emphysema is typically associated with weight loss and muscle wasting. The effect of obesity on COPD has not been well-studied. Limited epidemiologic data suggest that overweight or obese status in men may protect them against the risk for developing COPD, as well as mortality from COPD. It should also be pointed out that there is no plausible reason why obesity should protect against mortality in COPD. This phenomenon, well-characterized in other chronic diseases, such as heart failure, is referred to as the "obesity paradox".

Conclusions: Obesity in patients hospitalized for respiratory disease substantially reduces in-hospital mortality risk. More research should be aimed at resolving the obesity paradox. On the other hand, malnutrition is associated with important increased in in-hospital mortality.

V-114
AMYLOIDOSIS IN OUR AREA

I. Arias[1], M. González[2], E. Fonseca[3], J. Morís de la Tassa[3], E. Rodríguez[3], R. Fernández Madera[3], M. Barragán[1], S. Rubio[3]

[1]Department of Internal Medicine. Hospital Valle del Nalón. Riaño (Asturias), Spain. [2]Department of Hematology, [3]Department of Internal Medicine. Hospital de Cabueñes. Gijón (Asturias), Spain.

Objectives: To review the cases of amiloidosis in our area and obtain data of clinical presentation, therapy, prognosis and cardiac involvement.

Material and method: Retrospective case series between 1st January 1994 to 1st March 2012, obtained from medical history of biopsy confirmed cases.

Results: We identified 99 patients with mean age at diagnosis 70 years (range 25-84 years), 43 women and 56 men. All patients had biopsy-proven amyloidosis. There were 50 secondary amyloidosis, 41 light-chain amyloidosis, and 8 localized amyloidosis. Inflammatory diseases were presented in 9, blood diseases in 17, solid neoplasia in 5 and infectious diseases in 10. The main clinical manifestations were dysregulation of intestinal habit, heart failure and syncope. The affected systems were: kydney 61 (27 nephrotic syndrome), heart 43, digestive 31, autonomic nervous system 29, skin 8 and lung 1. Troponin I was elevated in 15. ECG was abnormal in 43 (atrial fibrillation or flutter 16, auricular-ventricular block and bundle-branch block auricular 6, pseudoinfarct pattern 8, low voltages 8, repolarization changes 5, and ventricular hypertrophy signs 1). Echocardiographic characteristics: 35 had left ventricular diastolic dysfunction, and 4 systolic dysfunction, ventricular hypertrophy 28, pericardial effusion 14, byrrefingency 16, auricular enlargement 16, valvulopathies 8, and pulmonary hypertension 8. In AL amyloidosis 26 had monoclonal component, 18 IgG subtype, and 22 Lambda light chain. 13 had Bence-Jones proteinuria and 18 renal insufficiency. The preferred sites for biopsy were abdominal fat 45, rectum 14, kidney 17, skin 8, endomiocardial biopsy 2, bladder 2, liver 3, lung 1, bone marrow 7, tongue 1 and necropsy 4. The treatment was in 18 Prednisone and Melphalan, 4 Bortezomib-Dexametsone, 2 Lenalinomide, 1 polychemotherapy and 8 required hemodyalisis. 42 patients had more than 2-years overall survival.

Discussion: Amyloidosis is a protein misfolding disorder in which soluble proteins aggregate as insoluble amyloid fibrils, that cause functional and structural organ damage. The most common form of systemic amyloidosis are light-chain amyloidosis, but it's the reactive AA amyloidosis the mostly detected in our area. Cardiac involvement may occur with or without clinical manifestations, and is considered as a major prognostic factor. There was 50% cardiac involvement found in our patients. The most commonly used treatment was Prednisone-Melphalan.

Conclusions: Patients with unexplained heart failure, hepatomegaly, nephrotic syndrome or peripheral neuropathy, should be evaluated for primary systemic amiloidosis, seeking evidence of a clonal plasma cell disorder with serum and urine immunofixation studies. Diagnosis of amyloidosis should be sought by biopsy of the abdominal fat or an involved organ. Cardiac involvement worsens the prognosis and may influence treatment strategies; therefore, all patients with known amyloidosis should be screened for cardiac amyloidosis even if they have no cardiac symptoms.

V-118
MALIGNANT PLEURAL EFFUSION AS THE FIRST MANIFESTATION OF CANCER

C. Solé, S. Bielsa, J. Porcel

Department of Internal Medicine. Hospital Universitari Arnau de Vilanova. Lleida, Spain.

Objectives: To compare tumor origin, demographic characteristics and survival rate between patients in whom pleural effusions represent the first symptom of cancer (group A) and those with a known cancer who subsequently develop a malignant effusion (group B).

Material and method: Retrospective analysis of all consecutive patients who were diagnosed with MPE in a university hospital (Lleida, Spain) during the 2006-2012 time period.

Results: Of 223 patients included in the study, 149 (67%) belonged to group A, and the remaining 74 to group B (Table). The median age of patients from the respective groups were 73 and 66 years (p = 0.07). The most common tumor origin for group A was lung (50%), whereas breast led group B (39%). Pleural effusion first pointed to the diagnosis of cancer in all mesotheliomas, 90% of lung tumors and > 80% of ovary and unknown primaries. Conversely, in 76% and 60% of effusions associated with breast and gastrointestinal tumors, patients had a previous history of cancer. In group B, the median time from the diagnosis of cancer to MPE development was 6 years for breast and 2 years for gastrointestinal tumors. The median survival was 6 months in both groups.

Discussion: Knowledge of tumor types which manifest primarily as malignant effusions has clinical interest.

Conclusions: MPEs are frequently the first clinical presentation of lung cancer, whereas most breast cancer associated effusions develop after an established diagnosis of the primary tumor.

Table 1. (V-118)

Tumor origin	No. of patients	Group A No (%)	Group B No (5)
Lung	83	75 (90)	8 (10)
Breast	38	9 (24)	29 (76)
Unknown primary	21	17 (81)	4 (19)
Lymphoma	18	11 (61)	7 (39)
Gastrointestinal	15	6 (49)	9 (60)
Others	48	31 (65)	17 (35)
Total	223	149 (67)	74 (33)

V-171
FATTY ACID PROFILE IN ADULT PATIENTS WITH PHENYLKETONURIA: IS THERE A NEED FOR FATTY ACID SUPPLEMENTATION?

L. Bosanska[1], N. Moench[1], K. Sari[1], J. Klein[2], K. Eder[3], K. Loschen[1], U. Ploeckinger[1], E. Moench[1]

[1]Centre of Excellence for Rare Metabolic Diseases, [2]Department of Pediatrics, Metabolic Laboratory. Charité Universitaetsmedizin Berlin. Berlin, Germany. [3]Institute of Animal Nutrition and Nutrition Physiology. Justus-von-Liebig-Universität Giessen. Giessen, Germany.

Objectives: The treatment of phenylketonuria (PKU), an inborn error of amino acid metabolism, consists of a dietary phenylalanine restriction together with an amino acid, vitamin and trace-element supplementation. Lifelong exclusion of fish from the diet may lead to a deficiency of essential fatty acids (omega-3- and omega-6 fatty acids) with its negative clinical consequences.

Material and method: 43 adult patients with PKU and 58 controls were included in the study. The serum concentrations of 26 free fatty acids (a short term parameter) and red blood cell membrane lipids (a long term parameter) were analyzed using gas chromatography. 5-day food records were analysed using Freiburg Food Database Program (Nutri Science GmbH 2004). 18 out of 43 PKU patients were receiving a supplementation of unsaturated fatty acid with their phenylalanine-free amino acid formula.

Results: According to the food records the intake of fat and especially saturated fatty acids was significantly lower in PKU-patients in comparison to the control group. In the phenylketonuria group lower blood levels of saturated fatty acids and higher blood levels of monounsaturated fatty acids were found in comparison to the control group. Most importantly, the docosahexaenoic acid (DHA; C22:6n-3) levels were lower in the phenylketonuria patients, although no differences in total omega-3- of omega-6-fatty acids were found between the groups. There was no difference in red blood cell membrane lipid content between the groups. Similarly, no differences were found in the phenylketonuria patients with or without fatty acid supplementation.

Conclusions: The low serum levels of docosahexaenoic acid (DHA; C22:6n-3) suggests an insufficient supply of this fatty acid in phenylketonuria patients. However, this seems to be partially compensated by monounsaturated fatty acids intake. In our study, the additional fatty acid supplementation had no effect on the measured parameters.

V-179
FAMILIAL HYPERCHOLESTEROLEMIA IN A LIPIDS UNIT

R. Macías Casanova, J. Torres Triana, L. Manzanedo Bueno, A. Prolo Acosta, S. Ragozzino, A. Mateos Díaz, E. Perianes Díaz, F. Sanz Ortega

Department of Internal Medicine. Hospital Clínico Universitario de Salamanca. Salamanca, Spain.

Objectives: To determine the principal characteristics found in patients diagnosed with familial hypercholesterolemia (FH) in the lipids unit.

Material and method: Descriptive study performed in the lipid unit of the University of Salamanca Clinic Hospital, we analyzed 56 patients with a mutation in the gen correspondent of familial hypercholesterolemia. The cases were diagnosed through genetic test called LIPOCHIP, and tested for a three year period.

Results: The most common type of mutation was the change of aminoacids (85.7%) and type of mutation most commonly found for the receptor gene LDL was the M049 (33.9%). The average age for diagnosis was 39 years old.

The distribution of the universe was female 69.6% male 30.4%. The 67.9% of the cases (38 patients) presented a MED PED score over 7. 62% of the patients had LDL levels > 200 mg/dl at the moment of the diagnosis.

Discussion: Familial hypercholesterolemia is an autosomal dominant disorder that causes severe elevations in total cholesterol and low-density lipoprotein cholesterol (LDLc). FH is a disorder of absent or grossly malfunctioning low-density lipoprotein (LDL) receptors. The LDL receptor gene is located on the short arm of chromosome 19; therefore, the inheritance pattern is the same for males and females.

Conclusions: The patients with a higher MED PED score have more probabilities to present a mutation for FH. The c LDL level is the best biochemistry diagnostic marker for familial hypercholesterolemia and has a direct relationship with causal defect. The most commonly affected gen is the gen of the LDL receptor and the most common mutation found was M049. We recommend the application of a lipids unit in the hospitals, this would lead to a premature diagnosis as well optimize the treatment, prevent and delay complications.

V-242
ASSOCIATION OF GENETICS POLYMORPHISMS WITHIN THE ENDOGENOUS OPIOID SYSTEM WITH ALCOHOL DEPENDENCE

C. de la Calle Cabrera[1], I. Pastor Encinas[1], M. Marcos Martín[1], L. Barrio Real[2], S. Inés Revuelta[1], M. Fernández Regueras[1], F. Laso Guzmán[1], R. González Sarmiento[2]

[1]Department of Internal Medicine II. Hospital Clínico Universitario de Salamanca. Salamanca, Spain. [2]Department of Medicine Molecular. Facultad de Medicina. Universidad de Salamanca. Salamanca, Spain.

Objectives: Alcohol is the most commonly drug of abuse in Europe. Chronic alcohol consumption is associated with the development of ethanol dependence in some individuals, which is influenced by genetic and environmental factors. The aim of our study was to determine whether the presence of certain polymorphisms within genes encoding receptors of the endogenous opioid system, one of the main systems involved in the neurobiology of addiction, is associated with alcohol dependence.

Material and method: Our study population included 300 patients from the Alcoholism Unit of the Hospital of Salamanca, which consumed more than 120 g of ethanol per day, and 157 healthy volunteers. Among patients, 113 of them had alcohol abuse, and 187 had alcohol dependence by DSM-IV criteria. We obtained DNA from all patients and controls and performed real-time PCR analysis of 10 polymorphisms located in the OPRM1, OPRL1, OPRD1 and OPRK1 genes, which encode the opioid receptors μ1, like 1, δ and k1 respectively. Results were statistically analyzed using the χ^2 test.

Results: Significant differences in genotype distribution of the A118G polymorphism of OPRM1 gene were found between alcoholic patients and controls, and between alcoholics with dependence and controls ($p < 0.05$). Namely, alcoholic patients had a higher frequency of AA genotype when compared to controls. We did not find any significant differences in the other analyzed polymorphisms

Discussion: Endogenous opioid system plays a key role in alcohol addiction, mainly through the activation of the mesolimbic dopamine system, which is a part of the brain reward system and is primarily responsible for the reinforcing properties of drugs of abuse. Genetic variability in this system between individuals, such as the result found in our study, may contribute to increased susceptibility to development of alcohol dependence.

Conclusions: In our study we have found that AA genotype of A118G polymorphism of OPRM1 gene is overrepresented in alcoholic patients with alcohol dependence, which can contribute to the development of this disease.

V-272
CO-RELATION BETWEEN C-REACTIVE PROTEIN/ALBUMIN RATIO AND LENGTH OF STAY FOR ACUTE MEDICAL ADMISSIONS

S. Roychowdhury[1], N. Patel[1], A. Chunduri[1], B. Chakraborty[2]

[1]Department of General Internal Medicine. Kettering General Hospital. Kettering, United Kingdom. [2]Department of Mathematics. University of Birmingham. Birmingham, United Kingdom.

Objectives: This paper examines the correlation between the ratio of serum C-reactive protein (CRP) to Albumin (markers of acute and chronic disease) and the length of stay (LOS) in the setting of an adult acute medical admissions unit (MAU).

Material and method: Data was collected prospectively for 497 acute unselected admissions to the MAU of Kettering General Hospital, United Kingdom. Of these, 399 cases were included in the final analysis and 98 cases were omitted as complete data was unavailable. Data was collected over a two week period and the outcome data obtained for all the patients. Using a '10 day' LOS 'cut-off' period, probability density functions were plotted.

Results: The plot below shows the probability density functions of CRP:Albumin ratio for the groups of patients with LOS less than 10 days and also for the patients with length of stay greater than or equal to 10 days.

Conclusions: It is evident the from the plot that the distribution of CRP:Albumin ratio for the patients with longer length of stay shifted to the right compared to the other indicating that patients who stay longer have higher CRP:Albumin ratio. Since the distributions of CRP:Albumin ratio for these two groups are skewed as observed above, a one-sided Wilcoxon rank sum test (also known as Mann-Whitney U test) was performed and a p-value of 0.0000000054 was obtained. This suggests that CRP:Albumin Ratio for the patients with LOS more than/equal to 10 days is significantly greater than that for the patients with LOS less than 10 days.

Table 1 (V-272)

Summary statistics of CRP/Albumin ratio of two groups of patients with different LOS	LOS less than 10 days	LOS more than or equal to 10 days
Number of patients	322	77
Mean	0.97	2.06
Median	0.25	1.03
Standard Deviation	1.78	2.59
Inter-quartile range	0.87	2.66
Minimum	0.08	0.09
Maximum	12.1	11.5

V-275
TWENTY-FIVE YEARS OF IDIOPATHIC CALCIUM NEPHROLITHIASIS: HAS ANYTHING CHANGED?

T. Meschi[1], A. Nouvenne[1], A. Guerra[1], F. Allegri[1], A. Ticinesi[1], B. Prati[1], G. Lippi[2], L. Borghi[1]

[1]Department of Clinical Sciences. University of Parma. Parma, Italy. [2]Department of Pathology and Laboratory Medicine. Parma University Hospital. Parma, Italy.

Objectives: To assess whether in the last 25 years lifestyle indicators of calcium stone formers in Italy have significantly changed and to establish a possible connection with the diffusion of Internet access in Italy.

Material and method: We examined the database of patients who underwent a complete clinical, dietary and urinary evaluation for new-onset ICN at the Stone Clinic of Parma University Hospital from 1986 to 2010. Patients were split into three groups on a chronological basis: group 1 (from 1986 to 1998, 561 males and 260 females), group 2 (from 1999 to 2004, 297 males and 169 females) and group 3 (from 2005 to 2010, 212 males and 237 females). For each patient, we recorded clinical and lifestyle data (blood pressure, age of onset of nephrolithiasis, number of episodes, physical activity, body weight, water intake) and the values of the basal urinary stone risk profile that had been performed at the time of the first evaluation. This urinary profile includes data on urinary 24-hour volume, sodium, potassium, chloride, calcium, phosphorus, uric acid, magnesium, oxalate, citrate, ammonium, urea, creatinine, pH. The supersaturation of calcium oxalate, calcium phosphate and uric acid was calculated through Equil software. We searched data about the diffusion of Internet connection among Italian families in the EUROSTAT-ISTAT reports.

Results: Over the time, we found a significant increase in water intake, both in males and females, (1.37 vs 1.78 litres in men and 1.21 vs 1.55 litres in women, Group 1 vs Group 3). There was a decrease in urinary sodium, calcium, phosphorus, chloride, magnesium and uric acid and an increase in urinary citrate and oxalate. Also the percentage of hyperoxaluria grew (27% to 34% in men, 10% to 17% in women). These changes were generally greater in females, particularly in urinary sodium (155 vs 140 mEq/day, Group 1 vs Group 3). We also found, both in males and females, a massive decrease in the supersaturation indexes for calcium oxalate (8.61 vs 6.36, Group 1 vs Group 3), calcium phosphate (1.58 vs 1,02, Group 1 vs Group 3) and uric acid (2.79 vs 1.75, Group 1 vs Group 3). The percentage of patients performing physical activity was significantly higher in Group 3 than in Group 1 (41% vs 8%), but mean body weight was substantially stable over time. We also found a significant decrease in mean blood pressure. Internet access among Italian families rose from 1998 (5.2%) to 2004 (31%) and 2010 (53%). At the same time, the seek for medical information on the web also rose (respectively 3%, 22%, 35%), especially among women.

Discussion: Idiopathic calcium nephrolithiasis (ICN) is a high prevalence disease. Its pathogenesis has not been fully understood, but it seems to be strongly related to lifestyle and dietary habits. In the last decades a change in the epidemiology of this disease in industrialized countries has been seen, with a rise of prevalence in women and a slight decrease in men. Our data show that lifestyle of patients with ICN at first episode in our country have changed becoming more adherent to an antilithogenic diet. This changes didn't follow a medical prescription but they were spontaneous: it is conceivable that they are due to a widespread diffusion of internet with related medical information, because a similar trend is detectable in these two phenomenons. Further studies are necessary to assess whether the lyfestile changes will lead to a decrease in stone recurrences.

Conclusions: The lifestyle of Italian idiopathic calcium stone formers have substantially changed over the last 25 years. In

particular, daily water intake significantly increased and salt consumption decreased, with a reduction in the risk for stone recurrence despite on urinary oxalate increase. These favourable habit changes could be in part related to the widespread diffusion of the Internet and to the spontaneous access to medical information that can be found in it.

V-277
INCIDENCE AND RISK PREDICTORS FOR ADVERSE EVENTS IN THE FOLLOW UP OF TRANSCATHETER AORTIC VALVE IMPLANTATION (TAVI) FOR THE TREATMENT OF DEGENERATIVE AORTIC VALVE STENOSIS

I. Pascual Calleja, R. Del Valle, L. Clavel Conget, P. Avanzas Fernández, C. Morís de la Tassa

Department of Cardiology. Hospital General de Asturias. Oviedo (Asturias), Spain.

Objectives: The main objective of this study is to analyze the incidence and adverse events predictors in our series of patients with severe aortic stenosis in which a transcatheter aortic valve implantation (TAVI) was performed.

Material and method: Patients admitted at our service with severe aortic valve stenosis whom underwent to TAVI with COREVALVE system from December 2007 to April 2012. Statistic analysis was performed with SPSS 19 program: percentages, chi square and Fisher exact test for discrete variables and mean, standard deviation (SD), median (minimum-maximum) for continuous variables.

Results: 116 patients were finally enrolled from December 2007 to April 2012. During the hospitalization period after TAVI, six patients died. Median of follow up was 393 (6-1562) days and mean 509 (SD 432) days. During the follow up period there were 16.6% new admissions for related cardiac causes (one half of them due to cardiac failure), 5,5% cerebrovascular events and 3,7% pacemaker implantations. The mortality rate was 10.9% during the follow up (42% cardiac related causes). Mortality is related to the following variables: previous coronary disease (18.2 vs 61%, p = 0,047), development of complications during the hospitalization period (17.7% vs 2.1%, p = 0.008), previous liver cirrhosis (66% vs 9.3%, p < 0.001), new admissions related to cardiac failure (37.5 vs 8%) and permanent pacemaker implantation (19.4 vs 6.8%, p = 0.05). New admissions because of cardiac failure are related with previous chronic renal failure (28.6 vs 5.3%, p = 0,015). Porcelain aorta was related to positive tendence of cerebrovascular events (25 vs 4%, p = 0,062. No predictors for the needing of permanent pacemaker implantation were found in the follow up.

Discussion: Degenerative aortic valve stenosis is the most frequent valvular heart disease in elderly patients. Transcatheter aortic valve implantation (TAVI) has became an effective and safety alternative option for the treatment of aortic stenosis in patients with high surgical risk. We think the follow up period is enough to support the results we have found. Concordant results with previous studies are shown and some significative determinants have been demonstrated. Low rate of mortality in this high risk sample of patients support the efficacy and security of TAVI.

V-281
REVISITING IN-HOSPITAL MORTALITY PREDICTION UTILITY OF INITIAL LABORATORY EVALUATIONS IN AN ECONOMICAL CONSTRAINED ERA

L. Bento, J. Pires, F. Aldomiro

Department of Internal Medicine. Hospital Prof. Doutor Fernando da Fonseca. Amadora, Portugal.

Objectives: The Portuguese economic crisis has culminated in the need for external financial assistance from the European Union and the International Monetary Fund (IMF) and has created the necessity for structural reform in the healthcare system, with particular emphasis on the need for a more rational use of services and control of expenditures. In this scenario, doctors seem to be more aware of costs and request cheaper analytical panels. An analysis of current practice in our Hospital revealed that there was a group of laboratory tests that was more frequently requisitioned than others. We aimed to determine the usefulness of the first three sets of laboratory evaluations obtained after admission in predicting mortality in an internal medicine ward of a tertiary hospital in the Lisbon district.

Material and method: All patients admitted to our Department during the first trimester of 2012 and who had at least 3 laboratory evaluations were included in this study. The afore-mentioned set of laboratory tests were made up of: a complete blood count; sodium; potassium; chloride; plasma creatinine; urea and C-reactive protein values – all were used as variables, being categorized according the cut-offs of our hospital. Data was collected from the DRG database of our department and revision of case notes. SATA 11® version was used for the statistical analysis. Contingency tables with Pearson chi-squared (χ^2) tests and pairwise correlations were used to identify variables associated with mortality (yes/no). Pertinent variables with a significant χ^2 statistic were used to build a multivariable logistic regression model for predicting mortality. The final model was evaluated using the area under the ROC curve and the Hosmer and Lemeshow test of goodness-of-fit. Estimated prevalence of the variables and odds ratios (OR) are reported with corresponding 95% confidence intervals (95%CI).

Results: A total of 503 subjects were included, and the majority were male patients (56.5% versus 43.5%). A total of 79 in-hospital deaths (15.7%) were identified during this period. Mortality was significantly ($p < 0.05$) associated with leukocytosis and neutrophilia (1st, 2nd and 3rd evaluations); hypernatremia, hyperkalemia and hyperchloremia (3rd evaluation); urea (3rd evaluation) and C-reactive protein (3rd evaluation). The multivariable logistic regression model only kept leukocytosis, urea and C-reactive protein at the third evaluation. Leukocytosis showed the strongest association, with an adjusted OR of 6.4 (95%CI: 2.4-9.4), followed by elevated urea levels with an OR of 4.78 (95%CI: 1.7-8.4) and finally elevated C-reactive protein (> 3 mg/dl) with an OR of 4.6 (95%CI: 1.8-10.2).

Discussion: We found that mortality was strongly associated with leukocytosis, high urea levels (> 50 mg/dl) and a C-reactive protein higher than 3 mg/dl at the third laboratory evaluation. One possible limitation in our study was the fact that we were blind to the patient's admission diagnosis, socio-demographic characteristics and co-morbidities. However we believe that these factors could never be exhaustively studied and therefore it seems unpractical to build risk factor scales for each admission's diagnosis. C-reactive protein's role on mortality prediction has been clearly demonstrated, however we identified two other variables (leukocytosis and urea level) that might play an important role in the prediction of mortality.

Conclusions: With the financial constraints Portugal is subject to, clinicians need to find ways to treat patients in a clinically sound and cost-effective manner. Laboratory evaluation of inpatients can be costly, therefore cheaper methods for predicting in-hospital mortality are necessary. Our study describes the usefulness of a

cheap set of laboratory tests in predicting mortality in patients admitted to an internal medicine ward. Future studies confirming our findings are warranted.

V-287
UTILITY OF COMPLEMENTARY TESTING IN THE STUDY OF ANEMIA IN HOSPITALIZED PATIENTS

A. Martínez Zapico, H. Gómez Rodríguez, C. Suárez Cuervo, C. Costas Sueiras, M. Fernández Almira, I. Piñero de Paz, S. de la Villa Martínez

Department of Internal Medicine. Hospital Universitario Central de Asturias. Oviedo (Asturias), Spain.

Objectives: Anemia is a frequent complaint in internal medicine due to the high number of cases in the general population. It is often diagnosed by chance when the patient performs a blood test for another reason. When a patient has anemia various endoscopic and imaging studies are performed in order to obtain a diagnosis. Sometimes these studies routinely apply regardless of the clinical data. This paper analyzes the usefulness of various complementary tests in the study of anemia.

Material and method: Data were collected from all patients in whom anemia was one of the main reasons for joining the Internal Medicine Department in a period of 6 months, from November 1, 2011 to April 30, 2012. Diagnostic tests performed and their usefulness to reach the final diagnosis were evaluated.

Results: We analyzed a total of 96 patients, who underwent abdominal ultrasound in 51 (53.1%), being useful in 12 (23.5%). CT was performed in 28 patients (29.2%) being helpful in reaching a diagnosis in 22 (78.6%). Endoscopic studies (gastroscopy and colonoscopy) were performed in 61 (63.5%) and 49 (51%) being useful in 34 (55.7%) and 27 (55.1%) cases respectively.

Discussion: In our hospital were performed numerous complementary tests. Gastroscopy was the most frequently performed, followed by ultrasound. The most useful was computed tomography. Ultrasound is often one of the initial tests but only in a small percentage of cases it is helpful. Computed tomography was performed more selectively, based on clinical data or findings in other studies, thus being useful in a much larger percentage of cases. The realization of large number of tests increases hospital stay assuming a high health care costs, so that their request should not be done routinely, but supported by data from medical records.

Conclusions: In our hospital were performed numerous complementary tests. Gastroscopy was the most frequently performed, followed by ultrasound. The most useful was computed tomography. Ultrasound is often one of the initial tests but only in a small percentage of cases it is helpful. Computed tomography was performed more selectively, based on clinical data or findings in other studies, thus being useful in a much larger percentage of cases. The realization of large number of tests increases hospital stay assuming a high health care costs, so that their request should not be done routinely, but supported by data from medical records.

V-288
VALPROIC ACID AND MEROPENEM INTERACTION: A RETROSPECTIVE STUDY

I. Bargiela, C. Araujo, R. Ribeiro, S. Alves, A. Ventura, C. Duarte

Department of Medicine 3. Hospital Prof Doutor Fernando da Fonseca. Amadora, Portugal.

Objectives: Interaction between valproic acid (VPA) and meropenem, resulting in a 60-100% drop in the VPA serum concentration in the first 24-48h, has been described in some published data. However, few is known about this interaction and its clinical repercussion. In fact, there is no guidance towards the proper clinical attitude. The aim of this study is to analyze this interaction and its clinical repercussion in hospitalized patients. Primary end points were to determine the percentage of patients that had a significant drop of VPA levels, to analyze the significance of that drop and its clinical repercussion.

Material and method: In a retrospective study of the population admitted in a local hospital in a year period, the authors analyzed the patients who were treated concomitantly with VPA and meropenem, in a total of 40 patients with 47 episodes. The inclusion criterion was the existence of at least one determination of VPA serum concentration in the week before the meropenem prescription and another during the concomitant treatment. A total of 18 patients with 18 episodes met this criterion. All of the patients were previously medicated with VPA. The considered VPA serum concentration value during concomitant treatment was the lowest one. The authors performed a statistical analysis of the 18 episodes using the Wilcoxon test.

Results: The studied group included 88.8% males and the median age was 67 years. The authors found that VPA serum concentration decreased in 100% of the analyzed patients. Only in one patient, despite of decreasing, VPA serum concentration remained in the therapeutic range. The mean value of VPA serum concentration before the prescription of meropenem was 59.6 µg/mL and during the concomitant treatment was 9.9 µg/mL, which represent a significant decrease of 83.3% ($p < 0.001$). The lowest value of VPA serum concentration during the concomitant treatment was 0.3 µg/mL. Epileptic seizures were observed in some patients. There were 2 patients that despite having 2 VPA serum concentration levels accessed were not included in the statistical analysis. The first one had no VPA levels accessed during the concomitant treatment (25.2 µg/mL before and 5.5 µg/mL three days after stopping meropenem) and the second one had no previous value of VPA serum concentration (1.9 µg/mL during the concomitant treatment and 85,6 µg/mL twelve days after stopping meropenem).

Discussion: The authors found a statistically significant drop in VPA serum concentration, consistent with the literature. Unfortunately, only 38,3% of the 47 analyzed episodes had at least 2 VPA serum concentration determinations, conditioning the conclusions of the present study. In addition, the paucity of VPA levels accessed in the first 24-48 h and after stopping the meropenem prescription did not allow the authors to compare their results to what is found in the literature. Considering the 2 episodes that were not included in the statistical analysis the authors believe that they corroborate the presented results, as the decrease of VPA levels found in the first case represents a drop of 78% even after 3 days without meropenem administration, and in the second case represents a significant increase in VPA serum concentration after stopping meropenem.

Conclusions: According to our results and to the reviewed literature we consider that the concomitant use of both drugs should be avoided. Despite this known interaction, no guidelines are available for patients who were previously medicated with VPA and require treatment with meropenem. It is mandatory to sensitize the medical community for the danger of this interaction and that some guidance is supported to the clinicians in order to prevent clinical repercussions such as epileptic seizures.

V-289
FAMILIAR AMYLOID POLYNEUROPATHY (FAP): EVALUATION OF TREATMENT IN A SERIES OF 5 CASES

J. Alfaro Fajardo, H. Vílchez Rueda, S. Urruela Caille, I. González Sayago, M. Fullana Barcelò, T. Bosch Rovira

Department of Internal Medicine. Hospital Universitari Son Espases. Palma de Mallorca, Spain.

Objectives: FAP is a systemic hereditary amyloidosis associated with mutation of transthyretin gene on chromosome 18 (Val30Met mutation), producing a mutant precursor protein which deposits itself on different tissues. This primarily affects the peripheral sensory, motor and autonomic nervous system. The only proven treatment is etiopathogenic (liver transplant). Our objective is to evaluate the evolution of the 5 patients according to the different treatment administered.

Material and method: Descriptive study of 5 patients diagnosed with FAP evaluating the treatment administered (etiopathogenic vs symptomatic) and the patients clinical outcome.

Results: Case 1. Male 73 yo, from Mallorca. Family History of FAP: 4 members (heterozygotic). Diagnosed in 2007 (heterozygote), the symptoms began 3 years earlier with paresthesias. Due to the patient's characteristics symptomatic treatment was decided. Last check up: increased paresthesias, severe muscular atrophy, weight loss, chronic diarrhea, orthostatic hypotension. Blood tests revealed hypoproteinemia and hypercholesterolemia. Echocardiogram (ECHO) revealed severe left ventricle (LV) hypertrophy with preserved ventricular function. Case 3. Male 40 yo, from Mallorca. FH: 2 members affected. Diagnosed in 2005 (heterozygote), the symptoms began 2 years earlier with diarrhea, erectile dysfunction and paresthesias. EMG findings compatible with FAP. ECHO: mitral and tricuspid insufficiency. No proteinurea. The patient received a liver transplant and prophylactic implantation of a pacemaker in 2006. Last check up: Glaucoma in left eye, remission of diarrheas, slight improvement of paresthesias, severe muscular atrophy and persistence of weakness of lower extremities and erectile dysfunction. Blood tests revealed normal blood protein, albumin and cholesterol levels. Objective and subjective clinical improvement. Case 4. Male 28 yo, from Mallorca. FH: 2 members. Diagnosed in 2008 (heterozygote), the symptoms began 2 years earlier with paresthesias in lower limbs, weight loss, erectile dysfunction and alternating diarrhea and constipation. EMG findings were compatible with FAP. ECHO: no anomalies. No proteinuria. The patient received a liver transplant and prophylactic pacemaker in 2009. Last check up: foot ulcer, persistence of paresthesias, persistence of diarrheas and erectile dysfunction. Orthostatic hypotension. No improvement after treatment. Case 5. Male 65 yo, from Mallorca. FH: 2 members (heterozygote). Diagnosed in 2006 (heterozygote), the symptoms began 18 months earlier with hypoesthesias, weight loss, severe muscular atrophy, difficulty to walk ECHO: LV hypertrophy and aortic insufficiency. No proteinuria. Not eligible for transplant; symptomatic treatment modality was indicated. Clinical evolution: difficulty to walk, weight loss, chronic diarrhea, depressive syndrome with autolytic intent. The patient died in 2009 due to FAP.

Discussion: FAP is a progressive and irreversible whose only current known treatment is etiopathogenic. Diagnosis is usually late. In our series 3 of the patients were not eligible for transplant and treated symptomatically. All showed disease progression; one of the patients died due to FAP. Two patients received liver transplants, one of them showed mild improvement; the other has shown progression of the disease without improvement.

Conclusions: FAP is a rare disease. Epidemiologically, Mallorca is the fifth in the world. The only effective treatment known at the moment is etiopathogenic, if possible performed within the first year of diagnosis. In those cases where etiopathogenic treatment is not possible, symptomatic treatment should be given.

V-292
ARE THE NEW SCALES OF RISK STRATIFICATION REALLY USEFUL FOR PREVENTION OF STROKE OR HAEMORRAGIC COMPLICATIONS IN ATRIAL FIBRILATION?

M. Igúzquiza Pellejero[1], L. Castro Figueroa[2], T. Matajira Chia[2], J. Montoya Arenas[2], C. Morandeira Rivas[3], A. García Noain[3], I. Lacambra Blasco[2]

[1]Department of Internal Medicine, [2]Department of Cardiology, [3]Department of Emergency. Hospital Clínico Lozano Blesa. Zaragoza, Spain.

Objectives: The aim of the study was to evaluate the impact of risk stratification and oral anticoagulant treatment according to the new recommendations of the ESC in the development of both, thromboembolic and bleeding events in patients with atrial fibrillation during one year follow-up.

Material and method: We performed a prospective observational study. The subjects were all patients diagnosed of atrial fibrillation (AF) who were discharged of the emergency room of the Clinic University Hospital of Zaragoza, between 01-03-2010 and 01-01-2011. All patients with a previous diagnosis of paroxysmal, persistent or permanent AF or those who developed new onset, were enrolled. We recorded clinical, demographic characteristics, oral anticoagulant therapy and the CHA2DS2vasc and HASBLED risk scores were performed. During one year follow-up the thromboembolic (TIA or Stroke) and haemorragic events registered in medical record were documented. The major bleeding was defined by Gusto's criteria or haemorragic stroke. The INR at the moment of the event was recorded too. Data were recorded in an SPSS 15.0 database. Comparisons were carried out by means, a chi square test and Fischer´s exact test when appropriate. Logistic regression was performed to determine independent predictor of tromboembolic and haemorragic events. For all tests, a P value < 0.05 was considered statistically significant.

Results: We included 364 patients, 54.7% women (199) and 45.3% men (165). 15 patients (4.1%) were < 45 years old, 55 (15.1%) 45-60 years old, 123 (33.8%) 60-75 years old and 171(47%) > 75 years old. 69.2% (252 patients) had a CHA2DS2Vasc score ≥ 2,28.3% (103 patients) had a score of 0, while the 2.5% (9 patients) had a score of 1. On the other hand, 50 patients (13.7%) had a high haemorragic risk by HASBLED score, while 314 (86.3%) had low haemorragic risk. 99 patients (27.2%) had a low risk for both, 206 patients (56.6%) had high thromboembolic risk and low haemorragic risk and 46 patients (12.6%) had a high risk for both. Thromboembolic complications occurred in 4.4% (16 patients), while haemorragic were observed in 2.2% (8 patients) In the group of high thromboembolic risk the 60.3% were discharged with OAC, whit an incidence of stroke/TIA in 9% (9 patients) in the group who were not anticoagulated, compared to 2% (3 patients) who received OAC, this being a statistically significant difference (p = 0.014). Notably, none of the 3 patients that received OAC were in therapeutic range. In the high thromboembolic risk group and low haemorragic risk, 8 cases (3.8%) a thromboembolic complications were found, all cases outside range of INR. With regard to haemorragic risk stratification, we observed that all patients who had a haemorragic event were classified as low risk (HASBLED score). The incidence of haemorragic complications in the OAC group was 3.1% vs 1.2% in the non OAC group, but this difference did not reach statistical significance (p = 0.59). We performed logistic regression for isquemic events, and the only factor that made up the CHA2DS2VASc score that reached statistical signification, was a history of stroke, perhaps due to the small size sample.

Conclusions: Most of they were stratificated into high thromboembolic risk group, by CHA2DS2Vasc score who must receive OAC according to the new ESC guidelines. All the isquemic events that were found during follow-up were presented in the non anticoagulation group or those with INR outside the therapeutic

range. We consider that the OAC in the therapeutic range is one of the major factors for the prevention of stroke/TIA in AF. The stratification of haemorragic risk through the HASBLED score was not able to distinguish which patients had bleeding complications, probably due to the small size of sample.

V-294
POISONING AND DRUG OVERDOSE IN A INTERNAL MEDICINE DEPARTMENT

A. Lazo Torres, M. Esteban Moreno, G. Parra García, P. Sánchez López, G. López Lloret

Department of Internal Medicine. Complejo Hospitalario de Especialidades Torrecárdenas. Almería, Spain.

Objectives: Accidental and intentional poisonings or drug overdoses constitute a significant source of aggregate morbidity, mortality, and health care expenditure. Although the true incidence is unknown due to underdiagnosis and underreporting. A brief initial screening examination should be performed on all patients to identify immediate measures required to stabilize and prevent deterioration of the patient. Our purpose was studied the epidemiological and clinical variables in patients with poisoning or drug overdose admitted in general hospital.

Material and method: Prospective study of 35 patients with poisoning or drug overdose admitted of Torrecárdenas Hospital from January 2010 until December 2011. We analyzed: age, sex, days in hospital, intensive care unit (ICU) stay and comorbidity. The data were analyzed by using SPSS 18.0 statistical package.

Results: The following variables were studied: age 45 ± 13 years, sex 13 males (37.15%)/22 females (68.85%). The average hospital stay was 8 days. 6 patients required ICU admission (17.14%). 6 patients had a history of psychiatric illness (17.14%) and 25 patients had multiple comorbidities (71.42%). 0 patients died. We analyzed the source of: Overdose drug type: digitalis intoxication in 22 patients (62.85%), methadone in 1 patient, valproic acid intoxication in 1 patient, carbamazepine toxicity 1 patients, paracetamol 2 patients, lithium 2 patients and tricyclic antidepressant 1 patients--poisoning cases: organophosphate 1 patients, cocaine 2 patients and boric acid 1 patients. Analyzing therapeutic families at hospital discharge: > 5 drug in 27 patients (77.14%) and < 5 drug in 8 patients (22.86%).

Conclusions: Accidental and intentional poisonings or drug overdoses are unusual diseases but very serious. In our study we found that patients were young and high comorbility.

V-296
NONINVASIVE EVALUATION OF PULMONARY HEMODINAMICS IN PATIENTS WITH CIRRHOSIS AND PULMONARY HYPERTENSION

I. Tudor, A. Gurghean, R. Dantes, A. Mihailescu, I. Bruckner

Department of Internal Medicine. Coltea Clinical Hospital. Bucharest, Romania.

Objectives: We thought to test whether we can do a noninvasive assessment of pulmonary hemodynamics in patients with chronic liver disease and pulmonary hypertension (PHT).

Material and method: From 347 patients with cirrhosis we selected 116 patients with cirrhosis and portal hypertension; we evaluated these patients by clinical examination, laboratory tests, abdominal ultrasound and echocardiography. We assessed pulmonary pressure by Doppler echocardiography, measuring pulmonary artery systolic pressure (PASP) and acceleration time (AT). We considered PHT when PASP > 35 mmHg and/or AT < 100 ms. Then we tried to evaluate the high flow state and pulmonary vascular resistance (PVR) by duplex echocardiography (2D and Doppler). The right atrial volume (RAV) index, cardiac index (CI) and assessment of inferior vena cava (IVC) and right atrial pressure (RAP) were used to define the high flow states, and ratio of peak tricuspid regurgitant velocity (TRV) to right ventricular outflow tract velocity time integral (VTIRVOT) to detect increased PVR (TRV/ VTIRVOT > 0.2). We evaluated pulmonary capilary wedge pressure (PCWP) indirectly, by left atrial diameter divided at body surface (left atrial diameter index – LAd index). There was also a control group for establish cut-off values for RAV index (32 ml/m^2), CI (2.3 L/min/m^2) and LAd index (2 cm/m^2).

Results: 27 patients (23%) had PHT. Most of them had a high flow state (19 pts, 70%), mostly by increased venous return with elevated RAP (16 pts, 84%); 1 patient had increased PVR, probably portopulmonary hypertension; 2 patients had elevated PCWP (LAd index > 2 cm/m^2). The results were missing at 2 patients because of bad image quality. There were 3 patients who had suboptimal Doppler tricuspid regurgitation signals. Echocardiography failed to characterize pulmonary hemodinamics in 5 patients with PHT (18.5%).

Discussion: Approximately 20% of cirrhotic patients develop pulmonary hypertension (PHT). In most cases the cause is hyperdinamic state which accompaniates portal hypertension; it is characterized by an increased venous return and high cardiac output. PHT in the setting of excess central volume is reflected by increased PCWP. Portopulmonary hypertension, which has as hemodinamic marker a high PVR, is a very rare condition with a negative prognostic impact and an important predictor of hemodynamic instability after orthotopic liver transplantation. The characterisation of pulmonary hemodinamics and the diagnosis of portopulmonary hypertension are made invasively by right heart catheterisation. But there were some studies which demonstrated a good correlation between invasive PVR measurement and TRV/ VTIRVOT ratio measured by Doppler echocardiography. Practically, all parameters which define pulmonary hemodinamics in these patients can be assessed directly or indirectly by echocardiography.

Conclusions: Pulmonary hemodinamics can be evaluated in majority of patients with PHT by echocardiography (81,5%). Most cases of PHT in patients with cirrhosis and portal hypertension is caused by hyperdinamic circulation, which is best evaluated by assessment of inferior vena cava. We can improve echocardiographic performance by using agitated saline to increase suboptimal Doppler tricuspid regurgitation signals and/or improving the image quality.

V-297
TAKAYASU'S ARTERITIS IN A THIRD LEVEL HOSPITAL

A. Arias Milla, E. Martínez Robles, P. Tutor de Ureta, S. Mellor Pita, M. Yebra Bango

Department of Internal Medicine. Hospital Universitario Puerta de Hierro. Majadahonda (Madrid), Spain.

Objectives: Takayasu's arteritis is a granulomatous vasculitis of a unknown etiology that affects the aorta, its major branches and the pulmonary arteries. The aim of our study is to analyze cases of Takayasu's arteritis diagnosed in our hospital and compare our patients with those of the literature.

Material and method: We reviewed all cases of Takayasu's arteritis diagnosed in a third level hospital in Spain from 1995 on. All patients fullfiled at least three out of the six criteria of the American College of Reumatology (ACR) for Takayasu's arteritis established in 1990. We analyzed age at diagnosis, nationality, symptoms at diagnosis, physical findings, laboratory and imaging studies, medical treatment, revascularization need and afterwards evolution, and compared all these data with those of the literature.

Results: Eleven patients were identified of which five were men and six women. The mean age at presentation was thirty-five years old (range from 18 to 54 years old). All of them were Caucasian. Only one patient had general syndrome at diagnosis. Hypertension was the most common presentation (82%) and was consequence of renal artery stenosis. Cerebrovascular symptoms were recorded in 27% and visual disorders in 36.6%. Most of the patients presented abdominal bruit (63%). Abdominal aorta and its branches were compromised in 82%. Elevated erythrocyte sedimentation rate (ESR) was reported in 6 patients. Stenotic affection was noted in six patients. Sixty-four percent required steroids at diagnosis, two of them required mycophenolate mofetil and metotrexate sequentially. In their evolution seven patients required percutaneous angioplasty. Stent implantation was performed in four cases. Two patients needed a surgical procedure. It was recorded one death attributed to tumoral disease.

Discussion: The mean age at diagnosis of our patients was similar to the previously published, not the sex, which showed a ratio (6:5) for females. As the sample was limited to European population our results could not reflect the higher incidence in Asians. General Syndrome led to diagnosis in 50% of the cases reported in literature, not in our series, in wich the main manifestations focused on cardiovascular and neurological affectation. Sixty per cent had abdominal bruit and claudication in limbs with ESR elevation similar to published. The most common treatment was steroids in the early stages of disease activity, 18% of them needed to add other drugs such as immunosuppressants to slow down the progression. Interventional procedures were followed in 63.3% of the patients. Eighteen per cent of the patients required bypass.

Conclusions: The natural history and prognosis of Takayasu's arteritis still remain poorly defined. Most cohorts are limited to Asian populations. Larger series with Caucasian patients are needed to define the course and evolution of the disease in those cases.

V-298
ACUTE CORONARY SYNDROMES: BLEEDING COMPLICATIONS, PREDICTORS AND LONG-TERM PROGNOSIS

I. López Neyra[1], J. Córdoba Soriano[1], R. Cordero Bernabé[2], M. Bellón Munera[2], C. Llanos Guerrero[1], J. Navarro Cuartero[1], M. Iglesias Mier[1], A. Gutiérrez Díez[1]

[1]Department of Cardiology, [2]Department of Internal Medicine. Hospital General de Albacete. Albacete, Spain.

Objectives: The most aggressive treatments have improved the prognosis of Patients (P) with acute coronary syndrome (ACS), but these treatments can also increase bleeding risk and reduce all the benefit. Our aim is to evaluate which factors can predict an increase of bleeding risk in patients with ACS and percutaneous coronary intervention (PCI).

Material and method: Prospective study of P with ASC who were treated with PCI and followed for a year. We study their basal characteristics, pharmacological treatment, technical characteristic of the PCI and the appearance of major adverse cardiac events (MACE). It is defined like death, myocardial infarction (MI), stroke, stent thrombosis or need to urgent revascularization. Bleeding complications were defined with ACUITY and GUSTO definitions.

Results: 351 P with a mean age of 65 ± 12 years (83.3% male). There were raised prevalence of cardiovascular risk's markers (31% diabetes mellitus) and treated with PCI (58% urgent). 97% of the P were treated with aspirin and clopidogrel, 18% with enoxaparin and 3% with tirofiban previously to PCI. During the PCI we used unfractionated heparin in 87%, abciximab in 29% and bivalirudin in 26%. Transradial access was used in the most interventions (87%). 6.2% MACE, 15% minor ACUITY hemorrhagic, 15% major ACUITY hemorrhagic, 0.9% minor GUSTO hemorrhagic and 1% major GUSTO hemorrhagic were registered. The age > 75 years old (25.3% vs 10.9%, p = 0.001), femoral access (30.2% vs 13.2%, p = 0.04) and weight < 65 Kg (30.3% vs 13.8%, p = 0.01) associated significantly with major ACUITY bleeding. The previous predictors and the use of abciximab (3.4% vs 0.4%, p = 0.02) associated significantly with GUSTO bleeding. There were no association between MACE and bleeding.

Conclusions: In our cohort with important use of transradial access and early pharmacological and invasive strategy is associated to good evolution in spite of high incidence of bleeding. The elderly and femoral access are bleeding predictors and we need to be more careful with that P.

V-304
CAUSES OF ADMISSION IN INTERNAL MEDICINE AT MOSTLY ELDERLY PATIENTS. A COOPERATIVE MULTICENTER STUDY

C. Arranz[1], R. Cordero[1], A. Caudevilla[2], N. Ortego[3], R. Tirado[4], M. Lambán[5], F. Rondero[6], J. Blázquez[1]

[1]Department of Internal Medicine. Complejo Hospitalario Universitario de Albacete. Albacete, Spain. [2]Department of Internal Medicine. Hospital Lozano Blesa. Zaragoza, Spain. [3]Department of Internal Medicine. Hospital de Especialidades San Cecilio. Granada, Spain. [4]Department of Internal Medicine. Hospital Comarcal Infanta Margarita. Córdoba, Spain. [5]Department of Internal Medicine. Hospital Royo Villanova. Zaragoza, Spain. [6]Department of Internal Medicine. Hospital de la Defensa. Zaragoza, Spain.

Objectives: Knowing the most common diseases suffered by patients admitted in internal medicine from Spanish hospitals.

Material and method: It is a part of a transversal multicenter cooperative study case-control of the GTO-SEMI, in which the cases are patients admitted for hip fracture and controls, patients of the same age, admitted to internal medicine without hip fracture. In this study involving 16 Spanish hospitals. It is a descriptive analysis of the causes of admission in internal medicine mostly elderly patients, a group comparable in age and sex with the group of patients with hip fracture.

Results: 381 patients took part into this study, 287 were women (75.4%) and 94 men (24.6%), with a median age of 82 years [IR: 77-87]. There was a predominance of cardiovascular diseases, 125 patients (32.8%) within this etiology most patients corresponded to episodes of decompensated heart failure (93), followed by episodes of ischemic heart disease (15), cardiac arrhythmias (14) and other cardiovascular diseases (3). The second group are the respiratory diseases, found in 113 patients (29.65%), with a predominance of respiratory infections (56), followed by episodes of respiratory failure (36), COPD (13), bronchial asthma (5) and finally other respiratory diseases (3). The third group refers to the infectious diseases not included in other etiologic groups, occurring in 61 patients (16.01%) within this group includes urinary tract infections (36), followed by acute gastroenteritis and fever syndromes not filiated with 8 episodes each one, infected ulcers (4), cellulitis (3) and endocarditis (2). Disorders of the gastrointestinal system are the following etiologic group with a total of 47 patients (12.33%), in which the largest number corresponds to gastrointestinal bleeding (13), followed by diseases related to bile duct (9), pancreatitis (5), decompensated cirrhotic (5), jaundice to study (4), ischemic colitis (3), episodes of partial bowel obstruction (3) and other gastrointestinal diseases (5). The neurological etiology is the fifth group, occurring in 23 patients

(6.03%), with a predominance of cerebral strokes (15 ischemic and 1 hemorrhagic), seizures (2) and other neurological diseases (5). Haematological abnormalities are due the following entry, which occurs in 21 patients (5.51%), the main one is the anemia study (19). In 14 patients (3.67%) the cause of admission was a deterioration of renal function. Other causes of admission were constitutional syndrome in 10 patients (2.62%), delirium in 7 cases (1.83%), electrolyte disturbances in 6 patients –hyponatremia, 5, and hyperkalemia, 1- (1.57%) and hyperglycemia and thromboembolic diseases in 4 cases (1.04%). The presence of nonspecific pain and skin lesions occurred in 3 patients (0.78%). Systemic disease, syncope and drug toxicity occurred in 2 patients in each group (0.52%). Finally there were a number of other diseases that occurred in 9 patients (2.36%).

Conclusions: Once ended our study we have noticed that there is a predominance of women over men with a 3:1 ratio. The main cause of hospitalization of patients in internal medicine is the cardiovascular disease, predominantly episodes of decompensated heart failure. In second place are respiratory problems and infections. Draws attention to the small number of thromboembolic events, taking into account the epidemiological characteristics of our patients.

V-305
PERCUTANEOUS CORONARY INTERVENTION FOR UNPROTECTED LEFT MAIN CORONARY ARTERY DISEASE: A COMPARISON BETWEEN IN-HOSPITAL MORTALITY PREDICTED USING LOGISTIC EUROSCORE AND OBSERVED

I. López Neyra[1], J. Córdoba Soriano[1], M. Bellón Munera[2], R. Cordero Bernabé[2], A. Gallardo López[1], J. García Casarrubio[1], M. Fernández Anguita[1], G. Gallego Sánchez[1]

[1]Department of Cardiology, [2]Department of Internal Medicine. Hospital General de Albacete. Albacete, Spain.

Objectives: Left Main Coronary Artery (LMCA) is a unique clinical condition and the predictive value of the risk scores in such patients is not necessarily as good as in more general population of cardiac patients. Our aim was to compare risk predicted using logistic EUROSCORE and actual outcomes in patients with left main coronary artery disease undergoing percutaneous coronary intervention with stent implantation (PCI).

Material and method: From 2005 to 2011, we studied prospectively 69 patients with severe unprotected LMCA disease that were not considered to be candidates for coronary artery bypass grafting (CABG) due to high surgical risk, poor distal beds or need for urgent revascularization who were undergoing PCI. We established two levels of surgical risk according to logistic EuroSCORE (≥ 15 (high risk) or < 15) and we studied the clinical and angiographic characteristics of the patients. We compared in-hospital mortality in each group using Chi-square test.

Results: We performed PCI in 69 patients (72.5% male) with a mean age of 72 years (38-88) and a mean logistic EuroSCORE 14.40 (2-50). Among baseline characteristics, 76.8% had hypertension, 39% diabetes mellitus and 7% showed at least moderate renal insufficiency (two patients on hemodialysis). The mean left ventricular ejection fraction of the group was 48% (20-70%) and in 69.6% of the patients the predominant location of the injury was the distal portion affecting the bifurcation while the rest were ostial or body lesions. Drug-eluting stents were implanted in 66 cases (95.7%) and we used support with intra-aortic balloon counter-pulsation in 15 cases (21.7%). 27 cases (39.1%) were urgent revascularizations. The procedure was successful in 66 (95.7%). We registered 6 in-hospital deaths (8.7%). 5 deaths occurred among patients undergoing urgent PCI compared with 1 death in patients in which PCI was elective (18.5% vs 2.4%; p = 0.033). In 28 cases (40.5%) logistic EuroSCORE was ≥ 15 and in 41 patients (59.5%) was < 15. The mean score of the first group was 25.36 (95%CI, 21.57 to 29.14) while in the second group it was 7.27 (95%CI, 6.17 to 8.36). The first group had 5 events (18.5%) while the second group had only 1 (2.4%) and this difference was statistically significant (p = 0.037). The mean score among patients who died was 31.17 ± 14.6 while the mean score among survivors was 13.03 ± 9.5 (p = 0.028).

Conclusions: The logistic EuroSCORE calculated in patients with LMCA disease is associated with in-hospital mortality after PCI. In our study, a logistic EuroSCORE ≥ 15 predicts significantly high mortality. On the other hand, in our series the real mortality of PCI is lower than estimated surgical mortality using logistic EuroSCORE.

V-306
TRANSRADIAL CARDIAC CATHETERIZATION IN PATIENTS CHRONICALLY ANTICOAGULATED: A NEW SAFE AND EFFECTIVE INTERVENTION

I. López Neyra[1], J. Córdoba Soriano[1], J. Jiménez Mazúecos[1], M. Bellón Munera[2], R. Cordero Bernabé[2], A. Gutiérrez Díez[1], M. Iglesias Mier[1], M. Rodríguez Carcelén[1]

[1]Department of Cardiology, [2]Department of Internal Medicine. Hospital General de Albacete. Albacete, Spain.

Objectives: Cardiac catheterization in chronically anticoagulated patients is performed after the anticoagulation has been withdrawn at least 48 to 72 hours before and in some selected patients, heparin is added to the treatment. The efficacy and safety of cardiac catheterization without removal of anticoagulation is not well known. Our aim was to asses this controversy.

Material and method: Prospective study of a population of 199 patients (P) undergoing elective transradial cardiac catheterization in which 30 P were chronically anticoagulated (Group A) and were compared with another contemporary group of 169 patients without anticoagulation therapy (Group B). The protocol of bandaging and time of compression was similar in both groups (hemostatic band for elastic compression during 2 hours). We assessed the development of complications after the removal of bandage while patients were still in laboratory and in the first 24 hours. Radial permeability was assessed by plethysmography and hematomas were defined in two categories: mild (5-10 cm) or severe (> 10 cm).

Results: Patients in Group A were older than those in Group B (72 ± 8 vs 65 ± 11 years old; p = 0.01). The most common cause of anticoagulation was atrial fibrillation (60%) and the mean International normalized ratio (INR) at the time of the procedure was 2.28 ± 0.4 (3.6% INR > 3.5). There was no difference in duration of procedure between both groups. All procedures were performed by transradial access without crossover to femoral access. When the bandages were removed, there was bleeding in 1.8% of Group B who required new compression compared with 0% in Group A (p > 0.05). There was no occlusion of the artery used in any group. In Group A we registered 10% of mild hematomas compared with 7.1% in Group B, without a significantly statistic difference. In the first 24 hours, no patient developed radial occlusion or bleeding and only 2.4% of patients of Group B developed a new hematoma compared with any hematoma in Group A (p > 0.05). None of the early or late hematomas call for any additional attitude or had clinical significance.

Conclusions: A quick radial compression protocol without removal of the oral chronic anticoagulation is safe in patients chronically anticoagulated avoiding the potential complications that may arise after the withdrawal of this medication.

V-309
ANALYSIS OF EARLY READMISSIONS AFTER DISCHARGE FROM AN INTERNAL MEDICINE DEPARTMENT

C. Maínez Saiz[1], A. Roldán Montaud[1], Y. Romero Pizarro[1], J. Montoro Lara[1], N. Vicente López[1], R. Ríos Garcés[1], A. Ramos Martín-Vegue[2], F. García López[3]

[1]Department of Internal Medicine, [2]Department of Admission, [3]Department of Nephrology. Hospital Universitario Puerta de Hierro Majadahonda. Madrid, Spain.

Objectives: To analyze the population of patients readmitted to an Internal Medicine Service (IMS) and identify the predictors for readmission. In a first phase of our study, the results of which we present, we studied the characteristics of patients readmitted within the first 30 days following discharge from the service in 2011.

Material and method: We analyzed data obtained by the Admissions Service, from the CMBD database, including dates of admission and discharge from the hospital both in the first admission and in the readmission, principal diagnosis, agreement between both diagnosis, length of stay, mean time to readmission, mortality and comorbidity using the Charlson index adjusted for age.

Results: We analyzed 487 episodes of readmission after discharge from the IMS during 2011. In the study period, 4292 patients were discharged, 16.1% of whom were readmitted within the next 30 days. The median age of patients was 78.3 years with a median of 82 years, 47.8% were males, 82% were over 70 years and 60% were over 80 years. Most patients were readmitted to the S. Internal Medicine (409 patients, 83.9%), 54 patients (11%) were admitted to other medical services and 23 patients (4.7%) to various surgical departments. The mortality of patients readmitted was 20.1% (98 patients), well above the overall mortality of patients admitted to IMS during the same period (12.1%). The main diagnoses at discharge were: pneumonia (30.3%), heart failure (21.5%), urinary tract infection (UTI)) (6%), cirrhosis and its complications (3%)), exacerbation of COPD (2.26%) and acute renal failure (1.4%). Similarly for the readmission the principal diagnoses were: pneumonia (33.6), heart failure (18.4%), UTI (4.1%), cirrhosis and its complications (3.2%), exacerbation of COPD (3, 2%), acute coronary syndrome (2.05%) and pseudomembranous colitis (1.2%). The diagnosis was coincident in 272 patients (56%). No significant differences in mortality were found between the groups of patients with or without the same diagnosis at each admission. There were no differences in length of stay in both groups (average 8.85 and 9, respectively), and it was also similar to the average hospital stay of patients admitted to the SMI during 2011 (8.37). The average time to readmission was 13.5 days. 51 patients (10.4%) were readmitted within 3 days and 120 (24.6% within 7 days. We did not find differences in main diagnosis or mortality. Our patients had an average comorbidity, measured by the Charlson index of 3.31 and 6.75 when it was adjusted for age. A high comorbidity (Charlson index equal or greater than 3) was found in 306 patients (62.8%).

Discussion: Unscheduled readmissions to the hospital are regarded with increasing interest as an indicator of quality of medical care. Furthermore, its reduction could lead to a significant decrease in health spending, however we do not know what percentage of these readmissions are avoidable and which factors can predict readmission. At this first stage in which we describe the population of readmissions, it is remarkable both the high concordance between the primary diagnoses in both admissions (initial and readmission) as the increased mortality of patients readmitted.

Conclusions: 16.1% of patients discharged from our Department of Internal Medicine were readmitted during the following 30 days. The median age and comorbidity (62.8% with a Charlson index of 3 or greater) in our readmitted patients is high. We found coincidence in the principal diagnoses in up to 56% of patients. Readmission appears to confer a higher risk of mortality.

V-310
USE INAPPROPIATE URINARY CATHETER INPATIENT OF INTERNAL MEDICINE DEPARTMENT

J. Lebrón Ramos, S. Domingo González, M. Martín Escalante, M. Uribe Pérez, M. Núñez Rodríguez, J. de la Torre Lima, J. García Alegría

Department of Internal Medicine. Hospital Costa del Sol. Marbella (Málaga), Spain.

Objectives: Describe the indications urinary catheter use inpatient of Internal Medicine Department (IMD) in the Costa del Sol Hospital, Marbella, Spain.

Material and method: A prospective analysis of patient admission in the (IMD) with urinary catheter between 1st april and 30th april of 2012 with a daily monitoring. We study comorbilities of these patients, use appropriate or not urinary catheter.

Results: 98 patients were analyzed. Mean age was 76 years and 56.1% was women. The average stay was 13.86 days and the mortality was 21.4%. Comorbilities were: 44.9% diabetes mellitus, 29.6% kidney failure (27.6% between 3 and 4 stages) and 10.2% immunosuppression. The mean Barthel index was 33 points (25% of patients had a total dependence). Main diagnoses at discharge were: 26.5% heart failure, 13.2% pneumoniae, 10.2% stroke and 10.2% sepsis. Indications use of urinary catheters were: 63% control of diuresis in patients with unstable, 8.2% neurogenic bladder, 7.1% urinary retention, 7.1 urinary incontinence in patients with sacral ulcers by pressure. 10% indicated no use of catheterization. Placement of the catheter was 78.6% of cases in the Emergency. The most frequent complication was urinary retention with 5% and need for re-catheterization and 13.3% of patients required catheterization at discharge.

Discussion: The urinary catheter is a technique not without complications. The catheter associated urinary tract infection is the most common problem is one of the leading causes of nosocomial infection in hospitals. Several studies promote the proper use of this technique to prevent these complications.

Conclusions: 1. Patients admitted to internal medicine requiring urinary catheter have a longer hospital stay, with a greater dependence and increased mortality. 2. The most frequent indication in the use of catheterization was the control of diuresis in the unstable patient. 3. In a high percentage of bladder catheterization was not indicated. 4. The most common complication was urinary retention requiring re-catheterization in a high number of patients at discharge.

V-312
OBESITY PARADOX IN ALCOHOLISM

E. García-Valdecasas Campelo, J. Ruiz Lacambra, E. González Reimers, R. Alemán Valls, J. Alvisa Negrín, C. Martín González, I. Hernández Betancourt, F. Santolaria Fernández

Department of Internal Medicine. Hospital Universitario de Canarias. San Cristóbal de La Laguna (Santa Cruz de Tenerife), Spain.

Objectives: Alcoholism leads to malnutrition and is related to impaired survival. Recently, it has been observed that obesity, in aged and chronic patients is related to a better survival. This is named obesity paradox. Obesity paradox has been scarcely studied in alcoholism and liver cirrhosis. The objective of our study is to analyze if overweight (BMI 25-30 kg/m^2) and obesity (BMI > 30 kg/m^2) or fat excess is associated to a better survival in alcoholics with and without liver cirrhosis.

Material and method: We included 342 male alcoholic patients, all of them drinkers of 80 or more g ethanol/day, mean age of 51

± 0.7 years, admitted to the internal medicine unit of the Hospital Universitario de Canarias. We assessed the nutritional status by BMI, mid arm anthropometry (mid arm circumference (MAC), mid arm muscle area (MAMA) and triceps skinfold (TSF)), total body dual energy X-ray absorptiometry (DEXA) assessing lean and fat mass, subjective assessment and hand grip. We separated alcoholics without liver cirrhosis, 63%, from cirrhotic ones, 37%. Survival was analyzed according to in hospital mortality, 22%.

Results: Hospital mortality was related to a bad nutritional status. An impaired subjective assessment was associated to a mortality of 36% (p = 0.009). Alcoholics with impaired feeding habits show a mortality of 34% versus 13% in those with normal nutritional habits (p = 0.012); alcoholics with a BMI < 20 kg/m^2 show a mortality of 24% whereas in those with a BMI > 30 kg/m^2 was 14% (p = 0.049). Alcoholics with a MAMA under the 10th normal percentile show a mortality of 33.3% (p = 0.002) and with a lean arm mass (DEXA) under the 10th percentile show a mortality of 28% (p = 0.01), whereas a low fat mass assessed by DEXA or by mid arm anthropometry was not related to mortality. Overweight and obesity were not only related with lower mortality, but also with a better nutritional status: better feeding habits, lesser weight loss, and higher lean mass with better hand grip.

Discussion: Our results shown a lower mortality in patients with overweight and obesity. Moreover, overweight and obesity were related not only with high fat mass but also with a better nutritional status with higher lean mass and better muscle function assessed by hand grip.

Conclusions: These results support the obesity paradox hypothesis with better survival in overweight and obese patients.

V-319
INFLUENCE OF ACUTE PORPHYRIA'S ACTIVITY ON SUBCLINICAL RENAL DISFUNCTION

A. González Estrada, C. Alarcón Garcelán, S. Rodríguez Suárez, L. Gómez Morales, P. García Ocaña, E. Pamies, J. Andreu, J. García Morillo

Department of Internal Medicine. Hospital Virgen del Rocío. Sevilla, Spain.

Objectives: The porphyrias are metabolic disorders, each resulting from the deficiency of a specific enzyme in the heme biosynthetic pathway. These enzyme deficiencies are inherited as autosomal dominant in acute porphyrias. Although there is small evidence, the long-term risk of chronic renal disease is increased in these diseases. The objective of this study was to describe in a cohort of patients with acute porphyrias the prevalence of renal disfunction and of several cardiovascular risk factors, and to analyze the association between renal disfunction and the activity of the disease.

Material and method: We conducted a transversal analysis of a cohort of 30 patients with acute porphyrias: acute intermittent porphyria (AIP), hereditary coproporphyria (HCP) and variegate porphyria (VP) in an Internal Medicine Department of the Virgen del Rocío Hospital in Spain. We analyzed several epidemiological, clinical and biological variables to value the activity of the disease, like ALA and PBG urinary levels, the number of acute attacks suffered, the need of treatment with hematin, as well as the evaluation of renal function (calculating the glomerular filtration rate using a Modification of Diet in Renal Disease formula: MDRD) and arterial pressure, glycemia and plasmatic cholesterol as cardiovascular risk factors. Quantitative variables were expressed as mean ± standard deviation (SD) and qualitative variables as absolute value and percentage. Between the studied variables a statistical analysis was performed using SPSS Statistics Software 15.0.

Results: 30 patients were studied with a mean age of 38.32 ± 12.7 years old. Proportion men/women was 30.3% and 69.7% respectively. The proportion of AIP was: 63.6%, of VP 9.1% and of HCP 63.6%. We established three groups according to the number of acute attacks suffered: 75.8% of patients belonged to group 1 (none or 1 acute attack) 12.1 to group 2 (from 2 to 5 acute attacks) and 12.1% to group 3 (more than five acute attacks). The percentage of patients who had received treatment with hematin at least once was 37.1%. The mean of glomerular filtration rate was 89.98 ± 32.16. PBG urinary levels were 7.73 ± 11 mg/24h and ALA urinary levels: 5.9 ± 5.4 mg/24h. The mean glycemia was 85.9 ± 9.7 g/dl and mean total cholesterol was 203.37 ± 48.5 mg/dl. Patients with persistently high PBG and ALA urinary levels had lower glomerular filtration rate (GFR), higher glycemia and higher total cholesterol levels. Previous treatment with hematin was associated with lower GFR and higher glycemia levels.

Conclusions: We describe a cohort of patients with acute porphyrias where the most common was AIP. In patients with a more active disease (measured by PBG and ALA urinary levels and by the necessity of treatment with hematin) chronic kidney disease was more prevalent, together with other cardiovascular risk factors.

V-320
ASSOCIATION OF THE PPARΓ GENE POLYMORPHISM PRO12ALA WITH TYPE 2 DIABETES MELLITUS

A. Tichalas[1], D. Agapakis[1], E. Satsoglou[1], A. Kouvatsi[2], K. Triantafillidis[2]

[1]Department of Internal Medicine. General Hospital of Goumenissa. Kilkis, Greece [2]Department of Biology. Aristotle University of Thessaloniki. Thessaloniki, Greece.

Objectives: The nuclear receptor PPARγ is implicated in the mechanisms of adipocyte differentiation as well as in glucose and lipid metabolism. A common polymorphism in the gene encoding PPARγ which is known as Pro12Ala has been associated with decreased risk for type 2 diabetes mellitus, as well as with various effects in weight, insulin resistance and blood pressure and many other clinical and biochemical traits. The aim of our study was the investigation of frequency of polymorphism of Pro12Ala in diabetic patients in the Northern Greek population.

Material and method: We studied 72 adult patients, 30 men and 42 women, with type 2 diabetes mellitus. The duration of illness, the type of anti-diabetic treatment and cardiovascular complications were recorded. DNA sample was collected and blood pressure, BMI, serum levels of lipids, fasting glucose, HbA1C were measured in all patients and were compared with data obtained from 25 control subjects.

Results: The Ala variant was found statistically significant lower in the group of diabetic patients (3.5% versus 10%, p < 0.01) as well as in that of diabetic patients treated with a thiazolidinedione (1.9% versus 10%, p < 0.01). Also, among diabetic persons, Ala variant was associated significant with higher body mass index (p < 0.05), lower fasting serum glucose levels (p = 0.05) and higher systolic blood pressure (p < 0.01). In the group of diabetic persons treated with a thiazolidinedione, Ala variant was associated with later onset of diabetes if adjustment for sex was taken into account (p < 0.05).

Discussion: The frequency of Ala variant in diabetic patients is generally low. Thiazolidinediones are PPARγ agonists with antidiabetic actions. PPARγ activation by thiazolidinediones is reduced when Ala variant is present. Pro12Ala polymorphism correlated with higher BMI, lower fasting glucose level and higher systolic blood pressure in diabetic patients.

Conclusions: The results obtained suggest that the Pro12Ala polymorphism protects against type 2 diabetes mellitus in the study population and affects some clinical traits in diabetic people.

V-324
ADEQUACY OF THE TREATMENT OF SPINAL METASTASES TO VALIDATED PROGNOSTIC SCALE: TOKUHASHI SCORE

L. Vela Manzano[1], S. Sánchez de las Matas Pena[2], F. Brun Romero[2], E. Sifuentes Díaz[1], C. Cano Gómez[2], I. Tinoco Racero[1]

[1]Department of Internal Medicine, [2]Department of Orthopedic Surgery. Hospital Universitario Puerta del Mar. Cádiz, Spain.

Objectives: To analyze if, after applying the prognostic scale of Tokuhashi to patients diagnosed with spinal metastases at our hospital, the therapeutic indication permitted is recommended in the literature, and assess adherence to the scale and prognostic consistency.

Material and method: A retrospective study of patients diagnosed with spinal metastases between 2006 and 2010 in our hospital (with a minimum of one year follow up after diagnosis). The study variables were: mean age, sex, Karnofsky performance status, number of vertebral metastases, number of extraspinal bone metastases, number of metastases in internal organs, metastases to major organs (brain, lung, liver, kidney), type of primary tumor, presence of neurological damage at the time of diagnosis, presence of pathologic fracture, type of treatment, survival from diagnosis, and in the case of patients who received surgery or radiotherapy, improvement or no pain and the index Karnofsky after them. Was applied to all patients Tokuhashi scale for spinal metastases and found adhesion and forecast consistency (certainty of the survival indicated by scale) of the scale. We excluded those cases in which clinical data were incomplete for analysis or in which follow-up was lost.

Results: 279 cases were analyzed. The mean age was 65 years (SD ± 13), being 60% (n = 168) males. Median survival was 12.8 months, with less than 6 months in 53% of patients. In 64.8% of total cases, the criteria Tokuhashi scale for therapeutic decision making, with a 71.6% consistency overall prognosis. 62% accounted for a score as Tokuhashi scale from 0 to 8 points, corresponding to a life expectancy less than 6 months according to this scale. Of these, 95.4% had adherence to the scale, rejected for surgery and received conservative treatment, and prognostic consistency of 68.7%, with a median survival of 6.15 months. Of those who had not reported adherence to the scale, the median survival was 9 months (being less than 6 months in 33% of them). They were treated by surgery (3 cases and 3 cases excisional laminectomy). Cases with scores between 9 and 11 points, corresponding to a survival depending on the scale between 6 and 12 months were 26.6% of cases, of which 13.4% had adherence to the scale proceeding to palliative surgery. The prognostic consistency was 42.8%, with a median survival of 22.7 months. In all other cases, adding that despite this score is not involved, received conservative treatment, with a median survival of 19.5 months. 11.3% of cases had a score between 12 and 15 points, so that upon the recommendation of the scale would intervene with curative surgery. Of these 22.7% were operated with each other for healing, presenting a prognostic consistency of 80% and a median survival of 30.8 months. The remaining cases, which showed no adherence to the scale were treated, in 1 patient with palliative surgery and the rest with conservative treatment. Median survival in these cases was 28.9 months.

Conclusions: In our study we have observed that despite the lack of adherence to Tokuhashi outcome scale, this does not translate into a decreased survival significantly. In addition, there has been a greater adherence to the scale when the recommendation that the score is conservative, and less adherent when the recommendation is the surgical approach (either palliative or curative).

V-326
CLINICAL FEATURES AND LONG-TERM RENAL OUTCOME IN ICELANDIC PATIENTS WITH APRT DEFICIENCY AND 2,8- DIHYDROXYADENINURIA

H. Runolfsdottir[1], R. Palsson[1,2], I. Agustsdottir[2], V. Edvardsson[1,2]

[1]Faculty of Medicine. University of Iceland. Reykjavik, Iceland. [2]Landspitali, The National University Hospital of Iceland. Reykjavik, Iceland.

Objectives: Adenine phosphoribosyltransferase (APRT) deficiency is an autosomal recessive disorder of purine metabolism that leads to excessive urinary excretion of the poorly soluble 2.8-dihydroxyadenine (DHA). Radiolucent kidney stones and chronic kidney disease (CKD) are common manifestations. The aim of this study was to assess the clinical features and long-term renal outcome in Icelandic patients with this disorder.

Material and method: The medical records of all 32 Icelandic patients listed in the APRT Deficiency Registry of the Rare Kidney Stone Consortium were reviewed for clinical features, including kidney stones, significant unilateral kidney damage, reduced kidney function and progression to end-stage kidney failure (ESKF). Data are presented as median and range.

Results: Of the 32 patients in the Registry, 18 (56.2%) were females. Median age at diagnosis was 27.3 (0.6-62.8) years and 15 (47%) presented in childhood. Clinical features included kidney stones in 17 patients (53%), CKD in 8 patients (25%) and reddish-brown diaper stain in 4 infants (12.5%). Nine patients (28%) were asymptomatic at the time of diagnosis. A delay in diagnosis of 7.6 (0.4-39.2) years occurred in 22 patients. The causes of this delay included confusion of DHA calculi with uric acid stones and of renal histopathological findings with other forms of crystalline nephropathy. Twenty-nine patients (90.6%) were successfully treated with allopurinol, while 1 patient experienced a severe hypersensitivity reaction to the drug and is currently being treated with febuxostat. Two patients (16%) progressed to ESKF at the age of 36 and 53 years. Seven additional patients (28%) had persistent CKD with estimated glomerular filtration rate < 60 ml/min/1.73 m2. Severe unilateral kidney damage was observed in 2 patients leading to unilateral nephrectomy in both cases.

Discussion: Nephrolithiasis and CKD are the most common manifestations of APRT deficiency. A significant diagnostic delay occurred in the majority of our cases and very likely contributed to kidney damage and impaired renal function.

Conclusions: Timely diagnosis and treatment of APRT deficiency are essential for successful outcome. It is important to increase awareness of this disorder among clinicians and pathologists.

COGNITIVE IMPAIRMENT AS A FORM OF PRESENTATION OF ACUTE INFECTIOUS MENINGOENCEPHALITIS: REPORT OF TWO CASES

R. Qanneta[1], G. García Pardo[2], A. Falcó Callau[3], M. March Domingo[3], C. Boqué Oliva[4]

[1]Department of Internal Medicine. Hospital Sociosanitari Francolí. Tarragona, Spain. [2]Department of Internal Medicine (Infection Control Group), [3]Emergency Medical Physicians, [4]Emergency Medical Unit Coordinator. Hospital Universitari Joan XXIII. Tarragona, Spain.

Objectives: The acute infectious meningoencephalitis is a priority health problem in the area of emergencies. We present two patients diagnosed of acute infectious meningoencephalitis in the Emergency room. One of the cases was caused by HSV type 1 while the other one by Pneumococcus.

Material and method: Descriptive analysis of two cases of acute infectious meningoencephalitis reviewing medical record data.

Results: 1st patient: 55 year old female patient, consulting for 24 hours of evolution of acute confusional state and seizures of right upper extremity associated to fever 39 ºC. Kerning and Brudzinski signs were positive. Cranial scan was normal. Urgent lumbar puncture (LP) was realized (leukocytes 995/mm^3 with 92% lymphocytes and normal glucose and protein). Intravenous Phenytoin and Acyclovir therapy were initiated. MRI was compatible with meningoencephalitis. Polymerase chain reaction of Cerebrospinal liquid (CSL) was positive for HSV type 1. Satisfactory evolution. 2nd patient: 51 year old male patient, who was diagnosed of acute myelogenous leukemia M3 in 1999 that had required chemotherapy and subsequent bone marrow transplant in 2006 for recurrence and since then he is in complete remission. Is brought to the emergency room for 48 hours of evolution of headache and fever 38 ºC that associates in the last hours of decreased of the level of conscience and generalized seizure. Physical examination showed Glasgow 12 with stiff neck and signs of left external otitis. Intravenous Phenytoin and an empirical antimicrobial therapy (Cefotaxime/Ampiciline/Acyclovir) were initiated. Cranial scan showed supratentorial hydrocephalus. Urgent LP was realized (leukocytes 1,695/mm^3 with 95% polymorphonuclear as well as glucose 20 mg/dL and protein 2.5 g/L). Gram stain has proved to be positive for encapsulated diplococci. We added intravenous dexamethasone and continued with cefotaxime. He has been admitted to intensive care unit. CSL culture was positive for Pneumococcus. MRI (2nd and 3rd image) was compatible with meningitis complicated with focal cerebritis and ventriculitis of the left occipital horn. Poor evolution requiring endotracheal intubation as well as ventricular drainage placement that showed low pressure intracranial. For poor prognosis tracheotomy was realized persisted in a coma situation.

Discussion: Several studies (Van de Beek. N Eng J Med. 2004) have detected factors associated to a poor prognosis of acute meningoencephalitis (defunction or persistent neurological sequelae) such as age and level of consciousness with presence of seizures as well as duration of disease before hospital admission and pneumococcal etiology as seen in the 2nd case that we present.

Conclusions: The clinical suspicion, an adequate history and clinical examination and an appropriate therapy of the acute meningoencephalitis in adult Emergency room are essential and become pillars for a correct approach and managing of this infection (time-dependent).

A-2
LOW BACK PAIN AS A FORM OF CLINICAL PRESENTATION OF INFECTIOUS SPONDYLODISKITIS (ISD): REPORT OF THREE CASES

R. Qanneta[1], J. Pi Sánchez[2], G. García Pardo[3], L. Florit Serra[4], E. Moltó Llarena[1]

[1]Department of Internal Medicine (Subacute Care Unit), [2]Geriatrics and Gerontology (Convalescence Unit). Hospital Sociosanitari Francolí. Tarragona, Spain. [3]Department of Internal Medicine (Infection Control Group), [4]Department of Internal Medicine (Hospital at Home Unit). Hospital Universitari Joan XXIII. Tarragona, Spain.

Objectives: We present three patients diagnosed of ISD. Two of the cases were elderly with multimorbidity while the other one was a young patient with AIDS.

Material and method: Descriptive analysis of three cases of ISD reviewing medical record data.

Results: 1st patient: 78 year old male patient, history of high blood pressure and COPD, who consults for back pain for days earlier with fever 38 ºC in the last 24 hours. 3 weeks before he has diagnosed of urinary tract infection that was treated with amoxicillin and clavulanic acid. Blood test showed C reactive protein 5 mg/dL and ESR 107 mm. Two blood cultures and one urine culture were positive for Enterococcus faecalis. MRI (ISD L2L3). Transthoracic/transesophageal echocardiography were realized and showed mitral valve vegetation. Intravenous antibiotic therapy was initiated (ampicillin and gentamicin) for 4 weeks and then Fluoroquinolone oral to complete 8 weeks. Satisfactory evolution. 2nd patient: 83 year old female patient, history of Type 2 Diabetes Mellitus, who consults for back pain and fever of several days of duration. Blood test showed C reactive protein 16 mg/dL and ESR 129 mm. Two blood cultures were negative. MRI (ISD L4L5). Bone biopsy was realized with culture positive for Streptococcus bovis. Transthoracic echocardiography and colonoscopy were normal. Intravenous antibiotic therapy was initiated (cefotaxime) for 4 weeks and then oral to complete 6 months. Satisfactory evolution. 3rd patient: 45 year old male patient, previous intravenous drug user with methadone replacement therapy, HIV/HCV coinfection since 1987 treated with adherence, who consults for progressive back pain following a transit accident in August 2010, associated to intermittent fever 39 ºC in recent weeks. Blood test showed C reactive protein 6 mg/dL and ESR 140 mm. Two blood cultures were negative. MRI (ISD L4L5 and epidural abscess with compression of the roots of the cauda equina). Transthoracic echocardiography was normal. Abscess biopsy was realized with culture positive for Candida albicans. Intravenous antibiotic therapy was initiated (amphotericin B) that has been changed to intravenous fluconazole (for 4 weeks) for adverse drug reaction. Then oral treatment was maintained for 6 months. Satisfactory evolution.

Discussion: The ISD is a rare entity which incident has increased in the last years due to a major life expectation with chronic diseases that suppose conditions for immunocompromised and for the high prevalence of AIDS. The association between a prolonged axial pain with or without neurological involvement, or fever and an elevated ESR continues to be fundamental in the diagnosis as seen in our three cases. The diversity of etiologic agents (Gómez Sánchez et al. Ann Med Int, 2004), avoids any empirical treatment schemes and makes essential a microbiological and histological study by blood cultures and biopsy such as our three cases.

Conclusions: MRI is the method of choice for suspected spondylodiskitis with a sensitivity of 100% in our three cases.

A-4
MALIGNANCY RELATED CAUSE OF DEATH AMONG HIV-INFECTED PATIENTS DURING THE HAART ERA. HOSPITAL UNIVERSITARIO LA PRINCESA, MADRID-SPAIN, 2006-2011

C. Gómez[1], J. Valencia[1], J. Sanz[2]

[1]Department of Infectious Diseases. Fundación Carolina-Fundación BBVA. Madrid, Spain. [2]Department of Infectious Diseases. Hospital Universitario La Princesa. Madrid, Spain.

Objectives: To describe the clinical, immunological and epidemiological features of Cancer patients living with HIV. To determine the incidence and prevalence of AIDS defining or non defining malignancies in HIV-infected patients during the HAART era. To determine the malignancies - associated morbidity and mortality in patients living with HIV in Highly Active Antiretroviral Treatment era.

Material and method: Descriptive, retrospective, cohort study. In 1,000 adult patients with HIV infection, in follow-up at the "Hospital Universitario de la Princesa" in Madrid – Spain between 2006 and 2011 period. We analized the Database generated by "Nostradamus Software" belonging to the hospital. All HIV-infected subjects with a diagnosis of malignancy were included in SPSS registry database and further processed.

Results: Sixty-eight HIV-infected subjects with malignancies were identified. The global prevalence was 6.8%. The annual incidence average was 11.3 malignancies in 1000 patients/year. 84.6% were male and the average age was 50.5 years old (25-81). 90% were Caucasian individuals. HIV spread was: 44.1% Intravenous Drug Users, 33.9% Men who have sex with Men (MSM), 15% Heterosexual. The HIV patients on HAART at the time of malignancy diagnosis were 77.9%. Individuals demonstrated a 339.9 cells per microliter (21-1044) CD4 count and the CD4 Nadïr rate was 147.9 cells per microliter (2-713). 56.9% had HIV-1 viral suppression (< 50 copies/ml). 20.9% were in virological failure at the time of malignancy diagnosis. The Antiretroviral combination frequently used was 2 NRTIs + 1 PI (47.1%). 83.9% reported active tobacco use or quit smoking at least 3 years ago (a pack of cigarettes/day). 37.9% had increased alcohol consumption. 43.8% and 20.6% were HBV and HCV coinfected respectively. The average time between malignancy diagnosis and HIV was 121 months (0-324). 28% (49/68) were AIDS-defining malignancies (ADM), 13% (9/68) Kaposi´s Sarcoma (KS), 13% (9/68) Intermediate and high-grade non-Hodgkin´s lymphoma (NHL) and 1.5% (1/68) invasive cervical cancer (ICC). The global prevalence of ADM in this cohort was 1.9% and the annual incidence rate was 3.2 by 1,000 patients/year. 72% (49/68) were Non-AIDS-defining malignancies (non-ADM), from which 25% (17/68) were lung cancer, 9% (6/68) hepatocellular carcinoma, 9% (6/68) anal cancer, 6% (4/68) Hodgkin's lymphoma (HL), 6% (4/68) skin cancer and the percentage left other malignancies. The global prevalence of non-ADM in this cohort was 4.9% and the annual incidence rate was 8.2 by 1,000 patients/year. The global mortality was 60.3%. 45% ADM patients died, meanwhile, from 66.7% non-ADM patients deceased.

Discussion: Nowadays, there are a lot of differences in causes of death in HIV patients, however malignancies are still one of the three first causes of death in some studies (CoRIS). The non-ADM were the most frequent underlying morbidity and mortality in the preHAART era, reaching about 90% of the malignancies in database in our hospital. This retrospective cohort, demonstrate that the incidence has been decreased at 28% and the mortality too, even less than non-ADM.

Conclusions: In the HAART era, the incidence of non-ADM is markedly superior than ADM. The most frequent malignancy in the cohort is lung cancer. The global mortality is high and even more in non-ADM.

A-5
INFLAMMATORY BOWEL DISEASE- ULTRASOUND ASSESSMENT OF THE ENTHESOPATY

C. Deliu, D. Neagoe, C. Hoanca, C. Miscu, S. Enculescu

Department of Medical Clinic I, UMF Craiova. Craiova, Romania.

Objectives: Enthesitis indicate the place of the tendons, ligaments, aponeuroses, or join to bone and one of the most common and specific manifestations of spondyloarthropathy. The objectives of the study were to determine the prevalence of subclinical entheseas involvement in inflammatory bowel disease (Crohn's disease and ulcerative colitis) patients in lower limbs.

Material and method: The study was included 40 patients diagnosed with inflammatory bowel disease aged between 35 and 42 years without known history of enthesal involvement. Besides, 40 healthy sex- and age- matched controls were included. Between patients with inflammatory bowel disease, 24 patient (M/F = 11/13, mean age 38.33 years) were affected by Crohn's disease and 16 patients (M/F = 9/7, mean age 32.23 years) of ulcerative colitis. Clinical examination and ultrasound were consecutively performed at each of the entheses to detect signs indicative of enthesopathy.

Results: A total of 160 enthesis in patient with inflammatory bowel disease were evaluated by ultrasonography. Enthesitis it was significantly more frequent in patient with inflammatory bowel disease than the control group (22.6% vs 4.36%). Between patients with this pathology, enthesitis was more common in patient with Chron's disease than ulcerative colitis patients (76.5%vs 23.5%). All patients had involvement enthesitis a longer duration of disease.

Conclusions: Our results indicate that enthesitis a characteristic clinical manifestation of spondyloartropathy, is an important clinical manifestation of inflammatory bowel disease, occurring frequently in patients with Crohn's disease with joint involvement. Additional studies are needed on the prognostic value of ultrasound findings to estimate clinical onset of enthesal involvement.

A-6
VORICONAZOL: FROM THE PRODUCT MONOGRAPH TO THE CLINICAL PRACTICE. EXPERIENCE IN A SECOND LEVEL HOSPITAL IN MADRID DURING 2011

N. Rebollo Aparicio[1], M. Morales Conejo[1], V. Moreno Cuerda[1], C. Calderón Acedos[2], J. Ruiz Galiana[1]

[1]Department of Internal Medicine, [2]Department of Pharmacy. Hospital Universitario de Móstoles. Móstoles (Madrid), Spain.

Objectives: Voriconazole is a wide spectrum triazole antifungal drug. The aim of this study is to analyze the indications for prescription of voriconazole, as well as the patient's characteristics and outcome, in 2011 at the Universitary Hospital of Mostoles.

Material and method: Retrospective study analyzing the clinical records and microbiological reports of patients treated with voriconazole in 2011. Definitive and probable invasive aspergillosis were defined according to the Invasive Fungal Infections Group.

Results: A total of 13 patients were treated with voriconazole during the time period analyzed. The clinical indications for which voriconazole was prescribed were: 1) definite invasive aspergillosis: 4 cases (30.8%), 2) invasive aspergillosis suspected: 4 cases (30.8%), 3) likely: 2 cases (15.4%), 4) Candida krusei fungemia resistant to fluconazole: 1 case (7.7%), and 5) Suspicion of systemic fungal disease with an alternative final diagnosis: 2 cases (15.4%). Baseline characteristics of the individual patients were as follows: mean age of 68.38 years (range 45-81 years). Nine patients (69.23%) had respiratory disease (chronic obstructive lung disease in 8 cases and idiopathic pulmonary fibrosis in one). Five patients had malignant diseases (3 patients with hematologic neoplasia, 1 patient with classic Kaposi sarcoma and 1 patient with non-small cell lung cancer). Eight patients (61.5%) had received antibiotic treatment during the previous month. Three patients had received chemotherapy recently, a patient had received a hematopoietic stem cell transplant in the last year and 8 patients were receiving glucocorticoid treatment. One case had no background immunosuppression and developed candidemia due to Candida krusei in a postoperative setting with a central line and on total parenteral nutrition. Average duration of voriconazole treatment was 30.8 days (range 2-47 days). All of the 5 patients (38.46%) with invasive fungal disease and microbiological confirmation presented complete clinical and microbiological response. Of the 8 cases (61.5%) in which voriconazole was administered empirically, 3 patients had clinical response, 3 patients died and 2 patients had no response and were finally diagnosed of some other pathology.

Discussion: Despite all efforts, voriconazole was prescribed without microbiological confirmation in 61.54% of cases. These patients received voriconazole because of a high clinical suspicion of invasive fungal disease based on clinical and radiological findings. It is noteworthy the differences in clinical outcomes between patients receiving voriconazole based on microbiological identification vs patients treated with variconazole empirically based on clinical data (cure rates 100% vs 37.55% respectively). This difference might be partially explained by the fact that some patients without microbiological confirmation probably did not have a fungal disease.

Conclusions: The main clinical indication for prescribing voriconazole was invasive aspergillosis (microbiologically confirmed or clinically suspected). Voriconazole has high cure rates among patients with microbiological confirmation of invasive fungal disease.

A-7
PROSTHETIC JOINT INFECTIONS: PROSPECTIVE OVERVIEW OF A COHORT OF PATIENTS IN THE LAST FIVE YEARS

A. Fernández Rodríguez[1], F. Brun Romero[2], P. Romero Cores[1], L. Vela Manzano[1], I. Ríos Holgado[1], A. de los Santos Moreno[1], F. Guerrero Sánchez[1]

[1]Department of Internal Medicine, [2]Orthopedic Surgery. Hospital Universitario Puerta del Mar. Cádiz, Spain.

Objectives: To analyze clinical and epidemiological data as well as medical and surgical management of patients with diagnose of prosthetic joint infection (PJI) of the knee and the hip in our hospital during the last five years.

Material and method: Prospective observational cohort study of adult patients with PJI diagnosed from January 1, 2007 to December 31, 2011 in our hospital, after implementation of a cooperation protocol between Internal Medicine and Orthopedic Surgery. The PJI were classified according to the classification of Tsukayama et al modified into 4 types: 1) early postsurgical infection or type I (< 1 month after the intervention); 2) late postsurgical infection or type II (> 1 month and < 1 year); 3) hematogenous infection or type III (> 1 year after surgery without symptoms); and 4) positive culture without previous suspicion of infection or type IV. The diagnosis was made by different samples: intraoperative cultures, pus macroscopic with negative cultures or presence of one or more sinus tract communicating with the joint. Analysis peformed using SPSS version 19.0.

Results: Sixty one patients were included, with a median age of 69 (IQR 39-91) years. Seventy two percent were women. Thirty-three cases (54.1%) were knee prosthesis, with an infection rate of 4.35%; 28 cases (45.9%) were due to infectious complications of hip replacement, with an infection rate of 2, 78%, 77.7% of which were total and 22.2% partial prosthesis. The reason for prosthetic replacement was: a) arthrosis (68.9%), b) closed fractures (19.7%)

and c) avascular necrosis of bone (5%). Seventy-four percent of patients had comorbidities, the most common were: diabetes (27.9%), heart diseases (24.6%) and obesity (23%). Half of patients had surgical risk factors related for infection: superficial surgical site infection (18.3%), bleeding (16.7%) and hematoma (15%). Independently, 44.9% had postsurgical risk primarily related to invasive procedures (23.7%) and direct trauma to the prosthesis (21.1%). Isolated microorganisms were coagulase-negative Staphylococcus in 53% (77.5% methicillin-resistant), Staphylococcus aureus in 13.8% (37.5% methicillin-resistant), and gram-negative bacilli in 7% of cases. The most common type of infection was chronic (60.3%), followed by hematogenous via (22.4%) and early (15.5%). Most of chronic infections (78.7%) were treated with two-stages refill supplemented with antibiotic treatment for 6 weeks according to the antibiogram. Early and hematogenous infections were treated with surgical debridement and retention of the prosthesis in the 63.1%. We have the follow-up to the year of 34 patients: 62.5% were asymptomatic, with decline in the acute phase reactants and maintaining of a good functional capacity (76.6%); 3 patients died, one of them by direct cause of infection.

Conclusions: In our cohort, there is a predominance of patients with co-morbidity due to an arising ageing population. At least, half of the patients had peri and post-surgical complications. Taking into account these two situations, we should try to identify the population at high risk of infection to perform a better prevention in them and avoid as far as possible new cases of infection, even indicating whether or not the surgical procedure. The most common etiology was similar as described in the literature, showing a slight increase of Staphylococcus spp. resistant to methicillin. Empirical antibiotic therapy should cover these microorganisms.

A-8
OUTPATIENT PARENTERAL ANTIMICROBIAL THERAPY: EFFICACY AND SAFETY IN INFECTIOUS PATHOLOGY PROCEEDING FROM THE EMERGENCY DEPARTMENT

A. Mujal Martínez[1], J. Sola Aznar[1], M. Hernández Avila[1], C. Aragüás Flores[2], M. Machado Sicilia[2], M. Baylina Melé[2], J. Oristrell Salvà[2]

[1]Home Care Unit. Internal Medicine Department, [2]Department of Internal Medicine Department. Hospital de Sabadell. Barcelona, Spain.

Objectives: To evaluate efficacy and safety of Outpatient Parenteral Antimicrobial Therapy (OPAT) in patients with an infectious disease proceeding from the Emergency Department (ED) and treated in a Home Health Care Unit (HHCU).

Material and method: Prospective evaluation of all patients admitted with infection to our HHCU for OPAT from 2008 to 2011. We compare two groups: patients coming from the ED were included in the study group while the rest of patients coming from other Departments were the control group. OPAT was self-administered by caregivers and/or patients with elastomeric infusion devices.

Results: We recorded 492 consecutive OPAT episodes, 92 coming from the ED and 400 coming from other hospital departments. Patients who came from the ED were olders (69.4 years vs 63.3, p = 0.005) with greater functional impairment (Barthel Index 77.2 vs 86.5, p = 0.05), a shorter hospital stay (11.1 days vs 21.3, p < 0.001), less use of central venous access (19.5% vs 61.5%, p < 0.001), higher proportion of urinary infections (42.4% vs 8.3%, p < 0.001), lower proportion of bone and joint infections (2.2% vs 12%, p = 0.005) and also lower proportion of intraabdominal infections (3.3% vs 17%, p = 0.001). The study group also presented a greater proportion of Enterobacteriaceae Extended-Spectrum Beta-Lactamase (ESBL) infections (13% vs 28.8%, p = 0.01) and a lower proportion of P. aeruginosa infections (7.6% vs 25.8%, p < 0.001). Cases proceeding from the ED were associated with a higher use of ceftriaxone (38% vs 16.3%, p = 0.001), lower use of anti-pseudomonal antibiotics (13% vs 28.8%, p = 0.002), a lower use of aminoglycoside (4.3% vs 16.5%, p = 0.003) and a lower use of simultaneous endovenous antimicrobial combinations (3.3% vs 19.3%, p < 0.001). Patients proceeding from the ED were neither associated with a higher risk of hospital readmission (p = NS), nor at 30 days after hospital discharge (p = NS) or at 90 days after hospital discharge (p = NS), nor a worse evolution of the infection (2.2% vs 2%, p = NS), nor an increased number of healthcare associated infections (3.3% vs 1.5%, p = NS). Similar results were observed when we analyzed the subgroups of patients admitted to the HHCU with respiratory infection or urinary infection. There was a greater number of complications in vascular access in patients proceeding from the ED but without statistical significance (33% vs 25%, p = 0.09). In the logistic regression analysis, the complications of venous access were related to the use of peripheral venous acess and with the duration of the endovenous treatment, but not with proceeding from the ED. The complications from venous access were mild in all cases and were solved in 93% of cases by nursing staff at patients' homes.

Discussion: Our work shows a high number of respiratory infections and a proportion of urinary, bone and joint and intraabdominal infections. These differences were due to the uptake of patients in surgical services and the protocolization of uncomplicated pyelonephritis between the HHCU and the ED in order to avoid hospital admission. The antibiotic administration was by elastomeric infusion devices manipulated almost exclusively by the caregiver or the patient. These results suggest that manipulation of the venous access by a trained caregiver or patient is safe. Finally we did not observe a higher number of hospital readmission.

Conclusions: Self-administered OPAT is effective and safe in patients proceeding from the ED. This modality treatment in the context of a HHCU does not lead to a worse evolution of the infectious process or a increase in rates of hospital readmission. HHCU is a good alternative to a conventional hospitalization.

A-9
HIV PATIENTS IN THE INTENSIVE CARE UNIT

M. Serrano Herrero[1], A. Millán Lozano[2], C. Gómez Del Valle[1], M. Crusells Canales[3], I. SanjoaquÍn Conde[3], M. Bucar Barjud[1], S. Letona Carbajo[3], R. Pelay Cacho[1]

[1]Department of Internal Medicine, [2]Department of Intensive Medicine, [3]Department of Infectious Diseases. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: A descriptive study of HIV patients admitted to the intensive care unit of our hospital over the past 6 years.

Material and method: A retrospective study which reviewed all cases of HIV patients admitted to the ICU of the Hospital Clinico Universitario Lozano Blesa in Zaragoza from 1 January 2006 to December 2011. The sample included a total of 82 patients which were collected epidemiological data, medical history, circumstances in relation to HIV infection, toxic habits, HBV coinfection and/or HCV diagnoses in relation to their admission to the ICU, clinical course and mortality.

Results: The average age of HIV patients admitted to the ICU was 53 years. There is a predominance of men (88%) compared to women (12%). 95% of patients were Spanish, 4% African and 1% from Romania. The reason for ICU admission was prompted by events in a 69% AIDS cases, while the remaining 31% is made up of non-AIDS events, that is increasing in the last years. With regard to AIDS events, the CD4 count is distributed with 94% of patients admitted for an AIDS event were less than 200 per mm3 and 6% had figures between 200 and 500/mm^3. Following AIDS events, no patient had undetectable viral load, with less than 10 000 copies of the virus by 80% and over 10,000 copies 20% of patients. 15% of patients were

infected with HBV and HCV, only 5% coinfected with HCV and 80% of them were free of co-infection. 20% of patients wore it at the time of ICU admission and yet the remaining 80% had no treatment. Among the highlights diagnoses mainly Pneumocystis jiroveci pneumonia followed by tuberculosis and cytomegalovirus. Almost 50% of these patients have a poor outcome and die during their ICU stay. With respect to non-AIDS events, patients with CD4 less than 200 per mm^3 is lower, 45%, 30% thereof with entry numbers of CD4 above 500 per mm^3. 60% of patients have an undetectable viral load, with only 15% of patients with more than 10 000 copies. 40% of patients are coinfected with HCV and 10% with HCV and HBV. 75% of cases had antiretroviral therapy and with respect to the pathologies of cardiovascular highlights, such as myocardial infarction present in up to 20% of cases, followed by problems of hepatic origin, postsurgical patients, drug overdose, pneumonia, cerebrovascular disorders, and multiple trauma.

Discussion: The age of HIV patients admitted to ICU is low. Most of our HIV patients are Spanish, followed by Africans. It remains most common cause of admission to the ICU the pathology associated with AIDS compared with non-AIDS disease, but this percentage is falling, this is due to improvements in treatment, implying increased survival of these patients and therefore, appearance of age-related pathologies. Patients admitted with AIDS events had lower numbers of CD4 and viral load higher than patients admitted with non-AIDS events such as heart disease. Highlights include heart disease as occurs in the general population.

Conclusions: 1. In patients not HIV-AIDS events are the main reason for ICU admission. 2. The non-AIDS events continue to give rise to income in the ICU significantly, especially in patients with antiviral treatment. 3. The set of cardiovascular disease is the main reason for ICU admission of non-AIDS events. 4. The increase in life expectancy in HIV patients after the advent of highly active antiretroviral therapy (HAART) are more frequent pathologies such as cardiovascular and chronic liver disease in these patients, which motivates more complications and increased ICU admissions of these patients.

A-10
COMPLICATIONS OF INTRAVESICAL BCG IMMUNOTHERAPY: TWO CLINICAL CASES

M. Cristó, I. Jou Segovia, S. Vega Molpeceres

Department of Internal Medicine. Hospital de Figueres. Figueres (Girona), Spain.

Objectives: Description of two cases of severe complications of intravesical BCG immunotherapy and their response to treatment.

Material and method: Revision of Hospital's computerized medical records.

Results: 1st clinic case: A 73 years old man with a history of superficial bladder tumour (1999), underwent several TUR. There was a High-grade superficial recurrence in Feb/11. He was treated with BCG monthly for a year. Occasionally he presented with urinary symptoms and fever after BCG instillation, requiring empirical antibiotic treatment. In March 2012 he attended the ER because of 24 hours of high fever and chills, a few hours after the last instillation of BCG. There was respiratory distress and haemodynamic shock. Blood cultures, sputum cultures, Gram and ZN were negative. CXR showed bilateral alveolar infiltrates and diffuse interstitial pattern. Chest CT: extensive bilateral pulmonary parenchymal involvement, with ground-glass infiltrates, patchy areas of consolidation with a tendency to coalesce predominantly in the posterior areas, and multiple micronodular opacities randomly distributed in both lungs. Bilateral pleural effusion. Tuberculosis (TB) treatment (RHE) was started, resulting in improved clinical, respiratory and biological parameters. Control thorax CT 3 months later: significant reduction of miliary pattern whith less micronodular oppacities. 3.5 months after the beginning of the symptoms, the patient had no other respiratory complications. 2nd clinic case: A 78 year old man, with history of high grade bladder cancer, diagnosed in early 2011. In 07/2011 he started weekly doses of BCG. 6 doses were completed without incident. Afterwich bladder cytology was negative. Another 6 weekly doses began on 02/03/2012. A few hours after the first instillation he had fever and chills. On 05/03/2012 he went to the ER with dyspnoea. Sat.O_2 92%. CXR: interstitial infiltrate predominantly in RLL. He was admitted with suspected lower respiratory tract infection and began treatment with Levofloxacin. After a rapid worsening of respiratory symptoms, on 06/03/2012 a chest CT reported: extensive areas of diffuse ground glass infiltrates and bilateral patchy areas of consolidation predominantly in posterior segments, associated with bilateral pleural effusion. Treatment started with high doses corticosteroids and specific tuberculosis treatment (RHE), alongside Levofloxacin. Clinical and biological parameters improved during the first 24 hours. On the second day of admission he had progressive dyspnoea and scattered wheeze in both lung fields, which did not improve with bronchodilators. ABG (FiO_2 100%): pH 7.04, PCO_2 110, PO_2 78, HCO_3-29.70; BEB -3.50, SO_2 88%. Blood cultures, sputum cultures, Gram and ZN were negative. Severe respiratory distress led to the patient's death two weeks after admission to ICU.

Discussion: We present one case with UTI, sepsis and pneumonitis and one with severe pneumonitis which occurred immediately after BCG bladder instilation. BCG is a live, attenuated strain of M. bovis, which is widely used as an adjuvant treatment in the management of non-muscle invasive urothelial bladder cancer. A localized BCG cystitis is the most common complication observed. Although serious complications following intravesical BCG are rare, infections like sepsis (0.4%) and pneumonitis (0.7%) have been reported. This risk may be increased if BCG is instilled too early following surgery or after traumatic catheterization. We have checked that all our protocols were strictly according to the international ones.

Conclusions: Complications of intravesical BCG for bladder malignancy are rare, appearing within hours after the procedure. They are very serious, and sometimes fatal, and can respond to steroid treatment and adequate anti-TB treatment.

A-11
TREATMENT OF PATIENTS WITH BACTEREMIA IN HOSPITAL AT HOME

M. Matesanz David, M. Rodríguez Cerrillo, A. Iñurrieta Romero, A. Poza Montoro, E. Fernández Díaz

Hospital at Home Units. Internal Medicine. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: Analyze the efficacy and safety of treating patients with bacteremia in a Hospital at Home (HaH) Unit.

Material and method: Prospective study including all patients admitted to HaH Unit in 2011 diagnosed with bacteremia. Patient characteristics, number of previous days in hospital, microbiology, treatment and clinical outcomes were analyzed.

Results: 28 patients with bacteremia were included. 52% were male. Mean age was 64 years (27-92). 21.4% of patients had neoplasia, 7% diabetes mellitus. 7% of patients had thrombocytopenia and 17.8% leukocytosis on admission to HaH Bacteremia was caused by gram negative bacilli in 53.5% of patients and by gram positive cocci in 46.5%. The most frequently isolated bacteria were E. coli and S. epidermidis. Mean stay in Hospital before admission to HaH was 2.2 days (1-7). Patients were referred from: Emergency department (42%), internal medicine (21%), urology (14%), oncology (10%) and surgery (10%). The most commonly used antibiotics were ceftriaxone and daptomycin. Switching from IV to oral therapy was possible in 39.2% of patients. All patients had a good outcome. None of patients was transferred to Hospital.

Discussion: Patients with bacteremia stay in Hospital to receive intravenous antibiotic even though the clinical condition is stable. Treatment and control of clinical evolution can be carried out at home.

Conclusions: Treatment of patients diagnosed with bacteremia in HaH is safe and effective alter a short period of hospitalization.

A-13
PROGNOSIS FACTORS IN BACTEREMIA CAUSED BY MULTIRESISTANT PATHOGENS

S. Olivera González[1], A. Valdivia Pérez[2], J. Marco Lattur[4], O. Esparcia Rodríguez[3], M. Marco Lattur[1], M. Gomis Mascarell[1], S. Pintos Martínez[1], P. Martín Rico[1]

[1]Department of Internal Medicine, [2]Department of Preventive Medicine, [3]Department of Microbiology. Hospital de Denia. Denia (Alicante), Spain. [4]Department of Internal Medicine. Hospital de Villa-real. Vila-real (Castellón), Spain.

Objectives: Determine the prognosis factors or predictors of poor outcome of multiresistant bacteremia caused by multirresistant bacteria.

Material and method: 89 patients diagnosed with bacteremia because of multiresistant bacteria (resistance to three or more families of antibiotics) were included in our study. Patients diagnosed in Hospital of Denia (Alicante), between February 2009 and April 2012. The studied variables were age, gender, length of stay, death, infection risk factors, medical history, service of admission, isolated germ, and treatment given. Statistical analysis was performed using SPSS 18.0.

Results: There were 72 isolates. The isolates were: E. coli ESBL + 44.4%, MRSA 29.2%, K. pneumoniae ESBL + 12.5%, S. marcescens 9.7%, and P. aeruginosa carbapenem-R 4.2%. The overall mortality was 22.1%. 29.4% of dead patients requiring OTI. Seed mortality was: K. pneumoniae 50%, 35% MRSA, P. aeruginosa 33.3%, E. coli 10.3%, and S. marcescens 0%. 70% of patients had predisposing factors: DM (21.9%), neoplasm (21.9%), hypertension (14.1%), COPD (7.4%), and CRF (6.3%). 10.8% of patients came from social and health institutions, and among these the mortality was 42.9%. 52.2% had a hospitalization in the previous 6 months, and among these patients the mortality was 28.1%. Mortality by gender was 44.4% in women, and 14.3% in men. For age, younger than 65 years was 14.7%, and over 65 years of 31.3%. In relation to the service of admission, mortality was 50% in the ICU, 28.6% in Internal M, 7.1% in the ER, and 0% in other services. A higher mortality in patients with clinical history of COPD (40%), alcoholism (33.3%), CRF (33.3%), DM (21.4%) and neoplasia (23.1%). On the end-point mortality, we found a relationship with the source of bacteremia ($p < 0.05$), OTI in the case of Klebsiella ($p < 0.05$), and previous surgery for MRSA ($p < 0.05$). In relation to all other factors studied, including nutritional status, presence of fever, leukocyte count, there were no statistically significant differences.

Discussion: The most common bacteria isolated was E. coli ESBL +, which corresponds to a high percentage of urinary bacteremia or sepsis. Mortality was higher in the case of patients requiring IOT, associated with higher mortality of K. pneumoniae, probably because of the co-morbidity experienced by patients who needed OTI. We have also found a relationship between poor prognosis and patients with MRSA bacteremia who had undergone previous surgery. Unlike other studies, in our case we have found not a worse prognosis in cases of malnutrition or other predisposing factors involving immunosuppression or comorbidities.

Conclusions: The germ more frecuently isolated was E. coli ESBL +, in conjunction with a high proportion of bacteremia of urinary origin. The germ with increased mortality was K. pneumoniae associated with need for OTI, which is a poor prognostic factor. Previous surgery, is a poor prognostic factor in the case of MRSA bacteremia.

A-14
ROTHIA MUCILAGINOSA: AN INOFFENSIVE HOST?

J. González Moreno[1], A. Cladera Serra[2], V. Fernández-Baca[3]

[1]Department of Internal Medicine, [2]Department of Hematology, [3]Department of Microbiology. Hospital Son Llàtzer. Illes Balears, Spain.

Objectives: To know the clinical impact of Rothia mucilaginosa (Rm) isolation in patients from an hematology department.

Material and method: We reviewed retrospectively positive Rm cultures isolated between 2002-2012 in the Hematology Department of Son Llàtzer Hospital in Palma. Blood and good quality sputum (no epithelial cells and at least 50 leukocites per field) specimens were Gram stained and inoculated on blood agar on chocolate plates incubated aerobically and anaerobically. We reviewed literature by using Pubmed, searching results for: "Rothia mucilaginosa", "Stomatococcus mucilaginosus", "Staphylococcus salivarus" and "Micrococcus mucilaginosus".

Results: We found 9 cases in which Rm was isolated (Table 1). Two cases were primary bacteremia and 7 were respiratory tract infections (1 pneumonia and 6 severe acute bronchitis). At the moment of infection patients had a median of 2,700 neutrophils (range 0-17,400). Both patients with primary Rm bacteremia had severe aplasia (0 neutrophils). Four patients (44.4%) had either respiratory or otolaryngologic chronic disease. In three cases (33.3%) co-flora was isolated. Quinolone susceptibility was tested in 7 cases, and in 6 of them (85.7%) Rm was resistant. In all 6 patients levofloxacin had been previously used. Penicillin resistance was found in 5 cases (55.5%) and erythromicyn resistance in 2 (22.2%). All strains were fully susceptible to carbapenems, third generation cephalosporins and aminoglycosides. The only registered death was not related with Rm infection.

Discussion: Although Rm is part of normal oropharyngeal flora, it has also been described as a pathogen, specially in immunosupressed patients. There is a wide spectrum of infections reported, mainly primary bacteremia, central nervous system infections, endocarditis and respiratory tract infections. As Rm is a Gram-positive, coagulase-negative, encapsulated coccus, presented in clusters, tetrads or pairs, it can easily be morphologically confused with other genera as Enterococcus and Staphylococcus. That is why Rm infections could be under-reported. Neutropenia is the most frequent risk factor for Rm bacteremia and was present in our two cases. To our knowledge only 11 cases of Rm pneumonia have been previously reported. We describe a new case of Rm pneumonia in which several risk factors were present. As previously noted Rm is present in normal oropharyngeal flora, and a positive result in sputum samples can lead to confusion. However, we think that in our cases Rm was a real pathogen because of the good quality specimens and the positive outcome of the patients under guided treatment. Quinolone resistance is common, specially in immunosupressed patients and in those previously treated with this drugs. Almost all of our strains showed quinolone resistance. Susceptibility to beta-lactams, macrolides and aminoglycosides varies. In our strains penicillin resistance was also frequent. We observed intact susceptibility to carbapenems and third generation cephalosporins.

Conclusions: Rm is an emerging opportunistic pathogen in immunosupressed patients, especially in those with previous quinolone treatment. We report one new case of Rm pneumonia,

Table 1 (A-14). Rothia mucilaginosa infections

Case	Age/ gender	Previous quinolone treatment	Specimen	Clinical presentation	Co-flora	Treatment	Predisposing condition	Neutrophils	Outcome	Q/P resistance
1	66/M	Yes	2 Blood cultures	Primary bacteremia	S epidermidis	Meropenem and teicoplanin	AML. XII cranial nerve paralysis	0	Death	Yes/No
2	90/F	No	1 Sputum	Acute bronchitis	Mixed flora	Erythromicyn	MM	600	Full recovery	Yes/Yes
3	58/F	Yes	3 Sputum	Acute bronchitis	No	Cefditoren	NHL. Asthma. Mucositis	2.100	Full recovery	Yes/Yes
4	73/M	No	3 Sputum	Acute bronchitis	No	Cefuroxime	Myelofibrosis. COPD	6.500	Full recovery	No/Yes

6	32/M	Yes	2 Sputum	Acute bronchitis	No	Imipenem	HD	3.700	Full recovery	Yes/No
7	58/M	No	3 Sputum	Pneumonia	No	Ceftazidime	MM. COPD	4.400	Full recovery	Not tested/No
8	67/M	Yes	1 Sputum	Acute bronchitis	No	Azithromycin	MM	17.400	Ful recovery	Not tested/Yes
9	18/M	Yes	2 Blood cultures	Primary bacteremia	No	Meropenem and teicoplanin	ALL	0	Full recovery	Yes/No

Q: Quinolone. P: Penicillin. M: Male. F: Female. AML: Acute myeloid leukemia. MM: Multiple myeloma, NHL: Non Hodgkin lymphoma. COPD: Chronic obstructive pulmonary disease. HD: Hodgkin disease. ALL: Acute lymphoid leukaemia.

which is rarely reported. Quinolone and penicillin resistance is common, so its use as empiric treatment is not recommended. Although vancomycin is considered as the first choice for Rm infection, empirical use of carbapenems or third generation cephalosporins seems to be a good and safe option.

A-15
INFECTIOUS SPONDYLODISCITIS: CLINICAL FEATURES OF 36 PATIENTS IN A HOSPITAL

J. Gómez Cerquera[1], I. Durán Palacios[2], J. Mosquera Lozano[1], R. Daroca Pérez[1], T. Elías Sánchez[1], M. Núñez Murga[1], M. Casañas Martínez[1], E. Mozos de la Fuente[1]

[1]Department of Internal Medicine, [2]Department of Radiology. Hospital San Pedro. Logroño (La Rioja), Spain.

Objectives: To describe the clinical characteristics of patients with spondylodiscitis at the Hospital San Pedro from2007-2011. To analyze the outcome of the C-reactive protein (CRP) and the erythrocyte sedimentation rate (ESR) as a marker of response to antibiotic treatment.

Material and method: We conducted a retrospective descriptive study of all patients diagnosed with spondylodiscitis in our hospital in the period 2007-2011. We identified the patients with symptoms and signs characteristic of this disease, magnetic resonance imaging (MRI) or computed tomography (CT) compatible. Data analysis was carried out using the SPSS software.

Results: Were identified 36 patients with spondylodiscitis. Mean age was 61 years old and the average hospital stay was 24 days. 61% of patients were male. One or more comorbid diseases were present in 66% of patients, being diabetes mellitus the most frequent one (22%). The most common symptoms were pain (94%) and fever (63%), while neurological symptoms were only present in 19% of cases. The most common location was the lumbar spine (55%) and the thoracic spine (36%). The MRI was performed in 95% of patients. Among microbiology findings, gram-positive bacteria were identified in 33% of patients, Mycobacterium tuberculosis in 19%, gram-negative bacteria 14% and no organism was identified in 33%. Gram-negative bacteria were isolated in patients with diabetes mellitus mainly, as well as in patients with renal failure and aged over 80 years old. The identification of the microorganism was performed by biopsy in 36% of cases, while blood cultures were positive in 30% of patients. Among patients with elevated CRP at diagnosis, 65% returned to normality after 2 weeks of treatment, while ESR remained elevated in 66%. Surgical treatment was performed in 25% of the patients; the most frequent indications were drainage of abscesses and spinal cord compression. After treatment, 61% had fully recovered, while 33% of cases had recovered with residual symptoms, pain mainly. Only one patient died (2%), because of sepsis by gram-negative microorganisms and concurrent infectious endocarditis.

Discussion: Spondylodiscitis is an infection that affects two vertebral bodies and their intervertebral disc. Incidence is low (estimated around 1-4/100,000 persons/year), but has steadily increased in recent years because of the frequent use of invasive procedures (intravenous and genitourinary access) as well as the use of intravenous drugs and increasing age of the population. The MRI is the most sensitive radiologic technique to detect spondylodiscitis. Mortality is low (< 5%) but early diagnosis and optimal treatment are very important for a favorable outcome.

Conclusions: Spondylodiscitis is primarily an adult disease. -Male patients are affected predominantly. One or more comorbid diseases were present in our study, mainly diabetes mellitus. Predominant causative organisms were Gram-positive bacteria. CRP

levels return to normality more rapidly than ESR after antibiotic treatment. Early antimicrobial therapy and timely surgical intervention are essential for an optimal outcome.

A-17
MORTALITY IN PATIENTS WITH INFECTIOUS DISEASES

L. Oriente Frutos[1], M. Galindo Andúgar[1], J. Castellanos Monedero[1], L. Fernández Clemente Martín Orozco[2], A. Martín Castillo[1], R. Cicuéndez Trilla[3], E. Mata Vázquez[4], J. Rivas Cortés[1]

[1]Department of Internal Medicine. Complejo Hospitalario La Mancha Centro. Alcázar de San Juan (Ciudad Real), Spain. [2]Department of Psychiatry. Hospital Provincial de la Misericordia. Toledo, Spain. [3]Department of Internal Medicine. Hospital General de Fuerteventura. Puerto del Rosario (Las Palmas), Spain. [4]Department of Internal Medicine. Hospital General de Tomelloso. Ciudad Real, Spain.

Objectives: To analyse the mortality in the Hospital de Tomelloso (HdT) in the inpatients with infectious diseases.

Material and method: Retrospective study with case search by CMBD (Basic Minimum Data Set) from April 2007 until July 2008. Review of the medical history. Analysis with SPSS version 15.0.

Results: There were 555 inpatients with infections in that period with the diagnosis of respiratory infection (205), pneumonia (186), urinary infection (66), sepsis (60), skin and soft-tissues infection (27), meningitis (5), peritonitis for intestinal ischemia (4) and endocarditis (2). There were included 45 patients who deceased, with males 60% (27), median age 82.7 years-old (range 68-97), and median stay of 3 days (range 1-55 days). The quarter of the patients had been admitted at least once in the previous year, 56% of cases had cognitive impairment and 20% had oncologic disease. Some clinical findings and laboratory tests are summarized in Table 1. When we compared them according to the kind of infections using an ANOVA test, we obtained a statistically significant difference for systolic blood pressure in peritonitis with intestinal ischemia ($p = 0.012$). Cultures were requested in 26 patients (58%), with 12 blood cultures (with 4 positive results), 17 urine cultures (3 were positives and 3 were contaminated) and other cultures in 8 cases (with 6 positive results). The isolated bacteria included Staphylococcus aureus (in 4 patients being methicillin-resistant in 3 cases), Staphylococcus epidermidis (3), Pseudomonas aeruginosa (1), Escherichia coli (1), enterococci (2) and Candida (2). The fever had not influence in the request of cultures in contrast with the type of infection (with no statistically significant differences).

Discussion: The infections with mortality above 10% of the inpatients were peritonitis for intestinal ischemia (100%), sepsis (18%) and skin and soft-tissues infection (12%). The absence of Intensive Care Unit and surgeon on guard duty in HdT is a deciding factor in the type of inpatients and the time of admission. The surgery was refused in all the patients with intestinal ischemia and it explains the high mortality. The presence of fever is not a factor for requesting cultures.

Conclusions: The type of hospital and the absence of several services are the main factors in the selection of the inpatients.

A-18
ACTINOBACULUM SPP INFECTION: A REPORT OF 12 CASES

S. Castellanos[1], M. Salvadó[2], V. Plasencia[2], C. Segura[3], J. Gómez[3], E. Serra[2], L. Sorli[1], J. Horcajada[1]

[1]Infectious Diseases Service, Department of Internal Medicine. Hospital del Mar. Barcelona, Spain. [2]Microbiology Laboratory. Reference Laboratory of Catalunya. Barcelona, Spain. [3]Department of Molecular Genetics and Microbiology. Universitat Autònoma de Barcelona (UAB). Barcelona, Spain.

Objectives: The aim of this paper is to describe a series of 12 patients with urinary tract infections or bacteremia caused by different species of this genus, especially A. schaalii.

Material and method: Setting: 600-bed university tertiary care hospital in Barcelona, Spain. From July 2007 until December 2011 the presence of Actinobaculum genus was routinely investigated in urine cultures and blood cultures.

Results: Bacteriology: during the study period, 2007-2011, 13 isolates of Actinobaculum spp. were obtained. Gram stain of urine samples showed gram-positive rods in the presence of many leukocytes. Actinobaculum schaalii in ApiCoryne gallery showed positive: α-glucosidase, pyrrolidonyl-arylamidase, hippurate hydrolysis, fermentation of ribose and maltose. Three patients had positive blood culture, in case number 2, the growth was in two anaerobic culture of the set of the two blood cultures. In case number 5, it grew in three bottles and in case number 7 in one aerobic bottle. Patients: Most of them had underlying diseases, being neoplasms (25%) and diabetes (16, 67%) the most frequent. Patient number 12 was treated with fosfomycin. All patients had a favourable outcome, with no deaths related to the infection. No recurrences were recorded.

Discussion: Our interest in finding species belonging to the genus Actinobaculum in our laboratory is due to our first patient observed in July 2007. Actinobaculum genus gives negative results to reductions nitrate, so nitrite urine dipstick screening tests are always negative. Similarly as in previous reports, all strains were susceptible to betalactamic antibiotics and resistant to ciprofloxacin. Microbiologists should be able to spread the role of these species belonging to Actinobaculum genus among the clinicians, in order to be aware of their pathogenic potential, especially A. schaalii. Unless microscopy of Gram's stains or wet smear will be used to screen urinary samples, specimens will often not be cultured in an atmosphere supporting growth of Actinobaculum genus. One useful possible clinical algorithm for detecting these infections in patients with clinical UTI, could be the presence of piuria with negative nitrites in the dip-stick conditions. Moreover, if the patient does not respond to empirical quinolones of cotrimoxazole the suspicion index should be higher.

Conclusions: Actinobaculum genus among the clinicians, in order to be aware of their pathogenic potential. One useful possible clinical algorithm for detecting these infections in patients with clinical UTI, could be the presence of piuria with negative nitrites in the dip-stick conditions. The majority of articles about these microorganisms have been published in North European countries.

Table 1 (A-17)

A-19
LIVER STIFFNESS IN INACTIVE HBV CARRIERS MEASURED BY TRANSIENT ELASTOGRAPHY. FACTORS ASSOCIATED WITH SEVERE FIBROSIS

A. Mena, H. Meijide, A. Castro, S. López, P. Vázquez, L. Bello, J. Baliñas, J. Pedreira

HIV and Hepatitis Unit. Internal Medicine Service. Hospital Universitario A Coruña. A Coruña, Spain.

Objectives: Liver stiffness measurement (LSM) by transient elastography is an accurate method for liver fibrosis assessment. The aim of this study is to determine LSM in a cohort of inactive HBV carriers and analyze the effect of different factors on liver fibrosis.

Material and method: Observational study with patients classified as inactive HBV carriers with EASL criteria (non-treated patients with negative HBeAg, normal ALT and HBV-DNA < 2,000 IU/mL, persistently) followed at a reference clinic in Spain. Diabetic, statin-taking and > 60 gr/day alcohol drinker patients were excluded. All with ≥ 1 valid LSM (> 10 right shots, ratio > 60% and IQR/LSM < 20%) and clinical and laboratory assessment at the same time. HOMA-index, and body mass index (BMI) were calculated. LSM > 7.5 kPa was considered severe fibrosis. Factors associated with severe fibrosis were explored using unadjusted and multivariate anjusted logistic regression analyses, with SPSS 18.0.

Results: 78 patients were included: aged 44 ± 12 years, male 69%, Caucasian 81%, BMI 25.7 ± 4.2 Kg/m^2, waist circumference 84 ± 14 cm, LSM 5.9 ± 2.6 kPa, HOMA 2.41 ± 0.17, ALT 31 ± 13 IU/L, undetectable HBV-DNA 17%. LSM correlates significantly only with HOMA (0.501, p = 0.001), triglycerides (0.461, p = 0.002), HDL-c (-0.536, p = 0.002) and waist circumference (0.449, p = 0.004). Of them, 17 (22%) had severe fibrosis. In the multivariate analysis (OR [95%CI], p), male sex (12 [2-28], < 0.001), HOMA > 2.8 (5 [2-20], 0.01), triglycerides > 150 mg/dl (8 [3-46], 0.01), HDL < 50 mg/dl (12 [4-34], 0.006) and elevated waist circumference (women > 80 cm, men > 94 cm) (3 [1-62], 0.05) remained as independent predictors of severe fibrosis; without statistical significance in LDL, BMI, age, transaminases, platelets count and HBV-DNA.

Conclusions: In inactive carriers, more than 20% have high LSM, despite the low ALT and HBV-DNA levels. -In them, parameters related with metabolic syndrome (low HDL, high triglycerides and HOMA and abdominal obesity) appear to be the main determinants of severe fibrosis and must be an important focus of attention. The follow-up of this cohort continue in order to evaluate the progression of fibrosis and the impact of interventions to reduce metabolic disturbances.

A-20
TUBERCULOSIS: DIFFERENT TYPES OF PULMONARY INVOLVEMENT

T. Leonor, R. Velho, H. Sarmento, J. Cotter

Department of Internal Medicine. AIto Ave Hospital Center. Guimarães, Portugal.

Objectives: The lungs are the most common site of involvement by Mycobacterium tuberculosis infection. Pulmonary manifestations of tuberculosis include primary, reactivation, endobronchial and lower lung field infection. Complications of tuberculosis frequently result from lung involvement and include: hemoptysis, pneumothorax, pleural effusion, bronchiectasis and, in some cases, extensive pulmonary destruction (cavities). The current presentation has the purpose of, using the authors daily clinical experience, reflect about the pulmonary involvement by tuberculosis infection and its possible complications in order to review some specificities related to the diagnosis, management and treatment of this disease.

Material and method: Revision of five clinical cases and literature review were performed. A 18 year-old Caucasian female, with no prior pathologic history, was transferred from another health institution to our Emergency Department after performing a chest X-ray that demonstrated the existence of a large volume hydropneumothorax. She presented with a clinical scenario, with one month of evolution, of asthenia, anorexia and weight loss, accompanied by productive cough and night sweating. 24 hours prior to the admission she developed, suddenly, a chest pleuritic pain and noticed the existence of fever. A 52 year-old Caucasian male was referenced by his Family Physician because he presented complaints of productive cough and pleurisy with one month of evolution. On admission he described resting dyspnoea, asthenia, anorexia and weight loss, night sweating and vespertine chills, ignoring the existence of fever. A 36 year-old Caucasian male observed in the Emergency Department after a sudden onset of haemoptysis. He also referred a two weeks prodrome of productive cough. A 54 year-old Caucasian male presenting with a clinic of fever, nonproductive cough and pleuritic chest pain in the left hemithorax base in the previous two weeks. He also described asthenia, anorexia and weight loss, as well as a notion of night sweating. A 51 year-old Caucasian male with an insidious evolution of dyspnoea, dry cough of vespertine predominance, chest pleuritic pain and night sweating with two months of evolution. He reported also the existence of constitutional signs and symptoms (asthenia, anorexia and weight loss).

Results: In the first case, a thoracic CT scan was made and confirmed the existence of a pleural effusion. The analysis of the last one demonstrated an empyema with ADA levels of 101.8 U/L (normal value < 40 U/L) and allowed the identification of Mycobacterium tuberculosis (also identified in sputum samples). The second and the third cases were diagnosed through the identification of the aforementioned microorganism in sputum samples (microscopy and culture examination). In the fourth case, all the cultural results were negative and the diagnosis was possible through the microscopic identification of Mycobacterium tuberculosis in the pleural biopsy fragment. In the last case, the identification of Mycobacterium tuberculosis was made in samples of bronchoalveolar lavage and urine; cervical, axillary and inguinal ultrasound confirmed the existence of ganglionar enlargement, interpreted as being secondary. All the patients were HIV negative.

Discussion: The clinical cases presented show the wide variety of possible pulmonary manifestations of tuberculosis infection and subsequent complications, as well as the complexity of its diagnosis and therapeutic management. The miliary tuberculosis case demonstrates the tuberculosis as a possible cause of multisystemic severe infection.

Conclusions: Tuberculosis remains an important cause of pulmonary infection. The World Health Organization estimates that more than two billion individuals are infected with this disease worldwide. The infection is associated with an enormous variety of clinical presentations, requiring from the clinician a high grade of suspicion and knowledge in order to promptly consider its diagnosis and initiate the proper investigation and therapeutic management.

A-21
EPIDEMIOLOGICAL ANALYSIS OF BACTERAEMIA IN A COHORT OF PATIENTS WITH BACTERAEMIA AT A SECOND LEVEL HOSPITAL

J. Hernández Roca[1], E. García[2], J. Herrero[2], A. Hernández[2], J. Gómez[3], E. Mené[2]

[1]Department of Internal Medicine. Hospital Universitario Rafael Méndez. Lorca (Murcia), Spain. [2]Department of Internal Medicine. Hospital Universitario Virgen de la Arrixaca. Murcia, Spain. [3]Department of Internal Medicine. University of Murcia. Murcia, Spain.

Objectives: Bacteraemia (B) accounts for a considerable proportion of all infections and it is associated to mortality and increased hospital costs. The aim of this study is to describe a cohort of patients with B at a second level hospital, to analyze the epidemiological factors of B.

Material and method: Observational study of a cohort of non-paediatric patients with B admitted at a second level hospital. Data collection from clinical records has been done according to a standard protocol. We analysed epidemiological, clinical, microbiological and laboratory data during 2010. Patients with B were identified by review of results of blood cultures from the hospital microbiology laboratory. Bacterial isolation, identification and sensitivity test (Vitek-2; Biomerieux, France) were performed by standard criteria. Mortality was assessed all through hospital stay.

Results: A total of 148 patients with true B were considered (44.6% gram positive bacteria; 48.4% gram negative bacteria and 6.9% C*andida* sp.) The multiresistant bacterias isolated was < 5%. The B distribution was: 55.4% community acquired, 15.5% health care associated and 28.5% nosocomial acquired. The 95.9% of the patients with B come from home and were diagnosed in the emergency service. The incidence of B was 0.85 cases per 1,000 person/year and 31.15 cases per 1,000 hospital admission/year. The sex distribution was 1.4 M/1 W with an age rate of 69.64 ± 14.7 years old. Regarding the comorbility, a 36.6% of the patients with B had an IMC > 30 and a 88.5% had a Mc Cabe-Jackson Index III. The range of hospitalization days was 19.9 ± 17.6 days. The most frequent sepsis focus infection was urinary, and *Escherichia coli* was found to be the most frequent bacteria isolate in blood cultures. The most frequent cause of hospital admission was the septic syndrome (29.8%). The 44% of the patients with B had a Piit punctuation of ≥ 3 points, and a 52% had an APACHE II score ≥ 15 points on their arrival at the emergency area. A 30.4% had a systolic blood pressure of < 100 mmHg, and a 29.05% had a diastolic blood pressure of < 60 mmHg. The most important predisposing factor was found to be central venous system as reached the highest percentage (30.4%). The most frequent complication was the respiratory distress (37.1%). Regarding to the laboratory results, the percentage of an hemoglobin rate < 12 g/dl was 62.8%, and the percentage of leukocitosis ≥ 12.000 cel/mm^3 was 54.7%. A total of 71.6% of patients received an adequate empirical antibiotic treatment and a total of 61.5% also received a correct treatment duration. Mean hospital stay was 20 days in which the mean internal medicine floor stay was 14 days. The Mortality rate was 24% (48.7% for nosocomial B, 29.4% for the B health care associated and 16.4% for the B community acquired). The mortality directly related with the B reached a 11.1%.

Discussion: In the Rafael Mendez University Hospital (RMUH), no differences were found between sex and age distribution of the hospital admission patients with B when comparing with other studies. The incidence in this hospital of B health care associated is lower, as well as the B community acquired, while the incidence observed in this hospital nosocomial B was higher than the incidence found by other authors. Moreover, the mortality rate associated to nosocomial B is remarkably high, probably due to an inadequate empiric antibiotic treatment, a wrong treatment duration or the fact that the patients had a Mc Cabe Jackson I. The incidence of multirresistant bacteria is low in this hospital, hence, this type of bacteria is not probably an important factor related with patients mortality.

Conclusions: In the RMUH, the incidence of B was found to be remarkably high. The gram-bacteria was the most frequent type of bacteria in the blood culture. The incidence of multirresistant bacteria was of low incidence. The high mortality observed for nosocomial B can be probably related with a wrong empiric or duration antibiotic treatment. Also, a Mc Cabe Jackson I or II can be considered an influence factor in the B mortality.

A-22
HCV-HIV CO-INFECTION: THE PROMETHEUS INDEX AS AN INDICATOR OF PATIENT FOR TREATMENT WITH BOCEPREVIR OR TELAPREVIR

T. Megino[1], M. Torralba González de Suso[1], G. Pindao[1], A. Espinosa[1], E. Luque[2], P. Chacón[1], L. Abejón[1], M. Rodríguez Zapata[1]

[1]Department of Internal Medicine, [2]Department of Clinical Pharmacology. Hospital Universitario. Guadalajara, Spain.

Objectives: Hepatitis C virus (HCV) infection is often present in patients with HIV. HCV is the main cause of end stage liver disease in these patients and it is also a prominent cause of death. Nowadays we have some new pharmacological treatments for this chronic infection, telaprevir and boceprevir. However, these drugs are very expensive and they have to be used only in patients with advanced liver disease. Our objective is to characterize (elastography, IL28b polymorphism and genotype and HCV viral load) our population to know how many people would qualify to use boceprevir or telaprevir drugs.

Material and method: This is a cross-sectional study. All patients seen at our HIV unit during the last two years and with at least a 1-year follow up were recruited for the study. Elastography, polymorphism of IL28b, genotype or HCV and viral load were studied (Prometheus index). Only those with genotype 1 and with grade 3 or 4 of Fibrosis in elastography were eligible to be treated with the new drugs.

Results: 179 patients with HIV infection were analyzed. 101 were HIV-HCV co-infected patients. Of them, 81% were men. The median age was 43 (IQR: 37-46). 88.8% of patients had a detectable HCV RNA. Genotype was done in 81.2% (62.2% presented genotype 1, 1.2% genotype 2, 15.9% genotype 3 and 20.7% genotype 4). The HCV viral load was greater than 800,000 IU/ml in 57%. 5.5% of patients also had HBsAg. IL28B polymorphism was characterized in 55 patients. 38.2% were CC, 58.2% were CT and 3.6% TT. Elastography was done in 67 patients (14.9% showed F0 fibrosis, 29.9% F1, 17.9% F2, 19.4% F3 and 17.9% F4). The Prometheus index median was 60.3% (IQR 32.2-85.7). 11 patients could be treated with the new antiviral therapies (9.9%). All of them have a Prometheus index under 50%.

Discussion: The probability of achieving sustained virological response with classic therapies can be reliably estimated prior to initiation of treatment using an index that includes 4 non invasive parameters, which are VL, genotype, liver stiffness and ILB28 polymorphism. HIV-HVC co-infected patients with a low probability of SVR to interferon plus ribavirin and those who have been already treated without an adequate response may benefit from the addition of direct-acting antiviral agents to their treatment regimen. In our country, these agents can be used for patients with a genotype 1 infection and an advanced liver disease. In our study, 11 patients qualified for this new therapy. Two of them had been already treated with interferon and ribavirin without any response. These new protease inhibitors may be used with a lead-in phase of

pegylated interferon and ribavirin. It is an advantage to assess the early response to therapy before commencing the direct acting antiviral agent. However, none of our patients should be included in a 4-week lead-in strategy, simply because none of them had a Prometheus index above 50%.

Conclusions: HCV remains a major problem in our setting. Prometheus index is a good tool to help the clinician to decide which patient should be treated with PEG-IFN plus RIB or to add direct acting antiviral agents. We have found that at least one out of ten patients should be treated with telaprevir or boceprevir drugs.

A-23
TUBERCULOSIS AND HIV CO-INFECTION: A LOCAL RETROSPECTIVE ANALYSIS TO ADDRESS A GLOBAL PROBLEM

R. Ladeiras-Lopes[1], A. Azevedo[1], T. Chuva[2], A. Neto-Rodrigues[3], N. Pereira[4], G. Cabral Campello[2]

[1]Cardiology Department, [4]Department of Internal Medicine. Gaia Hospital Center. Vila Nova de Gaia, Portugal. [2]Pedro Hispano's Hospital. Matosinhos, Portugal. [3]Pulmonary Diagnosis Center. Matosinhos Local Health Unit. Matosinhos, Portugal.

Objectives: Tuberculosis (TB) remains the second leading cause of death from infectious disease worldwide and people with HIV are 21-34 times more likely to develop active disease than people not infected with the virus. This work aimed to compare the subpopulation with TB/HIV co-infection to seronegative patients with TB, in Matosinhos, a city from Portugal, a medium-incidence TB country.

Material and method: Health records of patients diagnosed with TB between 2005 and 2010, treated in the Pulmonary Diagnosis Center of Matosinhos, were reviewed. Data collection was based on questionnaire application to each patient record, regarding demographical, clinical and treatment data. Differences between groups were considered statistically significant when $p \geq 0.05$ (two-sided).

Results: A total of 455 TB cases were included in the analysis (82% confirmed cases). All TB cases were screened for HIV coinfection. The prevalence of HIV coinfection among TB cases was 15.6%, with a median CD4+ cell count of 10^7/µL. Seropositive patients were more likely to have extrapulmonary involvement (40.8 versus 23% in seronegative patients; OR = 2.3; 95%CI: 1.4-4.0), and the most prevalent presentations were nodal (37.9%), milliary (20.7%) and meningeal (17.2%). Furthermore, the HIV coinfected patients showed more constitutional symptoms at diagnosis (fever, night sweats and fatigue) and confirmed cases were less likely to have positive acid-fast bacillus (AFB) smear (OR = 0.44; 95%CI: 0.24-0.80) and Mantoux test (≥ 5 mm) than seronegative patients. Cavitation in chest X-ray was also less likely in seropositive patients (21.3 versus 47.8% in seronegative patients; OR = 0.3; 95%CI: 0.14-0.62). Drug resistant TB rates were not influenced by HIV (11.5% in TB/HIV- versus 16.7% in TB/HIV+), and the overall rate of multidrug-resistant TB was 1.7%. However, seropositive patients were more likely to discontinue treatment than HIV-negative patients (10.9 vs 1.9%; OR = 6.39; 95%CI: 2.16-18.88).

Discussion: In our city from a medium-incidence TB country (Portugal) all TB cases had HIV serology, an important tool to allow a thorough approach to TB infection (overall, only 80% of TB European patients are routinely screened for HIV coinfection). However, TB/HIV coinfection prevalence in Matosinhos was 15.6%, a value superior to Europe overall prevalence of 6%. TB cases with HIV coinfection were more likely to have extrapulmonary involvement, constitutional symptoms on presentation, negative AFB smears and non-cavitating lung disease. Immunosuppression is probably one of the most important factors accounting for these findings. Furthermore, these patients showed greater treatment drop-out rates, stressing the need for development of effective strategies to adequately treat them. Notwithstanding, seropositive patients showed similar rates of drug resistant TB compared to seronegative cases.

Conclusions: Patients with TB/HIV coinfection are an increasing challenge to physicians. Besides clinical presentation, diagnosis and organ involvement are also different when we consider HIV serology of TB patients. Furthermore, these patients represent an excellent opportunity to overemphasize the need for treatment adhesion, in order to prevent the emergence of drug-resistant TB.

A-24
CLINICAL AND EPIDEMIOLOGICAL STUDY OF INFECTIONS IN ELDERLY PATIENTS ASSISTED IN INTERNAL MEDICINE WARDS IN SPAIN, FOCUSING IN RESPIRATORY TRACT, SKIN AND SOFT TISSUE AND ABDOMINAL INFECTIONS

J. Capdevila[1], N. Llevat[2], F. Mesa[2], on behalf of the Gerion Study Group*[1]

[1]Department of Internal Medicine. Hospital de Mataró. Mataró (Barcelona), Spain. [2]Medical Unit. Pfizer Specialty Care. Madrid, Spain.

Objectives: Ageing is an important characteristic of patients in internal medicine wards (IMWs), and infection diseases are among the most prevalent reasons for their hospitalization. The objective of this work was to find out primary clinical and epidemiological characteristics, as well as outcomes of skin and soft tissue bacterial infections (SSTI), respiratory tract infections (RTI), and abdominal infections (AI) in patients over 65 years of age, as well as their rates related to the total number of patients admitted in IMWs.

Material and method: Multicenter, nationwide, prospective, and epidemiologic study. Clinical, functional (Barthel index), social status (Duke-UNc scale), past medical history, and other epidemiological characteristics of patients of 65 years of age or older, with community acquired SSTI, RTI, or AI were prospectively recorded in two one-month time periods (winter and summer) at each participant centre. The included patients were followed until hospital discharge or at least 60 days from hospital admittance. At each of these time periods, the first 5 patients meeting diagnostic criteria were included for follow-up at each participant centre. The study was approved by the Hospital de Mataró Ethics Committee, according to the International Guidelines for Ethical Review of Epidemiological Studies (Council for the International Organizations of Medical Sciences –CIOMS-, Geneva, 1991).

Results: 50 IMWs took part in the study. During the two study periods, 2689 patients fulfilled diagnostic criteria for infection, 79.2% of which were 65 years of age or older. Among these patients, 638 (30.3%) had a diagnosis of respiratory tract infection, 407 (19.4%) urinary tract infection, 128 (6.1%) SSTI, and 147 (7%) AI, while the rest of patients had been diagnosed with other types of infection. Two hundred and forty-two patients were prospectively followed, 163 of them with RTI (67%), 55 with SSTI (22%) and 35 (14.3%) with AI. Half of these patients were male, with a mean age of 80.7 years. Functional status was low in 40% of these patients, and 23% were at risk of social exclusion. The mean hospital stay was 14.9 days, (2-115); the mean Charlson index was 2.6 (CI: 2.35-2.84); 31.8% (N = 77) of patients had received antibiotic therapy within one month prior to hospitalization. The most frequently prescribed antibiotics in the outpatient setting were beta-lactams 53.4% (39), quinolones 39.7% (N = 29), and macrolides 9.6% (N = 7). Etiologic microorganisms were found in 59% of cases, with S. aureus (MRSA in 42.5% of cases), and P. aeruginosa as the most relevant. ESBL E. Coli was only isolated in 2 cases. Inpatient antibiotic treatment was based on beta-lactams and quinolones in 75.5% and 40.2% of cases,

respectively. Recovery was achieved in 50% of cases, and clinical improvement in 41%. The 30-day mortality rate was 13.5%, and 58% of these deaths were related to infection.

Discussion: Infection is a leading cause of admittance in IMWs. Elderly subjects have different presentations forms and outcomes that merit their study to improve prognosis and health-care resources adaptation.

Conclusions: Infection is a primary cause of IMWs admittance in elderly subjects, with RTIs and UTIs as the most prevalent types of infection. Patients' characteristics may differ depending on the functional, social, and comorbid conditions of each subject. The management of these patients represents an important challenge for IMWs.

This study was sponsorized by Pfizer.

A-25
INFLUENCE OF DESIGN OF DISINFECTABLE NEEDLE-FREE CONNECTORS (DNC) IN CATHETER HUB COLONIZATION RATES AND ITS IMPORTANCE IN THE PREVENTION OF CATHETER-RELATED BLOODSTREAM INFECTION

J. Capdevila Morell[1], J. Yébenes Reyes[2], M. Delgado Capel[1], G. Sauca Subias[3], N. Arroyo[1], A. Albis[2], J. López[2], I. Anglade[2]

[1]Department of Internal Medicine Service, [2]Intensive Care Unit, [3]Microbiology Service. Hospital de Mataró. Mataró (Barcelona), Spain.

Objectives: Our aim was to compare the rates of colonization of central venous and arterial catheters hubs fitted with two types of disinfectable connectors used in critically ill patients.

Material and method: The study included all central venous and arterial catheters maintained for 3 or more days in patients admitted to a polyvalent intensive care unit. Patients were randomized to receive one of two types of DNC: a neutral pressure connector (Microclave, ICU Medical, San Diego, CA) or positive pressure connector (SmartsitePlus, Carefusion, San Diego, CA). Connectors were replaced every 7 days. The main outcome measure was the percentage of positive cultures (> 15 cfu) obtained on swabbing of the catheter hub. Swabs were taken of the central venous catheter medial hub and the arterial hub on days 3 and 7 of use under strictly sterile conditions until catheter withdrawal.

Results: We monitored 146 catheters (81 central venous and 65 arterial) in 70 patients, with a total cumulative risk of 1250 days. There were no cases of catheter-related bloodstream infection. The colonization rates at day 3 of insertion were 13.3% for the neutral pressure device and 10.8% for the positive pressure one. On day 7 of insertion the rates had increased to 16.6% and 17.7% respectively, with no statistically significant differences.

Discussion: Safety in patients requiring DNC use has been a source of controversy. The need to disinfect the connectors before use requires healthcare worker training, a fact that has been interpreted as a limitation of these devices. The results obtained with DNCs have been good in experimental models in which disinfection is correct, and in some studies in which participating nurses have been specifically instructed in their use. Negative experiences following incorporation of these devices into health practice have also been reported, in some cases attributed to unfamiliarity with the device and improper handling. Another subject of discussion, mainly generated from observational cohort studies, focuses on the safety of different connector designs. Some authors have reported increases in catheter-related bloodstream infection rates when the type of device is changed (particularly to positive pressure connectors), after excluding other factors that could contribute to the increase. The results of experimental studies indicate that the connector design is a determinant factor in this regard. Nonetheless, very few prospective studies have analyzed the impact of connector type on the rate of infections as we propose with this study. The absence of differences between the two connector models used in this study can be attributed to close adherence to catheter management recommendations on the part of the health staff. In our ICU, connector disinfection is one of the major points covered in the guidelines for endovascular catheter management, in addition to the choice of the safest insertion site, the technique for sterile insertion, early catheter withdrawal, and feedback strategies.

Conclusions: In our experience, neither the use of positive pressure connectors nor connector replacement every 7 days resulted in significantly more frequent colonization of central venous or arterial connectors.

A-26
HOME INTRAVENOUS ANTIBIOTIC TREATMENT (HIAT) IN A LOCAL HOSPITAL HOME UNIT (HU): A LONG WAY TO GO?

B. Massa[1], L. Alepuz[1], P. Cervera[2]

[1]Home Care Unit. Hospital de la Vila-joiosa. Alicante, Spain. [2]Department of Pharmacy. Hospital La Pedrera. Denia (Alicante), Spain.

Objectives: The HIAT is a common practice in the HUs and it is seen as a therapy that provides great benefits to both patients and health care systems. We consider the analysis and spreading of the practice developed by the different UHs very interesting in order to discover additional benefits. This allows the expansion of the services portfolio to other usually non-considered pathologies, keeping an appropriate efficiency. Objectives: retrospective study of the HIAT carried out by a Local Hospital HU to establish its characteristics, compared to those set in the national and international context.

Material and method: Descriptive analysis of HIAT records (47 treatment courses and 40 patients) referred to the HU between August 2011 and April 2012. The bibliographic review for comparison purposes is mainly focused on 3 parameters: Site of infection/most frequent diagnosis. Antibiotics used Route and methods of administration.

Results: The type of infection recorded was very heterogeneous. The most outstanding were the respiratory infection (20%), osteomyelitis on diabetes foot (20%), urinary tract infection (12%) and surgical wounds; while in other national series urinary and respiratory infection constitute up to 75% of the cases. If we draw together all the pathologies coming from the general surgery service, it reaches a 19% in our UH. Ceftriaxone is the most widely used antibiotic in all studies including this one (19%). By contrast imipenem, ertapenem and daptomycin, which scarcely appear in other series, represent 13%, 11% and 6.4% respectively. Most cases, even the most complex ones, were successfully solved at home. The unit's nursing staff administrated all treatments. The national studies do not reflect this piece of information and it is common in other countries the use of other methods, such as self-administration, administration carried out by caregivers, external companies, etc. The administration was mainly through peripheral venous access (85%) in continuous mode –with electronic pump or elastomeric infuser- (36%) and non-continuous mode (65%). This important issue is not usually tackled by the reviewed studies.

Conclusions: Regarding the use of HIAT there are a great variability in national and international series. The observed differences in the details of the therapy are probably a consequence of the prevalence of the pathologies treated by each HU, which is

strongly related with the service providers. Infections from general surgery service and osteomyelitis on diabetes foot gain a relevant role in our HU. Ceftriaxone constitutes the most widely used antibiotic although other once daily drugs such as ertapenem or daptomycin gain a considerable importance. The administration of daptomycin on a daily dose basis allows it to stand as an antibiotic with a great future in HIAT. We would like to emphasize the absence in our area of the self-administration method, which is widely used in other countries such as the USA (60%) or Canada (46%); the need of optimizing resources with patients and caregivers training programs is considered in order to make the self-administration possible.

A-27
REASONS FOR ANTIRRETROVIRAL TREATMENT CHANGES IN SPANISH HIV 1 PATIENTS IN 2011. SWITCH AUDIT STUDY

S. Hernández[1], M. Tasias[1], P. Viciana[2], E. Deig[3], J. Arranz[4], J. Pasquau[5], F. Vera[6], E. Pedrol[1]

[1]Department of Internal Medicine. Hospital Sant Pau i Santa Tecla. Tarragona, Spain. [2]Department of Infectious Diseases. Hospital Virgen del Rocío. Sevilla, Spain. [3]Department of Internal Medicine. Hospital de Granollers. Granollers (Barcelona), Spain. [4]Department of Internal Medicine. Hospital Universitario Príncipe de Asturias. Madrid, Spain. [5]Department of Internal Medicine. Complejo Hospitalario Virgen de las Nieves. Granada, Spain. [6]Department of Internal Medicine. Hospital General de Área Santa María del Rosell. Cartagena (Murcia), Spain.

Objectives: Until the past decade, immune/viral failure was the main reason for antiretroviral treatment changes. After HAART generalization the management of antiretroviral treatment toxicities was the most prevalent reason for treatment modification. Today, with the advent of new more potent and less toxic drugs as well as more convenient combinations may have changed the situation. We aim to describe the main reasons that today leads to ART changes in HIV+ patients in Spain in the current clinical practice.

Material and method: Multicentre, national, cross-sectional epimiological study. Eligible patients had to be HIV+ > 18 years old and under current ART that was going to be changed by any reason. Patients did sign inform consent. The study consisted in a single visit (change of treatment) in which data on social and demographic characteristics, HIV disease and ARV treatment were collected.

Results: 349 patients were included; mean age: 43.7 + 8.9 y, 70.5% male y 89.1% Caucasian. Main transmission categories were IVDU (36.4%) and heterosexual (36.4%). Mean time from HIV diagnosis was 11.3 + 7.6 y. 59.5% were CDC C category. Median CD4 nadir was: 155 cells/mm^3 and median CD4 at the time of switching was 467 cells/mm^3. 64.1% had undetectable viral load (< 50 cop / ml); 40.1% had HCV or HBV coinfection. Main reasons for treatment change were simplification (40.2%), treatment toxicities (29.2%) and immune/viral failure (20.1%). No significant correlations were found between reason for changing treatment and age, gender, race, nationality and level of education. Simplification was significantly the main reason both in employed and unemployed patients ($p < 0.01$).

Conclusions: Currently, treatment simplification was the most prevalent reason for a change of treatment even in advanced lines of treatment. This is so probably because of the advent of ARV drugs that are more potent and effective, with less toxicity and more convenient. Treatment simplification was significantly the first cause of treatment change in those patients who are currently working or seeking for a job. This highlights the need for simpler regimens that can adapt to an active life.

A-29
HIV INFECTION AND VENOUS THROMBOEMBOLIC DISEASE

A. Franco Moreno[1], C. de Ancos Aracil[2], V. Martínez Díaz[1], J. Ruiz Guiardín[2], A. Gimeno García[1], S. Arponen[1], M. García Navarro[1], A. Zapatero Gaviria[2]

[1]Department of Internal Medicine. Hospital de Torrejón. Madrid, Spain. [2]Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: Human immunodeficiency virus (HIV) infection has become a worldwide chronic disease. High activity antiretroviral therapy (HAART) has improved life expectancy and long-term HIV-related complications in these patients. There have been recent reports suggesting HIV infection may increase the risk of venous thromboembolic disease (VTED) by mechanisms not thoroughly understood. The aim of this study is to characterize a population of HIV infected patients with a diagnosis of established VTED.

Material and method: This is a descriptive study comprising 14 HIV positive patients diagnosed of VTED at the Hospital Universitario de Fuenlabrada from 2004 through 2010. Congenital and acquired risk factors for VTED were analized, as well as the current immunological status at the time of thrombosis, precedent opportunistic infections, neoplastic disease and inherited prothrombotic conditions.

Results: The incidence of VTED in our HIV population was 3.5%. The patients with VTED were 12 males (85.7%) and 2 females (14.3%), with an average age of 47 ± SD 10 years. The most frequent presentation was PE (42.9%), followed by proximal deep venous thrombosis (28.6%) and distal deep venous thrombosis (14.3%). No risk factor for VTED was identified in 10 patients (71.4%). Immobilization was the precipitating factor in three cases, and use of oral contraceptives in one case. C3 was the most frequent immunological stage (35.7%) at the time of diagnosis, followed by C1 (21.4%). 35.7% of the patients presented a viral load < 40 copies/mL, and CD4 were < 200/mm^3 in half the patients. A prior opportunistic infection was present in 7 patients (50%), 4 with a disseminated cytomegalovirus infection and 3 cases of pulmonary tuberculosis. 2 neoplasms were identified, one Kaposi sarcoma and one extranodal high-grade lymphoma. 64.3% of the patients were on HAART, of whom 50% were on a protease inhibitor. Elevated serum levels of Factor VIII and antiphospholipid antibodies were found in 10 patients (71.4%). An abnormal thrombophilia study was present in 78.6% of patients, the most frequent finding being Protein C deficiency (28.6%), followed by prothrombin gene G20210A mutation (21.5%) and Protein S deficiency (14.3%).

Discussion: The incidence of VTED in our series of HIV patients was 3.5%, higher than that of the general population. In our study the majority of the patients did not have a known risk factor. Most of the thromboembolic events seem to occur in patients with < 200/mm^3 CD4 count levels, and are more frequent in patients suffering from opportunistic infections. An inverse relation between immunological status and thrombosis risk has already been reported in some series. We cannot confirm this relation, since in our study patients presenting with VTED had CD4 count cells over 200/mm^3 as likely as below 200/mm^3. On the other hand, we found a high incidence of thrombophilic conditions. It has been reported that in HIV patients the hypercoagulable state is in relation with a decrease in anticoagulant proteins (AT III, protein C and S), inactivated by the release of microparticles from lymphocyte apoptosis. In our series the thrombophilia study was normal in only 3 patients (21.5%), with a prevalence of protein C and S deficiency ten times higher than that of the general population. Several studies have shown a prevalence of antiphospholipid antibodies of 82-92% in HIV patients, as well as an increase in Factor VIII serum levels, which was also found in our series.

Conclusions: We found a high prevalence of VTED linked with a primary hypercoagulable state in our HIV patients. We believe more

clinical and epidemiological studies are needed to acquire a better knowledge of the mechanism responsible for the hemostasis alterations found in this group of patients, in order to establish appropriate thromboprophylaxis strategies for VTED.

A-30
CORYNEBACTERIUM STRIATUM PROSTHETIC JOINT INFECTION: AN EMERGENT PATHOGEN. THREE CASES SERIES

M. Cornejo Saucedo[1], F. Brun Romero[1], I. Ríos Holgado[1], E. Sifuentes Díaz[1], I. Guerrero Lozano[2]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital Universitario Puerta del Mar. Cádiz, Spain.

Objectives: Corynebacterium striatum is a Gram-positive, aerobic and facultative anaerobic bacillus. It was considered a saprophytic microorganism of skin and mucous membranes, but recently has been implicated in respiratory infections, endocarditis, and less frequently, meningitis, arthritis, and other sites infections. In the last years, a growing number of prosthetic joint infections has been described. Our aim is to analyze this issue.

Material and method: Descriptive study of three consecutive cases of prosthetic knee infection by Corynebacterium striatum occurred in the last six months. The diagnosis was established by culturing samples joint (arthrocentesis and/or surgical specimens). The samples were cultured on blood agar and thioglycolate. The identification was carried out using the API Coryne system (bioMérieux). The sensitivity and resistance spectrum were determinated used the CLSI rules. Prosthetic joint infection was classified using Tsukayama et al modified scale, in: 1) type I or early postsurgical infection (< 1 month after surgery); 2) type II or late postsurgical infection (> 1 month and < 1 year after surgery); 3) type III or hematogenous infection (> 1 year after surgery without symptoms); and 4) type IV or positive culture without prior suspicion of infection.

Results: Case 1: 80-years old male who was undergone total knee arthroplasty replacement in November 2011. Three months later, appears swelling in the knee, performing the diagnosis of late postsurgical infection by arthrocentesis and surgical sampling (joint fluid, synovial, prosthesis, bone-prosthesis interface and bone), which grew Corynebacterium Striatum sensitive to vancomycin, linezolid and tetracycline. It was resistant to penicillin, aminoglycosides, quinolones, macrolides, rifampin and fosfomycin. Case 2: 74 years old woman with left total knee replacement in July 2010. Three months later, noted signs of inflammation in her knee. Empirical treatment was initiated with levofloxacin, and incomplete response was achieving. In December 2011, the diagnosis of late postsurgical infection was established. In the surgical samples, Corynebacterium striatum sensitive to vancomycin, macrolides and linezolid grew up. It was resistant to rifampicin, penicillin, aminoglycosides, quinolones, fosfomycin and tetracycline. Case 3: 55-years old woman who had been treated with left total knee replacement seven years earlier. She develops a hematogenous prosthetic joint infection secondary to cellulitis of the left leg. In surgical specimens grew Corynebacterium striatum sensitive to penicillin, vancomycin, linezolid and tetracycline. It was resistant to rifampicin, aminoglycosides, quinolones, fosfomycin and macrolides. In all three cases monotherapy with linezolid was used, proceeding to prosthetic replacement in two times technique.

Discussion: In the last six months, have been diagnosed three cases of prosthetic joint infection by *Corynebacterium striatum* in our health district. The acquisition was hematogenous mechanism (1) and surgery (2). In all cases, *Corynebacterium striatum* showed a complex sensitivity and resistance spectrum, with difficulty in selecting a suitable antibiotic: good joint penetration, oral presentation and tolerability in prolonged treatment. There are no recommendations in the literature about the most appropriate treatment in these processes; moreover, the usual resistance to rifampicin, macrolides, tetracyclines and fosfomycin leaves us in most cases to use monotherapy with linezolid as only therapeutic option.

Conclusions: It is necessary to deep in the acknowledgment of these infections and to optimize the type and duration of antibiotherapy.

A-31
IMPLANTATION OF AN INTERLEVEL PILOT PROGRAM (PRIMARY CARE/SPECIALIZED CARE) TO REDUCE THE RATE OF LATE DIAGNOSIS IN HIV

M. Cornejo Saucedo[1], E. Chaves Rodríguez[1], F. Brun Romero[1], C. Fernández Gutiérrez del Álamo[2], M. Rodríguez Iglesias[2], J. Girón González[1], M. Soto Cárdenas[1]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital Universitario Puerta del Mar. Cádiz, Spain.

Objectives: Evaluation of implantation of an interlevel pilot program (Primary Care/Specialized Care) to reduce the rate of late diagnosis in HIV in our health area.

Material and method: Study population: health area of Cadiz. Intervention measures: promotion of the realization of a HIV test in situations defined as risk indicators, and to promote their realization in the general population (Primary Care users). Itinerant sessions were performed in the health centres of our health area during January to March of 2011. The absolute number of requests for serology submitted from Primary Care and the characteristics of new HIV cases in 2011 were analyzed, comparing with data from the periods prior to the implantation of the program.

Results: The number of requests for HIV serology submitted from Primary Care was 2,138 in 2010 and 2,551 in 2011, with an increase of 20% after implantation of the program. The number of new HIV cases was 21 in 2009, 31 in 2010 and 18 in 2011. In 2011, 61% of new diagnoses were made in Primary Care, while in 2009 and 2010 this occurred in 50% of cases. The proportion of late diagnosis (< 350 CD4+) observed in the period previous to the implantation of the program was 38-48%, decreasing to 27% after implantation of the same. The proportion of cases with AIDS-defining criteria or < 200 CD4+ was also lower in the post-implantation period (11% in 2011, 29% in 2009 and 2010).

Discussion: In the recent years has seen a change in the profile of patients with a new diagnosis of HIV infection. Consequently, the proportion of patients with late diagnosis is high, which has important implications for disease control both individually and in the context of public health.

Conclusions: The implantation of a program to promote HIV screening in Primary Care could be a useful tool to decrease the rate of late diagnosis in HIV, and patients may benefit from treatment before the immune status becomes unfavourable.

A-32
PROSPECTIVE, OBSERVATIONAL STUDY TO DETERMINE THE IMPROVEMENT IN NEUROPSYCHIATRIC SYMPTOMS AFTER CHANGING THE RESPONSIBLE ANTIRETROVIRAL DRUG TO NEVIRAPINE. THE RELAX STUDY

S. Hernández[1], M. Tasias[1], J. Márquez[1], B. Clotet[2], J. Llibre[2], A. Curran[3], E. Pedrol[1]

[1]Department of Internal Medicine. Hospital Sant Pau i Santa Tecla. Tarragona, Spain. [2]HIV Unit. Hospital Universitari Germans Trias i Pujol. Badalona (Barcelona), Spain. [3]Department of Infectious Diseases. Hospital Universitari General Vall d'Hebron. Barcelona, Spain.

Objectives: To evaluate the improvement in psychiatric symptoms attributable to changing the antiretroviral drug responsible for such

Table 1 (A-32)

	Baseline (n = 129)	1 month (n = 112)	3 months (n = 100)	p value	p value
PSQI > 5,significant alteration of sleep	96.9%	60.7%	44%	< 0.001	< 0.001
Anxiety and depression	86.8%	46.4%	32%	< 0.001	< 0.001
Mean score and% of normal somnolence	8.3 ± 4.7 (65.9%)	6 ± 4 (89.3%)	5.5 ± 3.6 (91%)	< 0.001	< 0.001
Compliant patients	65.9%	75.9%	81%	0.036	0.013
Good quality of life	57.5 ± 18.9%	69.8 ± 19.7%	73.6 ± 16.8%	< 0.001	< 0.001

symptoms to nevirapine (NVP), with evaluations at 1 and 3 months after the change. The tools used were a sleep test (Pittsburgh Sleep Quality Index [PSQI]) and Hospital Anxiety and Depression Scale (HADS).

Material and method: Prospective, national and observational study that included HIV-1 patients with: age over 18 years; change of antiretroviral treatment (ART) to nevirapine due to CNS side-effects; a PSQI score > 5; a HADS score ≥ 10 on the day of starting NVP treatment; and no psychoactive drug treatment initiated during the 6 weeks prior to starting treatment with NVP. Other data: clinical and demographic details and administration of the Epworth somnolence scale, the Medical Outcomes Study-short form 30 items (MOS-SF-30) quality of life scale and the Simplified Medication Adherence Questionnaire (SMAQ).

Results: 129 patients were included in the study. The drug changed was efavirenz in 89.9% of cases. Reason for the change: sleep disturbances in 75.2%, anxiety in 65.1%, other psychiatric disturbances in 38.7%, attention disturbances in 31%, and other reasons in 31%; a mean of 2.4 neuropsychiatric disturbances were detected in each patient. The CD4 lymphocyte count rose from 582 ± 261 to 619 ± 299 in the third month. 3 patients had developed an HIV viral load at the end of the study. The differences produced by the change are shown in Table 1. 29 patients withdrew from the study: nevirapine-related toxicity (9); loss to follow-up (7); voluntary withdrawal (4); other reasons (9).

Discussion: The majority of ART are of similar efficacy. The differences between them are largely due to their tolerance/toxicity profiles. In this context, adverse effects involving the central nervous system (CNS) are of particular importance in the NNRTI class and may occur with other antiretroviral drugs. However, nevirapine has only very rarely been associated with these effects.

Conclusions: The study shows that the change to nevirapine from a drug that is causing neuropsychiatric disturbances is effective in resolving those disturbances, with an improvement in all the parameters studied (quality of sleep, anxiety/depression scale, and somnolence). This leads to better adherence and a better quality of life of the patients, with no detriment to their immunological and virological control.

A-33
USEFULNESS OF BLOOD CULTURES IN COMMUNITY-ACQUIRED PNEUMONIA IN AN INTERNAL MEDICINE DEPARTMENT

P. Demelo Rodríguez, M. Barrientos Guerrero, B. Andrés del Olmo, A. González Munera

Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: Primary objective of this study is to analyze the usefulness of blood cultures in patients hospitalized in an Internal Medicine Department with the diagnosis of community-acquired pneumonia. As secondary objectives, we analyzed the epidemiological features of these patients, the mortality rate and the most frequently isolated microorganisms. Also, we evaluated whether blood cultures were collected in patients with this pathology in our center.

Material and method: Medical records of all patients admitted to Internal Medicine Department with the diagnosis of community-acquired pneumonia (confirmed by X-Ray) during year 2011 were reviewed, and we registered the number of blood cultures collected, microorganisms isolated and the epidemiological features of this patients.

Results: Clinical records of 351 patients were revised. 154 patients (43.9%) were women, with a mean age of 69.14 years (SD 19.31). Blood cultures were collected in 193 (55%) of all patients, and were positive in 15 of them (7.77% of those patients who had blood cultures collected). The most frequently isolated microorganism was Streptococcus pneumoniae (60%). The mortality rate was 6%. The average stay was 8.32 days (SD 11.55).

Discussion: Community-acquired pneumonia is a very common disorder, with an overall rate of 5 to 6 cases per 1000 persons per year. It is associated with a high morbidity and mortality in hospitalized patients. In our study, we observed a low rate (7.77%) of positive blood cultures. Other studies situate this rate in 7 to 16%. Although within the range, this low rate could be due to technical problems in collection or early beginning of antibiotic treatment, considering that we did not take into account whether blood cultures where collected before or after the beginning of antibiotic treatment. Considering this results, the usefulness of blood cultures in hospitalized patients with community-acquired pneumonia is low. However, several studies support blood cultures collection, most of them based in the fact that when positive, they establish a definite diagnosis. Besides, it is a great source for tracking resistance patterns, and it has a widespread use with very few complications. An interesting fact is the number of blood cultures taken in our center. Although we are unable to compare these results with other series, we consider that blood cultures were avoided in a high number (45%) of patients.

Conclusions: The usefulness of blood cultures in community-acquired pneumonia in our center was low, but within the range observed in other studies. Besides, the most frequently isolated microorganism was Streptococcus pneumoniae. According to several studies, this should not be taken as a fact against blood cultures collection, but we should enhance other techniques to obtain microbiological affiliation (sputum, antigens, etc.). In our center, blood cultures were not collected in an elevated number of patients.

A-34
STUDY OF URETHRAL SWABS AT A TERTIARY HOSPITAL. A ONE-YEAR EXPERIENCE

J. Polo Sabau[1], C. López Rodríguez[1], E. Petkova Saiz[1], A. Lorenzo Almorós[1], C. Marconi[1], A. de Molnar d'Arkos-Millorete[1], I. Mahillo Fernández[2], I. Gadea-Gironés[3]

[1]Department of Internal Medicine, [2]Department of Epidemiology, [3]Department of Microbiology. Fundación Jiménez Díaz. Madrid, Spain.

Objectives: To describe the prevalence of urethral swabs with a positive result and those clinical features more likely related with

them. We also studied the microbiological spectrum and resistance patterns of collected samples.

Material and method: Retrospective review of clinical and microbiological data from all urethral swabs received at our institution during the year 2011. Cases were obtained from the database of the Microbiology Department. Fisher's and T-Student tests were used for statistical analysis.

Results: A total of 535 urethral swabs were analyzed. Mean age of patients was 35.9 years (SD 12.3), 2.8% were diabetic, 9.3% were HIV-infected, and 4.9% and 1.9% had HBV and HCV infection respectively. Sample collection was made by primary care physicians in 279 cases (52%), at the Emergency Department in 129 (24%), by urologists in 61 (11%), and at the Internal Medicine Department in 30 (5.6%). 256 cases (47.85%) had a positive result; 213 of them were monomicrobial. In 105 cases (19.6%) a prior history of sexually transmitted disease (STD) was recorded. Mean ages of patients with positive and negative results were 33.9 and 37.8 years respectively ($p = 0.0002$). The probability of having a positive result was significantly higher among patients with HIV infection (59.5 vs 39.2%; $p = 0.028$), prior history of STD (54.9 vs 37.4%; $p = 0.024$), urethral discharge (49.6 vs 29.9%; $p = 0.004$), and dysuria (47.1 vs 31.5%; $p = 0.031$). The presence of fever, local ulceration or lymphadenopathies did not significantly raise this probability. The most-frequently-found microorganisms were: Chlamydia trachomatis (81 cases), Haemophilus parainfluenzae (65), Neisseria gonorrhoeae (55), Ureaplasma urealyticum (43), Streptococcus agalactiae (33), Staphylococcus aureus (7), Candida albicans (6), Mycoplasma hominis (5), Escherichia coli (3), Haemophilus influenzae (3), Streptococcus disgalactiae (3), Streptococcus pyogenes (2), Enterococcus (1), Neisseria meningitidis (1), and herpes simplex type 1 (1). Susceptibility to Ceftriaxone was found in all cases with both Neisseria gonorrhoeae and Haemophilus parainfluenzae growth and to Penicillin G in all cases with Sreptococcus agalactiae isolation. Regarding Neisseria gonorrhoeae, resistance was found in 67.3% of cases for Penicillin G, 49.1% for Ciprofloxacin, and 67.4% for Tetracycline. Isolation of Chlamydia trachomatis, Haemophilus parainfluenzae and Neisseria gonorrhoeae was found in patients with younger age (mean age 30.1, 33.8, and 32.04 years respectively; $p < 0.005$).

Discussion: There is a significant amount of patients in which a urethral swab is obtained, and about half of them in our series yields a positive result. False-negative cases could also be considered in patients with a previous antibiotic therapy or due to technical errors in sample collection. Organisms like Chlamydia or Neisseria are clearly associated with urethritis, whereas a pathogenic role cannot be so well established in others, such as Streptococcus agalactiae, although they may use this portal of entry for systemic infections.

Conclusions: Urethritis remains as a major clinical and epidemiological problem, with a large number of suspected cases in our area annually. The diagnostic yield of urethral swabs approaches half of cases in our experience. Positive results are more likely to occur in HIV-infected patients, in those with previous STD and in the presence of urethral discharge or dysuria. Patients with a positive result were significantly younger. According to resistance patterns encountered in our series, currently recommended initial antibiotic therapy should still be effective.

A-35
PRESENTATION OF 3 PATIENTS WITH ALVEOLAR HEMORRHAGE AND ARDS INDUCED BY WEIL'S DISEASE

C. Spyridonidou, D. Stoimenis, E. Lazoudi, A. Lalia, G. Paraskevopoulos, N. Papaioannou

1st. Department of Internal Medicine. General Hospital G. Papanikolaou. Thessaloniki, Greece.

Objectives: Weil's disease is the icteric form of leptospirosis representing about 10% of the patients infected by leptospira. Weil's disease is characterized by multisystem dysfunction. Over the last decade the incidence of pulmonary involvement has increased up to 70% of the patients. We present three cases of Weil's disease that were complicated with pulmonary hemorrhage and Acute Respiratory Distress Syndrome (ARDS). Different outcome was recorded in these patients.

Material and method: Three patients were admitted to our department within a two-month summer period and diagnosed with Weil's disease. Demographic characteristics, clinical signs and symptoms, laboratory tests, radiologic imaging, treatment and outcome were recorded.

Results: The first patient was a 70 year-old farmer who presented with fever, severe jaundice, thrombocytopenia and ensuing epistaxis. His renal and hepatic laboratory markers were normal. On day 4 the patient established hemoptysis and acute respiratory failure type I due to ARDS. A CT scan of the chest revealed diffuse alveolar hemorrhage and bilateral ground-glass opacities. He required endotracheal intubation and intensive care management. He was treated with iv ceftriaxone. Diagnosis of leptospirosis was suggested by a positive ELISA IgM test. He was discharged the Intensive Care Unit (ICU) 4 days later. 1 -, 3- and 5- month follow-up identified the development of mild restrictive pulmonary disease. The severity of pulmonary involvement contrasted with the absence of renal dysfunction. The second patient, a 60-year-old man who dealt with agricultural works, was admitted to our department because of fever, myalgias and fatigue. His lab tests showed acute renal injury, hepatic impairment and severe jaundice (total bilirubin = 50 mg/dl). On admission day he was transported to ICU due to acute respiratory failure and septic shock. Mechanical ventilatory support was instituted for 16 days. The patient received ceftriaxone and ciprofloxacin. Leptospirosis was confirmed by positive IgM and IgG ELISA test. The CT scan of the chest demonstrated diffuse alveolar infiltrates. The patient fully recovered without any remaining pulmonary lesions. The third patient was a 30-year-old farmer who visited the hospital 10 days after the onset of symptoms. He presented with high fever, dyspnea and jaundice. The lab tests revealed anemia, thrombocytopenia, renal and hepatic impairment. The CT scan of the thorax showed bilateral interstitial infiltrations, ground-glass appearance and pleural effusion. On the second day, the patient developed severe respiratory acidosis. He was admitted to ICU and required respiratory, hemodynamic and renal assistance (hemodialysis). He received ceftriaxone and polymyxin. Leptospirosis was certified by positive ELISA IgM and IgG tests. Death occurred within 7 days of admission due to multiorgan failure.

Discussion: Pulmonary manifestations of Weil's disease may range from mild respiratory symptoms to the presence of ARDS. Alveolar hemorrhage in leptospirosis is secondary to vasculitis with endothelial damage and uncorrelated with inflammation. Our patients exhibited ARDS and respiratory failure, but had different outcome that was possibly related to other disease manifestations. Renal injury, thrombocytopenia and delayed diagnosis are associated with increased morbidity. Although there is some evidence that high doses of corticosteroids may be beneficial in the late phase of ARDS due to leptospirosis, our patients did not receive such therapy, but were treated with appropriate antimicrobial therapy at presentation.

Conclusions: Leptospirosis may be presented as or lead to severe alveolar haemorrhage and ARDS even in the absence of hepatic dysfunction or renal failure. Clinicians should be aware of these manifestations of leptospirosis, especially in endemic areas.

A-36
ACUTE PYELONEPHRITIS IN HOSPITALIZED PATIENTS: USEFULNESS OF BLOOD AND URINE CULTURES IN OUR ENVIRONMENT

A. González Munera, M. Barrientos Guerrero, B. Andrés del Olmo, P. Demelo Rodríguez

Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: Primary objectives of this study are to analyze the collection of blood and urine cultures and to examine which microorganisms are the most frequently isolated in patients diagnosed of acute pyelonephritis in an Internal Medicine Department during a whole year. Secondary objectives were to analyze the epidemiological features of patients diagnosed with pyelonephritis, mortality rate and isolation of extended-spectrum beta-lactamase (ESBL) producing bacteria.

Material and method: Medical records of all patients with the diagnosis of acute pyelonephritis hospitalized in an internal medicine department during year 2011 were reviewed. There were also registered the number of blood and urine cultures collected, its results, and the microorganisms isolated. We analyzed these data with SPSS 18.0.

Results: 176 patients were included in our study. 126 patients (71.6%) were women, with a mean age of 45.61 (SD 19.63). Urine cultures were collected in 160 (90.9%) of all patients, and were positive in 112 (70.0%) of them. Blood cultures were collected in 143 (81.3%) of all patients, and were positive in 36 of them (25.2% of those patients who had blood cultures collected). The most frequently microorganism isolated was Escherichia coli, as well in blood as in urine cultures (75% and 88.4% respectively). Other microorganisms isolated were Klebsiella pneumoniae (4.5%), Enterococcus faecalis and Proteus mirabilis (2.7% each of them), and Staphylococcus saprophyticus (1.8%). 4.5% of isolated microorganisms were ESBL producing bacteria. The average stay was 4.15 days (SD 2.81). None of the patients died during their hospital stay.

Discussion: Acute pyelonephritis is a complicated variant of urinary tract infection, which is one of the most common infectious diseases at all ages, both in men and women, but clearly more frequently in women. Urine culture and antimicrobial susceptibility testing of uropathogens should be performed in all patients with acute pyelonephritis in order to adjust antimicrobial treatment. 30% of our patients did not get any microbial isolation, although most of them had urine cultures collected. These results may come from previously started antibiotic treatment. In our department, 18.7% of patients admitted had no blood cultures collected, while the collection of three blood cultures is recommended in every admitted patient with pyelonephritis. The microbial spectrum of pyelonephritis consists mainly of Escherichia coli (75 to 95 percent depending on the studies), with occasional other species of Enterobacteriaceae, such as Proteus mirabilis and Klebsiella pneumoniae, and Staphylococcus saprophyticus. The rate of ESBL bacteria is increasing with the abuse of antibiotical treatment, but in our sample it still remains quite low.

Conclusions: The percentage of positive cultures in our environment is similar to that in other studies. We should be aware of the importance of blood cultures, as well as urine cultures, for the adjustment of antimicrobial treatment. The isolation of microorganisms helps us in order to avoid broad spectrum antibiotics in sensitive bacteria, so that we can keep ESBL to a minimum. Escherichia coli remains the most commonly isolated microorganism in pyelonephritis.

A-37
ULTRASOUND FINDINGS IN ACUTE PYELONEPHRITIS

B. Andrés del Olmo, A. González Munera, P. Demelo Rodríguez, M. Barrientos Guerrero

Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: Primary objective of this investigation was to analyze the most frequent findings in ultrasound in patients hospitalized in an Internal Medicine Department with diagnosis of acute pyelonephritis, and whether these findings are related with the disorder. As secondary objectives, we registered how often ultrasound test was performed in these patients in our center. We also analyzed the epidemiological features of patients diagnosed with pyelonephritis and mortality rate.

Material and method: We revised medical records of all patients hospitalized in an Internal Medicine Department during year 2011 with diagnosis of acute pyelonephritis and collected ultrasound findings. These data were analyzed using SPSS V.18.

Results: Clinical records of 176 patients were revised. 126 patients (71.6%) were women, with a mean age of 45.61 (SD 19.63). Ultrasound was performed in 111 (63.7%) patients, but 48 of them (42.9%) had a non pathological result. Amongst the other results, lithiases were the most frequent result (21.7%), followed by urinary tract dilation (17.2%), prostate enlargement (14.1%) and pyelonephritis data (10.9%). Only two of the admitted patients wore indwelling urinary catheter. The average stay was 4.15 days (SD 2.81). None of the patients died during their hospital stay.

Discussion: Pyelonephritis is a complicated variant of urinary tract infection, which is one of the most common infectious diseases at all ages, both in men and women, but clearly more frequently in women. Among the diagnostic tests used to study pyelonephritits one of the most useful is ultrasonography. It is of help to evaluate the presence of an underlying anatomic abnormality, to detect a process that may delay response to therapy, or to diagnose a complication of infection. Although there are no clear recommendations for the indication to perform an ultrasonography in pyelonephritis, patients with symptoms beyond 48 to 72 hours after appropriate antibiotic therapy should be explored for complications.

Conclusions: Most patients with pyelonephritis undergo radiologic evaluation of the upper urinary tract withultrasonography. Many abnormalities can be found but, by far, lithiasis is the most common.

A-38
THE VALUE OF NAPROXEN TEST AS A DIAGNOSTIC METHOD TO DIFFERENTIATE CAUSE OF FEVER

O. Coskun[1], A. Karakas[1], E. Arslan[2], C. Eyigün[1]

[1]Department of Infectious Diseases, [2]Department of Internal Medicine. GATA. Ankara, Turkey

Objectives: Fever of unknown origin is still remains a perplexing problem to both clinicians and investigators. Lysis of fever upon administration of the antipyretics favors a presumptive diagnosis of neoplastic fever. On the contrary, failure of lysis usually points to an infectious etiology. The naproxen test was first described by Chang and Gross in 1984 as a reliable diagnostic method test for differentiation of neoplastic fever from non-neoplastic fever. In addition, several studies in febrile cancer patients have suggested that nonsteroidal anti-inflammatory drugs (NSAIDs) abolish tumor-related fever, as opposed to fever caused by infections. Several authors have advocated using the naproxen test to differentiate neoplastic from non-neoplastic fever in patients presenting with fever of unknown origin. In this study we aimed to determine the

diagnostic value of the naproxen test in patients with a prolonged febrile illness.

Material and method: This study was performed retrospectively on consecutive hospitalized patients due to fever at infectious diseases department. Twenty patients with fever at least for seven days at least 38 ºC, suspected or confirmed infectious, neoplastic and connective tissue disorders were included to study. There should have been no antimicrobial intake for at least 48 hours. Before management of fever, naproxen sodium were administrated 250 mg every 12 hours per orally for two days to all patients.

Results: Median age 38 years, 16 and 4 of them were male and female respectively. Infectious diseases etiology was detected at 15 patients. 12 and 3 of them responded to naproxen test at the first and second days respectively. Although 2 and 1 of the patients with non-infectious etiology responded to naproxen test at first and second days respectively. Two of non-infectious etiology patients remained unanswered.

Discussion: Based on several studies involving febrile cancer patients, naproxen has been proposed as an aid in the differential diagnosis of cause of fever because its antipyretic effect has been presumed to be specific for neoplastic fever. We assessed the value of the naproxen test in an unselected group of patients with a prolonged febrile illness of unknown etiology. It has been reported that antipyretic effect of naproxen on fever in cancer patients was better than patients with infectious etiology.

Conclusions: In this small number, uncontrolled retrospective study we concluded that the naproxen test, does not has diagnostic value in differential diagnosis of fever etiology. Further randomize control, large studies are needed to validate these finding.

A-39
CYTOMEGALOVIRUS REACTIVATION IN ULCERATIVE COLITIS PATIENTS

A. Muñoz[1], E. Guerrero[2], A. Vizuete[1], L. de Matías[1], A. Herrero[1], F. Marcos[1]

[1]Department of Internal Medicine. [2]Department of Gastroenterology. Hospital Nuestra Sra. del Prado. Talavera de la Reina (Toledo), Spain.

Objectives: The spectrum of human illness caused by cytomegalovirus (CMV) is diverse and mostly dependent on the host. Infection in the immunocompetent host is generally asymptomatic. Nevertheless, severe organ specific complications have been reported. Gastrointestinal involvement with CMV can occur in the setting of primary infection, the presence of abnormal mucosal surfaces prior increases the risk. Evidence of gastrointestinal CMV in patients with pre-existing inflammatory bowel disease has been described. Objective: to know the profile of the patients with ulcerative colitis (UC) and CMV in our health area.

Material and method: Descriptive retrospective observational study has been performed in the Hospital Ntra. Sra. del Prado, Talavera de la Reina, Toledo. Data were collected from UC symptomatic patients affected by CMV mucosal infection simultaneously in an endoscopic study. Diagnosis was defined by polymerase chain reaction (PCR) and/or immunohistochemistry (IHC) in biopsy specimens from January 2010 to December 2011.

Results: We took a total of 8 patients at an average age of 48 years old (23-78), 65.5% were male. The time period evolution of the UC was 6 years (0-12). 50% of the cases affected procto-sigmoid colon and the other 50% left hemicolon. In 87.5% (7) the evolution of the UC had been torpid with numerous outbreaks and multiple treatments: 5-ASA 100%, steroids 87.5%, immunomodulators 87.5%, biological therapies 75% and antibiotics 100%. The diagnoses were made by taking colon biopsies. PCR was carried out detecting CMV in 87% and IHC was positive in 37.5%. The CMV IgM serology was negative in 100% of the performed cases. All patients received treatment with oral valganciclovir and clinical improvement was achieved in 87%. However, there was a steroid-naïve patient who was simultaneously diagnosed with UC and CMV who evolved adversely, showing pancolitis and toxic megacolon that leaded him to death. An endoscopic review was done in 4 patients; PCR was maintained positive for CMV however IHC was found negative in all cases.

Discussion: In agreement with other published studies, the factors that seem to favor the reactivation of CMV are the evolution time period and immunosuppressant treatments. However, there might be other factors responsible for reactivating the CMV in naïve patients. Probably these factors, still unknown today, are capable of causing a more aggressive course of the disease. The steroid-naïve patient in our report was a 78 years old (the oldest in our study) and, in contrast to the others patients, he also had an important atherosclerotic involvement. On the other hand, the persistence of the positive PCR and negative IHC in the revised patients seems to indicate that the CMV, like other herpes viruses, could be latent in the tissues after treatment and future reactivations would not be improbable. Non quantitative PCR would not be useful to know if we are dealing with an active infection, IHC would.

Conclusions: 1. Both the evolution time and the immunosuppressive therapies favor the reactivation of CMV. 2. There might be other factors that reactivate the CMV in naïve patients such as the old age and atherosclerosis. 3. The treatment with valganciclovir has been shown to improve the acute infection. Nevertheless, CMV remains latent in gastrointestinal tissues, as it has been demonstrated by post-treatment PCR studies. However it would be necessary to quantify CMV copies. 4. To diagnose the acute disease the IHC analysis would be the most appropriate technique. 5. Further research could identify if a secondary prophylactic treatment should be carried out in this group of patients.

A-40
SPONDYLODISCITIS CAUSED BY ESCHERICHIA COLI

A. Sáenz Gutiérrez[1], E. Marchán Carranza[1], G. Esquinas Blanco[1], C. Lozano Cejudo[2], P. Calderón Jiménez[1], M. Mañas García[1], D. Bellido Pastrana[1], J. Gijón Rodríguez[1]

[1]Department of Internal Medicine. Hospital General de Ciudad Real. Ciudad Real, Spain. [2]Department of Radiology. Hospital Santa Bárbara. Puertollano (Ciudad Real), Spain.

Objectives: To review patients with spondylodiscitis caused by Escherichia coli.

Material and method: To describe those patients with the diagnosis of spondylodiscitis caused by Escherichia coli, on admission in the Internal Medicine Department, General University Hospital of Ciudad Real, during one year. We analize clinical, microbiological, diagnostic and therapeutic features.

Results: Case 1: 83 year-old male who had been hospitalized and received treatment with iv amoxicillin-clavulanic acid due to a bacteremia caused by E. coli the previous month. This time, the patient was admitted because of a bilateral low back pain, worse with the efforts, with no irradiation and fever up to 39 ºC. Hemocultures were positive to Escherichia coli, nalidixic acid resistant. Uroculture were also positive to E. coli. A CT-scan showed disc space narrowing at T11-T12, with a soft tissue mass associated, suggesting spondylodiscitis. The MRI confirmed the diagnosis. A treatment with ceftriaxone was iniciated. Case 2: 78 year-old male. The patient was admitted in our department because of fever and chills. Three days later the patient complains about low back pain. In the hemoculture grew E. coli multisensitive to antibiotics. Because of persistent low back pain, MRI was done, and showed cortical lysis at the lower face of L2 and the upper face of L3. There

was also a small subligamentary abscess L2-L3. Levofloxacin was the antibiotic used.

Discussion: Osteomyelitis is an inflammatory process that affects the vertebra and the intervertebral disc. It is accompanied by bone destruction and it is caused by an infecting microorganism. Its incidence increases with the age, being more frequent over 50 years old. The most important infecting organism is Staphylococcus aureus, followed by Mycobacterium tuberculosis (Pott's disease). Less common, but also important pathogens include Brucella (in Mediterranean countries), and Candida. E. coli is not a typical microorganism and is responsible of this entity in only a 0.7-6.6% of the cases according to the literature. Pathogens can reach the bones of the spine by three basic routes: hematogenous spread, direct inoculation (surgery or trauma) or contiguous spread. The main clinical manifestation is back pain, accompanied or not by fever (up to 50% of the cases), subacute course. The diagnosis is suspected on the basis of clinical features and abnormal imaging tests. When microbiologic tests are negative, it is mandatory to confirm the diagnosis by aspiration of the infected intervertebral disc space or vertebral bone. The most serious complication of vertebral osteomyelitis is neurologic impairment. Most, but not all, patients have gradual improvement in back pain after therapy is begun, and the pain typically disappears. The best way to reduce the morbidity and mortality associated with vertebral osteomyelitis is to limit the time between the onset of symptoms and the initiation of appropriate therapy. The treatment consists on antibiotics as soon as the diagnosis is suspected, given during 8 weeks. Surgery is required in the cases of cord compression, drenage of big abscesses or progression of disease despite adequate treatment.

Conclusions: Spondylodiscitis caused by E. coli is not common. It is most frequently described in patients over 50 years old because of hematogenous spread (tipically: urinary tract infection). Antibiotic treatment must be given early. Surgery is chosen in cases of cord compression, drenage of big abscesses or progression of disease despite adequate treatment.

A-41
SPONDYLODISCITIS, AN UNCOMMON BUT IMPORTANT CLINICAL PROBLEM

O. González Casas[1], F. Olgado Ferrero[1], F. Calvo Cano[1], N. Nogales Muñoz[2], A. Vera Tome[2], F. Rodríguez Vidigal[2], J. Caballero Trenado[3], A. Muñoz Sanz[2]

[1]Department of Internal Medicine, [2]Infectious Diseases Unit, [3]Department of Traumatology. Complejo Hospitalario Universitario de Badajoz. Badajoz, Spain.

Objectives: To describe a series of spondylodiscitis attended in the Infectious Diseases Unit of an University Tertiary Hospital.

Material and method: This is a retrospective study of 66 patients who were diagnosed of spondylodiscitis in a period of 19 years (1993-2012). We analyzed the epidemiology, etiological diagnosis, clinical presentation, radiological diagnostic tests, and evolution.

Results: The age at admission was 63 ± 15 years, and 65.2% were male. Sixty per cent came from rural area. Nine patients were immunocompromised, other nine had spinal surgery in the previous 6 months and twenty-two had a documented infection in the previous two months. Regarding microbiological studies, blood cultures were positive in 29/59 cases (50%) and the exudates analysis was diagnostic in 14/37 cases (28%). In 68% of patients different microorganisms were isolated: twenty-five GPC (S. aureus/20% S. coagulase negative/13%, E. faecalis/7.7%, Streptococcus spp/ 4.6%), seven GNB (E. coli 6%), seven M. tuberculosis/9%, two Brucella spp/3%, one C. burnetti/1.5% and one C. albicans/1.5%. Clinical data: The mean duration of symptoms was 90.2 days. The most frequent were: pain (92.3%), fever (54.5%) and neurological deficit (32.3%). There were significant differences in mean duration of symptoms according to the microbiological aetiologies: M. tuberculosis (275 days), Candida spp. (270 days), unknown-aetiology (89 days), Gram-positive cocci (GPC) (62 days), Coxiella burnetii (45 days), Gram negative bacilli (GNB) (26 days), and Brucella spp. (15 days). Complications occurred in forty-one patients: paravertebral abscess (35%), psoas abscess (25%), extradural-epidural abscess (17.5%) and valvular endocarditis (12.5%). Radiological diagnosis: The images tests most frequently used were plain radiography (100%), MRI (82%), and scintigraphy (48%). Evolution: Forty seven per cent of patients required surgery, and 9% were admitted to the intensive care unit. Only one patient died.

Discussion: Our experience is quite similar to the reported in the literature. There are a male predominance and a mean age of 60-70 years. The clinical presentation is usually subacute (mean duration of symptoms of 90.2 days). Because the symptomathology is nonspecific, it is very important to suspect it to get an early and correct diagnosis. In our series, the most common aetiology was S. aureus, although tuberculosis continues to have a significant impact. By other hand, a significant number of cases remained undiagnosed. Regarding microbiological diagnosis, blood cultures has higher performance than the exudates culture. In our opinion, is very important to obtain blood cultures before the beginning of an empirical treatment. As a rule, we think that in patients with heart disease, bacteraemia or infection with gram-positive bacteria is very recommendable to discard endocarditis. Complications are very frequent as local complications (epidural abscess, spinal cord compression and psoas abscess) or distance complications (valvular endocarditis). Near a half of the patients required surgical treatment. In general, the clinical evolution is favourable.

Conclusions: Spondylodiscitis is an uncommon disease but should be suspected in patients with risk factors such as immunodeficiency, previous spine surgery or bacteraemia. It is recommended to do blood cultures before starting empiric antibiotic treatment. This, plus radiological studies, will permit an early and appropriate diagnosis. Although local complications are very uncommon and a half of patients need surgical treatment, the final evolution is usually good.

A-42
REVIEW OF ADMISSIONS WITH SUSPICION OF TUBERCULOSIS IN THE LAST YEAR

M. Varas Mayoral, B. Díaz Pollán, M. Núñez Orantos, V. Isernia

Department of Internal Medicine III. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: To evaluate the admissions with suspected tuberculosis to an Internal Medicine unit with respiratory isolation beds over the past year.

Material and method: Our unit depends on the Internal Medicine Department. For many years, the number of admissions of patients with tuberculosis infection has been high, due to the availability of respiratory isolation rooms with negative pressure, necessary for the diagnosis and treatment of this pathology. We retrospectively reviewed all admissions to our unit during the past year (from May 1st, 2011 until April 30th, 2012) who were derived with the request of "ruling out tuberculosis" or similar. The preliminary diagnostic was made in most cases upon admission of the patients to the Emergency Department. In few cases, patients were derived for study from other hospital services.

Results: We found a total of 27 cases with an initial suspicion of tuberculosis. Pulmonary tuberculosis was the most common in 85% of patients, although other locations such as lymph node tuberculosis, spondylodiscitis, peritoneal tuberculosis, or tuberculous meningitis were also identified. 60% were male, with a

mean age of 46 years; nine patients were immigrants, 7 from Central and South America, and 2 from Eastern Europe. The main symptom was haemoptysis, followed by fever of more than two weeks of evolution, with or without pathology lesions suggestive of pulmonary tuberculosis on chest X-ray, (test made on all patients upon admission). In patients having productive cough, sputum was collected for culture and staining for acid-fast bacilli, in a first determination in the Emergency Department, being positive in less than 25% (6). Once in our unit, we systematically proceeded to the completion of three daily serial cultures of urine samples (27) and sputum (in patients having productive cough, 21). If the suspicion was high and cultures were negative, a bronchoscope is carried out. Mantoux test was also performed in all patients, with positive results in 50% of cases. The main risk factor identified was alcohol (40% of the patients) being or not homeless; its place of origin (33% immigrants); HIV co-infection (20%); previous contact with tuberculosis, personal history or family member (10%); or history of malignancy disease (10%). We confirmed the diagnosis in 16 cases. The treatment of choice was with four drugs, according to current Spanish guidelines. We performed the study of resistances in all the obtained positive samples: resistance was found to a drug used in the treatment of choice in only two patients. Patients were referred to the outpatient clinic where they were reviewed, but only 22 patients attended the appointments. We used the directly observed treatment program in 2 patients who were required for different reasons.

Discussion: In our study the likelihood of success in the diagnosis is not very high because too much attention is paid to the most common symptoms (haemoptysis and prolonged fever) and risk factors, rather than to the diagnostic tests at admission time (sputum culture and chest radiography). We believe it is important to conduct systematic studies to rule out this disease: high number of samples, Mantoux, even invasive techniques such as bronchoscope or puncture-aspiration (PAAF) of the lesion. Likewise we highlight the significant number of immigrant patients who have been diagnosed with this pathology, but we found a low incidence of resistance to treatment.

Conclusions: The likelihood of success with an admission with suspected tuberculosis is intermediate. Risk factors associated with suspected tuberculosis are alcoholism, homelessness, immigration and HIV. The risk of resistant tuberculosis in our area is low (< 5%).

A-43
AMBULATORY BLOOD PRESSURE MONITORING: ARE VIH PATIENTS MORE HYPERTENSIVE THAN THE GENERAL POPULATION?

M. Romero Jiménez[1], E. Sánchez Ruíz-Granados[1], M. Pérez Tristancho[2], J. Fajardo Picó[2], F. Rivera de los Santos[3], I. Suárez Lozano[2]

[1]Clinical Management Unit of Internal Medicine, [2]Clinical Management Unit of Infectious Diseases. Hospital Infanta Elena. Huelva, Spain. [3]FABIS. Área Hospitalaria Juan Ramón Jiménez. Huelva, Spain.

Objectives: The goal of our survey was to determine the prevalence of hypertension in VIH-patients through clinic blood pressure measurement and ambulatory blood pressure monitoring.

Material and method: We designed a prospective survey with a group of VIH patients from Huelva Provincial Prison, formerly treated by the Infanta Elena Hospital Department of Infectious Diseases in the city of Huelva. Scope of the survey: Huelva Provincial Prison is located in the southwest of Andalusia, Spain. The Infectious Disease Department of the Infanta Elena Hospital in Huelva provides specialized care to VIH patients through the sanitary module located in the penitentiary and the hospital admission module in Infanta Elena Hospital. Patients: Ninety-eight adult VIH patients were gathered from the Provincial Prison of Huelva. Inclusion criteria: VIH-Infected patients over 18 who signed the informed consent to participate in the survey which was approved by the Research Committee Penitentiary Institutions. Exclusion criteria: Patients with secondary hypertension, chronic use of illegal drugs (cocaine or amphetamines), those ones who did not sign the informed consent, those ones with an arm circumference larger than 42 cm (16.53 inches), those ones with atrial fibrillation or those who simply refused to participate in the survey. Blood pressure measurements: According to the recommendations of the European of Cardiology and ESH. The first measurement was carried out after 5 minutes of complete rest. Three pressure measurements were taken every 2 minutes. For ambulatory blood pressure measurement we used a validated and calibrated monitor, Spacelab model 90207.

Results: 98 patients were included in our survey. Ambulatory blood pressure measurement was performed in 72 patients and 26 rejected the procedure. The prevalence of clinical hypertension after a single measurement was 15.3%. The prevalence of clinical hypertension after two measurements, taking the average of 1st and 2nd, was 11.1%. The prevalence of clinical hypertension after three measurements, taking the average 1st, 2nd and 3rd resulted 12.5%. The prevalence of hypertension, taking the average of 2nd and 3rd, the value was 11.1%. The prevalence of hypertension after ABPM was 11.1%. Considering the 1st measurement for the diagnosis of hypertension, there are 36.4% (4/11) of the patients with white coat hypertension and 1.6% (1/61) with masked hypertension. If we consider the average of 1st and 2nd, it decreases to 12.5% (1/8) with white coat hypertension and 1.5% (1/64) with masked hypertension. With the meaning of 1st, 2nd and 3rd white coat prevalence is 11.1% (1/9) and masked hypertension disappears. The patients' average age was 43 years old, 7.1% were women. 28.6% suffered from AIDS. The average level of CD4 was 437 cell/mm^3. 20,973.69 mean viral load. Hepatitis C virus infection was 85.7%.

Discussion: The prevalence of hypertension in VIH-patients is not clearly defined. There are surveys pro and against a higher prevalence of hypertension among these patients. The surveys range from 5.2% to 36%. The prevalence of hypertension in the general population is 30% higher than what we found in our survey.

Conclusions: The estimated prevalence of hypertension by ABPM in VIH patients is 11.1%. Measuring clinic blood pressure three consecutive times and taking the average of 2nd and 3rd measurements avoid masked hypertension and isolated clinical hypertension values.

A-44
HEPATITIS C VIRUS GENOTYPES IN THE HIV-INFECTED PATIENTS

B. Roca, E. Resino, M. Penades, D. Díaz

Department of Internal Medicine. Hospital General, Universitat Jaume I. Castellón, Spain.

Objectives: Genotype is a relevant prognostic factor and a key determinant of treatment in hepatitis C virus (HCV) infection. While subtype, of at least genotype 1, plays a role in resistance to the virus, so it will probably be taken into account in the treatment of HCV infection in the near future. As genotype and subtype prevalence substantially vary among communities, knowledge in this field is necessary to adequately plan management strategies in every region.

Material and method: Cross-sectional study to assess and report prevalence of genotype and subtype of HCV of all patients who were performed those tests in the province of Castellon, Spain, from January 1, 2006 through December 15, 2011. A logistic regression analysis is carried to assess the relationship of basic demographic data with infection with genotype 1 or other genotype of HCV.

Results: A total 1764 patients are included. Mean of age is 43.9 ± 12.4 years; 1266 (71.8%) are male, and 487 (27.6%) are HIV coinfected; 2007 is the year with the largest number of patients included: 367 (20.8% of the total). The result of the test is indeterminate in 185 (10.5%) patients. Of 1579 patients with available result, 1066 (67.5%) have genotype 1, 262 (16.8%) genotype 3 and 176 (11.1%) genotype 4. Of the 1050 patients with genotype 1 in whom virus subtype is determined, 544 (51.8%) have subtype 1b and 487 (46.4%) have subtype 1a, while 19 (1.8%) have mixed subtypes. An association is found between HIV coinfection and HCV infection with genotype other than 1 virus (p = 0.048).

Conclusions: Genotype 1 is less prevalent in the HIV-infected populations than in the HIV-non-infected population.

A-45
RELATIVE BRADICARDIA AS A CLINICAL PATTERN. ANALYSIS OF PREVALENCE AND ETIOLOGICAL SPECTRUM

J. Polo Sabau[1], C. Nogales Nieves[1], D. Nuevo Ejeda[1], C. Hidalgo Collazos[1], P. Atencio[1], E. Reyes Larios[1], I. Mahillo Fernández[2]

[1]Department of Internal Medicine, [2]Department of Epidemiology. Fundación Jiménez Díaz. Madrid, Spain.

Objectives: To know the prevalence of relative bradycardia (RB) among febrile patients attended at the Emergency Department and the causes that lead to this clinical finding.

Material and method: Retrospective review of clinical records of all consecutive patients presenting with fever. RB was considered according to previously published criteria: Age > 13 years or more, temperature > 102 ºF or more, simultaneous measurement of pulse and temperature, normal sinus rhythm, absence of heart-rate-lowering medication and a heart rate > 10 beats per minute below the expected physiological response.

Results: During a six-month period a total of 218 patients (111 females, 107 males) aged 13 years or more and with a body temperature of 102 ºF (38.9 ºC) or more were collected. Mean age was 52.1 years (SD 22.7). Patients had a history of diabetes mellitus in 14.7% of cases, smoking in 29.4%, alcohol consumption in 12.8%, arterial hypertension in 34.9%, HIV infection in 6.9%, use of glucocorticoids in 7.8%, and known heart disease in 15.6%. From total of cases, 109 patients (50%) met criteria for RB. Among patients with RB, an infectious disease was found in 101 cases (92.7%). The main clinical infectious syndromes associated with this condition were genitourinary tract infection (26.6%), non-tuberculous respiratory tract infection (22.0%), gastrointestinal infection (9.2%), skin and soft tissue infection (8.3%), ORL infection (7.3%), viral infection (4.6%), tuberculosis (3.7%), hepatobiliary infection (2.8%), and febrile neutropenia (2.8%). Non-infectious diagnoses were: fever without an overt infectious source (4 cases), drug-induced fever (2), myeloma (1), and alcohol intoxication (1). In 38 cases (34.9%) at least one microorganism was detected either by culture, direct microscopic examination or serologic or genetic techniques. Microbiological agents found were: Escherichia coli (14 cases), coagulase-negative Staphylococcus (6), Mycobacterium tuberculosis (4), Klebsiella pneumoniae (4), Staphylococcus aureus (4), Epstein-Barr virus (2), Cytomegalovirus (2), Streptococcus pneumoniae (2), Shigella sonnei (1), Morganella morganii (1), and Bacteroides spp. (1). There were no differences regarding sex or mean age between patients with and without RB (51.8 and 52.3 years respectively, p = 0.884). As for clinical conditions of patients, only the presence of a previously known heart disease showed a decrease in the likelihood of having RB (32.4% vs 53.3%, p = 0.0389).

Discussion: According to our results, RB is present in half of febrile patients attended at the Emergency Department. In previous reports this finding has been associated with gram-negative intracellular microorganisms, but many other agents can be involved. Although RB is thought to be more frequent in certain infections, such as those produced by Legionella, Chlamydia pneumoniae or Salmonella typhi, it does not seem to be an aid for making presumptive diagnoses in view of the wide spectrum of clinical syndromes and microorganisms found in our study.

Conclusions: In our experience, RB is a frequent clinical finding among febrile patients. The most frequent diagnoses were genitourinary and non-tuberculous respiratory tract infection. Most cases are associated with an infectious disease, but no specific association regarding clinical syndromes or microorganisms could be found. The appearance of this finding is less likely in patients with a prior history of heart disease.

A-46
BACTEREMIA CAUSED BY MULTIRESISTANT MICROORGANISMS: THREE YEARS STUDY

S. Olivera González[1], J. Marco Lattur[2], A. Valdivia Pérez[3], M. Cherner Kevorkian[1], J. Chordá Ribelles[1], M. Jordán Lluch[1], N. Lozano Escortell[1], P. Martín Rico[1]

[1]Department of Internal Medicine, [3]Department of Preventive Medicine. Hospital de Denia. Denia (Alicante), Spain. [2]Department of Internal Medicine. Hospital de Villa-real. Villa-real (Castellón), Spain.

Objectives: Describe the characteristics of bacteremia because of multiresistant pathogens, and factors related to the origin of infection (nosocomial, community-acquired, or health care-associated).

Material and method: 89 patients diagnosed with bacteremia because of multiresistant bacteria (resistance to three or more families of antibiotics), were included in our study. Patients were diagnosed in Hospital of Denia (Alicante), between February 2009 and April 2012. The studied variables were age, gender, length of stay, death, infection risk factors, medical history, hospital unit of admission, isolated germ, and treatment given. Statistical analysis was performed by SPSS 18.0.

Results: There were 72 isolates. The mean age was 68.38 years (range 15-95). 73.6% were male. The isolates were: E. coli extended-spectrum-betalactamase (ESBL) 44.4%, Methicillin-resistant S. aureus (MRSA) 29.2%, K. pneumoniae ESBL 12.5%, *S. marcescens* 9.7%, and P. aeruginosa carbapenem-resistant (carbapenem-R) 4.2%. There were no bacteremia by multiresistant A. baumanni. Hospital units of origin were: Internal Medicine 41.2%, Emergency Room (ER) 22.1%, Intensive Care Unit (ICU) 17.6%, Surgery 8.8%, Urology 5.9%, and Ear-Nose-Throat Unit (ENT), Home Care Services (HCS) and Traumatology 1.5%. Regarding risk factors for infection we observed: catheter insertion 76.1%, urinary catheter 31.3%, previous surgery 34.3%, TPN (total parenteral nutrition) 19.4%, orotracheal intubation (OTI) 25.44%, pacemaker 7.5% and stent 10.4%. Distribution of germs in each unit was: Internal M. (E. *coli* ESBL 53.6%, MRSA 39.3%, K. pneumoniae ESBL 3.6%, S. marcescens 3.6%), ICU (K. pneumoniae ESBL 50%, MRSA 16.7%, S. marcescens 16.7%, E. coli ESBL and P. *aeruginosa* 8.3%), Surgery (P. aeruginosa 33.3%, E. coli ESBL 33.3%, S. marcescens 33.3%), ER (MRSA 40%, E. coli ESBL 46.7%, K. pneumoniae 6.7%, S. marcescens 6.7%), Urology (E. coli ESBL 100%), ENT (S. marcescens 100%), Traumatology (E. coli ESBL 100%), and HCS (MRSA 100%). As for the origin of bacteremia, 46.7% were nosocomial infections, 40% associated with health care, and 13.3% community-adquired bacteremia. Mortality in each of them was 42.9% in the nosocomial origin, and 0% in community and health-care associated infections. As for factors related to the origin of bacteremia, there was a statistically significant relationship with the isolated germ (p < 0.05), admission in the previous 6 months (p < 0.05), long stay at hospital (p < 0.001), and needing of OTI (p < 0.05), unrelated to

the other studied factors. Also there was a statistically significant relationship between the origin of bacteremia and mortality ($p < 0.05$).

Discussion: In our study the Service with a larger number of isolates was Internal Medicine. As in the literature, the most common risk factor in our patients was the vein catheter insertion, followed by urinary catheter and previous surgery. As expected, the most common etiology was nosocomial, followed by health care-associated and community acquired, these last 2 with mortality rate 0%. Risk factors for acquiring this type of infection is the long stay at hospital, admission in the hospital the previous 6 months, and isolated microorganism. It was also observed in our study, a relationship between the risk of infection with K. pneumoniae in the case of OTI, and MRSA in the case of patients who have undergone previous surgery, so we must think of this background to establish appropriate empirical antibiotic treatment.

Conclusions: The most common risk factor for acquisition of infection was venous catheter insertion. The most common cause of bacteremia in our hospital was nosocomial, with the highest mortality, and therefore poor prognosis. OTI is a risk factor for K. pneumoniae infection, and previous surgery for MRSA infection.

A-47
SEVERE LEPTOSPIROSIS IN A DISTRICT HOSPITAL IN THE REGION OF ASTURIAS

P. Martínez García[1], I. de la Iglesia Fanjul[1], M. Villanueva Montes[2], J. Ferreiro Celeiro[1], G. Castaño de las Pozas[2], A. Fernández Pantiga[1], R. Martínez Gutiérrez[1], L. Alcuria Ledo[1]

[1]Department of Internal Medicine, [2]Department of Respiratory Medicine. Hospital San Agustín. Avilés (Asturias), Spain.

Objectives: Describe the clinical and epidemiological characteristics of patients admitted in a district hospital with the diagnosis of leptospirosis between the period of 2003 to 2011.

Material and method: A retrospective and descriptive study of patients admitted in our hospital during the period from 2003 to 2011 with compatible clinical and positive serology for Leptospira IgM by ELISA. Epidemiological data, clinical manifestations, reasons for admission to ICU, APACHE-II (Acute Physiology and Chronic Health Evaluation) score on admission to ICU, treatment, average length of stay and clinical evolution were collected.

Results: 11 cases of leptospirosis were identified, 9 males (82%) and 2 women (18%). The median age was 51 years (29-72). There were risk factors in 63.63% of cases: 4 patients lived in rural areas in contact with animals, 1 suffered a rat bite, 1 was a miner and another in contact with residual waters. None of the cases had recently travelled abroad or practiced watersports. 5 cases appeared in summer, whilst 2 in each of the other seasons. The average duration of symptoms before going to the Hospital was 6.8 days. The 63.6% of patients (7) were admitted to the Internal Medicine ward, 18.2% (2) to ICU, 1 in Nephrology and 1 was followed up in the Internal Medicine outpatient clinic. The 81.8% (9) were cases of Weil syndrome and only 18.2% (2) as anicteric leptospirosis. The 9 cases of Weil syndrome, 8 were admitted to ICU and the other to Nephrology. The most frequent clinical manifestations were: fever (91%), myalgia (64%), haemorrhage (64%), jaundice (64%), abdominal pain (45.45%), headache (34%), chills (28%), cough (28%), rash (28%), diarrhea (18%), splenomegaly (18%), dyspnea (18%), chest pain (18%), nausea and vomiting (18%), and pharyngitis (9%). The main reasons for ICU admission were the coexistence of SIRS, renal failure and hypotension. On ICU admission the mean APACHE-II score was 23 (9-56) which corresponds to an average of 40% predicted mortality (range 9.9-99). On ICU admission 6 patients presented severe sepsis and 2 septic shock. Hemorrhagic manifestations occurred in 72.7% of the cases of leptospirosis (8), in the form of conjunctival, gastrointestinal, urinary, epistaxis, petequial injuries, hemoptysis, alveolar hemorrhage and a case of hemorrhagic shock by hemoperitoneum secondary to spontaneous splenic rupture. Hepatorenal involvement in 72.7% (8) and 4 associated oliguria, were 2 of them precised extrarrenal filtration techniques, and all patients recovered their kidney function on discharge. Pulmonary manifestations in 36.4% (4), such as cough, chest pain, massive hemoptysis with alveolar hemorrhage and respiratory distress with severe respiratory insufficiency (3 required invasive mechanical ventilation, 1 traqueostomy). There was a case of acalculous cholecystitis. 7 patients were treated with ceftriaxone ant 2 with Penicillin G. 5 patients received vasoactive drugs. The average length of hospital stay was 18 days and UCI 13 days. All patients survived.

Discussion: Anicteric leptospirosis is the most common form, however in our study there were fewer cases, probably underdiagnosed due to favourable evolution and self-limiting. As in other studies, the disease was more common in males, and influenced by seasonal changes and rural situation. It is more common in temperate or tropical climates, being also an occupational and recreational hazard for people who work outdoors, with animals or in areas with contaminated water. In our study no patients informed of overseas visits, so it is important not to exclude leptospirosis in the differential diagnosis.

Conclusions: 1. Leptospirosis is not uncommon in our environment. 2. The majority of the cases diagnosed were the more severe form of leptospirosis. 3. It is important to include it in the differential diagnosis of a febrile syndrome with severe sepsis or organ failure. 4. Generally it has a good prognosis with early diagnosis and treatment.

A-48
RETROSPECTIVE ANALYSIS OF CEREBRAL ABSCESSES

F. Olgado Ferrero[1], A. Calvo Cano[1], O. González Casas[1], M. González Cordero[3], N. Nogales Moreno[2], A. Vera Tomé[2], F. Rodríguez Vidigal[2], A. Muñoz Sanz[2]

[1]Department of Internal Medicine, [3]Department of Medical Oncology, [2]Department of Infectious Pathology. Complejo Hospitalario Universitario de Badajoz. Badajoz, Spain.

Objectives: Description of the epidemiology, clinical, and microbiological characteristics of cerebral abscesses (CA) attended at the Infectious Diseases Unit of a third level hospital.

Material and method: This is a retrospective study of the patients diagnosed of CA from January 1990 to March 2012. We analyzed the personal data, CA location, pathogenesis, associated infections, causative agents, treatment, and outcome.

Results: The series is composed of 82 patients (57 males and 25 females) with a mean age of 49.4 ± 20.4 years (range, 10-90). In 80.5% of the cases the clinical presentation was as a unique CA, while in 19.5% there were two or more lesions. Location and pathogenesis: The most common locations were frontal (49.3%) and parietal lobes (34.7%). The most probable mechanisms of spreading were: traumatic/surgical, 30 (36.6%), contiguous focus, 26 (31.7%), hematogenous, 17 (20.7%), and cryptogenic 9 (11%). Associated infections: Sinusitis was found in 24.4% of patients, otomastoiditis in 8.5%, meningitis in 17.1%, valvular endocarditis in 9.8%, and pneumonia in 11%. Patients with sinusitis were significantly younger compared with those without sinus involvement (32.1 ± 14.6 vs 54.9 ± 19.0 years, $p = 0.0001$). By other way, patients with post-surgical CA were also older than those without surgery (61.6 ± 16.0 vs 42.7 ± 19.6 years, $p = 0.0001$). Furthermore, they had an isolated CA more frequently than non surgical patients (96.5% vs 71.7%, $p = 0.007$). Microbiological diagnoses: Blood cultures were positive only in 14 cases (17.1%) but final microbiological diagnoses were reached in 66 of them (80.5%). Overall, Streptococcus spp, anaerobic or mixed flora were identified in 29 patients (35.4%),

Staphylococcus. aureus or Staph. coagulase-negative in 24 (29.3%), gram-negative bacilli in 8 (9.8%), and Nocardia spp in 4 (4.9%). In 16 patients (19.5%) the causative agent could not be identified. Furthermore, Staphylococcus spp (Staph. aureus and Staph. coagulase negative) were isolated in 78.3% of post-surgical CA, while Streptococcus spp, anaerobic or mixed infections were isolated in 71% of non post-surgical abscesses (p = 0.001). Treatment and Outcome: Ninety-two percent of patients received surgical treatment plus several different antimicrobials. Only 3 (3.6%) patients died. The mortality of patients with endocarditis is higher than those with no endocarditis (25% vs 1.4%, p = 0.024).

Discussion: Our experience, in terms of age, sex, performance of blood cultures, location and etiology are similar to that described in the international literature. In a high percentage of cases we reached an etiologic diagnosis, but blood cultures have a scarce diagnostic efficacy. We can discriminate two large groups of CA: post-surgery, in older people with a clear predominance of Staphylococcus spp, and those associated with sinusitis or other infections, with a lower age and more prevalence of Streptococcus/anaerobic. A majority of the CA required surgical (and antimicrobial) treatment. The observed mortality is lower than the reported in other studies. The presence of endocarditis is usually associated with more severity.

Conclusions: 1. In our area, post-surgical CA is more frequent in old people. 2. The most frequent form of clinical presentation is usually as a solitary cerebral lesion. 3. Staphylococcus spp is the main etiology. Sinusitis is usually associated with younger age and CA is produced mainly by Streptococcus/anaerobic. 4. Finally, CA global mortality is low, but the patients with concomitant endocarditis have an increased risk of death.

A-50
NINE YEARS OF TUBERCULOSIS: A DESCRIPTIVE STUDY COMPARING IMMIGRANTS AND NATIVE POPULATION IN A MAJORCAN HOSPITAL

J. González Moreno[1], M. García Gasalla[1], A. Serrano[1], C. Cifuentes[1], I. Mir[2], M. Pérez-Seco[3], A. Pareja[4], A. Payeras[1]

[1]Department of Internal Medicine, [2]Department of Pneumology, [3]Department of Microbiology, [4]Department of Epidemiology. Hospital Son Llàtzer. Illes Balears, Spain.

Objectives: To analize the clinical differences of tuberculosis (TBC) between immigrants and native population.

Material and method: We reviewed retrospectively all cases of tuberculosis diagnosed in Son Llàtzer Hospital in Palma de Mallorca between January 2003 and December 2011. We collected demographic and clinical data. For statistical analysis we used SPSS PASW Statistics 18® and Epidat 3.1.

Results: A total of 500 patients were diagnosed of TBC in the time of study. Of these 199 (39.8%) were immigrants. Between immigrants most were Bolivian (29.64%), Senegalese (11.05%) and Nigerian (10.05%). Both native and immigrant cases of TBC trend to increase in time, even though such increase seems to be more pronounced in non-native population. Comparing both groups we have found that immigrants were significantly younger and they had less male predominance. They were also less smokers, alcoholics and parenteral drugs abusers (PDA). Finally they used less immunosuppressive drugs and they had more positive tuberculin test (TT) and positive bacilloscopy results. No differences in treatment resistance, treatment adherence and outcomes were found between groups.

Discussion: Tuberculosis between immigration and native population have been previously compared. Although drug resistance is described to be more frequent in foreign-born population, we found not differences between groups, anyway immigrants were initially treated more frequently with four drugs. They have been considered to lose follow up more frequently that natives, which we have not seen in our population. Immigration has an important impact in the number of tuberculosis patients while native patients also trends to increase in our population. That means that globally the incidence of tuberculosis is growing in our area, unlike described in other studies. In the current contest of financial crisis, the measures applied to health policy in our country don't allow illegal immigrants to access to the public health system. If the previously described trend continues in time, the consequences of such measures can be catastrophic for all the population.

Conclusions: In our population significant differences in TBC resistance, treatment adherence and related mortality have not been found between immigrants and native, so their management should not be different. The number of TBC cases is increasing not only between immigrants but also in native population and current changes in health policy may have serious consequences.

A-52
CLOSTRIDIUM DIFFICILE ASSOCIATED DIARRHEA'S IN AN INTERNAL MEDICINE WARD

S. Moreira da Silva, M. Carvalho, A. Gomes

Department of Internal Medicine. Centro Hospitalar de S. João. Porto, Portugal.

Objectives: Clostridium difficile associated diarrhea's (CDAD) incidence has increased in the last decade. Antibiotic use is the most widely recognized risk factor, closely followed by hospitalization and old age. The goal of this study was to describe the incidence and characteristics of CDAD in hospitalized patients in an internal medicine ward.

Material and method: A retrospective analysis was made. An electronic coding system was used to select inpatients with a diagnosis of "intestinal infection by Clostridium difficile or colitis" or "infectious enteritis and gastroenteritis", between 2007 and 2011; the data was collected from the patients' electronic file.

Results: The selection criteria retrieved 92 cases, 55 of whom had one positive diagnostic test: toxin assays or endoscopy. The average age was 73 years old (range 17-90) and 67% were females. Previous exposure to antibiotics was ascertained in 71% of patients, of which 64% were beta-lactam antibiotics and 18% were quinolones. 19 patients had previous hospital admission in the last 30 days. The toxin assay was positive in 65% and colonoscopy was positive in 45% of cases. Regarding treatment, 56% were treated with metronidazole in monotherapy, 9% with vancomycin in monotherapy and 9% with association of both antibiotics. The average duration of therapy was 11 days. 20% of patients had to be admitted to intensive/intermediate care units due to complications. There were 4 relapses, 3 of which had been treated with metronidazole in monotherapy. In all, 8 patients died during their hospitalization. An annual mean incidence of CDAD of 172/100,000 hospitalizations was obtained; [159/100,000 in 2007 and 256/100,000 in 2011].

Discussion: The incidence of CDAD in the elderly is higher, and the majority of patients were previously exposed to antibiotics, mainly beta-lactams. The main method of diagnosis used was the toxin assay. Nearly half of the patients were treated with metronidazole in monotherapy, and the relapses occurred more frequently with this treatment. Admission to intensive/intermediate care units were needed in a fifth of the patients, an important marker of the seriousness of this condition.

Conclusions: We observed an increased incidence of CDAD in 2011. Probably the criteria use of large spectrum antibiotics will avoid a large number of CDAD and its complications. We believe that early treatment with vancomycin in severe CDAD will improve the outcome of patients.

A-53
EPIDEMIOLOGICAL DIFFERENCES BETWEEN INFLUENZA A VIRUS SUBTYPE H1N1 AND INFLUENZA A VIRUS SUBTYPE H3N1 AMONG HOSPITALIZED PATIENTS IN THE COMPLEJO ASISTENCIAL UNIVERSITARIO DE BURGOS

A. Blanco[1], R. Cabo[1], C. Dueñas[1], S. Molinero[1], G. Megías[2], C. Labayru[2], V. Portillo[1], E. Salazar[1]

[1]Department of Internal Medicine, [2]Department of Microbiology. Complejo Asistencial de Burgos. Burgos, Spain.

Objectives: To analyze the demographic and comorbidity differences among patients affected by influenza A virus subtypes H1N1 (season 2010-2011) and H3N1 (season 2011-2012).

Material and method: In this retrospective cohort study we included 107 hospitalized patients attended in the Internal Medicine and the Pneumology department in a tertiary care hospital during 2010 and 2012. Two groups were compared: the first one included 30 patients affected by influenza A virus subtype H1N1 attended between October 2010 and April 2011, and the second one consists of 77 patients affected by influenza A virus subtype H3N1 attended between October 2011 and April 2012. The diagnosis of influenza was confirmed using the PCR technique both in nasopharyngeal aspiration and throat culture, and serology. Demographic data and comorbidities were also recorded and compared between both groups.

Results: Men and women were equally distributed in both groups (50%). Patients infected by subtype H3N1 were younger (mean age 47.5 years) than those infected by H1N1 were (mean age 68.8 years). Comorbidity analysis included several cardiovascular risk factors that were more prevalent in subtype H3N1 such as hypertension (54.5% vs 30%), diabetes mellitus (24.7% vs 13%) and dyslipidemia (27.3% vs 20%). Smoking was more frequent in subtype H1N1 (36.7% vs 20.8%). Other diseases analyzed such as COPD and congestive heart failure were also more frequent in subtype H3N1 than in H1N1 (40.3% vs 13%) and (27.3% vs 10%) respectively. Asthma was present in a 20% in both groups.

Discussion: Different outbreaks of influenza arise every year. This epidemiologic descriptive study reveals the changing nature of the antigenic properties of influenza viruses. Their subsequent expansion depends upon numerous factors. The morbidity caused by influenza in the general population is substantial. Increased rates of morbidity and mortality occur in older patients and in those with underlying comorbidities. In our study, we have analyzed the epidemiological differences, and we have found a diagnostic age noticeably higher in subtype A H3N1, associated with an increasing comorbidity in these patients.

Conclusions: Subtype H3N1 seems to affect to older population and it is associated with an increase in comorbidity. Age is a preliminary factor regarding the subtype virus which causes the infection.

A-54
RISK FACTORS ASSOCIATED WITH MORTALITY AND HOSPITAL READMISSION IN PATIENTS WITH ESBL-PRODUCING BACTERIA BLOODSTREAM INFECTIONS

E. Perianes-Díaz[1], I. Novo-Veleiro[1], K. Solís-Díaz[1], A. Prolo-Acosta[1], I. García-García[2], G. Alonso-Claudio[1]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital Universitario de Salamanca. Hospital Clínico. Salamanca, Spain.

Objectives: The aim of the present study was, on the one hand, to evaluate the incidence of ESBL-producing bacteria bloodstream infections in our hospital and, on the other hand, to analyze risk factors associated with in- hospital and six-month mortality, as well as with readmission in patients admitted for these infections.

Material and method: We conducted a forty-month retrospective cohort study (January of 2008 to April of 2011) using culture databases from Microbiology Service of our hospital (University Hospital of Salamanca) to identify all ESBL-producing bacteria isolated on bloodstream cultures during the study period. We collected social, epidemiological, clinical and analytical data from medical history of each patient. A descriptive study was performed analyzing differences between infections caused by Escherichia coli or Klebsiella pneumoniae. We also analyzed factors associated with in-hospital and six-month mortality. For quantitative variables comparison we used the Student´s t test when two groups were compared and the ANOVA test when more than two groups were compared. For qualitative variables comparison we used the Chi-square test, using Fisher´s exact test when expected frequency was less than 5. SPSS statistical program version 18 was used.

Results: 68 patients were included, 45 (66%) of them were men and the average age was 71.3 (SD = 20.3) years. The average score obtained by applying the Charlson´s index was 3.6 (SD = 2.3) points. The number of cases increased from 13 during 2008 to 24 in 2010. Escherichia coli caused 73.5% of bloodstream infections and Klebsiella pneumoniae was responsible of 26.5% of them. Different risk factors were associated to infections due to each kind of bacteria, urinary tract was the most common infection origin for E. coli infections (47%) and abdominal origin was the most common for K. pneumoniae infections (39%). K. pneumoniae was more frequent on critically ill patients than E. coli (33% vs 4%, p = 0.001) and E. coli healthcare associated infections were more common (50% vs 39%, p = 0.026), none of the K. pneumoniae infections had a community origin. The main risk factor associated to in-hospital mortality was bladder catheterization at admission (p = 0.013). Immunosuppression, neoplasms and chemotherapy were the main statistically significant associated factors to six-month mortality (p < 0.05). The same factors and also a higher score on Charlson's index and previous antibiotic treatment were the main risk factors associated with readmission during the six month period after discharge (p < 0.05).

Discussion: Several studies have shown that immunosuppression and neoplasm are risk factors associated with mortality due to ESBL-producing bacteria bloodstream infections. Appropriate initial antibiotic treatment seems not to increase mortality in these infections, as our study confirms. Previous studies identified venous catheterization and intubation as risk factors associated with short term mortality, by contrast, we find only one factor associated (bladder catheterization). Risk factors for readmission have been poorly studied until now, the present study identifies immunosuppression, neoplasias, comorbidity and previous antibiotic treatment as significant factors in this sense.

Conclusions: ESBL-producing bacteria bloodstream infections incidence is increasing in our healthcare area. Invasive procedures like bladder catheterizations are risk factors associated with higher mortality due this kind of infections. Immunosuppression, neoplasms and chemotherapy are the main risk factors associated with higher six-month mortality and readmission in these patients.

A-56
ASSOCIATION OF TUBERCULOSIS AND LYMPHOMA: A RETROSPECTIVE STUDY FROM 1994 TO 2010

A. Rodríguez Álvarez[1], L. Rey González[1], E. Seco Hernández[1], M. Iglesias Fernández[2], I. Fernández Regal[1], V. Pérez Carral[1], P. López-Mato[1], A. Chamorro Fernández[1]

[1]Department of Internal Medicine, [2]Department of Hematology. Complejo Hospitalario Universitario Ourense. Ourense, Spain.

Objectives: The prevalence of tuberculosis (TB) in Galicia (a region in the northwest of Spain) exceeds the national and European averages. TB may be associated with lymphoma, before, during or

Table 1 (A-56). Summary of the most relevant results

Sex	50% V 50% M	Location of tuberculosis	
Age at diagnosis of lymphoma	72.58 (41-87)	Pulmonary	50%
Months of each diagnostic	20.42 (0-84)	Extrapulmonary	58.3%
Mortality	41.7%	Disseminated	8.3%
Pronostic markers of lymphoma		Diagnosis of tuberculosis	
Low albumin	41.7%	BAAR	33.3%
B2 microglobulin high	50%	Lowenstein culture	75%
Elevated ESR	66.7%	PPD +	16.7%
Anemia	41.7%	Granulomas	16.7%
Elevated LDH	25%	PCR	8.3%
Lymphoma Treatment		TB Treatment	
Treatment with Rituximab	33.3%	3 drugs	66.7%
Corticosteroid	91.7%	4 drugs	25%
Transplant MO	0%		

after this. Although there are cases series associating tuberculosis and hematological diseases in general, we have not found case series of this association with lymphoma specifically. The aim of this study is to evaluate epidemiological, clinical, diagnostic and therapeutic characteristics in diagnosed cases of tuberculosis and lymphoma.

Material and method: A retrospective study of 12 stories between 1994 and 2010, with tuberculosis and lymphoma diagnosis, was made. Diagnosis of tuberculosis was defined as: Ziehl-Nielsen staining, culture Lowenstein, noncaseating granulomas or PCR positive results. Diagnosis of lymphoma was defined as pathological features in tissues.

Results: Between the most relevant results, we describe the concurrent presentation in the diagnosis (50%), lymphoma previous to TB (25%) and TB previous to lymphoma (25%). It was remarkable, the frequency of extrapulmonary tuberculosis (58.3%), Lowenstein culture positivity (75%) and the 100% of non-Hodgkin lymphomas (3 large cell B, 2 gastric MALT lymphoma and 2 immunocytomas). There was only one HIV-positive patient. Mortality was 41.7%, in 2 cases driven by tuberculosis. Other relevant results see Table 1.

Conclusions: Our results suggest a high temporal coincidence in the diagnosis of both conditions (50%) but there are few recorded cases, as in the available literature, where we found only case reports.

A-57
LIVER ABSCESS: AN EXTENDED EXPERIENCE

L. Mao Martín[1], M. Martín Azcarate[1], L. Cabeza Osorio[2], L. Pérez Díaz-Guerra[1], N. Pérez Méndez[1], D. García Lorenzo[2], R. Serrano Heranz[2]

[1]Emergency Service, [2]Department of Internal Medicine. Henares Hospital. Coslada (Madrid), Spain.

Objectives: To learn about the clinical characteristics of liver abscess (LA) diagnosed in patients in our hospital.

Material and method: The medical records of patients diagnosed with LA are reviewed in the Henares Hospital (Coslada, Madrid) in the period since its opening to the present (2008-2012), expanding the experience on the previous review presented at the XXXII National Congress of Internal Medicine, 2011.

Results: It includes a total of 13 patients (8 men and 5 women) with a median age of 64. The cryptogenic origin is set to a total of 9 cases (69%); the other four to urinary sepsis, fibrosing chronic pancreatitis, ulcerative colitis with immunosuppressive medical treatment and advanced/infiltrating colon neoplasia. Among the clinical manifestations we can emphasize that up to 9 patients had fever or low grade fever (69%), 11 concerned right hypochondrium pain and/or epigastrium (85%). Other symptoms were nausea in 4 patients (31%), constitutional syndrome in 3 patients (23%), or diarrhea in 2 patients (15%). From this series of cases 2 patients had 2 or more abscesses (15%) and in 10 of the total patients (77%) the size was greater than 3 cm. The main antibiotic therapy was a Carbapenem in 5 patients (38%), followed by Piperacillin Tazobactam in 3 patients (23%). Other invasive procedures were complementary to antibiotic treatment: surgical drainage in one patient and percutaneous in 7 patients (54%). A total of 9 patients had microbiological isolation, monomicrobiano in 31% of cases (Morganella morganii, Streptococcus viridans, Klebsiella pneumoniae, and Peptostreptococcus) and polymicrobial in 38% (Including some germs to highlight as Gemella morbillorum, Enterococcus faecium and avium, Streptococcus viridans and anginosus or Klebsiella oxytoca). As serious complications noted in this case series, 5 patients (38%) suffered from septic shock in their follow up, not of initial presentation. Only two patients relapsed at discharge. No mortality attributable to LA in the cases presented.

Discussion: The LA is an entity of low incidence in the hospital. According to other series of patients, the LA is predominant in males and its onset occurs during the 5th and 6th decade of life. Despite the increase in submitted cases, it continues the high proportion of cases whose etiology is cryptogenic. Among the personal background only six patients had diabetes mellitus and 1 of them enolic habit to consider; in this series we include the importance of the diseases treated with biologic agents (anti-TNF) and immunosuppressants. It is noteworthy that the classic triad of presentation (fever/low-grade fever, pain in the epigastric/right hypochondrium and jaundice) has low expressiveness. Regarding the etiology from microbiological point of view, new provided cases are more likely to be polymicrobial although there is no history of recent antibiotic takes or differences in comorbidities. Although the mortality rates are estimated at 2-30% in the largest series, there were no death cases in our series. In the extended series the development of septic shock has been more frequent (previous series [12.5%], compared to the current [80%]).

Conclusions: LA remains a diagnostic and therapeutic challenge for doctors, especially in the Emergency Services, place of admission of these patients. High suspicion and appropriate diagnostic tests are essential pillars in order to establish early empiric antibiotic therapy in hopes of percutaneous drainage

techniques if deemed appropriate, to improve the vital prognosis of the patient. The use of new biological therapies can lead us to new risk groups whose early identification may be crucial for the evolution of these patients.

A-58
BACTEREMIAS CAUSED BY ESBL-PRODUCING MICROORGANISMS IN THE LAST TWO YEARS IN THE COMPLEJO ASISTENCIAL DE BURGOS

V. Portillo[1], E. Salazar-Thieroldt[1], S. Molinero[1], A. Blanco[1], R. Cabo[1], M. Mantecón[2], E. Ojeda[2], J. Boado[1]

[1]Department of Internal Medicine, [2]Department of Microbiology, Complejo Asistencial de Burgos. Burgos, Spain.

Objectives: To analyze the clinical and demographical data of patients who presented positive blood cultures for ESBL-producing enterobacteriaceae and to register the resistance pattern of the isolates and the hospital death rates of these patients.

Material and method: Retrospective study that includes patients admitted in the Complejo Asistencial de Burgos in the years 2010 and 2011 who presented positive cultures for ESBL-producing microorganisms. 30 patients were included. Age, sex, infectious focus, in-hospital stay, department in which they were admitted, infection acquisition site (nosocomial, community-acquired or health care-related) and death rates were registered. Health care-related acquisition was assigned to patients under hemodialysis, under home hospitalization or those who reside in social health centers. Finally, the sensitivity pattern of all the isolates was registered.

Results: The ESBL-producing microorganisms isolated in the blood cultures were E. coli in 28 cases and K. pneumoniae in 2 cases. The infectious focus was urinary in 20 cases (66.66%), respiratory in 3 (10%) cases and abdominal in other 3 (10%) cases. The number of male and female patients was the same. The average age of the patients was 76.56 years (range 52-93 years), and most of them were admitted to the medical wards (66.66%). The infections were classified into nosocomial or health care-related acquisition in 28 patients (93.33%), and the average in-hospital stay was 12.46 days. We only found two cases (6.66%) of strictly community acquired infection. 80% of the isolated strains were not quinolone-sensitive, 66.66% of the strains were Trimethoprim/Sulfamethoxazole resistant and 29 isolated were sensitive to one of the tested aminoglycosides. Out of the 30 analyzed patients, 8 died during the hospitalization in which the bacteremia was acquired (26.66% of the total).

Discussion: Extended-spectrum beta-lactamases are enzymes generally mediated by plasmids and produced by Gram-negative bacteria. They are able to hydrolyze expanded-spectrum cephalosporins and monobactams. These enzymes have been described in E. coli, K. pneumoniae and, to a lesser extent, in other enterobacteriaceae. The first ESBL-producing microorganisms were described in 1983. They hinder the treatment of the infections in which they take place because, usually, the microorganisms that produce them are also resistant to other groups of antibiotics (quinolones or aminoglycosides). In the past, most of the ESBL-producing enterobacteriaceae were K. pneumoniae, and they are associated with epidemic nosocomial outbreaks, frequently in the Intensive Care Units. However, this epidemiological profile has changed with time.

Conclusions: In our patients, the infection mainly had an urinary origin and was acquired in-hospital or for health-care related causes. The infectious symptoms were mainly observed in the medical wards of our center. The main ESBL-producing enterobacteriaceae were E. coli. Our patients presented high in-hospital death rates.

A-59
Q FEVER IN LEÓN: A REPORT OF 32 CASES

P. Dios Díez[1], A. Muela Molinero[1], S. García Escudero[1], E. Castelar[1], C. Sardiña González[1], C. Ferrero Sanz[1], I. Fernández Natal[2], E. Valverde[2]

[1]Department of Internal Medicine, [2]Department of Microbiology. Complejo Asistencial de León. León, Spain.

Objectives: Incidence and characteristics of Q fever in our health area. Evaluate the management of this disease that we have done in last 10 years.

Material and method: Retrospective study, which lists all cases with positive Coxiella burnetii serology in the health area of Leon from 2001 to 2011. Data were provided by the microbiology and coding services. We reviewed medical reports, collecting epidemiological, clinical, biochemical, microbiological, treatment and outcome data. We performed a descriptive statistical analysis.

Results: 32 cases with a mean age of 49 ± 19.4 years. 88.2% were male, and have a Charlson comorbidity index of 1 ± 1.57. 75% were diagnosed in the spring and summer. The most common symptom was fever, which affected 97% of the patients studied, followed by others such as musculoskeletal pain (41.2%), cough (29.4%) or dyspnea (14.7%). The most prevalent clinical form was pneumonia, followed by febrile syndrome (40.6%) and hepatitis (9%). Only one case of endorcarditis was described. Diagnosis was made in all cases by determination of acute Coxiella burnetii serology (82%). 24 patients were treated with doxycycline, but in half the cases with inadequate duration (less than 15 days 46%). 21.8% of patients didn't receive any specific antibiotic. From the point of view of evolution, most of the patients had a favourable course, although 2 had recurrent febrile episodes.

Discussion: Q fever is an infrequent infectious disease, caused by Coxiella burnetii. It is usually under diagnosed, because of self-limited forms. It is directly related to milk consumption and contact with contaminated aerosols from domestic animals, so it is more frequent in spring and summer, as was seen in our study. Most patients have epidemiologic risk factors justifying the infection, and live in rural areas, which do not differ from other previous studies in different regions of Spain. The clinical presentation is highly variable. In our study, respiratory forms were the most important, which is consistent with other publications, where we can appreciate that pneumonia is the most common form in the north of Spain. Treatment of patients with Q fever is irregular, and sometimes unnecessary, and many were treated with inappropriate antibiotics, and sometimes not necessary follow-up. This occurs in our study, where nearly half the patients received less than fifteen days treatment.

Conclusions: Q fever is an infectious disease with low incidence in our country, and its associated with animal contact. The most frequent clinical presentation is pneumonia. It has a favourable outcome even without treatment. In our hospital its management is not appropriate.

A-60
SPONDYLODISCITIS – AN 11-YEAR STUDY

P. Correia Azevedo[1], T. Judas[1], A. Gomes[2], T. Nunes Da Silva[3], J. Namora[1]

[1]Department of Internal Medicine, [2]Department of Infectious Diseases, [3]Department of Endocrinology. Hospital García de Orta. Almada, Portugal.

Objectives: Spondylodiscitis is an inflammation of the intervertebral disc related to an underlying infection, usually associated with vertebral osteomyelitis. Clinical features are frequently

nonspecific implying a delay in diagnosis. In elderly, complaints of spinal degenerative osteoarthrosis and osteoporotic vertebral fractures are a confounding factors. As it is important an early diagnosis of this pathology, the detection of the pathogenic agent and the choice of a correct therapy, in order to decrease morbidity and mortality, the authors decided to study the patients admitted in an Internal Medicine Department.

Material and method: Retrospective analysis of patients' records, who had been admitted with spondylodiscitis in the last 11 years. We studied predisposing factors and associated diseases; clinical, laboratorial and radiological changes; therapeutics and outcome.

Results: We analysed 15 patients (8 women), average age 65.5 years. The most frequently associated pathologies were osteoarticular (4), endovenous toxicophilia (3), recent sepsis (3), urinary tract infection (2), tuberculosis in the past (2) and diabetes (2). Nine patients presented with functional disability, 5 had local pain, in 4 positive Lasègue sign was detected, in 3 a heart murmur was present and in 1 a paravertebral mass was palpable. Laboratory findings revealed anaemia in 12 patients, mean reactive C protein was 9 mg/dL and mean erythrocyte sedimentation rate was 92.5 mm in the 1st hour. Spinal magnetic resonance confirmed the diagnosis in 13 patients. Blood cultures were performed in 13 patients (positive in 4, Gram-positive agents), needle biopsy in 11 (positive in 2) and 1 patient was submitted to open biopsy. Urine cultures were positive in 3 patients. Echocardiogram was performed in 4 and signs of endocarditis were detected in 2. Concerning the treatment, 7 patients were treated empirically (average duration 134.9 days, median 55 days) and 7 patients with specific therapy (average duration 92.3 days, median 45 days); in 1 case the treatment was not documented. Regarding the outcome 7 patients were cured, 5 presented with minor neurologic deficits, 1 relapsed and 2 patients died, 1 death related to Spondylodiscitis.

Discussion: The reduced statistical sample provided limited data. However, the clinical and laboratorial changes, as well as the magnetic resonance diagnostic accuracy were similar to the findings in literature. Blood cultures and needle biopsies rendered fewer positive results. Endocarditis was investigated in selected patients, such as infections due to Gram-positive organisms, positive blood cultures and predisposing heart conditions. Concerning therapy, only 2 patients had treatment duration lower than recommended.

Conclusions: Spondylodiscitis is an infrequent diagnosis in an Internal Medicine Department. Back pain complaints should alert for the possibility of this pathology. Efforts should be done in order to obtain microbiological cultures in suspected cases and infectious endocarditis should be investigated in adequate settings. However, treatment was adequate and the majority of patients had a good outcome.

A-61
INCIDENCE OF MARSA IN MURCIA (VEGA ALTA DEL SEGURA)

S. Ruiz García, D. García Noguera, J. Navarro Fuentes, A. Martínez Blázquez

Department of Internal Medicine. Fundación Hospital de Cieza. Cieza (Murcia), Spain.

Objectives: In our hospital (de la Vega Lorenzo Guirao) we are taking a register about the incidence of MARSA (methicillin-resistant staphylococcus aureus) since 2005. With this analysis we are controlling changes occurred in last year in our population in order to set up control ways. Our patients belong to three towns: Cieza, Abarán and Blanca, with nearly 55.000 habitants and with three nursing home.

Material and method: We use SELENE as informatic tool. This intranet let us to access to medical histories of patients and the selection of them if they have a positive culture in nasal samples. In the same way we can know if our trying of eradication of bacteria is being useful.

Results: Incidence registered of MARSA in our hospital is always above our indicator (0.25) since we are measuring data (2005-2011). Last year (2011) we had 0.4 × 1,000 stays, more or less the same rate that years before. We analysed the incidence for medical or surgical services and we can observe than the meanly proportion of cases occur in internal medicine. In the same way, the percentage of methicillin-resistant in the Staphylococcus isolated in culture have been progressively increasing in the last year until present 60% (2011).

Discussion: MARSA is a big problem worldwide, and, of course, in our region, probably for the important amount of ancients and nursing home that we have. With the analysis of this data we can understand that we have to establish control measures in order to try to stop this epidemic. In this discussion we analysed the different ways that are described and we are using.

Conclusions: With this study we try to transmit that is important to know with is the rate of MARSA in our hospitals as well as our average of culture isolation of this bacteria for trying establish control ways.

A-62
COMMUNITY ACQUIRED PNEUMONIA: A SINGLE-CENTER RETROSPECTIVE STUDY OF HOSPITALIZED PATIENTS DURING A 12 MONTH PERIOD

R. Pereira[1], P. Russo[1], C. Torre[2], C. Patricio[1], I. Vendrell[1], F. Silva[1], A. Estriga[1], A. Castro[1]

[1]Department of Internal Medicine, [3]Hospital Santo António dos Capuchos, Centro Hospitalar Lisboa Central, Portugal. [2]Faculdade de Ciências Médicas. Universidade Nova de Lisboa.

Objectives: The authors studied the patient population admitted in Central Hospital Santo António dos Capuchos with the diagnosis of Community Acquired Pneumonia (CAP) during a 12 month period, between January 1st 2010 and December 31st 2010. This study analyses patient demography, in-hospital mortality and CAP etiology. Other clinical, laboratorial and prognostic data was collected for further analyses.

Material and method: We retrospectively reviewed all cases of Pneumonia (defined as diagnosis coding ICD-9: Pneumonia And Influenza, 480-488) admitted in our hospital during 2010 and selected all patients who presented at the Emergency Department with clinical and radiographic de-novo evidence of CAP, as defined by the British Thoracic Society (in Thorax, 2009(64) Supl. III). Data was collected from digital records. The following parameters were analysed: gender, age, immunosupression (defined as previous chemotherapy or radiotherapy, HIV infection, oral steroid treatment or asplenia), length of hospitalization, in-hospital outcome, CAP etiology. Data was analysed using SPSS v.17.

Results: The number of all-cause Pneumonia diagnosis during the study period was 688 of which 334 hospital admissions corresponded to CAP, representing 3.40% of all hospital admission (n = 9,834). Mean age was 68.64 ± 19.49 years; male patients represented 57.80% (mean age 65.39 ± 19.13 years, correspondent female mean age 73.09 ± 19.16 years). Median hospitalization time was 8 days (range 1-109). Twenty percent (n = 60) of the patients had had previous hospitalization in the last 90 days. Immunosupression was present in 24.25% (n = 81) of our study population. Overall in-hospital mortality rate was 23.35% (n = 78) with a mean age 77.79 ± 17.15 years, versus hospital discharged patients mean age of

65.85 ± 19.33 years. Patients sixty-five years or older (≥ 65y) represented 63.77% (n = 213) and had an in-hospital mortality of 30.52% (n = 65); those ≥ 80y represented 33.50% (n = 112) and had an in-hospital mortality of 40.18% (n = 45). Of the deceased patients 83.33% were ≥ 65y. CAP etiology was established in 10.78% (n = 36) of patients. Streptococci was found in 41.67% of cases (n = 15), Influenza with pneumonia in 19.44% (n = 7), Klebsiella pneumoniae 8.33% (n = 3), Aspergillus 8.33% (n = 3), Mycoplasma pneumoniae 5.56% (n = 2), Citomegalovirus 5.56% (n = 2), Meticilin-resistant Staphylococcus aureus 5.56% (n = 2), Pseudomonas 2.78% (n = 1) and 2.78% (n = 1) for Legionella pneumoniae.

Discussion: In Portugal CAP represents about 3% of all hospital admissions/year and 2.66 cases per 1,000 population. As compared to the reference work (RW) [Froes et al, 2003: Community-acquired pneumonia in adults in Mainland Portugal – Incidence and mortality in hospital inpatients between 1998 and 2000] our overall and ≥ 65y mortality rates were higher (RW 17.3% and 21.5% respectively) while age and gender distribution were similar. Streptococci infection remained the most frequent CAP etiologic agent but in our work viral and fungal etiologies were high. Our institution is a reference center for HIV, Oncology and Hemato-oncology and has a growing population of immunosupressed patients; furthermore the H1N1 influenza pandemy in 2010 caused significant Pneumonia admissions. These facts may potentially explain the increased mortality and the CAP etiologies in our study. Further subgroup analyses may clarify these data.

Conclusions: CAP is an ever evolving concept. It is an important cause of morbidity, mortality and hospital admissions. Mortality and etiology are affected by aging, growing immunosupressed patient population and pandemic events such as H1N1.

A-63
PSOAS MUSCLE ABSCESSES, EPIDEMIOLOGY AND DIAGNOSIS

A. González Munera, M. Ferrer Civeira, M. Clavero Olmos, A. García-Espona Pancorbo, R. Salomón Pérez, C. López González-Cobos, D. Salor Moral, M. Villalba García

Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: Psoas muscle abscess is a rare entity that must be considered in the differential diagnosis of febrile syndrome. We wanted to analyze the epidemiological characteristics of patients admitted to our hospital diagnosed of psoas muscle abscess.

Material and method: We present a retrospective study of cases of psoas muscle abscesses. We reviewed medical records of adults over 18 years, HIV negative, admitted in our hospital from January 2001 to December 2010.

Results: The number of cases is 15 patients, 11 male (73.3%) and 4 women. The mean age was 66.6 years (SD 15.4). The time elapsed since the onset of symptoms to the establishment of diagnosis varied from 1 to 450 days, with a mean of 52.07 (SD 116.11). The characteristics of the abscesses were, in relation to origin, primary 13.3% and secondary 86.7%. Etiologically, according to the source of the infection, the most frequent are intra-abdominal infections (40%) and bone infections (26.7%). The microbiological filiation was obtained in 12 cases (80%), with culture of the abscess in 8 cases, blood cultures in 2 cases a 1 patient was diagnoses by peritoneal fluid culture. Monomicrobial abscesses represented 53.3%, 7 of them (46.6%) caused by Gram + microorganisms. 8 patients were immunocompetent and 7 patients suffered from any kind of immunosupression (46.7%). The prognosis was satisfactory in most of the cases: complete remission in 11 patients (73.3%). We observed 3 cases of recurrence (20%) and only one immunosuppressed patient died.

Conclusions: Diagnosis of psoas muscle abscess forces to search for a primary infection. The most frequent are intraabdominal infections, especially in immunocompetent patients. Microbiology shows mostly Gram + and monomicrobial abscesses. The prognosis is satisfactory despite the delay in diagnosis.

A-64
TEN YEARS OF ECHINOCOCCOSIS IN CANTABRIA

C. Amado Diago[1], M. Cimas Valencia[3], C. Armiñanzas[2], M. Gutiérrez Cuadra[2], M. Fariñas[2]

[1]Department of Neumology, [2]Infectous Diseases Unit. Hospital Valdecilla. Santander (Cantabria), Spain. [3]Department of Internal Medicine. Hospital El Bierzo. Ponferrada (León), Spain.

Objectives: Echinococcosis is one of the most important zoonotic parasitic diseases of Mediterranean and South American countries. The diagnosis is based essentially in imaging techniques and serological techniques and its treatment continues being eminently surgical, although anti-parasitic drugs are also used. The aim of this work was to review the epidemiological, clinical, radiological, analytic and treatment data of patients with hydatid disease in Cantabria (North of Spain).

Material and method: We retrospectively analyzed all clinical, diagnostic and treatment data of patients diagnosed with echinococcosis from 2001 to 2011. All data were included and processed with the SPSS version 20.0.

Results: Fifty nine patients were included (0.9 cases /100,000 inhabitants/year). Thirty three (55.9%) were male. Mean age was 55.57 years (SD 19.0). Eleven (20.4%) patients presented comorbidities as cancer (3), hepatitis (2), hemolytic anemia, diabetes, renal transplant, neurodegenerative diseases and tuberculosis (1 patient each). Abdominal pain was the initial presentation in 23 (39%) patients, back pain in 1 and incidental finding during abdominal surgery in 1 patient (1.7%). In 26 cases (46.5%) there were no symptoms and the diagnosis was made as incidental finding in imaging techniques. Fever was present only in 3 (5.1%) patients. The liver was the most affected organ with 53 (89.8%) patients. Five (8.5%) cases presented pulmonary lesions. One (1.7%) patient presented vertebral cysts. Peritoneal cysts were observed in 1 (1.7%) patient. Combination therapy (surgery plus anti-helmintic treatment) was received by 20 (33, 9%) patients, surgery alone by 20 (33.9%), fine needle aspiration plus albendazol by 2 (3.4%), and albendazole alone was used in 2 (3.4%) patients. Fifteen (25, 4%) patients did not receive specific treatment (nine of which were calcified cysts). Twenty six patients (44.1%) were from cities in Cantabria, 23 (39%) from the rural area of Cantabria, 4 (6.8%) from other parts of Spain, 3 (5.1%) from other countries, in 3 cases (5.1%) we did not have a record of where the patient was living. Five (8.5%) patients died for complications of their basal illness.

Discussion: The results we found do not differ in matters of age or gender in results found in other studies. Liver alone was predominantly affected in this study similar to previous epidemiological data reported, but in our case at significant higher rates. We did not find any significant relationship between comorbidities and mortality or the diagnosis of echinococcosis.

Conclusions: Echinococcosis is an unusual infection in Northern Spain. Less than half of the patients presented abdominal pain as the initial symptom and the diagnosis was made mainly as incidental finding during imaging techniques. The liver was the most frequently affected organ. Less than 50% of patients received combination therapy with surgery and albendazol. None of the patients died due to echinococcosis.

A-65
RISK FACTORS FOR MORTALITY IN PATIENTS TREATED WITH MEROPENEM PROLONGUED VERSUS BOLUS INFUSION

R. Rodil Fraile[1], M. Landecho Acha[1], J. Beunza Nuin[1], J. Azanza Perea[3], A. Gómez-Guiu Hormigos[3], J. del Pozo León[2]

[1]Department of Internal Medicine, [2]Infectious Diseases Area, [3]Department of Clinical Pharmacology. Universidad de Navarra. Pamplona (Navarra), Spain.

Objectives: There is limited data on the effect of meropenem (MEM) prolonged infusion (PI) on mortality. Our main objective was to identify the factors associated to mortality (overall and infection-attributable mortality) among patients treated with PI of MEM (180 minutes) compared to those treated with bolus infusion (30 minutes) in patients admitted to critical care units (CCU) and in general hospital wards (GHW).

Material and method: We conducted a retrospective cohort study of patients who received at least 3 doses of intravenous MEM from October 2000 to November 2010 at the Clínica Universidad de Navarra, Spain. Treatment was adjusted for renal function according to recommendations. We stratified the analysis by place of admission, categorized as CCU or GHW. Logistic regression was used for risk assessment.

Results: We included 956 patients, 520 (54%) admitted to CCU and 426 (46%) to GHW. There were 306 (59%) and 105 (24%) patients treated with PI in CCU and GHW, respectively. A total of 52% had a documented infection, 34% respiratory, 24% intraabdominal, and 8% urinary tract infections. Overall mortality was 21% (31% for CCU and 10% for GHW). Duration of MEM administration in CCU or GHW was not related to overall mortality (OR 1.01, 95%CI 0.99 to 1.00, p = 0.66; OR 1.00, 95%CI 0.99 to 1.01, p = 0.28). However, patients admitted to CCU were nearly twice as likely to die during admission if treated with albumin (OR 1.95, 95%CI 1.18 to 3.21, p = 0.01) or corticosteroids (OR 2, 95%CI 1.24 to 3.23, p < 0.001) or vasoactive drugs (OR 2.48, 95%CI 1.45 to 4.24, p = 0.001) or immunosuppressors (OR 2.13, 95%CI 1.27 to 3.59, p < 0.001), required invasive mechanical ventilation (OR 1.93, 95%CI 1.22 to 3.06, p = 0.01), or a renal replacement technique (OR 1.86, 95%CI 1.08 to 3.17, p < 0.01). The longer admission days, the lower mortality risk (OR 0.91, 95%CI 0.87 to 0.95, p < 0.001). Patients admitted to GHW had higher risk of mortality when treated with albumin (OR 7.49, 95%CI 3.12 to 17.94, p < 0.001) or corticosteroids (OR 2.39, 95%CI 1.03 to 5.54, p < 0.01). Mortality risk was 15 times higher among patients who required the use of noninvasive mechanical ventilation (OR 14.9, 95%CI 3.75 to 59.19, p < 0.001). By contrast, solid organ transplantation was a mortality protective factor in GHW (OR 0.09, 95%CI 0.01 to 0.83, p < 0.01). Infection-attributable mortality was 8% (13% for CCU and 3% for GHW). Duration of MEM administration in CCU or GHW was not related to overall mortality (OR 1.00, 95%CI 0.99 to 1.00, p = 0.97; OR 1.01, 95%CI 0.99 to 1.01, p = 0.16). Among patients admitted to CCU, the probability of death related to infection was 3 times higher among those treated with vasoactive drugs (OR 2.65, 95%CI 1.34 to 5.22, p = 0.01) or corticosteroids (OR 2.49, 95% 1.25 to 4.93, p = 0.01). Non-invasive mechanical ventilation was a risk of infection-related mortality, tripling the appearance of events in these patients (OR 2.94, 95%CI 1.6 to 5.41, p < 0.001). Patients receiving longer antibiotic treatment with MEM were less likely to die due to infection (OR 0.82, 95%CI from 0.77 to 0.88, p < 0.001). Among patients admitted to GHW we found a strong association between death and the use of albumin (OR 11.4, 95%CI 2.27 to 57.23, p < 0.001) and the use of noninvasive mechanical ventilation (OR 31.41, 95%CI 5.49 to 179.72, p < 0.001).

Conclusions: Patients admitted to CCU and treated with corticosteroids or vasoactive drugs or under mechanical ventilation (invasive or noninvasive) have higher risk of either overall mortality or infection attributable mortality. However, patients admitted to GHW have increased risk of both overall and infection attributable mortality when treated with albumin or under noninvasive mechanical ventilation. PI of MEM had no effect on mortality, when compared to intermittent administration of MEM.

A-66
RISK FACTORS OF POORER OUTCOMES IN COMMUNITY ACQUIRED PNEUMONIA DURING PREGNANCY

S. García Rubio[1], P. Garmilla Ezquerra[1], F. López Gutiérrez[1], M. Aller Fernández[1], S. Neila Calvo[1], L. Urbina Soto[1], J. de Miguel Sesmero[2], S. Echevarría Vierna[1]

[1]Department of Internal Medicine, [2]Department of Obstetry and Gynecology. Hospital Valdecilla. Santander (Cantabria), Spain.

Objectives: To study the risk factors implicated in a poorer outcome in community acquired pneumonia during pregnancy.

Material and method: We revised the data from clinical charts of patients discharged from our centre with the diagnosis of community acquired pneumonia during pregnancy between January of 2000 and September of 2011. We registered, at admission, all information about age, weeks of pregnancy, heart rate (HR), systolic blood pressure (SBP), oxyhemoglobin saturation ($SatO_2$), $SatO_2$ divided by the oxygen inspiratory fraction ($SatO_2/FiO_2$), glycemia, uremia, serum creatinine (Cr), natremia, C reactive protein (CRP), temperature, leucocyte count (LC), hemoglobin (Hb) and platelet count (PC). We recorded the data concerning the length of stay (LOS) and length of stay in intensive care unit (ICU). We selected 68 patients meeting our criteria. The patient characteristics are shown in table 1.

Results: The mean LOS was 6.81 days (2-21). None of the 68 patients died. Three patients (4.4%) needed ICU admission. We found statistically significant correlation between platelet count on admission, $SatO_2$ and $SatO_2/FiO_2$ with LOS. We found a very strong statistically significant correlation between leucocyte count, platelet count and hemoglobin with ICU LOS, but this correlation may be biased because of the low incidence of ICU admission. The correlations (Pearson) and their statistically significance are shown in table 2.

Table 1 (A-66). Patient characteristics

	Age	Week of pregnancy	HR	SBP	Temperature (oC)	$SatO_2$ (%)	$SatO_2/FiO_2$
Mean (range)	32.26 (18-44)	28.3 (10-40)	100.34 (59-142)	114.76 (80-140)	37.76 (36-40)	96.44 (80-100)	436.63 (90-476)

Table 2 (A-66). Correlations between SatO2, SaO2/FiO2 and platellets with hospital LOS

	$SatO_2$ (p)	$SatO_2/FiO_2$ (p)	Platellets (p)
Hospital LOS	-0.304 (0.03)	-0.565 (< 0.01)	0.322 (0.01)

Discussion: Pregnant patients with community acquired pneumonia and lower $SatO_2$ or $SatO_2/FiO_2$ had a longer length of hospital stay. A higher platelet count on admission may be related to a longer hospital length of stay reflecting a more intense acute phase reaction.

Conclusions: The LOS in community acquired pneumonia during pregnancy is related to the oxygenation status.

A-67
DIGITAL CLUBBING: A NEW MARKER OF HIV INFECTION?

F. Rodríguez Gómez, F. Martínez Marcos, J. Fajardo Picó, M. Pérez Tristancho, M. D. Merino Muñoz, J. M. Lomas Cabezas, I. Suárez Lozano

Infectious Diseases Unit. Hospital Infanta Elena and Hospital Juan Ramón Jiménez. ASOMEI (Medical Association Infectious Diseases). Huelva, Spain.

Objectives: Digital clubbing (DC) is associated with a variety of diseases including cystic fibrosis, bronchiectasis, cirrhosis, cyanotic heart disease and cancer. Its prevalence in patients with HIV infection has been poorly investigated. The aim of this study was to determine the prevalence of clubbing in a cohort of HIV patients and its possible relation to variables related to HIV infection itself or its associated diseases.

Material and method: Cross-sectional study at a 265-bed hospital which provides specialized care to a population of 165,000 inhabitants, Huelva (Spain). The cohort consists of 369 adult patients whose data are collected at the Hospital Infanta Elena through an electronic medical record (AdvancedHiv®) specifically designed for HIV disease. At the time of cohort inclusion, an informed consent form was obtained for each subject and registered in the informatics application. Clubbing assessment was based on the presence of Schamroth's sign (disappearance of the normal diamond-shaped window observed when dorsal surfaces of terminal phalanges on opposite fingers are opposed). The following qualitative variables were analyzed: sex, age, weight, height, body mass index, years of HIV infection, CDC categories, number of cigarettes smoked per day, CD4 and plasma viral load in the first and last visit, number of antiretroviral treatment regimens, liver function test, hypertension, diabetes, lipodystrophy, hepatitis B or C virus infection. We estimate hepatic fibrosis by the APRI, Forns and FIB4 test or by fibroscan. Qualitative variables were analyzed by means of Chi square test or Fisher's exact test when indicated, whereas quantitative variables were analyzed by means of the Mann-Whitney or the Student's test. Those variables which were statistically significant in univariate analysis were included in a multivariate analysis.

Results: The study included 267 patients of which 49 (18.4,%, 95%CI 14%-23%) had DC. 45 out of 49 (91.8%) patients with clubbing smoke or had been smokers vs 162 out of 217 (74.7%) patients without clubbing (p = 0.009). 40 out of the 49 (81.6%) patients with clubbing belong to the stage C versus 143 out of 217 (65.9%) patients without clubbing (p = 0.032). 42 out of the 47 (89.4%) patients with clubbing had chronic HCV infection versus 142 out of 214 (66.4%) patients without clubbing (p = 0.02). 26 out of 49 patients (53.1%) with clubbing showed cirrhosis compared to 71 out of 216 (32.9%) patients without clubbing (p = 0.008). Other variables were associated with the presence of clubbing in the univariate analysis: male (95.9%) versus female (82.5%), (p = 0.018); weight (64.9 Kg vs 72), (p = 0.001), body mass index (22.1 versus 24.8, p = 0.001), previous history of IDU (77.6% vs 53.9%, p = 0.002), years of HIV infection (19.6 versus 14.5, p = < 0.001).

Discussion: We found an 18% prevalence of clubbing in HIV patients in our study. Lower weight and body mass index were associated with the presence of clubbing in males. A history of drug addiction and a prolonged HIV infection were also associated with the presence of clubbing in males. The presence of clubbing was also associated with HCV chronic infection and cirrhosis measured by noninvasive methods (APRI, Fibroscan, Forns and FIB4).

Conclusions: We found a high prevalence of HIV patients with clubbing. HIV infection should be considered in the differential diagnosis of acquired digital clubbing.

A-68
PRO-INFLAMMATORY MARKERS OF COMMUNITY ACQUIRED PNEUMONIA DURING PREGNANCY ARE RELATED TO POORER OUTCOMES AT BIRTH

S. García Rubio[1], A. Córdoba Alonso[1], C. Marcote Ibáñez[1], J. Valbuena Balbas[1], M. García Hoyos[1], C. Salas Pelayo[1], J. de Miguel Sesmero[2], S. Echevarría Vierna[1]

[1]Department of Internal Medicine, [2]Department of Obstetry and Gynecology. Hospital Valdecilla. Santander (Cantabria), Spain.

Objectives: To establish a relationship between clinical and laboratory parameters that reflect a pro-inflammatory state with poorer outcomes at birth in pregnant women who had community acquired pneumonia during pregnancy.

Material and method: We revised data from clinical charts of 68 pregnant patients who had community acquired pneumonia (CAP) between January of 2000 and September of 2011, including previous history of chronic lung disease, alcohol consumption, injection drug use, complete blood cell counts at admission and 48 hours later, C reactive protein (CRP), maternal oxyhemoglobin saturation divided between the inspiratory oxygen fraction ($SatO_2/FiO_2$), type of antibiotic treatment and maternal length of stay. We later registered the data of weight at birth, first and fifth minute Apgar test, cord blood pH, fetal mortality, and presence of fetal malformations.

Results: We could only recover data from 64 children of the 68 pregnancies. Twelve pregnancies (17.4%) were delivered by cesarean section. There were 3 preterm deliveries (4.4%) and 2 preterm delivery threats (2.9%) and only one case (1.5%) of fetal death. Two (2.9%) newborns showed symmetrical intrauterine growth restriction. The most frequently used antibiotics for the treatment of community acquired pneumonia were betalactams (62.7%). The statistically significant correlations (Pearson) we found are shown in table 1. We found no statistically significant association between the need of performing a cesarean section, type of antibiotic treatment, previous history of chronic lung disease, alcohol consumption or injection drug use with fetal mortality, presence of fetal malformations, preterm delivery or the need of ICU stay. When considering the pregnancy week when CAP occurred as 2 periods (first period from week 0 to week 19 and a second period from week 20 to the end of pregnancy) there was a statistically significant difference in the newborn´s weight at birth with mean weights of 3,050 g, for the first period, and 3,366.4 g for the second period (95%CI, p = 0.05).

Discussion: Inflammatory markers (leucocyte count) during pregnancy CAP may predict poorer birth outcomes (5th minute Apgar test and weight at birth). Better oxygenation parameters ($SatO_2/FiO_2$) during pregnancy related CAP seems to be correlated with better birth performance tests (Apgar). There may be less negative impact on child weight and fetal cord blood pH if the CAP occurred later during pregnancy.

Conclusions: Pro-inflammatory markers of CAP during pregnancy may be risk factors of poorer outcomes at birth.

Table 1 (A-68). Statistically significant correlations (Pearson)

	Pregnancy week when CAP occurred (p)	Maternal leucocyte count when CAP occurred (p)	Maternal $SatO_2/FiO_2$ when CAP occurred (p)
Weight at birth	0.292 (0.032)	-0.307 (0.024)	ns
1st minute Apgar	ns	ns	0.391 (0.01)
5th minute Apgar	ns	-0.299 (0.03)	0.492 (< 0.01)
Fetal cord blood pH	0.584 (< 0.01)	ns	ns

ns = Non statistically significant correlation.

A-69
CLINICAL SUSPICION OF MEDITERRANEAN SPOTTED FEVER: SERIES OF CASES (2004-2011)

M. Fernández, D. Rejas, A. Castro, R. Calderón, I. Navas, M. Tojo, J. Canora, A. Zapatero

Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: Mediterranean spotted fever is an infection caused by Rickettsia conorii which is transmitted by tick bites, which are highly prevalent in southern Europe. It is characterized by high fever, rash and sometimes a scar at the point of inoculation (black spot). The diagnosis is based on epidemiological and clinical signs and confirmed by serology and immunohistochemistry. Corroborate the etiologic diagnosis in the acute stage is very difficult so to a large clinical suspicion is obliged to initiate empirical antibiotic treatment. Description of the patients seen in internal medicine, in which discharge report consisted diagnosis of Mediterranean spotted fever, from the opening of the Hospital Universitario de Fuenlabrada (HUFLR), located in the south of Madrid in June 2004 to December 2011.

Material and method: descriptive study of diagnosed cases of spotted fever in the HUFLR Mediterranean. The following variables were analyzed epidemiological, clinical and laboratory parameters: age, sex, month of diagnosis, contact with dogs, the appearance of "black spot", presence of rash, clinical manifestations, treatment received, changes in the clinical diagnostic technique. As analyzes: white blood cell count and platelets, transaminases, plasma sodium value.

Results: There were 9 cases with suspicion of Mediterranean spotted fever, three of them in 2011, with a pattern of presentation in months with high temperatures (June-October). These are patients with a mean age 69.59 (range 32-85). Two-thirds (6/9) are male. 78% of cases (7/9) enter (half day admission: 3.4). With respect to the clinic all the cases had developed fever and maculopapular rash termometered. The presence of "black spot" was observed in 6 cases. With respect to other clinical headache in 3 cases, 3 cases only 2 myalgia and presence of lymphadenopathy. Among the analytical data thrombocytopenia in 1 case (11%) (mean: 169,000), absence of leukocytosis in 8/9 (89%), elevated transaminases (GGT and GPT) and hyponatremia in one case (mean, 137). The serology was positive in only 2 cases (22%).. Biopsy was performed in four cases being positive in one case confirmed the diagnosis by PCR, another showed a thrombotic vasculopathy with perivascular inflammation, another was given as viral rash and one was negative. 100% were treated with doxycycline. Except one died of septic shock in which the diagnosis was confirmed by autopsy, all cases had good clinical outcome.

Discussion: Mediterranean spotted fever is an infection caused by Rickettsia conorii which is transmitted by tick bites, which are highly prevalent in southern Europe. It is characterized by high fever, rash and sometimes a scar at the point of inoculation (black spot). The diagnosis is based on epidemiological and clinical signs and confirmed by serology and immunohistochemistry. Corroborate the etiologic diagnosis in the acute stage is very difficult so to a large clinical suspicion is obliged to initiate empirical antibiotic treatment.

Conclusions: The diagnosis is based on clinical suspicion in most cases. Not as common to find thrombocytopenia and hyponatremia but a normal figure of leukocytes and elevated transaminases. Suspecting start empirical antibiotic treatment with doxycycline submitted the most favorable clinical outcome. The presence of black spot is highly suggestive of infection with R. conorii. In our series has shown the limited utility of serology with the majority of negative cases. In our series, biopsy, was useful only to confirm the diagnoses in one of the 10 cases.

A-70
CLINICAL FINDINGS OF ACUTE PARVOVIRUS B19 INFECTION, A SERIES OF 17 ADULT PATIENTS IN A HOSPITAL IN MURCIA (SPAIN)

L. Strobosch Conesa[1], M. Martín Cascón[1], A. Pinos Blanco[1], C. Casañ López[2], M. Ruiz Gómez[1], J. Lozano Herrero[1], M. Page del Pozo[1], C. Ramírez Almagro[2]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital General Universitario Morales Meseguer. Murcia, Spain.

Objectives: Describe the most common clinical features and laboratory findings in adult patients with acute Parvovirus B19 infection.

Material and method: We performed a descriptive, cross-sectional retrospective analysis, which included patients diagnosed with acute Parvovirus B19 infection, by positive serum control. This was determined with IgM antibodies by ELISA (ELISA microplate Euroimmun®) in a period of 5 years (January 2008 to May 2012). We included a total of 17 adult patients that were diagnosed in the departments of Rheumatology, Hematology and Internal Medicine. Pregnant patients were not studied due to the lack of Gynecology department in our hospital.

Results: Of the patients studied, 76% were women and 24% male, aged between 21 and 78 years (mean = 44 years). The most frequent clinical manifestations were: arthralgia (65%) and arthritis (53%), asthenia (47%), fever (47%), skin lesions such as hematoma, purpura and rash on trunk and limbs (41%), myalgia (35%), rhinorrhea (29%) and odynophagia (24%). Hemogram alterations were expressed in approximately half of the patients with leukopenia (53%), anemia (41%), and thrombocytopenia (53%). As for the biochemical analytes, results showed an increase of lactate dehydrogenase (LDH) (76%), ALT (53%), AST (47%) and alkaline phosphatase (65%). Only two patients had positive autoantibodies, although these subjects had been previously diagnosed with autoimmune disease.

Discussion: Parvovirus B19 infection is common throughout the world. Mostly known as the virus responsible for the fifth disease, or erythema infectiosum in children, that is characterized by the facial rash in the form of slapped cheeks. In adults it is more prevalent among young women, where the main findings are joint symptoms, as revealed in our results. We have observed skin lesions which are less characteristic than the rash seen in children. These lesions were mild hematomas, and rashes, predominantly in limbs and trunk. The alterations in cell blood count (anemia, leukopenia, and thrombocytopenia) that we observed corroborate previous literature, without identifying any case of transient aplastic

anemia. In a significant amount of subjects, abnormalities in biochemical analytes as LDH, alkaline phosphatase and transaminases, were exposed. In pregnant women, hydrops fetalis and abortions have been described; notwithstanding, we were not able to provide this information in our study, since our hospital does not count with a Gynecology-Obstetrics department. Some series have linked the virus with autoimmune disorders. In our case subjects, we did not find a relationship between Parvovirus B19 infection and autoimmune disorders. Although there have been reports of myocarditis, nephritis, vascultitis, and neurological disorders, we have no reference of these in our study.

Conclusions: In patients (young women) with articular manifestations, nonspecific skin lesions, fever and other flu-like symptoms, along with possible alterations in the hematological series (mild or moderate), and/or liver enzymes, it seems reasonable to determine IgM antibodies in serum, to rule out the possible acute infection of Parvovirus B19.

A-71
ASSESSMENT OF SUITABLE USE OF TIGECYCLINE

R. García Caballero[1], R. Escudero Sánchez[1], M. González Anglada[1], A. Prieto Callejero[2], M. Barrera Ruiz[1], R. Alonso Navarro[1], C. Crespillo Andujar[1]

[1]Department of Internal Medicine, [2]Pharmacy Hospitalary Department. Hospital Universitario Fundación Alcorcón. Madrid, Spain.

Objectives: Tigecycline is a broad-spectrum antibiotic, recently marketed, with restricted hospital use. We studied the situations where the drug is prescribed, the therapeutic indications, and patient characteristics, in order to assess the effective use of antibiotic. The aim of the study was to analyze the use of tigecycline in our hospital.

Material and method: We collected patients taking tigecycline in 17 months. We analyze the clinical variables, Charlson comorbidity index, therapeutic indications and microbiological isolates. Information was obtained from electronic medical history, and the analysis was performed using SPSS 15.0.

Results: During 17 months, 42 patients were treated with tigecycline, 59.5% were men, the median age was 80 years old; and 31% came from elderly residents. In 73% of the cases, the prescription was made by a medical service; 38% of the total were from internal medicine, 19% surgery, 9.5% digestive, 9.5% vascular surgery, 9.5% intensive care unit, 7.1% traumatology, 2.4% neurology, 2.4% urology and 2.4% oncology. The median Charlson index was 6 points. 42.9% of the patients were diabetics, and 11.9% cirrhotics. The main indications were soft tissue infection and abdominal infection (28% in each one). Other infections were urinary (23.8%), post-surgical (9.5%), pneumonia (4.8%) and other (5.9%). The microorganisms involved in these infections were Gram negatives 26.2%, Gram positives 21.4%, multiresistants 16.7%, ESBL 11.9%, MARS 11.9% and mycobacterias 2.4%; non microorganisms were insolated in 9.5% of the culture. 40.5% of the microbiological isolates were resistant to several antibiotics. In 28.6% of the patients, tigecycline was used empirically; and in 38.1% as an alternative due to allergies to the first choice's antibiotic (81% to penicillin). In cases where antibiotics were administered before tigecycline, carbapenems (31%), vancomycin (21.4%) and quinolones (16.7%), were the greatest. 57.1% received an antibiotic concomitantly, of which 26.2% were aminoglycosides (mainly amikacin) and 19% quinolones. In 57% of the cases, the pattern could be changed after the results of antibiogram came to carbapenems in 16.7%, quinolones in 14.3% and beta-lactams in 7.1%. The median duration of treatment was 9 days. The average stay in hospital was 46 days. 20 patients had adverse reactions, but in no case were severe reactions. The cases in which antibiotics were stopped, was in one patient for adverse reactions (elevated INR), 18 patients by treatment's adjustement and 17 because the pattern ended. 23.8% of patients died during hospitalization.

Discussion: Tigecycline is a new drug wich use is restricted to the hospital. According to the analysis data, it's mainly prescribed in multipathological patients, allergies to other antibiotics or isolates of multiresistant microorganisms. The main indications were infections in soft tissues and abdominal infections.

Conclusions: We can conclude that tigecycline is well used in our hospital for its main indications.

A-72
USE OF URINARY CATHETERIZATION IN AN INTERNAL MEDICINE SERVICE

A. Barbosa, F. Castaño Romero, R. Sánchez, I. Novo Veleiro, H. Ternavasio de la Vega, F. Laso, M. Marcos

Department of Internal Medicine. Hospital Universitario de Salamanca. Hospital Clínico. Salamanca, Spain.

Objectives: The main objective was to evaluate the number of indwelling bladder catheters placed among patients admitted in an Internal Medicine ward and the incidence of catheter acquired urinary tract infections (CAUTIs) and other complications. We also aimed to determine risk factors associated to CAUTI and urinary bacterial flora.

Material and method: During a period of 3 months, we conducted a prospective observational study in hospitalized patients in an Internal Medicine ward. Patients were evaluated daily to check for the presence of indwelling catheters, which were indicated by attending physicians. Urine samples were collected on the 1st and 4th day of catheterization and epidemiological, clinical, and analytical data were prospectively recorded. Quantitative variables were compared using the Student´s t test and qualitative variables by means of the χ^2 test, using Fisher's exact test when necessary. SPSS statistical program version 18 was used.

Results: During the study period, 451 patients were admitted to the Internal Medicine ward. Fifty-four of them (12.0%; mean age 79.9 years [SD 11.5], 53.7% males) had an indwelling catheter placed on admission or during hospitalization, for a total of 621 days of catheterization (mean of 11.7 days for each patient). Among patients with catheter, 19 patients (35.2%) came from a nursing home, 9 (16.7%) had a long-term catheterization, 19 (35.2%) were diabetic, 10 (18.5%) had been hospitalized in the previous 3 months and 25 (46.3%) had received antibiotic treatment during the last 3 months. The median score obtained in the Charlson comorbidity scale was 3 (interquartile range [IQR] 3) and the Barthel scale for evaluation of ability in performing activities of daily living was 20 (IQR 60). Thirteen patients (24.1%) had significant bacteriuria on the 4th day of catheterization or earlier and 9 of these patients had CAUTI (1.45 CAUTIs/100 catheter-days). Nine of the 13 patients who had significant bacteriuria (69.2%) were females and 8 (61.5%) lived in a nursing home. The most frequent microorganisms isolated were Enterobacteriaceae (58.3%) followed by Candida spp. Nine patients (16.7%) were diagnosed from sepsis secondary to UTI and 5 patients (9.3%) developed septic shock. Twelve patients (22.2%) who had been catheterized died (22.2%), 6 of them of severe sepsis. Remarkably, patients who had positive urinary cultures as well as those who developed severe sepsis or died had a greater dependence according to the Barthel scale (mean difference > 20 points).

Discussion: In accordance with the current trend in internal medicine, our sample of patients with indwelling bladder catheters is comprised of elderly patients with a high burden of comorbidity, moderate to severe dependence, and frequent use of the health system. In this clinical setting, patients had many underlying risk factors for developing UTIs, such as living at a nursing home, long-term catheterization, diabetes mellitus, prior hospitalization and

antibiotic treatment, and, of note, long-term catheterization. As expected, microorganisms most frequently isolated in urine cultures were Enterobacteriaceae and Candida spp, the latter suggesting a situation of colonization rather than infection. Finally, it should be noted the high frequency of serious complications presented by these patients, particularly the high mortality rate. This can be partly explained by the clinical profile of these patients and further studies with larger samples should be carried out to establish the actual relationship between urinary catheterization and the development of complications in these patients.

Conclusions: Hospitalized patients in internal medicine wards with urinary catheters have a high-risk profile for serious complications during hospitalization. Compliance and adherence to clinical guidelines for prevention of UTI should be encouraged and the development of specific protocols would be of help to reduce the length of catheterization as well as the risk of complications.

A-73
CLINICAL CHARACTERISTICS OF THE INFECTIVE ENDOCARDITIS IN ZAMORA'S HOSPITAL

A. de la Vega Lanciego[1], G. Hernández Pérez[1], P. Sánchez Junquera[1], J. Soto Delgado[1], E. Martínez Velado[1], M. Mateos Andrés[1], M. Chimeno Viñas[1], T. Garrote[2]

[1]Department of Internal Medicine, [2]Admission Service. Complejo Asistencial de Zamora. Zamora, Spain.

Objectives: To analyse the cases of endocarditis in order to improve diagnosis.

Material and method: The records of the patients diagnosed with endocarditis in the Health-care Complex of Zamora from January 1st -- 2000 to December 31st --2012 were reviewed. The following data were collected: age; sex; cause of admission; presence of a new murmur; fever; constitutional syndrome; heart failure; valve vegetation detected or not and which type of echocardiogram documented it; blood cultures and isolations; pathological valves; identification of a portal of entry for bacteremia; anemia; leukocytosis; ESR; splenomegaly; and immunodeficiency. We compared our results with those in the literature.

Results: Twenty seven patients were analysed, 16 males (59.3%) and 11 females (40.7%). Age ranged from 30 to 85 years with an average age of 67. Fever was the most frequent cause of admission: 19 cases (70.3%). Other causes of admission were: dyspnea and edema 11.1%, low consciousness level 11.1%, constitutional syndrome 7.4% and chest pain 3.7%. A new murmur was detected in 10 cases (37%), fever in 21 (78%), constitutional syndrome in 11 (44.4%), heart failure in 7 (26%) and leukocytosis in 15 (55.5%). ESR increased in 15 patients (78.9%). Seventeen had anemia (62.9%). There were 3 cases of splenomegaly (11.1%). Twenty five cases of valve vegetations (92.6%) were found, 40% of them diagnosed by transthoracic echocardiography (TTE). Transesophageal echocardiography (TEE) was done in 64% of patients. Cultures were positive in 22 (81.5%). The microorganisms found in order of frequency were: S. viridans (different subspecies), 7 cases (25.9%); S. aureus, 7 cases (25.9%); S. bovis, 3 cases(11.2%); Enterococcus, 2 cases (7.4%) and Granulicatella adiacens, S. agalactiae and Salmonella enteritidis, 1 case (3.7%) each. The affected valves were: mitral (76.9%), aortic (15.4%), mitral and aortic (3.8%) and tricuspid (3.8%). There were two cases of HIV infection (14.8%). One of them had the tricuspid valve affected, in relation with the use of injected drugs. The recognized portals of entry were: oral cavity (29.6%), abdominal way (29.6%), urinary tract (7.4%) and parenteral way in injecting drug users (IDUs) (3.7%).

Discussion: Clinical characteristics of our endocarditis are very similar to those in the literature. The most relevant fact was that 18.5% of the cultures were negative, in contrast to 5-15% related in the literature. This is probably due to the fact that 44.4% of our patients received antibiotics before endocarditis diagnosis. All the studied patients comply with the Duke criteria. A vegetation was seen in 92.6% of the cases, similar to data published in the literature. However, only 40% of them were documented by transthoracic echocardiography, different from the 65% recorded in the literature. The other cases were diagnosed by transesophageal echocardiography. Both techniques were performed in the same patient in 24% of the cases. There are no differences between our results and those shown in the literature in terms of the affected valves. The microorganisms found are also the same.

Conclusions: Clinical characteristics of endocarditis in our study are similar to those described in the literature. It is necessary to insist on correct extraction of blood cultures before starting antibiotics. The diagnostic techniques used in our hospital are the appropriate ones and the microorganisms isolated are also similar to those recorded in the literature.

A-74
CHANGING EPIDEMIOLOGY OF INFECTIVE ENDOCARDITIS

A. Calvo Cano, O. González Casas, F. Olgado Ferrero, M. González Cordero, N. Nogales Muñoz, A. Vera Tomé, F. Rodríguez Vidigal, A. Muñoz Sanz

Infectious Diseases Unit. Complejo Hospital Universitario de Badajoz. Badajoz, Spain.

Objectives: The aim of our study is to know the epidemiology of infective endocarditis (IE) in our area and its evolution in the last few decades.

Material and method: This is a retrospective study including all patients who fulfilled modified Duke criteria admitted to a university centre in Spain between January 1990 and December 2008. We compared two periods: 1990-1999 (62 cases), and 2000-2008 (87 cases). Information was obtained from medical records. Statistical analysis was performed using SPSS software. We used χ^2 tests to examine differences in categorical variables and Student's t-test for quantitative ones, considering significant a p value less than 0.05.

Results: A total of 149 consecutive patients with IE was evaluated, 73, 8% were men, with a mean age 54 ± 17 years. Involved cardiac valves were: mitral (37, 9%), aortic (26.2%), and both (10.4%). Tricuspid valve was affected in 28 (18, 8%), most were intravenous drug users (18 cases), and a few have an implanted peacemaker (5). There were 116 cases (77, 9%) of native valves infections, and 28 (18, 8%) of prosthetic valves. Etiology: the most common causative microorganisms were Staphylococci (38.9%) (S. aureus 21, 5%, S. epidermidis 17.4%), Streptococci (22.8%), and Enterococci (8.7%). Thirty seven patients (24.8%) had negative-culture endocarditis (NCE). Serological study and PCR technique in explanted valves were diagnostic in 15 of the NCE patients: Coxiella burnetti (9), Chlamydophila pneumoniae (1), Brucella spp. (3), Tropheryma whipplei (1), and Bartonella spp. (1). In 14, 7% cases there was no aetiological diagnosis. Global outcome: surgical intervention was performed in 46 cases (30, 9%). The in-hospital mortality rate was 11, 5%. Comparative analysis of the two periods: the mean age of patients has progressively increased (46 ± 19 years in the first period vs 60 ± 14 years in the second; $p < 0.0001$), as well as the rate of cases of prosthetic valve endocarditis (11.3% and 24.1%; $p < 0.0015$). Percentages of patients with involvement of tricuspid valve have fallen in recent years (37, 1% and 5.7%; $p < 0.0001$). Intravenous drug users were more frequent in the first period (30.6% and 1.1%: $p < 0.0001$). The microbiological spectrum has changed in the last years: S. aureus was the most common pathogen in the first era (32.2% vs 16.2% Streptococcus spp. and 13% Staph coagulase-negative; $p < 0.03$), while in the second one there was an increase of streptococcal and coagulase-negative

bacteria (12.6% S. aureus, 20.7% S. coagulase-negative and 26.4% Streptococcus spp.; $p < 0.03$). Surgical treatment has increased during the second period (16.2% and 41.4%; $p < 0.001$), as well as the mortality rate (3.2% and 17.2%, $p < 0.007$).

Discussion: In our study, with the usual limitations of a retrospective analysis, we found significant changes in the epidemiology of EI. Twenty two years ago, patients admitted to our hospital were younger people, with a higher proportion of intravenous drug users, and tricuspid and native valve endocarditis. S. aureus was the main pathogen. In the most recent period, we attended older patients with more prosthetic valve endocarditis. Streptococci and S. coagulase-negative were the principal aetiology. However, despite microbiological and histological studies, a significant group of patients (14.7%) still remains with no aetiological diagnosis.

Conclusions: 1. In our area, the microbiological spectrum of IE has changed in the last years.2. The change of habits in risk population and the incorporation of new invasive techniques could be involved in this epidemiologic issue. 3. Still, there is a considerable proportion of cases with no definitive microbiological diagnosis.

A-75
TUBERCULOUS MENINGITIS SECULAR TRENDS IN VIGO (NW OF SPAIN) IN COMPARISON WITH GALICIA AND SPAIN

J. Montes Santiago, V. Rodil, B. Machado, J. Álvarez, J. López Otero, R. Pérez Álvarez, G. Rey

Department of Internal Medicine. Complejo Universitario de Vigo. Vigo (Pontevedra), Spain.

Objectives: Central nervous system tuberculosis, most often meningitis TB (TBM), is difficult to recognize and has a high mortality (15-40%), despite the availability of effective drugs. In Spain TBM constituted 1.3% of total TB [96/7,089 (2010]. There is a slow decline of TBM in Spain -rates per 100,000 inhabitants: 0.18 (1997) to 0.14 (2011), although absolute cases remains inmodified [69 (1997), 64 (2011)]. This study is focused on the epidemiology of TBM in our sanitary area (Vigo) and its comparison with that of Galicia and Spain.

Material and method: We examined TBM cases from the Complejo Hospitalario Universitario de Vigo (CHUVI) according to the data obtained from the Minimum Basic Data Set (MBDS) at hospital discharge. It was used for TBM the diagnostic code 013.0 of the International Classification of Diseases 9th ed (ICD-9CM). We used for calculations a reference population of 437,181 inhabitants for CHUVI (2010). These data were compared with reported rates for Galicia and Spain obtained through the system of notifiable diseases (EDO: Enfermedades de Declaración Obligatoria), yearly available at the website of the National Epidemiology Center /Institute of Health Carlos III (www.isciii.es).

Results: There was a global decrease in rates of TBM in Spain, Galicia and Vigo. However, rates in Vigo and Galicia remained elevated with respect to Spain (median for the 1997-2011 period: 1.37 (Vigo); 0.84 (Galicia) and 0.22 (Spain). In Galicia TBM constituted 2.9% of global TB (2010) (1.3% in Spain). In the overall 1997-2011 period, 19% (17/86) of TBM in Vigo were concurrent with HIV, although in the last five-year period 2007-2011 only a patient out 20 (5%) was coinfected with HIV.

Discussion: Like global TB, MTB is decreasing in Spain, but it still remains a significative problem in Vigo and Galicia.

Conclusions: MTB rates in Spain are decreasing, like global TB. However, Vigo and Galicia presents significantly higher rates than Spain, although these differences appear to be gradually reduced. There is markedly decrease in the TBM in patients with HIV.

A-76
INFECTIVE ENDOCARDITIS - A 5 YEAR RETROSPECTIVE STUDY IN AN INTERNAL MEDICINE UNIT

S. Ledo[1], C. Almeida[2], C. Machado[2], G. Brasil[1], C. Paiva[1]

[1]Internal Medicine Unit, [2]Cardiology Unit. Hospital do Divino Espirito Santo, EPE. Ponta Delgada, Portugal.

Objectives: Characterization of patients diagnosed with IE in an Internal Medicine Unit on a peripheral hospital, during 5 years.

Material and method: Retrospective study of patients with definitive diagnosis of IE, according to Duke's criteria, during 5 years.

Results: Were identified 41 patients with IE in the hospital, and 43.9% (18) were in an Internal Medicine Unit. The mean age was 61.6 years and 50% were male. Risk factors: previous antibiotic treatment (55.6%), invasive procedures (33.4%), presence of valvular disease (27.8%) and intravenous drugs users (11.1%). The most prevalent clinical presentation was fever (83.3%), followed by heart murmur (33.3%) and heart failure (27.8%). The transesophageal echocardiogram confirmed the diagnosis in 77.8% of the patients. The most frequent localization was valvular (94.4%) and all of the valves were natives. In 47.1% of the patients, the aortic valve was involved and the mitral in 41.2%. The characterization of the vegetation occurred in 11 patients, of which 45.5% had a dimension superior to 10mm. The pathogen was identified in 50% of the cases, of which methicillin-sensitive Staphilococcus aureus and Streptococcus viridians, were the most frequent (22.2% each). The antibiotic treatment most used was the association of the vancomycin and gentamicin (33.3%). The mean duration of treatment was 4.4 weeks. One (5.6%) patient required urgent surgical intervention. In 33.3% of the patients occurred complications, as valvular dysfunction (33.3%), septic shock and cerebral emboli (5.6% each). The mean duration of hospitalization was 35.8 days. There was a mortality rate of 16.7%.

Conclusions: The diagnosis of Infective endocarditis remains a challenge for the Internist, highlighting the high level of suspicion necessary for the prevention of the complications and for the decrease of morbilidity associated.

A-79
CHARACTERISTICS OF BACTEREMIA IN A GENERAL HOSPITAL

I. Rodríguez-Montoliu[1], J. Grau-Amorós[1], R. Benítez[1], A. Calderón[2], T. Falgueras[2], A. Morcillo[3]

[1]Department of Internal Medicine, [2]Department of Microbiology, [3]Department of Nursing. Hospital Municipal de Badalona. Badalona (Barcelona), Spain.

Objectives: Description of the clinical and epidemiological characteristics of cases of bacteremia attended by a general hospital over a period of 3 years.

Material and method: Retrospective analysis of blood culture isolates from a prospective cohort of all cases of bacteremia attended between 1st January 2009 and 31st December 2011 in a 130-bed general hospital without obstetric, paediatric or ICU services, with an urban reference population of approximately 235,000. The results were analysed using the Student t-test and chi^2 test and the SPSS programme. Statistical significance was established as $p < 0.05$.

Results: In the 390 episodes of bacteremia identified, 424 microorganisms were identified and 26 cases were polymicrobial. A total of 77.7% of cases occurred in the community setting (C), 12.3% in hospitalized patients (H) and 10% in social health facilities (SH). The mean age was 72.75 years (C 70.9, H 75.4, and SH 84.2 years) with significant differences between C and H or SH ($p < 0.001$) but

not between H and SH. A total of 84.6% of SH patients had severe dependence (Rankin scale 4 or 5) compared with 28.2% of the total cohort ($p < 0.001$). H had more comorbidity (66.7%), of which the most frequent were: diabetes mellitus (29.2%), neoplasm (20.8%), chronic obstructive pulmonary disease (25%) and chronic renal failure (18.8%): only the latter two comorbidities were significantly different between groups ($p = 0.015$ and 0.045, respectively). A total of 86.1% C and 74.4% SH had no extrinsic risk factor, whereas 12.5% of H were carriers of central venous catheters, 18.8% of urethral catheters and 25% had undergone major surgery. The main focus of bacteremia was urinary in C (41.9%) and SH (61.5%), and catheters in H (31.3%). In 14.4% of cases the primary was not determined, due to transfer to reference hospital (4.8%), not attending subsequent outpatient appointments (5.9%), or death within 72 hours after admission (7.9%). Overall mortality was 12.8%, but the differences between C (9.2%), H (27.1%) and SH (23.1%) were significant ($p = 0.001$). The most frequently isolated microorganism was E. coli (43.6%), with no difference between groups. There were clear differences between groups in isolations of Staphylococcus sp, which accounted for 37.9% of isolations in H versus only 6.6% in C and 2.6% in SH. ESBL-producing enterobacteria were found in 5.4% of cases and MRSA in 2.3%. Early antibiotic treatment (within 6 hours) was initiated in 94.6% of cases, and consisted principally of amoxicillin clavulanate (51.8%), quinolones (22.3%) and second and third generation cephalosporins (11.3%).

Conclusions: 1. In hospitalized patients, central lines are the most important source of bacteremia. 2. Cases of bacteremia in geriatric patients are mainly of urinary origin. 3. Mortality is high in cases of nosocomial bacteremia occurring in both hospitalized patients and residents of geriatric facilities.

A-80
INFLUENCE OF OBESITY AND MALNUTRITION ON INFECTIOUS DISEASES ADMISSIONS

R. Calderon[1], S. Nistal[2], E. Madroñal[1], A. Asenjo[2], I. Perales[2], A. Zapatero[1], R. Barba[2]

[1]Department of Internal Medicine. Hospital Rey Juan Carlos. Móstoles (Madrid), Spain. [2]Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: Obesity is a risk factor in other conditions, like high blood pressure, heart disease and type-2 diabetes. However, recent studies have shown that obese people with chronic diseases have a better chance of survival than normal-weight individuals. This finding has been called the "obesity paradox". Malnutrition is a common problem in patients with chronic or serious diseases, there are a lot of studies that have repeatedly demonstrated how clinical malnutrition negatively affects the recovery from a disease, trauma or surgery, and it is generally associated with an increase in morbidity and mortality both in acute and chronic patients. Our aim is to analyze the influence of obesity and malnutrition on in-hospital mortality and re-admittance 30 days after discharge in patients admitted for infectious disease.

Material and method: Data from the Minimum Basic Data Set (MBDS) from all patients discharge from all the Departments of Internal Medicine (IM) of the Spanish National Health hospitals between the years 2005-2009 were selected. We analyzed those patients with a Major Diagnostic Category (MDC) equal to 18 –Infectious disease-. The Major Diagnostic Categories (MDC) is formed by dividing all possible principal diagnoses (from ICD-9-CM) into 25 mutually exclusive diagnosis areas. Patients with a diagnosis of obesity (ICD-9: 278.00-278.09) or malnutrition (ICD-9: 260-263.9) were also identified. The mortality indexes of obese and malnourished patients were compared against the subpopulation without theses diagnosis.

Results: 90,189 infectious admittances were analyzed, with 4,023 (4.5%) diagnosis of obesity and 2,620 (2.9%) of malnutrition. In-hospital global mortality reached 17.7%, 13.1% in obese patients and 17.9% in non-obese; $p < 0.001$. Obese patients showed a lower in-hospital mortality risk (OR 0.69 95%CI 0.62-0.76) than non-obese after adjusting for possible confusing factors (age, sex, CharIson index, acute respiratory failure). Mortality in malnourished patients was 27.8% vs 17.4% in non-malnourished; $p < 0.001$. Malnourished patients had a much higher risk of dying while in hospital (OR 1.54 95%CI 1.39-1.70) even after adjusting for possible confusing factors.

Discussion: Obesity has been associated with increased susceptibility to acute infections, including those of the lower respiratory tract. Obesity affects the control of the respiratory cycle, increases airway resistance and the work of breathing, impairs respiratory muscle function and gas exchange, increases the risk of aspiration, and increases the volume of distribution for certain antibiotic drugs. Also, obesity-associated derangements in the homeostasis of leptin and adiponectin (adipokines) have been linked to impaired innate and adaptive immune responses to infectious challenges. Counter intuitively, we found that obesity was significantly associated with decreased in hospital mortality in patients with infectious disease. Our results together with those of previous studies suggest that obesity may have a paradoxical protective effect against in-hospital mortality from infected patients. Without questioning the detrimental effects of obesity in the health of people, the prospect of unrecognized obesity-associated factors that protect against the progression of infectious diseases deserves further consideration and study.

Conclusions: Obesity in patients hospitalized for infectious disease substantially reduces in-hospital mortality risk. More research should be aimed at resolving the obesity paradox.

A-81
POOR PROGNOSTIC FACTORS OF BACTEREMIA IN A GENERAL HOSPITAL

R. Benítez[1], J. Grau Amorós[1], I. Rodríguez Montoliu[1], A. Calderón[2], T. Falgueras[2], G. Tolchinsky[1]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital Municipal de Badalona. Badalona (Barcelona), Spain.

Objectives: To analyze factors associated with mortality due to bacteremia in a general hospital.

Material and method: Retrospective analysis of a prospective cohort of all cases of bacteremia attended between 1st January 2009 and 31st December 2011 in a 130-bed general hospital without obstetric, paediatric or ICU services, with an urban reference population of approximately 235,000. The results were analysed using the Student t-test and chi^2 test and the SPSS programme. Statistical significance was established as $p < 0.05$.

Results: Of the 390 cases of bacteremia included, 40 were excluded due to transfer out or were lost to follow up after five weeks. Therefore, 350 cases were finally analyzed, of which 48.3% were male, with a mean age of 73.3 years, and 28.9% had severe dependence. A total of 76.9% of cases occurred in the community setting, 13% in hospitalized patients and 10% in social health facilities. In the 53.1% of patients with comorbidity, the most common were: diabetes mellitus (24%), neoplasm (16.3%), chronic obstructive pulmonary disease (13.7%) and chronic renal failure (9.1%). In the 29.9% of patients with ≥ 1 risk factor bacteremia, the most common were: urinary catheter (7.4%), major surgery (4.6) and chemotherapy (4.6%). The most common foci of bacteremia were urinary (42%), abdominal (21.7%) and respiratory (10.9%) and the origin was not determined in 13.4% of cases. The most frequently isolated microorganisms were E. coli (45.4%) and S. pneumoniae (8%), while 6.6% of cases were polymicrobial. ESBL-

producing enterobacteria were found in 4.9% of cases and MRSA in 2.3%. Empirical antibiotic treatment was started within 6 hours of clinical presentation in 94.6% of patients. The main drugs used were amoxicillin-clavulanate (52.9%), quinolones (21.7%) and cephalosporins (10.9%). A total of 14.3% of patients died: their mean age was 79.3 years versus 72.3 years for survivors (p = 0.005). Of patients who died, 10.4% came from a community setting, 28.3% were hospitalized patients and 25.7% came from social health facilities (p = 0.001). There was a higher mortality rate in nosocomial patients (hospital and social health) than in community-dwelling patients (27.2% versus 10.4%; p < 0.001). Dependence (p < 0.001), unidentified focus (p = 0.004) and bacteremia due to MRSA (p = 0.001) were risk factors for mortality. Comorbidity and extrinsic risk factors were not significant factors. Early empiric antibiotic treatment was associated with a higher cure rate (86.7% vs 13.3%, p = 0.012), but no significant differences were found with respect to the choice of antibiotic

Conclusions: 1. Age and severe dependence were negative prognostic factors. 2. Bacteremia in the community and early initiation of empirical antibiotic therapy was associated with better outcomes. 3. The focus of infection remained unknown in a high percentage of patients who died.

A-82
A GROUP OF PATIENTS WITH WHIPPLE'S DISEASE DIAGNOSED IN THE UNIVERSITARIO MARQUÉS DE VALDECILLA HOSPITAL

E. Cobo García[1], A. González-Torre González[1], S. Qiu Liu[1], M. Lisa Gracia[1], A. Córdoba Alonso[1], P. Juárez Mancia[2], F. Ortiz Flores[1], M. Valero Díaz de Lamadrid[1]

[1]Department of Internal Medicine, [2]Department of Family and Community Medicine. Hospital Valdecilla. Santander (Cantabria), Spain.

Objectives: Review the diagnosed cases of Whipple´s disease (WD) in the last twenty years in our hospital, describing the clinical features and the utility of the diagnostic tests.

Material and method: This is a retrospective study in 5 patients (80% men) diagnosed of WD in the HUMV (Santander, Spain) from 1989 to 2012. Data regarding the clinical history, age, personal history, way of presentation, clinical features, as well as data coming from the physical exploration, was retrieved. Besides, the delayed time until the diagnosis took place, was also analysed. Also, laboratory data, such as sedimentation rate (ESR, mm/h), C-reactive protein (C-RP mg/dl), haemoglobin (Hb g/dl) and albumin (g/dl), was registered. Information coming from the immunologic studies (RF, citrulinated peptide, ANA, ANCA) and the malabsorption test with D-xilosa in urine (normal > 1 g/5h), as well as the level of total and free testosterone (ng/dl), SHBG (nmol/l), D-vitamin (25-OHD ng/dl), was collected. From the image tests, presence of lymphadenopathy and location in scanner were obtained, also including measurement of bone mass through dual X-ray absorptiometry (t-score). Furthermore, the type of biopsy performed (duodenal or rectal), the histology and the molecular determination through Polymerase Chain Reaction (CRP in tissue or synovial liquid) was recorded. The type of treatment received (antibiotics) and the mortality also were included.

Results: The average age at the diagnosis was of 62 ± 15 years. All patients had lose weight (14 ± 3 kg). 60% displayed diarrhoea (5 ± 1 months) and 60% showed fever. In the physical examination, 2 patients had arthritis in elbows and ankles. The average time to diagnosis was of 63 ± 25 months. 80% of the cases showed an increase of the inflammatory reactants (ESR > 33 mm/h, C-RP > 7.25 mg/dl). Anaemia was registered in all of the cases (Hb < 12 g/dl) and hypoalbuminemia (albumin < 3.5 g/dl). Immunological studies in patients with palindromic rheumatism were absolutely normal. D-Xylose test was abnormal in 3 of 4 cases (0.29 ± 0.19 g/5h). The average of 25-OHD was of (17.8 ± 7.3 ng/ml) half of them had less than 20 ng/ml. In the scanner, 100% presented abdominal lymphadenopathies, 40% thoracic and 20% peripheral. The diagnosis of WD was done through microscopy, displaying Tropheryma whippelii inside positive PAS macrophages in a rectal biopsy, in 3 duodenal ones, and in a myocardial and cerebral necropsy. Furthermore, 40% had a positive C-RP for T. whippelii in duodenum and 20% in synovial fluid. One patient had osteopenia (CL-1.2, Femoral Neck density -1.1) and other one had osteoporosis (CL t-score: 2.5, Femoral neck density -1.8) Two cases received treatment with G-Penicillin (1.2×10^6 U/day) and Streptomycin (1 g/24 ev) during 14 days, followed by oral Cotrimoxazole (160/800 mg/12h) during 1 year. Another 2 cases received Ceftriaxone (2 g/12h ev) during 2 weeks (4 weeks in the hypothalamic hypogonadism), followed by Cotrimoxazole (160/800/12h) during 1 year. One died without being diagnosed. In our series, 2 patients were diagnosed nine years ago of a PR, with a periarticular and axial affectation, as well as subcutaneous nodules. Both presented clinical features of hypogonadism, including impotence and decrease of sexual desire of 10 ± 2 months; one of which presented hypothalamic hypogonadism, showing a normal cranial MRI. One of the cases after treatment with methotrexate presenting worsening symptoms.

Discussion: Patients with WD have frequently a general syndrome and an important loss of weight, associated to diarrhea, fever and lymphadenopathy. As all these data are common to other illnesses, a duodenum biopsy and microscopy study should be performed to reach the correct diagnosis. Delay in diagnosis is not rare, but once WD has been diagnosed, response to appropriate antibiotic treatment is usually good. We consider that for those patients diagnosed of not well-defined rheumatic diseases, with a bad development, an extensive study of this disease should be performed.

Conclusions: WD has a difficult diagnosis, which demands a high clinical suspicion, above all in patients with not well-defined rheumatic diseases or after immunosuppressive treatment.

A-83
SEPTIC ARTHRITIS OF THE PUBIC SYMPHYSIS: REVIEW OF 7 CASES

I. Marañón Zabalza, E. Fonseca Aizpuru, M. García Alcalde, E. Rodríguez Ávila, D. Cuervo Blanco, A. García Vallina, J. González Vallés, J. Morís de la Tassa

Department of Internal Medicine. Hospital de Cabueñes. Gijón (Asturias), Spain.

Objectives: Assess clinical features of septic arthritis of the pubic symphysis (SAPS) and provide tools for differential diagnosis between it and sterile osteitis pubis.

Material and method: All SAPS cases diagnosed in Cabueñes Hospital from 1991 to 2011 were revised in a retrospective descriptive manner. Medical bibliography was reviewed. Diagnosis was done when clinical, microbiological and imaging features were compatible, and excluded when lacking any of them.

Results: Seven patients fullfiled the criteria. Clinical picture showed groin pain 5 (71.4%), antalgic gait 4 (57.1%) and pubic tenderness or pain 4 (57.1%). Concerning laboratory tests, C-Reactive Protein -raised in 4 out of 6 patients (66.7%)-, Erythrocyte Sedimentation Rate -2/4 (50%)-, leukocytosis -1/5 (20%)-, left shift -2/5 (40%)-and procalcitonine -1/1 (100%)- were used for initial approach. Blood, urine and direct specimen cultures were performed: 2/5 (40%) blood cultures were positive for methicillin-sensitive S. aureus; 4 specimen cultures were positive (100%) for polymicrobial, meticillin-sensitive S. aureus, multi-resistant P. aeruginosa or Staphylococcus constellatus. In urine

cultures, 1/3 (33.3%) was positive for E. coli and 1/3 for multi-resistant P. aeruginosa. Imaging showed positive results in 4/4 (100%) both CT and MRI, 5/5 (100%) scintigraphy, 4/6 (66.7%) radiographies and 1/4 (25%) ultrasound. Common features were symphysis widening, collections and bone destruction. Diagnosis delay was less than 1 day on 3 patients (42.9%), less than 1 week on 1 (14.3%) and more than 1 month on 3 (42.9%). Females with urinary incontinence surgery accomplish for longest delays. Already known risk factors can help choosing empiric antibiotics and incontinence surgery was the most prevalent (42.9%). 85.7% of our patients had a point of entry that could explain a transient bacteremia. Treatment is antibiotics, 57.1% needed a surgical procedure. Combinated treatment was the rule: 6 patients had 3 or more antibiotics; ciprofloxacin (85.7%), gentamycin (57.1%), amoxicillin-clavulanate (42.9%) and cloxacillin (42.9%) accounted for the highest prescription. Outcomes were usually good (57.1% without complications nor sequelae), but there is a risk for local complications (42.9%) and local sequelae (28.6%, often worsening of urinary incontinence). We report one death, due to a stroke during admission.

Discussion: Our work resembles main features of our patients with SAPS. The longest series published (Ross et al.), reported 100 cases, making the point of the low incidence, perhaps consequence of misdiagnosis with osteitis pubis, a common aseptic condition that resolves without specific management. This happens too because septic arthritis is often contained by immune system and can resolve without antibiotics. Our 7 cases were similar to the literature. We noted a less frequent onset with fever (42.9 vs 74%) and more groin pain (71.4 vs 41%). Laboratory findings disclosed nonspecific inflammatory response and imaging was the most powerful diagnostic tool (100% positive with MIR, CT and schintigraphy): it matches with previous data. Blood cultures had intermediate sensitivity, higher at direct specimen cultures (100% positive). Management was first medical: endovenous antibiotics for a long span of time; in all but one case, more than one drug was necessary. Surgery was performed in 57.1%, the same rate found in previous data. Outcomes were most good, but 2 cases of urinary incontinence worsened and a stroke and death in an elderly and comorbid patient happened. We estimate that an important number of cases of osteitis pubis lack of a microbiological research for ruling out SAPS, so we ask for awareness about misdiagnosis.

Conclusions: Septic arthritis of the pubic symphysis is an illness with an estimated high rate of underdiagnosis. Microbiology research is desirable when assessing any osteitis pubis, which can have an overseen infection underlying. Women after urinary incontinence surgery are specially prone to SAPS. Given the reduced number of cases, it is not possible for us to make diagnostic or therapeutic advices.

INFECTIOUS DISEASES IN PREGNANCY OUR EXPERIENCE AS CONSULTANTS IN AN OBSTETRICS CLINIC

M. Abínzano Guillén[1], S. Clemos Matamoros[1], A. Villanueva Fortún[1], M. Ruiz Castellano[1], C. Larrañaga Azcárate[2], E. Huarte Arregui[1], R. Arnaez Solis[1], P. Fanlo Mateo[1]

[1]Department of Internal Medicine, [2]Department of Obstetrics. Hospital Virgen del Camino. Complejo Hospitalario de Navarra B. Navarra, Spain.

Objectives: To describe characteristics of infectious diseases in pregnant women.

Material and method: Descriptive study of some pregnant women attended both as inpatients and outpatients. A total of 310 pregnant women were enrolled in the study, and 52 of them had an infectious disease.

Results: The average age of the patients was 33 versus those infected who were 31. Nationalities: Spanish (61%), Latin Americans (21%) and Africans (13.4%). The kinds of infections that we attended are shown in T. 1.

Discussion: In this study we have investigated the occurrence of infections and complications during gestation period. We concluded that the most frequent infection was the respiratory followed by the urinary ones, and the rest was a miscellany that includes, malaria, tuberculosis and listeriosis. The frequency of the above mentioned processes did not change according to the nationality or the complications. All the patients received antibiotic treatment allowed in pregnancy. There was neither any fetal loss nor any mother death. A patient had to be attended in the Medical Intensive Care Unit with respiratory sepsis. Three premature childbirths were registered as complications, two preeclampsias and a patient developed diabetes mellitus secondary to steroid treatment. The third quarter of pregnancy was the most frequently affected by infections. All the cases evolved favourably. All the patients were valued again after discharge at Internal Medicine Clinic as outpatients.

Conclusions: Pregnancy is considered to be a time of major susceptibility to infectious diseases that must be detected in time and treated properly in view of the potential risk of obstetric (premature childbirth) and systemic complications. The collaboration between the departments of Obstetrics and Internal Medicine is essential in the diagnosis, treatment and follow-up of these patients.

Table 1 (A-84). Type of infections and frequency

Respiratory infections	Pneumonia	38.3%
	No pneumonia	18%
	Sepsis	1%
Flu	H1N1 influenza virus	13.4%
	Seasonal flu	4%
Urinary tract infections	Kidney infection	5.7%
	Lower urinary tract infection (E. coli)	4%
Malaria		4%
Bacterial meningitis		2%
Listeriosis		2%
Brucellosis		2%

A-85
BLOODSTREAM INFECTIONS IN AN INTERNAL MEDICINE DEPARTMENT

A. González, F. Hidalgo, M. Vivancos, A. Domínguez, D. Benito, J. Rojas Marcos, I. Barbolla, S. Diz

Department of Internal Medicine. Hospital Ramón y Cajal. Madrid, Spain.

Objectives: To describe the clinical characteristics, microbiological profile, treatment, associated complications and mortality in patients with bloodstream infection (BSI) in an Internal Medicine ward.

Material and method: A descriptive study on significant bacteraemia detected from December 1st, 2011 to May 15th, 2012 in an Internal Medicine department of 114 beds in a tertiary hospital. Through this period, we describe the demographic, microbiological, clinical data and outcome of the patients affected with a BSI. We recollected the positive blood cultures of our patients and we exclude those which suggested contamination. We consider appropriate treatment when the antibiotic used was effective in vitro according to the antibiogram susceptibility.

Results: A total of 67 positive blood cultures (for significant bacteraemia or fungaemia) were isolated from 63 patients, with

an incidence of 3.7% during this period. The mean age was 81.3 years (range: 40-97) being 66.7% older than 80 years. Females were predominant (60.4% vs 39.6%). The mean Charlson score was 2.6 (SD: 1.7). For functionality index our patients had a mean of 53.5 in Barthel index and 33.3% of patients had an F-G Katz index. Bloodstream origin was 43.3% community, 43.3% nosocomial and 13.4% healthcare-associated. The isolates were 47.7 Gram-positive (GP) cocci, 44.8% Gram-negative (GN) bacilli and 7.5% fungi (with 6% polimicrobiane including anaerobes). The pathogens most frequently isolated were Escherichia coli (31.3%; 70% of GN bacteria), Coagulase-negative Staphylococci (CoNS) (16.4%; 34.4% of GP organism) and Staphylococcus aureus (11.9%; 25% of GP). All fungi were Candida species (3 C. albicans, 1 C. glabrata, 1 C. parapsilosis). In 26 episodes (38.8%) the patient did not have SIRS criteria; the others (41) had a clinical feature of sepsis (22), severe sepsis (11), septic shock (5) and multiorganic failure (3). The most frequent source of infection was urinary (35.8%) followed by abdominal (17.9%). Nine bacteraemias (13.4%) were related with intravascular devices, causes by GP bacteria (7) and Candida albicans (2). In 66 cases (98.5%) the patient received empirical treatment, which was appropriate in 42 (63.3%). The antibiotics used were: Piperaciline/tazobactam (26.8%), amoxiciline/clavulanic (19.4%), quinolones (16.4%), cefalosporines (14.9%) and meropenem (14.9%). Complications included 2 patients who were admitted to ICU (with endotracheal intubation), 8 required vasoactive drugs and 2 needed surgery. The global mortality was 23.9%.

Discussion: We detected a higher percentage of non-community BSI (56.7%) than in other series. This data could be explained because of the characteristics of our population. As shown in other studies, E. coli is the most frequent pathogen in our cohort and as a group GP cocci were the main isolates. We have a proportion of candidaemia of 7.5% of a BSI, similar to that found in other series, (3 nosocomial and 2 health-care associated). We found 43.3% of the bacteraemias were nosocomial in origin; the main pathogen group was GP cocci (55.2%) associated to intravenous devices (24.1%); they presented with sepsis in 62% and the treatment was initiated or started empirically in 96.5% of the cases but only appropriate in 44.8%. Despite that the principal antibiotic prescribed was piperaciline-tazobactam, it is remarkable the high prevalence of inappropriate treatment (36.3%); this may be explained by the high prevalence of nosocomial bacteraemias, the predominance of GP cocci and the isolation of extended-spectrum beta-lactamase enterobacteriae and Candida species. We found a mortality rate of 23.9%, this result is a little higher than that seen in other series, this could be due to the clinical profile of our patients and the higher percentage of inappropriate empirical therapy.

Conclusions: Bacteraemia remains a significant problem, regarding morbidity and mortality both for community and nosocomial origin. Measures should be implemented for the prevention of nosocomial bacteraemia, as well as to identify risk factors for resistant organisms, which can help to improve the empirical treatment prescribed.

A-86
IMPACT OF SUBACUTE THYROIDITIS PRESENTING AS FEVER OF UNKNOWN ORIGIN IN A TERTIARY HOSPITAL

C. Voulgari, S. Siasiakou, R. Giannas, C. Karagiannis, S. Paximadas, S. Pagoni

3rd Department of Internal Medicine. Athens Regional Hospital G. Gennimatas, University Medical School. Athens, Greece.

Objectives: Subacute thyroiditis is a painful, inflammatory disease of the thyroid gland, probably of viral origin. It is an uncommon but important cause of fever of unknown origin (FUO). We investigated FUO in 97 patients and recorded the frequency of subacute thyroiditis presenting as FUO in the studied population in respect.

Material and method: We investigated 136 (61 male) patients with FUO hospitalized between January 2011 and April 2012 at our Internal Medicine Department.

Results: The median age of the patients was 48.5 years (median range: 24-87 years). Eleven patients (8.08%) were over 65. Mean duration of hospitalization was 22.5 ± 13 days. Infectious diseases were the most common causes of FUO. Tuberculosis (n = 15, 11.0%), infective endocarditis (n = 6, 4.4%), abdominal abscess (n = 6, 4.4%), brucellosis (n = 5, 3.7%), urinary tract infection (n = 5, 3.7%), atypical pneumonia (n = 16, 11.8%). Cytomegalovirus infection or encephalitis was diagnosed in 51 (37.5%) patients. The second most common causes of FUO were collagen vascular diseases (n = 16, 11.8%) determined as vasculitis syndrome, adult Still's disease (n = 4, 2.9%), systemic lupus erythematosus, Behçet's disease, juvenile ankylosing spondylitis. Neoplasm was found in 12 (8.8%) patients; (non-Hodgkin lymphoma, Hodgkin lymphoma, chronic myeloid leukemia, gastrointestinal tract carcinoma, breast adenocarcinoma). Subacute thyroiditis was diagnosed in 22 (16.2%) patients. On admission, ten patients (7.4%) were neutropenic.

Discussion: Infectious diseases are the leading diagnostic category of FUO in our study. Subacute thyroiditis was more common than expected. An etiological diagnosis could not be reached in six (4.4%) patients who were followed for 1 year. Five of these patients completely recovered, and one patient died.

A-87
CLOSTRIDIUM DIFFICILE INFECTION IN HOSPITALIZED PATIENTS: A TWO YEAR RETROSPECTIVE REWIEV

A. Romero Alegria[1], E. Puerto Pérez[1], N. Cubino Bóveda[1], P. Miramontes González[1], J. Sánchez Tocino[2]

[1]Department of Internal Medicine. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca, Spain [2]General Surgery. Hospital Universitario de Salamanca. Hospital Virgen de la Vega. Salamanca, Spain.

Objectives: To identify risk factors for infection with Clostridium difficile in hospitalized patients in our department in the University Hospital of Salamanca.

Material and method: This is a retrospective review of the cases of clostridium difficile isolated in the Department of Internal Medicine of the University Hospital of Salamanca in a period of two years. All patients with positive culture results for Clostridium difficile toxin from January 1st 2010 to December 31th 2011 were eligible for inclusion in the study. Registered data included age, sex, previous antimicrobial therapy, hospitalization 30 years prior to admission, surgery or any type of immunosuppression.

Results: There were 9 cases, 66.6% women and 33.3% men; the mean age was 82 years. 77.7% of the patients had received prior antibiotic treatment with beta-lactam antibiotics. 33.33% of the patients had had surgery and 31% had suffered some kind of immunosuppression.

Discussion: Clostridium difficile is the leading cause of healthcare-associated infectious diarrhea. Although Clostridium difficile is part of normal flora in some healthy individuals, patients with selective risk factors are often vulnerable to the toxigenic potential of this virulent healthcare pathogen. The spectrum of Clostridium difficile infection is highly variable, ranging from mild to severe illness, presenting with single to multiple disease recurrences. Antibiotic use is the most widely recognized and modifiable risk factor for C. difficile-associated diarrhea. Other established risk factors include hospitalization and advanced age (dramatic increases in the incidence and severity of healthcare-associated C. difficile infection have occurred over since 2000, particularly in patients over age

65). Possible additional risk factors are surgery or cancer chemotherapy and hematopoietic stem cell transplantation. The association between cancer chemotherapy and C. difficile infection may be related to the antimicrobial effect of chemotherapeutic agents and/or their immunosuppressive effects.

Conclusions: Prevention and eradication of Clostridium difficile infection require a multidisciplinary approach, including early disease recognition through appropriate surveillance, implementation of effective contact isolation strategies, adherence to environmental controls, judicious hand hygiene, evidence-based treatment, and management that includes antibiotic stewardship, continuous education of healthcare workers, and administrative support.

A-88
EXTRAPULMONARY TUBERCULOSIS. A REVIEW OF THE LAST 5 YEARS

M. Sánchez[1], E. Niño[1], J. Ruiz[1], J. Ramos[1], N. Msabri[1], A. Smithson[2], M. Bastida[3], M. Torres[1]

[1]Department of Internal Medicine, [2]Emergency Department, [3]Microbiology Department. Fundació Hospital de l`Esperit Sant. Barcelona, Spain.

Objectives: Tuberculosis (TB) can affect by hematogenous, lymphatic or contiguous spread to any organ or body tissue, both at the primary infection as when a reactivation occurs. The most common form is the pulmonary disease (P-TB). The diagnosis of extrapulmonary-TB (EP-TB) requires a high index of suspicion, as it presents with non-specific symptoms, the difficulty to obtain representative samples, and the poor rentability of the smear and cultures. The best regimen of treatment for EP-TB is not fully clear. The aim of this study is to analyze the clinical, epidemiological and microbiological characteristics and the evolution of the EP-TB diagnosed at our center.

Material and method: A retrospective study between January 1, 2007 and December 31,2011 was carried out. We reviewed the medical records of all the patients diagnosed with EP-TB. Epidemiological, clinical, microbiological and treatment data were collected. Cases of EP-TB were defined by a positive culture for M. tuberculosis (microbiological criteria), histological samples showing necrotic granulomas (histological criteria), a biochemical study of organic fluids compatible plus an elevated ADA (biochemical criteria)or by a favourable response to the antituberculous treatment in the absence of an alternative diagnosis (clinical criteria).

Results: Among the 92 patients diagnosed as TB during the study period, 35 were EP-TB (38.04%). The diagnosis was made by microbiological criteria in 23 cases (65.7%), histological criteria in 7 cases (20%), biochemical in 4 (11.4%) and by clinical suspicion in 1 (2.9%). The EP involvement was pleural in 14 cases (40%), nodal in 13 (37.1%), abdominal in 4 (11.4%), musculoskeletal in 4 (11.4%), central nervous system in 1 (2.9%) and parotidal in 1 (2.9%). There was associated P-TB in 10 cases (6 pleural + P-TB, 2 nodal + P-TB, 1 abdominal + P-TB, 1 musculoskeletal + P-TB). 8 patients were Spanish (22.9%), 20 Asian (57.1%, 13 from Pakistan, India 3, Bangladesh 1, China 2), 3 from South America (8.7%, 1 from Brazil, Bolivia 1, Peru 1), 2 from North Africa (57% Morocco), 2 from Sub-Saharan Africa (5.7%, 1 from Senegal, Equatorial Guinea 1) and 1 from Eastern Europe (2.9% Moldova). 71.4% of the patients were male. Mean age at diagnosis was 38.9 ± 13.9 years (51.1 years among the Spanish, 33.6 among foreigners). 42.9% were smokers and 11.4% had chronic alcoholism. 1 patient was pregnant at the diagnosis. The more frequent comorbidities were: chronic lung disease (5.7%), heart disease (5.7%), diabetes mellitus (2.9%), cirrhosis (5.7%), connective tissue disease (2.9%). None of the patients was HIV+, 5.7% had pharmacologic immunosuppression. The most common symptoms were fever (40%), cough (34.3%), sweating (22.9%), dyspnea (17.1%), chest pain (20%), expectoration (20%) and a growing mass (28.6%). The average time of onset was 59.4 ± 80 days. 94.3% of the patients required hospitalization, 13.2 ± 9.8 days-long on average. Among the 23 cases with a microbiological diagnosis, we had antibiogram in 18, and we found resistance to first-line antiTB drugs in 5 (27.7%). The treatment regimen used in most cases (62.8%) was 2 months of isoniazid (H), rifampicin (R), pyrazinamide (P) ± ethambutol (E) followed by 4 months of RH. In the remaining cases the treatment was extended until9-18 months, without using other drugs. In 4 cases, steroid therapy was added (11.4%). The treatment was performed on an outpatient regimen in all cases, in 4 patients we used a directly observed treatment regimen. 5 patients were lost during the follow-up (14.3%). The evolution was successful to healing in all patients except 1 patient with meningeal TB who was exitus during the hospitalization.

Conclusions: EP-TB represents 38.04% of the TB diagnosed in our center. The most frequent forms are nodal and pleural TB. Most patients with EP-TB were foreigners and young. In most cases the diagnosis was microbiological, and it was more frequent in cases associated with P-TB (90% vs 56%). In many cases we initiated treatment before microbiological confirmation (40%). Among the positive cultures with antibiogram, we found resistance to first-line antiTB drugs in 27.7%. The most frequent resistance was to isoniazide. In most cases we used a 6-month regimen for treatment (2IRP/IRPE+4IR), with a correct evolution in all of them, except for 1 meningeal TB.

A-89
SEVERE SEPSIS IN HOSPITAL VIRGEN DE LAS NIEVES OF GRANADA

A. Fernández Miralbell[1], I. Valenzuela Salas[2], V. Sotorrío Simó[1], C. Santiago Díaz[1], C. Hidalgo Tenorio[1]

[1]Department of Internal Medicine, [2]Department of Dermatology. Complejo Hospitalario Virgen de las Nieves. Granada, Spain.

Objectives: To analyze compliance with quality standards for severe sepsis in our hospital and to identify weaknesses or deficiencies in the application of this process and seek opportunities for improvement.

Material and method: We have performed a retrospective study of patients with severe sepsis treated in the emergency department of our hospital (January 2010-December 2011) and analyzed them according to five criteria of the quality standards of the the Andalusian Health Service (Table).

Results: We included 50 patients (average age: 79.7 years; men/women: 42/58%). We found only one of the evaluated criteria has obtained an acceptable result which is the identification of the infective focus at an early stage, and early extraction of blood cultures, early antibiotic therapy and completion in the clinical history of time to perform those tasks has achieved results below the quality standards.

Discussion: Severe sepsis is a prevalent disease with high mortality and morbidity, often associated with chronic conditions, whose outcome depends largely on the correct actions performed early. The multidisciplinary approach and compliance with quality standards will optimize the results in terms of survival and quality of life for these patients.

Conclusions: The management of severe sepsis in our hospital is likely to improve, given the results obtained. To do this we consider essential to develop hospital protocols and awareness of health personnel about the importance of early extraction of blood cultures prior to initiation of early empiric antibiotic therapy.

Table (A-89). Criteria of the quality standards of the Andalusian Health Service

Criteria	Accomplishment	Minimal Standard	Optimal Standard
Blood culture taken in the first hour	26% (14-38%)	75%	> 90%
Antibiotic administered within one hour	52% (38-66%)	75%	> 90%
Blood cultures taken before antibiotic administration	28% (16-40%)	80%	95%
Identification of the infective focus in the first 6 hours after onset	88% (79-97%)	75%	> 90%
Filling in in the clinical history of time of performance of tasks	48% (34-62%)	75%	> 90%

A-90
ADHERENCE TO OPTIMIZATION PROGRAM ON ANTIMICROBIAL PRESCRIBING FOR ADMITTED PATIENTS AFTER TRANSFER FROM ICU (INTENSIVE CARE UNIT) TO A WARD

A. Cuenca[1], L. Benítez[1], E. Muñez[1], T. Álvarez-Espejo[1], M. Fernández-Tomás[1], C. Pérez-Velilla[1], V. Saavedra[2], A. Ramos[1]

[1]Department of Internal Medicine Unidad infecciosas, [2]Department of Pharmacy. Hospital Universitario Puerta de Hierro Majadahonda. Majadahonda (Madrid), Spain.

Objectives: Prescription of an a inappropriate antimicrobial therapy is a common problem that is associated with multiresistant bacteria selection and patient mortality. Setting an effective and low cost strategy could significantly improve the current situation. Our work consists in evaluating the percentage of adherence to recommendations made by a team of experts in antimicrobial therapy (TEAT).

Material and method: Prospective study in a cohort of patients after transfer from ICU to a ward in the H.U. Puerta de Hierro. The patient enrollment period was 2 months, november and december of 2011. TEAT reviews cases and provides a recommendation for modification or maintenance of antimicrobial therapy. Adherence to recommendation is evaluated in this study.

Results: One hundred thirty-six patients were analyzed of which 59.6% are male and 40.4% women. The median age was 60.8 years and average age was 59.7. Average stay in ICU was 6.6 days. The patients were transfer more frequently to surgical departments, and of these, thoracic surgery (30.1%), general surgery (16.2%) and neurosurgery (8.1%), were the most frequent. In the medical departments, the most frequent were cardiology (9.6%), internal medicine (4.4%) and liver transplant (4.4%). Of the cases reviewed, 40.7% had no infection. One hundred eighteen infectious processes were reviewed, of which 27.9% were respiratory, 28.8% were abdominal and 24.57% had not an established source of infection. The antimicrobials most frequently received by the infected population were piperacillin-tazobactam (9%), linezolid (7%), ciprofloxacin (7%), meropenem (6%), levofloxacin (5.5%), amoxicillin clavulanate (5%) and fluconazole (4%). Of all infected cases (59.3%), 20.3% received a recommendation on antimicrobial therapy (58.3% to remove and 33.3% to change therapy). These recommendations were accepted in 66% of the cases.

Discussion: Despite the need to implement strategies to optimize antimicrobial therapy use, in Spain only 40% of hospitals has introduced a strategy to improve antibiotic prescribing. Currently it is essential to achieve a strategy to develop a rational use of antimicrobial therapy to ensure their effectiveness. Our study demonstrates an effective strategy that optimizes the use of antibiotics and that a simple and cheap intervention achieved a great percentage to adherence. Most of the patients included were discharge to surgical departments because the surgical ICU is the one with largest number of patients. Our study suggests the effectiveness of this strategy among physicians with less experience in the use of antimicrobial therapy. There's is great use of broad spectrum antimicrobial therapy because the patients included have criteria for nosocomial infection. The evaluation of these patients by TEAT allows the removal of broad-spectrum antimicrobial therapy in a great percentage of patients.

Conclusions: The prescription of antibiotics to ICU discharge is correct in a large number of patients. Adherence to the program of optimization of antibiotic therapy is high. The study of the patients after transfer from ICU to a ward by TEAT is an effective strategy in optimizing the use of antibiotics, that could reduce the emergence of bacterial resistant, could reduce mortality associated to infections and could also allow a reduction in pharmaceutical spending. Larger sample sizes are needed to obtain more conclusive data.

A-91
DESCRIPTIVE STUDY OF CASES OF NOCARDIOSIS PRESENTED JANUARY 1995 TO APRIL 2012 IN A COMMUNITY HOSPITAL IN SOUTHEASTERN SPAIN

B. Martínez López[1], N. Gonzalo Giménez[2], J. Gregori Colomé[1], I. González Cuello[1], I. Sánchez Rodríguez[1], C. Jiménez Guardiola[1], V. Martínez Sempere[1], A. Lucas Dato[1]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital Vega Baja de Orihuela. Orihuela (Alicante), Spain.

Objectives: Introduction. Nocardiosis is an infection caused by aerobic gram-positive bacteria of the genus Nocardia. It mainly affects immunocompromised patients with underlying disease or predisposing although cases have been reported in healthy patients. The presentation is usually the pulmonary, cerebral or skin and its course is usually chronic and prone to relapse.

Material and method: We analyzed the clinical and epidemiological and microbiological characteristics of 22 patients who were isolated microorganisms of the genus Nocardia from January 1995 to April 2012.

Results: Factors of risk of nocardiosis: 1. COPD 75% 2. Corticotherapy 15% 3. Systemic diseases 10% Microbiological isolation: 1. Nocardia asteroides 55% 2. Nocardia carnea 15% 3. Nocardia farcinica 5% 4. Nocardia cyriacigeorgica 5% 5. Others 20% Clinical presentation: 1. Pneumonia 65% 2. Pleural effusion 15% 3. Lungs nodules 10%.

Conclusions: As in other series, we note that the nocardiosis is more frequent in males of age advanced with some factor of immunosuppression, mainly chronic obstructive pulmonary disease, corticotherapy and the presence of systemic disease such as rheumatoid arthritis. The commonest format was pulmonary involvement in all of them and the isolation of Nocardia was conducted mostly in sputum culture. With regard to treatment, all patients were treated from the microbiological discovery of Nocardia with cotrimoxazole with an average duration of 6 months. Finally, in our series have found a relatively low mortality with respect to other studies, probably in connection with the low prevalence of species associated with increased mortality as the N. farcinica, or the absence of severe and prolonged immunosuppression situations such as transplants and hematologic diseases.

A-92
KLEBSIELLA PNEUMONIAE ESBL OUTBREAK IN NEONATAL UNIT

S. Iftimie[1], A. López[1], I. Pujol[2], F. Ballester[2], R. Cullell[3], M. Saballs[1], A. Castro[1]

[1]Department of Internal Medicine, [2]Department of Microbiology, [3]Department of Pediatry. Hospital de Sant Joan de Reus. Tarragona, Spain.

Objectives: Klebsiella pneumoniae producing beta extended spectrum lactamase (ESBL) is involved in many of nosocomial outbreaks due to its easy cross-transmission. We report our experience in controlling an outbreak in a neonatal unit with capacity for 15 infants, in a second level hospital with 326 beds.

Material and method: The determination sensitivity to antibiotics was performed by the system WalkAway MicroScan (Siemens) and disk diffusion techniques. After identification of the first case of ESBL Klebsiella pneumoniae bacteremia was activated the protocol for monitoring and controlling an outbreak of nosocomial infection. Perineal swabs were performed for all patients admitted to the unit, contact precautions were instituted, insisting on increasing hand hygiene measures. It limited the admission of patients in the neonatal unit, enabling a space with separate staff for newborns infected/colonized. Environmental samples were collected followed by thorough cleaning of the room. It raised the level of suspicion of infection by this organism in patients who have been assisted in this unit. It was also decided to perform perineal swabs as active surveillance for all newborns admitted to the unit once a week, for patients on this ward and medical staff who came into contact with unit patients and parents of patients colonized/infected. We warned the hospital that were in contact with neonatal patients in our hospital. It declared the outbreak to the Department for Health.

Results: All strains showed the same phenotype of multidrug resistance and ESBL production. Were detected: 6 colonized patients (positive perineal swabs), 2 patients with bacteremia of intestinal origin (all premature and all properly cured). No culture was positive for ESBL Klebsiella pneumoniae in 72 samples carried out to health workers, 5 to relatives, 42 environmental samples. Strains were studied by molecular epidemiology, all had the same pulsed-field pattern. There were several sessions with the medical staff emphasizing measures to prevent cross-transmission.

Discussion: Control of the outbreak is complex, it takes teamwork. It is necessary to maintain the level of high alert to new outbreaks.

Conclusions: The source of infection was not detected. It was demonstrated that all strains had the same pattern, strict isolation measures, hygiene helped control the outbreak quickly.

A-94
INFECTIOUS PROSTATITIS AS A CAUSE OF FEVER WITHOUT APPARENT SOURCE

I. Novo Veleiro[1], M. Hernández Cabrera[2], F. Cañas[3], E. Pisos Álamo[2], A. Francés Urmeneta[2], M. Delgado Yagüe[2], A. Barbosa Ventura[1], J. Pérez Arellano[4]

[1]Department of Internal Medicine. Hospital Universitario de Salamanca. Salamanca, Spain. [2]Infectious Diseases Unit and Tropical Medicine, [3]Department of Microbiology. Complejo Hospitalario Universitario Insular de Las Palmas. Las Palmas, Spain. [4]Department of Medical and Surgical Sciences. Universidad de Las Palmas de Gran Canaria. Las Palmas, Spain.

Objectives: The aim of this study was to describe all cases of prostatitis diagnosis in our unit over a period of five years, analyzing specifically the clinical presentation and the organisms responsible.

Material and method: We conducted a retrospective cohort study including all patients diagnosed from 1st of August 2006 to 31st of July 2011. The inclusion criterion was a consistent positive result after performing the Meares-Stamey test. Epidemiological, clinical, analytical and microbiological data were collected from clinical history of each patient. All cases with two or more bacteria isolated from cultures were considered as polymicrobial. A descriptive study was performed, analyzing clinical and microbiological characteristics. We specifically analyzed the association between clinical presentation (only symptoms, symptoms and fever or only fever) and epidemiological, analytical or microbiological findings. For quantitative variables comparison we used the Student's t test when two groups were compared and the ANOVA test when more than two groups were compared. For qualitative variables comparison we used the χ^2 test, using Fisher's exact test when expected frequency was less than 5. SPSS statistical program version 18 was used.

Results: 39 cases of prostatitis were diagnosed during the study period, the average age was 44 (SD = 12) years. 17 of them (44%) presented any kind of immunosuppression (14 by HIV infection). 51% related regularly anal sex with other men. 12 patients (31%) presented only symptoms like pelvic pain or dysuria (group I), 8 patients (20.5%) referred symptoms and fever (group II) and 19 (49%) fever without symptoms (group III). ESR was significantly higher in patients from group III ($p < 0.05$). There was no significant difference on PSA levels between the three groups, and it was elevated only in 5 patients. 66.6% of cases were caused by a unique bacteria and coagulase-negative staphylococci were the most frequently isolated (4 cases), followed by Escherichia coli, Corynebacterium glucurunolyticum and Streptococcus mitis (3 each). Among the polymicrobial prostatitis Enterococcus faecalis (5 cases) and E. coli (4 cases) were the most frequent responsible agents. Monomicrobial origin was more frequent among patients from group III (79%) than from the others (54%).

Discussion: Prostatitis presentation as fever of unknown origin is infrequent, ours is the first cohort study in this way. E. faecalis and E. coli are the most frequent isolated bacteria from prostatitis, but coagulase-negative staphylococci are not common etiologic agents. Polimicrobial origin is more frequent in our series than in previous. These differences may be due to the high percentage of patients with anal sex habits. The only biomarker that has shown usefulness in the diagnosis of prostatitis is ESR, much more than PSA, and it could be considered as a useful tool.

Conclusions: The main focus of our study lies in the atypical presentation of a high percentage of the diagnosed prostatitis, as fever without symptoms. We believe it is necessary to consider this condition in the differential diagnosis of a patient who complains of fever of unknown origin.

A-95
EVALUATION OF INFECTIOUS UNIT IN INTERNAL MEDICINE

B. Díaz Pollán, M. Núñez Orantos, M. Varas Mayoral, V. Issernia, V. Estrada Pérez, M. Téllez Molina, J. Vergas García

Department of Internal Medicine III. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: Our department of Internal Medicine includes a specific HIV-infectious diseases Unit, that carries out his activity both in conventional hospitalization and by way of monographic consultations (HIV, hepatitis confection, tuberculosis, STD) and, occasionally, revision of immigrant and traveler pathology and patients that other departments send us. In our hospital the interconsultation demand for Internal Medicine is very intensive, so that an Interconsultations Unit was set up seven years ago with great success thanks to the full-time dedication of two doctors. The Interconsultations Unit has served mainly in the surgery services;

having a major role in General Surgery, Urology, Neurosurgery, Vascular Surgery, Otolaryngology, Orthopedics and Psychiatry Departments. In the last year (since May 2011) after the recent works of adaptation of main building hospital, a new specific Interconsultation Unit has been created to take over infectious diseases interconsultations; through the traditional route (request in the department secretary) or directly by calling to the pager. This project is carried out specifically by means of two doctors responsible for the conventional hospitalization of infectious diseases in the Internal Medicine department.

Material and method: We intend to analyze the number of interconsultations attended by our Unit, in the period from May 2011 to April 2012.

Results: We have served a total of 36 interconsultations in a regulated manner with monitoring during the entire stay, having made at least four visits to patients. The cause of the request is heterogeneous. We have seen 6 cases in ICU for HIV related problems, especially in relation to treatment or AIDS disease. In the first month we attended several patients (5) with prosthetic and surgical orthopedic materials infection, but stopped attending these patients after the Internal Medicine department decided by consensus to appoint for these tasks a specific physician from the general Internal Medicine interconsultations program. 6 interconsultations came from other surgical departments (Neurosurgery, General Surgery, Cardiac Surgery and Vascular Surgery), having all interventions been effective, facilitating the control of nosocomial infection and therefore hospital discharge. Additionally, we have followed Otolaryngology inpatients (3) with suspected TB; we initiated treatment and after follow-up in our consultations, in two of them the final diagnosis was not TB (one was a necrotizing external otitis in relation to Aspergillus and neck abscess in other caused by a bacterial cyst gill infection). We also gave support to diagnosis and control of infectious diseases in medical services: Cardiology, Hematology and Internal Medicine, consulted for HIV-related pathology (3) and regarding fever of unidentified infectious cause (3). It is remarkable the significant number of interconsultations related to Rheumatology hospitalization (10), since their patients present complex and severe infections related to immunosuppressive states of adjuvant treatment.

Discussion: We believe that we offer to our hospital a rapid and specific management of both HIV pathologies (related to advanced disease) and in specific treatment or in the treatment complications. Moreover, our infections disease Unit helps in the nosocomial infections control and antibiotic management, so important in the era of multi-resistant germs.

Conclusions: The Internal Medicine interconsultations with infectious disease profile are necessary and should be encouraged because they help in the infection control, especially in the nosocomial infection and the advice of specific antibiotics. The Internal Medicine interconsultations with infectious disease profile help develop multidisciplinary units so important nowadays for the management of inpatients who consume more resources. The Internal Medicine interconsultations with infectious disease profile help the early discharge.

A-96
EVALUATION OF THE SIDE EFFECTS OF TIGECYCLINE

R. Escudero Sánchez[1], R. García Caballero[1], M. González Anglada[1], A. Prieto Callejero[2], B. Sánchez Sauce[1], M. Ruiz Muñoz[1]

[1]Department of Internal Medicine, [2]Department of Pharmacy Hospitalary. Hospital Universitario Fundación Alcorcón. Madrid, Spain.

Objectives: Tigecycline is a broad-spectrum antibiotic recently marketed. We studied the situations where the drug is prescribed, the therapeutic indications, and patient characteristics, in order to assess the use of antibiotic and their adverse effects.

Material and method: We reviewed 42 reports of patients admitted in HUFA, for 17 consecutive months, through the institutional computer system. We collected the characteristics of the individual variables, according to Charlson comorbidity index and therapeutic indications by medical notes, nursing comments and analytical data. The analysis was performed using SPSS 15.0.

Results: During 17 months, 42 patients were treated with tigecycline, 59.5% were men, the median age was 80 years old; and 31% came from elderly residents. In 73% of the cases, the prescription was made by a medical service; of the total were 38% from internal medicine, 19% surgery, 9.5% digestive, 9.5% vascular, 9.5% intensive care unit, 7.1% traumatology, 2.4% neurology, 2.4% urology and 2.4% oncology. The median duration of treatment was 9 days. 23.8% of patients died meanwhile their hospitalization. The median Charlson index was 6 points. 42.9% of the patients were diabetics, and 11.9% cirrhotics. The main indications were soft tissue infection and abdominal infection (28% in each one). Other infections were urinary (23.8%), post-surgical (9.5%), pneumonia (4.8%) and other (5.9%). 47.6% of patients had some type of adverse reaction: gastrointestinal effects (nausea, vomiting and abdominal pain) 23.8%, increased INR 14.3%, mild thrombocytopenia 11.9%, diarrea 4.8%, rash 2.4% pruritus and phlebitis 2.4%. Adverse effects were analyzed by age, sex, comorbid with diabetes, liver failure, renal failure and immunosuppressive therapy, only one finding was statistically significant, with p 0.012 in patients with liver failure. It was observed that 100% of patients with liver failure had any adverse effects, of which 40% were elevated INR and 40% thrombocytopenia. Only in one case the treatment must be stopped because of adverse effect (increased INR), in 17 patients the pattern were ended, and in 18 patients by treatment´s adjustment to carbapenems in 16.7%, quinolones in 14.3%, and beta-lactams in 7.1%.

Discussion: The tigecycline adverse reactions are similar to those observed in other tetracyclines, that mostly are mild gastrointestinal effects. It was observed a statistically significant association between patients with liver failure and hematologic disorders.

Conclusions: It's needed to have a special attention to those patients with liver failure, in order to avoid hematologic disorders, because it can means the treatment's suspension. Taking into account the above we can conclude that tigecycline is a well tolerated drug, in spite of the important comorbidity of the patients presented in our study.

A-97
EVALUATION OF ADULT PATIENTS WITH MEASLES

B. Díaz Pollán[1], M. Nuñez Orantos[1], M. Varas Mayoral[1], V. Isernia[1], J. Mariano Lázaro[2], J. González del Castillo[3]

[1]Department of Internal Medicine III, [2]Department of Preventive Medicine, [3]Emergency Department. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: Since the beginning of 2011 a measles outbreak has been detected by the health authorities of the Comunidad de Madrid (CAM) that has affected over 743 people. This measles outbreak is the most important since the end of the last decade, included all the exanthematous diseases. 40% of observed cases correspond to people in adulthood.

Material and method: We intend to evaluate all cases of adult patients (more than 16 years old) who were admitted to the Hospital Clínico San Carlos (population area of over 700,000 inhabitants, in a tertiary hospital) with this diagnosis. Therefore, we studied retrospectively all cases that required admission in both in the short stay unit under the Emergency Department and in Internal Medicine Department.

Results: Despite the significant measles outbreak registered in the CAM, few adults have required admission in the hospital for this reason: a total of 11 patients registered since the beginning of the epidemic. The mean age was 30 years, being most of them men (9) and with a risk factor: not well vaccinated, immunocompromised or pregnant. The chief complaint was persistent fever in all cases, along with rash onset. The presumed diagnosis was accurate in all cases and the income was related with the significant involvement of the patient, although without signs of gravity assessed by SIRS, pneumonia, respiratory failure or liver involvement. The reason for income was pregnancy in 2 cases and in clinical instability in the other 9 patients. The evolution of the patients was good, without pneumonia, but with onset of hepatitis in 50% of cases, conjunctivitis, and rash persisting longer than in the pediatric population. The discharge was early in all of them, under 7 days of hospitalization (mean 3.5 days), although follow-up visits were required both for confirmation of infection and for analytical recovery. Among the cases there was only one source case. Regarding vaccination, none of them have receive a vaccine according to current WHO recommendations (starting dose between 9 and 15 months of age with booster shot at 4 years), either because of their immigrant origin (5 of them) or date of birth before these guidelines were implemented (before to 1988).

Discussion: Although measles is not a high risk rash illness (except for the possibility of progressive paralysis), a greater impairment has been demonstrated when occurring in adulthood. Generalized vaccination in childhood has drastically reduced the possibility of developing this disease, but since the beginning of this century we have been witnessing different outbreaks in Spain (in different regions) and in the rest of Europe. Both the abrupt appearance of unvaccinated migrating population, and the tendency to non-vaccination of children in certain sectors of the population has contributed to this problem. Moreover, as we have seen in our patients, the main manifestations of the disease are similar to mononucleosis syndrome: important overall involvement, severe flu-like state along with persistent fever associated with conjunctivitis, and hepatitis. Although neurological disorders are feasible, at present the incidence is so low (1:1,000,000) that no cases have been reported (neither among those declared in the CAM so far, week 20, 2012). Pregnant patients have had no complications so far (having spent more than three months after diagnosis).

Conclusions: Exanthematous diseases with available vaccines have been down to the near disappearance in the late nineties. But since the beginning of this decade the outbreaks of these diseases are gradually increasing, according to data from the CAM, being remarkable the current outbreak of measles that our region still suffers. Among cases of adult measles, the possibility of developing a disease that requires income is below 10%, being prolonged fever, hepatitis and general malaise the main causes of hospitalization.

A-98
PREVALENCE OF HIGH RISK HPV INFECTION IN FEMALE SEX WORKERS IN SPAIN

N. Pérez[1], M. Ibarguren[1], M. Elola[1], A. Fuertes[1], I. Sanz[1], G. Cilla[2], X. Camino[1], M. Von Wichmann[1]

[1]Infectious Diseases Department, [2]Clinical Microbiology Department. Hospital Universitario Donostia. Donostia-San Sebastián (Guipúzcoa), Spain.

Objectives: Infection with high-risk genotypes of human papillomavirus (HPV) is the leading cause of cervical cancer. Prevalence data are variable depending on the population studied. The aim of this study is to determine the prevalence of HPV types in cervical samples and define epidemiological characteristics of women at significant risk of exposure (sex workers).

Material and method: This is a cross sectional study. We included all female sex workers (FSW) attending a sexually transmitted infection clinic in San Sebastián (Spain) to which we had taken a sample for cervical HPV detection by Polymerase Chain Reaction (PCR) between January 2009 and November 2011. GP5/GP6 primers were used and the genotyping was performed by InnoLIPA (Innogenetics). All had negative HIV serology and none were vaccinated against HPV. Variables collected were: birth, country of origin, regular partnership and condom use on genital and oral sex.

Results: For the analysis 6 of 313 women were excluded due to an unknown or undetermined HPV result. The mean age was 33 years (range 19-53). Overall HPV prevalence was 20.2%; 19% (17% high risk) in Americans (n = 251), 16% (13% high risk) in Europeans (n = 38) and 9% (4.5% high risk) in Africans (n = 22). HPV prevalence showed a decreasing trend by age; 36.8% for 25 years or younger, 19.5% for 26-34 and 10.4% for 35 years or greater ($p < 0.001$). The 16 genotype was the most prevalent (15.1% of all carriers), followed by type 35 (10.8%) and type 52 (7.5%), all of them with a high oncogenic risk. The prevalence of genotype 18 was 2.2%. Of the 93 HPV detected 63 were high risk (67.7%). Of the 62 positive women 75.8% (47) had at least one type of high risk and 19.4% (12) carried two high-risk types simultaneously. The genotypes covered by vaccines (16/18) showed a frequency of 4.9% in Americans, 7.9% in Europeans and 5% in Africans. Among women who use condoms during genital sex 19.8% had a positive result for HPV compared to 28.6% in those who did not. In addition, among women who use condoms during oral sex the prevalence was 21.3% compared to the 19.6% among those who did not. Depending on whether they had or not a regular partnership, the prevalence was 23.2% and 16.9%, respectively (differences not statistically significant).

Conclusions: The prevalence of HPV in cervical samples was 20% in our cohort of FSW being the most prevalent genotype 16. More than three quarters of those infected had at least one high risk genotype, which warns of the importance of screening and early diagnosis of potentially malignant lesions. There were not significant differences depending on the geographic area or a regular partnership.

A-99
SHORT REVIEW OF LISTERIA MONOCYTOGENES INFECTION: MAIN CLINICAL PRESENTATIONS AND ATYPICAL FORMS

S. Alves, S. Ventura, I. Bargiela, C. Araújo, R. Ribeiro, T. Cruz

Department of Medicine III. Hospital Professor Doutor Fernando Fonseca. Amadora, Portugal.

Objectives: Listeria monocytogenes, although an uncommon cause of illness in the general population, is an important pathogen in pregnant women, neonates, elderly individuals and immunosuppressed patients and, unless recognized and treated, results in significant morbidity and mortality. Listeriosis usually presents as a self-limited acute gastroenteritis in immunocompetent patients or with invasion of central nervous system (CNS) and sepsis of unknown origin in the immunosuppressed host. Currently, studies of atypical presentations of listerial infection are insufficient and little information exists in the medical literature about other clinical manifestations of listeriosis. After having a patient admitted to our ward with listerial pneumonia, it is our aim to review the cases of listeriosis in our hospital and understand the main clinical presentations of this infectious disease, with a special emphasis to the atypical presentations.

Material and method: We diagnosed a listerial pneumonia in a patient with history of diabetes mellitus and Hodgkin's lymphoma, presenting with lower respiratory tract infection and a blood culture positive for Listeria monocytogenes. We subsequently reviewed all cases of positive cultures for this pathogen in our hospital between January 2007 and May 2012 and identified 14 cases. We excluded 2 cases as they occurred in pediatric population. We reviewed each clinical file in order to identify the form of presentation, treatment and final diagnosis.

Results: We identified 12 cases of listeriosis in adult patients. The main form of identification was from blood (9) and cerebrospinal fluid (CSF) cultures (5) and one of the isolates was from a vertebral laminectomy. All patients, but one, had some form of immunosuppression, the most common being diabetes (5) and HIV infection (4). The main form of presentation was as sepsis of unknown origin (8) although clinical signs of meningitis were also present in 3 cases. Half of the patients were diagnosed CNS listerial infections and 3 were diagnosed severe sepsis of unknown origin. Three patients had uncommon listerial infections: 1 spondylodiscitis and 2 pneumonias. Antibiotherapy was initiated in all patients but one and duration of therapy was adjusted according with diagnosis, preexisting illnesses, and clinical course, being longer than 2 weeks in the majority of the cases.

Discussion: Our small series revealed listerial infections to be rare and majorly affecting immunosupressed patients (92% of our patients had some form of immunosupression). Despite in the overall population gastroenteritis seems to be the most frequent diagnosis associated to listerial infections, we found no such diagnosis in our patients (we admit they might be underdiagnosed as the majority of these patients present with self-limited brief clinical complaints and hardly ever get to be tested for blood or stool cultures). On the other hand, and accordingly to the literature, the majority of our patients had severe CNS infections. It is presently recommended that all patients in whom listeria infection is suspected, be tested for blood and CSF cultures to exclude CNS involvement. All of our patients were tested for blood cultures but only half (and whose meningitis was suspected) had lumbar punction done. Although most of our patients were treated for an average period of 3 weeks, antibiotherapy for listerial infections can be extended to 4-8 weeks in immunossupressed patients or in those with severe form of disease. It is interesting to notice that 3 of our patients had atypical presentations of listeriosis. There are only a few cases reported of Listerial pneumonia, occurring most frequently in patients with Hodgkin's lymphoma, but we found no references to spondylodiscitis caused by this pathogen.

Conclusions: Although uncommon, atypical presentations of listeriosis can occur. It is of extreme importance to confirm listerial infection and find its origin since it determines the choice and duration of antibiotic treatment. In cases of atypical presentation such as the ones reviewed, choosing the length of treatment can be challenging, and it is often empirical, since there is little, recommendations concerning the therapeutical approach in such cases.

A-100
PERSISTENCE OF HPV INFECTION IN FEMALE SEX WORKERS A PROSPECTIVE OBSERVATIONAL STUDY

N. Pérez, M. Elola, M. Ibarguren, A. Fuertes, I. Sanz, H. Azcune, M. Von Wichmann, X. Camino

Infectious Disease Department.. Hospital Universitario Donostia. Donostia-San Sebastián (Guipúzcoa), Spain.

Objectives: The infection with high-risk genotypes of the human papilloma virus (HPV) is the leading cause of cervical cancer. The use of condoms has proven to be effective in heterosexual couples, however, we have insufficient data at higher risk of exposure. The aim of the study was to analyze the risk factors for infection/reinfection with HPV in cervix in a cohort of female sex workers (FSW).

Material and method: This is a prospective observational study. We included all female sex workers (FSW) attending a sexually transmitted infections (STI) clinic in San Sebastián (Guipuzcoa, Spain) to which we had taken, in two different visits, at least two samples for cervical HPV detection by Polymerase Chain Reaction (PCR) between January 2009 and November 2011. GP5/GP6 primers were used and the genotyping was performed by InnoLIPA (Innogenetics). All had negative HIV serology and none were vaccinated against HPV. Variables collected were: year of birth, regular partnership, condom use in genital and oral sex, HPV genotype and date of each visit. To evaluate the evolution over time of genotypes we compared 2 groups: patients who remain negative or become negative after an initial positive result (variable "negative") and patients who become positive after a first negative sample or a persisting positive result for either the same genotype or another (variable "positive"). Data were analysed with a chi-square test and a t-test for equality of means with a bilateral significance of p = 0.05.

Results: We included 101 women with the following features: mean age 32 years (range 20-50), 50.2% had a regular partnership and the prevalence of systematic use of condoms in genital and oral sex were 90.7% and 46.3%, respectively. The median number of visits was 2 (range 2-9) with a mean follow up of 17 months (SD 10.5). The geographical origin was 84% Latin Americans, 10% Europeans and 6% Africans. Thirty-two women had a positive result during the follow up, of whom, 11 acquired the infection or acquired new genotypes, 11 retained the same genotype, 9 converted negative after an initial positive result and 69 remained negative.

Conclusions: In our cohort with high frequency of reexposure frequent use of condoms has not shown a protective role against HPV reinfection or persistence. Conversely, we could not demonstrate that couples who do not usually implement preventive measures are at a higher risk. Only age is close to statistical significance in the resolution of infection.

Table 1 (A-100)

	% positives	p* Pearson's chi-square
Regular partnership (No/Yes)	22.7%/19.6%	0.707
Condom use in genital sex (No/Yes)	27.3%/21.6%	0.669
Condom use in oral sex (No/Yes)	21.3%/23.1%	0.8,0

Table 2 (A-100)

	Age (mean years)	p (bilateral significance of T test for equality of means)
Negatives/Positives	33.7/30.1	0.054
Regular partnership (No/Yes)	32.3/32.2	0.841*
Condom use in genital sex (No/Yes)	30.1/32.3	0.195*
Condom use in oral sex (No/Yes)	32.3/31.9	0.678*

Multivariate analysis.

A-101
ADEQUACY OF TREATMENT FOR METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS (MRSA) BACTERAEMIA

J. Mateo González[1], J. Cama Barbieri[1], A. Ramírez López[1], A. Zurita Estarrona[1], S. Reus Bañuls[1], E. Merino de Lucas[1], J. Portilla Sogorb[1], A. Ciller Tomás[2]

[1]Infectious Disease Unit, [2]Microbiology Service. Hospital General Universitario de Alicante. Alicante, Spain.

Objectives: To determine the adequacy of treatment for methicillin-resistant Staphylococcus aureus (MRSA) bacteraemia.

Material and method: Review of clinical histories of patients admitted from January 2011 to December 2011 at the Hospital General Universitario de Alicante (800 beds) with MRSA bacteraemia, defined as the presence of MRSA in blood-cultures. Endpoint: Correct antibiotic treatment according to clinical guidelines. Consider appropriate treatment according to: 1) The type of drug: Vancomycin or Daptomycin at recommended dosage. Linezolid was considered appropriate in other focus than primary bacteraemia or endocarditis. 2) Duration: Fourteen days for uncomplicated primary bacteraemia, or pneumonia or bacteraemia from skin and soft tissue. Four to six weeks for complicated bacteraemia, endocarditis, and osteoarticular infection. Also collected data on age, sex, origin of bacteraemia (primary, central catheter, pneumonia, endocarditis, arthritis/osteomyelitis, infection of skin and soft tissue) and the acquisition (community or nosocomial), Vancomycin MIC and consultation with infectious disease unit.

Results: Twenty-six cases of MRSA bacteraemia were reported, and in 42% Infectious Disease Unit (IDU) consultation was request. The median age was 67 [Range 10-93], 54% were male. The origin of the infection was central venous catheter (35%), endocarditis (15%), primary bacteraemia (15%), pneumonia (15%), skin and soft tissue (8%), urinary (4%), arthritis (4%) and osteomyelitis (4%). Seventy-three percent of cases were nosocomial and 27% community-acquired. The MIC (Minimum Inhibitory Concentration; mcg/ml) of Vancomycin determined by e-test was = 1 (54%), ≤ 0.5 (23%) and = 2 (19%). Sixty-two percent were treated with Vancomycin. Appropriate antibiotic treatment was administered in 88%. There were 3 cases inadequately treated because of the use of another antibiotic not indicated (beta-lactams or quinolones).

Discussion: MRSA bacteraemia usually has a nosocomial origin related to central venous catheter infection. Despite the existence of guidelines for the management of MRSA infection, a high number of patients do not receive the optimal treatment. Although our study has not included clinical endpoints, the inappropiateness of the treatment has been related to a negative outcome and increased mortality, so the goal in the management of MRSA bacteraemia should be that every patient receive adequate treatment. This year, our centre is carrying out a program for optimazing the manegement of bacteraemia. Risk factors associated with inappropriate treatment have not been reviewed because of the small number of patients.

Conclusions: Twelve percent of the patients with MRSA bacteraemia admitted in a General Universitary Hospital do not receive adequate treatment, and this could negatively impact in the outcome.

A-102
EXTENDED-SPECTRUM B-LACTAMASE PRODUCING ENTEROBACTERIACEAE IN URINE CULTURES: A CASE-CONTROL STUDY

A. Arca[1], J. Lamas[1], L. Novoa[1], C. Casas[1], M. Fernández[2], M. Rodríguez[2], J. Bermúdez[1], J. de la Fuente[1]

[1]Department of Internal Medicine, [2]Department of Microbiology. POVISA. VIgo (Pontevedra), Spain.

Objectives: Extended spectrum B-lactamase (ESBL) are enzimes found in some enterobacteriaceae that confers them higher resistance to multiple antibiotics. Many risk factors have been related to the appearance of these ESBL producing enterobacteriaceae (ESBLPE) such as hospital admittance, recent antimicrobial drug exposure, living in nursing homes, urinary catheter, etc. The aim of this study is to evaluate the clinical evolution and the risk factors related to the appearance of ESBLPE in the urine cultures.

Material and method: We designed a retrospective case-control study. Using the database of the microbiology laboratory of our hospital, we identified all the positive urine cultures realized during the year 2011. We included all the urine cultures positives to ESBLPE from both inpatients and outpatients of all hospital services. Samples from pediatric patients and from relapses of urinary tract infection were excluded. For each positive culture we selected two random positive culture with other pathogens as control. Clinical and laboratory parameters from clinical histories were used to create a database. Data of the antibiotic treatment received were collected. Clinical evolution was evaluated analysing the mortality at 30 days and the relapse rate. We used Chi-squared and Fisher´s exact bilateral tests (qualitative variables) and the Mann-Whitney U and Student's t tests (quantitative variables) for univariant analysis. Logistic regression was used for multivariate study.

Results: We included 98 positive cultures to ESBLPE from 78 patients and 196 positive urine cultures to other microorganism. Risk factors for ESBLPE in the univariate analysis were: living in nursing homes (OR 6.9; 95%CI 2.4-19.6; $p < 0.01$), antimicrobial drug exposure in previous 90 days to urine culture (OR 2.78; C.I.1.6-4.6; $p < 0.01$), previous treatment with trimethoprim-sulfamethoxazole (OR 9.4; 95%CI 1.04-86.1; $p = 0.03$), fosmomycin (OR 6.5; 95%CI 1.7-25.4; $p < 0.01$), penicillin (OR 2.9 95%CI 1.4-5.9; $p < 0.01$), carbapenems (OR 7.1; 95%CI 1.4-36; $p < 0.01$), betalactham antibiotics (OR 2.4, 95%CI 1.3-4.3; $p < 0.01$) and glycopeptide antibiotics (OR 5.8; 95%CI 1.1- 30.8; $p = 0.03$). Risk factors for ESBLPE in the multivariate analysis were: living in nursing homes (OR 8.6; 95%CI 2.9-25.5; $p < 0.01$), chronic liver disease (OR 3.1; 95%CI 1.1-7.9; $p = 0.02$), solid organ transplant (OR 9.9; 95%CI 1.05-93.5; $p = 0.04$), antimicrobial therapy in previous 90 days (OR 1.9 95%CI 1.06- 3.5; $p = 0.02$). The presence of ESBLPE was associated to inadequate initial empirical antimicrobial therapy ($p < 0.01$). A higher relapse rate ($p < 0.01$) and mortality ($p = 0.05$) was associated to initial inadequate antimicrobial therapy.

Discussion: The growing incidence of ESBLPE is an emerging public-health concern and we must be aware in order to suspect the presence of these microorganisms on patients with risk factors. In our study we identified risk factors associated to the appearance of these bacterias in the urinary tract such as living in nursing homes, previous antimicrobial treatment, solid organ transplant and chronic liver disease. Our findings are similar to those described in the literature, supporting the fact that we must evaluate the possibility of using antibiotics of broad spectrum (such as carbapenems) as empirical therapy in patients with an urinary tract infection and risk factors, especially in the presence of severe infection, since we found a worse prognosis and a higher mortality rate in those patients in whom therapy with broad spectrum antibiotics was delayed.

Conclusions: Living in nursing homes, previous antimicrobial treatment, solid organ transplant and chronic liver disease are risk factors associated to the presence of ESBLPE in the urinary tract. We must consider the use of broad spectrum antibiotics in patients with a urinary tract infection and risk factors to ESBLPE.

A-103
TARGET POPULATION CHARACTERISTICS OF TUBERCULOSIS IN A GENERAL HOSPITAL OF MURCIA

V. Martínez Pagán[1], M. Ruiz Campuzano[1], M. Alcántara Zafra[1], E. Cascales Alcolea[2]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital Rafael Méndez. Lorca (Murcia), Spain.

Objectives: The increased prevalence of tuberculosis in the last decade has been associated with the HIV pandemic, the longer life expectancy of people with immunosuppression, use of drugs that affect cellular immunity and, especially, with the increased immigration from the developing world. This facts, made us plan this descriptive study about our population affected by Tuberculosis, in an area where the immigrant population has now reached nearly about 40% of the total population. Objectives: determine the epidemiological characteristics of the population belonging to Area III of Lorca with tuberculosis, its location, method of diagnosis, drug resistance rates, association with immunosuppression and other risk factors, and mortality during hospitalization or at six weeks after discharge.

Material and method: Retrospective cross-sectional study in which we analyzed the data collected from medical records of patients admitted to our hospital, reference of the Murcia Health Area III, between 2006 and 2010, both inclusive, whit tuberculosis as a diagnosis at any location.

Results: The sample included 110 patients, of whom 67.3% were male and 32.7% were female, with a mean age of 35.74 years. Most of the population, 43.6%, was from South American origin, 33.6% were Spanish, 19.1% African and 3.6% from Eastern Europe. The average stay was 18.5 days and mortality rate was 3.63% (4 cases). As for the location of the disease 72.7% were lung, and 27.2% of extrapulmonary location divided into: 15.5% pleural, 1.8% pericardial, 1.8% Meningeal, 0.9% genitourinary, 0.9% gastrointestinal, 1.8% lymph nodes, and 1.8% spinal. Within the patients with pulmonary tuberculosis, 56.4% were bacilliferous. The diagnosis was made by microbiological techniques in 68.2% of cases, by analysis of biological fluids in 20.9%, from biopsy at 3.6% and 7.3% of clinical diagnosis. We only managed to regain antibiogram in 80 patients. Of these, 6 patients (7.5%) had resistance to isoniazid (ISH), 3 were resistant to ISH and streptomycin (3.75%), 1 was resistant to ISH, streptomycin and ethionamide (1.25%) and 1 was resistant to ISH, R and streptomycin (1.25%). Regarding the most important risk factors, in 48.71% of the cases we found no medical or epidemiological factors of interest, 12.82% had intimate contact or were cohabitants of patients diagnosed with tuberculosis, and 7.69% were active smokers.

Conclusions: In 2008, more than 80,000 cases of Tuberculosis were declared in the European Union, representing only a 1% decrease over 2007. In that year, Spain reported one of the largest incidence rates of Tuberculosis in Europe with 18.4 cases per 100,000 inhabitants, only beated by Romania and Great Britain; with 30% of the cases occurring in immigrants and with rates of primary resistance, according to the last NATO reports, of 8.3% and 1.3% of multidrug resistance. In the period of study, the incidence in our area was 13.86 cases/100,000 inhabitans/year, with 66.4% of cases occurred in immigrants, and a resistance rates of 12.5% and multidrug resistance of 1.25%, figures well above the national average. In view of these results, testing sensitivity to antibiotics routinely in our area and its monitoring annually its crucial, given the potential variability that cause migration waves in our population.

A-104
PULMONARY ASPERGILLOSIS AND CHRONIC OBSTRUCTIVE PULMONARY DISEASE: AN ASSOCIATION UNDERESTIMATED

A. Piqueras Martínez, M. Martín-Toledano Lucas, A. Lizcano Lizcano, R. Rubio Díaz, A. Alguacil Muñoz, M. Flores Chacartegui, A. Gonzales Caruancho, V. Cano Llorente

Department of Internal Medicine. Complejo Hospitalario de Toledo. Toledo, Spain.

Objectives: To describe the clinical forms of infection by aspergillus at our hospital and epidemiological factors most frequently seen in patients affected.

Material and method: In the Hospital of Toledo (Spain), which serves 420.000 people, were reviewed by computer coding system all hospital discharge letters, which include the words "aspergillosis" and "aspergillus" in the last 10 years. Initially 106 patients were found, 7 of them were excluded because of sample contamination.99 patients constituted the study subjects. Collected data, included clinical, radiological, and pathological and microbiological variables as well as diagnostic interpretation and treatment.

Results: During the study period, 99 patients were diagnosed of aspergillosis. Of these patients, 78 (77.2%) were males. 16 (16.16%) were colonized, while 83 (83.83%) had a form of pulmonary aspergillosis, characterized as aspergiloma (13.3%), allergic bronchopulmonary aspergillosis (ABPA) (14.45%) and invasive pulmonary aspergillosis (IPA) (72.3%). Of these cases of IPA, according to the criteria of European Organization for Research and Treatment of Cancer/Invasive Fungal Infections Cooperative Group (EORTC) and the National Institute of Allergy and Infectious Disease Mycoses Study Group (MSG), 6 of them were possible, 53 probable and 1 proven. The dominant species was A. fumigatus (78.7%) and less common were A. niger (7%) and A. flavus (1.9%). 57 cases were patients with chronic obstructive pulmonary disease (COPD) and 31 immunocompromised patients, 13% of them had hematological malignancy, 15.7% other malignancy and 46% solid-organ transplant recipients. The host factors identified were: corticosteroids or T cell immunosuppressive agents, prolonged use of antibiotics and history of neutropenia. 61.1% of patients were treated, 37% received voriconazole, 15.7% itraconazole, 0.9% echinocandin and 9.3% azol and echinocandin.

Discussion: Aspergillus spp. are ubiquitous fungi acquired by inhalation of airborne spore and may cause life threatening infections depending on immune status and the presence of underlying disease. There are different clinical forms of aspergillosis, in our population the most frequent is IPA. Risk factors described in the literature are treatment with corticosteroids, T cell immunosuppressive agents, prolonged use of antibiotics and history of neutropenia which consist with those described in our series. For immunocompromised patients there are defined risk factors, diagnostic criteria and practice clinical guidelines that simplify the management of these patients. However, despite growing evidence suggests that COPD patients are at higher risk of developing invasive forms of aspergillosis, standardized diagnostic criteria don't exist and there are few studies about this population. In our study, 64% of patients with IPA were COPD, slightly higher than values reported in the literature, ranging from 30% and 50%. Most of the COPD patients are severe COPD with several reasons for susceptibility to IPA or colonisation, such as prolonged use of

corticosteroid therapy, frequent hospitalization, antibiotics treatment and co-morbid illnesses (diabetes mellitus, malnutrition).

Conclusions: -The clinical form of aspergillosis most frequently seen in our patients was invasive pulmonary aspergillosis.-Most of our patients were male, severe COPD, with prolonged treatment with corticosteroids. To date, frequency of IPA in COPD patients has been poorly documented, but recent reports have demonstrated that these patients are a risk group. For these reasons we think that further studies should be performed in these patients.

A-105
CLINICAL AND ANALYTICAL DIFFERENCES BETWEEN THE INFLUENZA A VIRUS SUBTYPE H1N1 AND INFLUENZA A VIRUS SUBTYPE H3N1 AMONG HOSPITALIZED PATIENTS IN THE COMPLEJO ASISTENCIAL UNIVERSITARIO DE BURGOS

R. Cabo[1], A. Blanco[1], G. Megías[2], S. Molinero[1], M. Mantecón[2], C. Dueñas[1], V. Portillo[1], J. Lorenzo[1]

[1]Department of Internal Medicine, [2]Microbiology Department. Complejo Asistencial de Burgos. Burgos, Spain.

Objectives: To analyze the clinical course and analytical laboratory differences between the influenza A virus subtype H1N1 and influenza A virus subtype H3N1 among hospitalized patients in the Teaching Hospital in Burgos during the seasonal periods 2010-2011 and 2011-2012 respectively.

Material and method: This is a retrospective cohort study in which 107 patients were analyzed in the Internal Medicine and Pulmonology departments in a tertiary care hospital. Two groups were compared: the first sample consists of 30 patients affected by influenza A virus subtype H1N1 between October 2010 and April 2011, and the second sample consists of 77 patients affected by influenza A virus subtype H3N1 between October 2011 and April 2012. The diagnosis was confirmed using the PCR technique in nasopharyngeal aspiration and throat culture. We made a comparison between the clinical manifestation and the analytical alteration of the samples.

Results: In the sample of influenza A virus subtype H1N1, patients showed, in frequency order, respiratory symptoms such as cough (86.7%), expectoration (23.3%), dyspnoea (56.7%) and bronchospasm (40%). Other symptoms were fever (80%), myalgia (60%), digestive symptoms (36.7%) and pleuritic pain (23.3%). In the sample of the influenza A virus subtype H3N1 patients showed respiratory symptoms like cough (85.7%), expectoration (55.8%), dyspnoea (71.4%) and bronchospasm (58.4%); also the results showed fever (74%), myalgia (24.7%), digestive symptoms (19.5%) and pleuritic pain (16.9%). The arterial blood gas was applied to 85% of the patients at their arrival to the hospital, subtype H1N1 evinced pO_2 < 60 in 53.8% and subtype H3N1 in 61.5%. We want to emphasize the discovery of leucopenia (20%) in subtype H1N1, opposite to leukocytosis (22%) in subtype H3N1.

Discussion: Influenza is a respiratory illness which spreads mostly in winter throughout the world, and it is caused by influenza viruses' type A or B. Several signs and symptoms are involved with the upper and/or lower respiratory tract, along with other systemic illnesses such as fever, headache, myalgia, and weakness. Although this infection is self-limited in the general population, it is associated with two important factors: increased morbidity and mortality in high-risk populations. Our research has found clinical differences between influenza A H1N1 (2010-2011) and influenza A H3N1 (2011-2012).

Conclusions: There are clinical signs in both infectious processes that together with the total number of leukocytes, could reinforce the diagnosis to one type or the other.

A-106
EFFICACY AND TOXICITY OF PEGYLATED INTERFERON ALPHA 2A AND RIBAVIRIN IN PATIENTS COINFECTED WITH HIV-HCV

E. Luque López[1], M. Torralba González de Suso[2], T. Megino Moreno[2], A. Lázaro López[1], M. Rodríguez Zapata[2]

[1]Department of Pharmacy, [2]Department of Internal Medicine. Hospital Universitario. Guadalajara, Spain.

Objectives: The HCV is a factor that independently predisposes to the emergence of hepatic fibrosis. Hepatic decompensation is the second leading cause of death in HIV patients co-infected with HCV. Getting a sustained viral response after treatment reduces complications, liver-related mortality, HIV progression and mortality unrelated to liver disease. Our objective was to study the efficacy and toxicity of antiviral treatment with Peginterferon (PegIFN) + Ribavirin (RBV) in our population and analyze the variables associated with sustained virological response (SVR).

Material and method: Design: Retrospective cohort study. We included all patients with HIV-HCV coinfection who began treatment for HCV between March 2003 and January 2011 at our center. For genotypes 1 and 4, the intention was to try it for 48 weeks for genotypes 2 and 3, for 24 weeks. The main variables collected were: HCV genotype; baseline HCV-RNA; percentage of responders at end of treatment and percentage of patients with SVR. Other variables were age and sex; mean duration of treatment; percentage of patients discontinuing treatment; grounds for termination of treatment; baseline CD4 cell count; ART early HCV; serial values of hemoglobin, ALT, neutrophils and platelets; doses of PegIFN and RBV; variables related to toxicity and management of adverse effects associated with medication.

Results: During the study period 42 patients were included. In an intent-to-treat analysis, 38% of patients had SVR. 2 were lost in the follow up (4.7%) whilst 4 patients discontinued due to toxicity (9.5%). There were 16 virologic failure during treatment (38%) and 4 after its suspension (9.5%). 20% required treatment with G-CSF and 20% with erythropoietin. The PegIFN and RBV doses were changed by 11.4%. The variables associated with SVR were: polymorphism in the IL28B gene favorable (CC versus CT/TT) with OR: 7, CL95%: 1.14 to 43.0; p = 0.001; undetectable viral response at week 12 (OR 26, CL95%: 2.8 to 241, p = 0.001) and a duration of 6 months versus 12 months (OR 0.083, CL95%: 0.009 to 0.76, p = 0.022). Neither sex, age, genotype, baseline HCV CV, ART, viral response at week 4 or modification of PegIFN nor RBV were associated with SVR.

Discussion: The efficacy of PegIFN and RBV in our cohort is similar to that observed in clinical trials (ACTG 5071, APRICOT, Laguno, RIBAVIC, etc.). Toxicity is not negligible. It is noteworthy that classical variables such as genotype, baseline viral load of HCV or rapid viral response (undetectable VL week 4) were not associated with SVR in our study. This may be due to small sample size and possible lack of association of relevant variables or for not adjusting for multivariate analysis (due to small sample size).

Conclusions: PegIFN and RBV Treatment in patients with HIV-HCV co-infection, showed no effectiveness and toxicity is not negligible. The favorable polymorphism of the IL28B ++++ (CC), an undetectable VL at week 12 and a prolonged duration of treatment (12 months) in our study was associated with SVR.

A-107
PROSTHETIC JOINT INFECTIONS IN THE ORTHOPEDIC SURGERY DEPARTMENT. REVIEW OF THE YEAR 2011

M. Vázquez Ronda[1], M. Vivas del Val[2], S. Martín Barba[1], A. Gallegos Polonio[1], J. Magallanes Gamboa[1], K. Marín Mori[1], L. de Matías Salces[1], F. Marcos Sánchez[1]

[1]Department of Internal Medicine. Hospital General Nuestra Señora del Prado. Talavera de la Reina (Toledo), Spain. [2]Emergency Department. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: To describe the etiology and treatment of prosthetic joint infections diagnosed during the year 2011 in the Orthopedic Surgery Department.

Material and method: A retrospective observational study of the prosthetic joint infections diagnosed in the Orthopedic Surgery Department of the Nuestra Señora del Prado Hospital during the year 2011 was performed.

Results: 16 medical records of patients with the diagnosis of prosthetic joint infections in 2011 were reviewed. Among these, 5 were diagnosed and treated according to the current medical Guidelines, 4 did not follow any formally established treatment and 5 had an uncertain diagnosis. The most common location of infection was the knee (50% of cases) followed by the hip (44%). The most common etiologic agent was Staphylococcus sp. present in 62.5% of patients (10 out of 16), being the methicillin-sensitive S. aureus the predominant agent in 50% of cases (8 out of 16) followed by S. epidermidis, S. capitis. Other microbiological agents involved were E. faecalis, Pseudomonas sp, C. albicans and S. agalactiae (one case each). The prosthetic material was removed in all the prosthetic joint infections in which treatment Guidelines were followed. One was a septic shock due to early infection and the rest were late infections. On the contrary, in the 4 cases that did not follow the treatment Guidelines surgical cleaning of the prosthesis was performed even though they should have been removed because they were late infections of prosthetic joints. In 44% of the patients quinolone (levofloxacine) was used, followed by beta-lactams (amoxicillin-clavulanate). In most cases rifampicin was the second antibiotic added to the treatment. In only one case linezolid was used due to the resistance to other antibiotics. There was only one.

death in the group of prosthetic joint infections who did not follow the treatment Guidelines.

Discussion: The infection and loosening of the prosthetic joint are the main and most feared potential catastrophic complication of the Orthopedic Surgery patients. It involves potential skeletal deformities, delayed reimplantation, severe decreasing of quality of life and a high economic cost. In the last decade the incidence of prosthetic joint infections has decreased due to the improvement of surgical techniques and antibiotic prophylaxis, 1.5% in hip prosthesis infections and 2.5% in knee prosthesis infections. The agent most commonly involved according to the published data is Staphylococcus sp, including S. aureus and coagulase-negative Staphylococcus, present in 22% of infections. This fact is also seen in our study. Given that the surgical treatment is not well defined and since unsatisfying results were obtained, removal of prosthetic material is recommended in all cases with the exception of early prosthesis infections during the first 3 weeks after implantation. Correct surgical treatment was only performed in 4 out of 16 cases. Clinical Guidelines recommend the use of rifampicin associated with quinolones for the treatment of infections caused by Staphylococcus sp, as the treatment of choice. Beta-lactams and glycopeptides are recommended for gram positives cocci infections. The use of linezolid is only recommended if there is any resistance to other antibiotics. Quinolones should rather be used for treatment of enterobacteria and P. aeruginosa. In our study all patients received antibiotic treatment according to the current published guidelines.

Conclusions: The results of predominant etiological agent and the treatment chosen in our study agree with other studies published. We must stress the proper surgical management as the main factor that determines the satisfactory outcome of the prosthetic infections. The most affected joints in which a proper treatment according to the clinical Guidelines is performed, are the knee and the hip.

A-108
NEUROLOGICAL MANIFESTATIONS OF ACUTE Q FEVER REPORT OF TWO CASES

M. Raya Cruz[1], C. Gállego Lezaún[1], M. García Gasalla[1], C. Cifuentes Luna[1], T. Forteza Forteza[2], V. Fernández Baca[2], C. Gallegos Álvarez[2], A. Payeras Cifre[1]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital Son Llàtzer. Illes Balears, Spain.

Material and method: Introduction: Coxiella burnetii the agent of Q fever produces a variety of clinical syndromes. In the course of acute Q fever, severe headache is frequently observed but other neurological manifestations are unusual. Aseptic meningitis, encephalitis or encephalomyelitis and peripheral neuropathy have been described. Furthermore, a Guillain Barré syndrome has exceptionally been observed. A total of 90 acute Q fever cases were recorded from January 2003 to December 2011 in the Hospital Son Llàtzer in Palma de Mallorca (Spain) and were reviewed for neurological complications. Patients were considered to have acute Q fever when serological procedures showed Coxiella burnetii phase II titers IgM positive 1:40 or a four-fold increased of the IgG titer beween two consecutive assays with appropriate clinical criteria.

Results: Case 1: A 35-year-old man was admitted to hospital with a 4-days history of severe headache fever and vomiting. The physical examination was normal except by the presence of nuchal stiffness. Laboratory test showed AST 155 U/L, ALT 193 U/L, GGT 87 U/L and LDH 864 U/L, VSG 23mm/h and PCR 153.5 mg/L. Cerebrospinal fluid (CSF) obtained by lumbar puncture showed a white cell count of 12 cel/mm3 (lymphocytes) and a protein concentration of 47.0mg/dl. Culture for bacteria, mycobacteria and virus were all negative. Chest radiography, cranial CT and transthoracicechocardiography were normal. Serological tests for HBV, HCV, Rickettsia, CMV and Epstein-Barr virus were all negative. Antibody titer for Coxiella burnetti were positive: IgG Phase II 1/5120 and IgM Phase II 1/320. The patient was diagnosed of lymphocyte meningitis due to Coxiella Burnetti and received treatment with doxicicline 14 days, with complete recovery. Case 2: A 34-year old man intravenous-drug abuser visited the emergency room, complaining of progressive tetraparesis and headache. On admission, the initial exam demonstrated right facial nerve paresis; manual muscle testing revealed grade 3/5 proximal and 4/5 distal and global arreflexia was observed. Laboratory test revealed AST 73 U/L, ALT 137 U/L, GGT 209 U/L and ESR 22 mm/h. CSF examination demonstrated absence of pleocytosis and proteins 66 mg/dl) and PCR of S. agalactiae, H. influenzae type b, S. pneumoniae and N. meningitidis were negative. Culture of CSF and blood did not grow any bacterial. Electrophysiological studies showed a severe acute axonal neuropathy in sural nerves. Chest X-ray was normal. Autoimmunity study including antiGM-1 IgM antibody and anti ganglioside antibody were negative. Serological testing for HIV, syphilis, Epstein-Barr virus, CMV, Varicella-Zoster virus, Borrelia burgdorferi and Mycoplasma were all negative, except for Coxiella Burnetti (IgG phase II > 1/80 and IgM phase II 1/40). An acute inflammatory radiculoneuropathy type Guillain Barré syndrome (axonal variant) was diagnosed and the patient begun treatment with intravenous

immunoglobulines. Clinical improvement was observed, the patient was discharged and lost to follow-up.

Conclusions: The clinical evidence of CNS involvement is not a rare feature of acute Q fever infection and Coxiella burnetii should be considered as a possible etiology of meningitis or meningoencephalitis as well as Guillain Barré syndrome in our area.

A-110
SKIN AND SOFT TISSUE INFECTIONS RELATED TO THE DIABETIC FOOT

A. Hernández Milián[1], M. Pérez de la Blanca[1], M. Raya[1], J. Ferullo[1], C. Gallego[3], A. Nadal[2], P. Díaz Antolín[3], A. Payeras[1]

[1]Department of Internal Medicine, [2]Department of Dermatology, [3]Department of Microbiology. Hospital Son Llàtzer. Illes Balears, Spain.

Objectives: The aim of this study was to describe epidemiological, clinical, microbiological characteristics and treatment of skin and soft tissue infections related to diabetic foot in our setting.

Material and method: A retrospective study of all patients, over 14 years old, who were admitted to Hospital Son Llàtzer between January 2002 and December 2011 were studied all of them suffered diabetic foot plus one of the following diagnosis: subcutaneous abscess or cellulitis/lymphangitis/erysipelas.

Results: We studied 63 cases in 50 patients, 68% males and 30% women, with an average age of 65 (range 43-91) years. Most of the cases, 50 (79%), were admitted to General Surgery ward, followed by Internal Medicine, 10 cases (15.9%), and other departments, 3 cases (4.8%). In 54 (85.7%) cases the diagnosis was cellulitis/erysipelas/lymphangitis while in 9 (14.3%) was subcutaneous abscess. Seventy three percent were considered community adquired, 14% health-care related and 3% nosocomial. Number of cases remained stable over the years. None patient were HIV-infected or UDPV. In 34 (54%) episodes patient was been treated with antibiotic 6 months before admission. In 26 (41.3%) episodes the patient has a diagnosis of peripheral vascular disease, 12 (19%) cerebral vascular disease, 3 (4.8%) coronary disease and 8 (12.7%) end stage renal disease requiring hemodialysis. A culture of soft tissue focus was collected in 27 episodes, being positive in 25 (39.7%), with the following microbiological isolates: 10 (15.9%) S. aureus (2 MRSA), 6 (9.5%) flora mixed aerobic-anaerobic, 5 (7.9%) E. coli and other enterobacteria, and 1 case (1.6%) of S. pyogenes and P. aeuriginosa respectively. Also, in 5episodes blood cultures were positive (2 S. aureus) In 44 episodes (69.8%) empirical treatment was with monotherapy and the more prescribed antibiotic were quinolones, in 24 (38.1%) cases, followed by beta-lactam other than penicillin, in 20 (31.7%). A change of antibiotic was performed in 19 (30.2%) cases, being the main reason after microbiological results followed by clinical impairment in 3 (15%). Surgical debridement was necessary in 25 (39.7%) episodes, and one amputation was required in 16 (25.4%). Medical complications were presented in 9 (14.2%) episodes: 5 (7.9%) cases with severe sepsis, 3 (4.8%) with shock, and 1(1.6%) with septic metastases. Eleven (22%) patients died during admission, where 3 cases (6%) were related due to infection.

Conclusions: Soft tissue infections in patients with diabetic foot in our setting are frequently community acquired, being the cellulitis the most frequent diagnosis, and most of them are admitted in Surgery wards. S. aureus is the main isolated microorganism with a low prevalence of MRSA. Quinolones monotherapy is empirical threatment most prescribed. Amputation is frequent and mortality seems to be negligible.

A-111
THE USE OF BLOOD CULTURES IN AN INTERNAL MEDICINE DEPARTMENT

J. Trindade Nave, G. Nobre de Jesus, T. Gaspar, L. Santos Pinheiro, M. Lucas, R.M.M. Victorino

Department of Internal Medicine 2. Hospital Santa Maria. Lisboa, Portugal.

Objectives: Blood cultures (BC) remain the major diagnostic test for hematogenic infections but criteria for BC use is still debated. The current tendency is to perform less BC with larger volume samples and more strict indications. Several factors have been pointed to what seems to be an excessive use of this test contributing to increased length of stay (LoS) and hospital costs. Recent guidelines for the use of this test have been published. Data about BC utilization in general Internal Medicine (IM) wards is scarce. We aim to characterize the utilization and evaluate the usefulness and costs of BC in an IM ward.

Material and method: Observational study with 12 month retrospective data collection from the hospital admissions in an IM ward of a University Hospital. For BC positivity analysis a representative sample of 400 patients was selected. The admissions were classified in 2 groups (with and without infectious condition) for comparative analysis. Data sources: clinical and microbiologic tests electronic databases. Main variables recorded: demographic patient data (gender and age); LoS; discharge destiny and deaths; diagnosis (coded with the International Classification of Diseases 9th revision and recoded with the Clinical Classifications Software); number of BC (total and positive) and Elixhauser and Charlson comorbidity indexes for each episode.

Results: There were 4160 admissions with female predominance (55.6%). The mean age was 73.0 years and the average LoS was 6.9 days. The death rate (DR) was 11.4%. In the patients with a final diagnosis of infection (56.9%) the gender distribution (females: 56.9%) was similar to the group without infection (53.7%) but the mean age was higher (74.7 vs 70.7 years ($p < 0.001$)). We also found a significant difference in the mean LoS (8.2 vs 5.3 days ($p < 0.001$)) and DR (12.3% vs 10.3% ($p = 0.05$)). There was a higher number of diagnosis and Elixhauser score in the group with infections (7.8/2.7 vs 6.2/2.1; $p < 0.001$) but similar values in the Charlson score (2.2 vs 2.2). Blood cultures were performed in 37.3% of patients (50.9% among the group with infections and 19.4% in those without). The total number of BC was 4353 (86.4% aerobic). In the 1553 patients with BC the gender distribution (52.5% females) and mean age (73.4 years) were similar to those without BC. Nevertheless the average LoS (9.5 days) and DR (14.0%) were higher ($p < 0.001$). This profile was present in the split analysis of BC with or without infections. The average number of BC per episode was 2.8 with no differences regarding the presence of infection. In 5.0% of patients only 1 BC was made and this was seen across both groups and in 63.0% of cases fewer than 3 samples were collected. The global BC positivity rate was 11.2% (13.6% in patients with infections and 4.5% in those without). The gross estimation of costs directly related to BC ranges 56,000€ annually. In a logistic regression model including age, sex and LoS as additional independent variables, the strongest predictor for BC utilization was the presence of an infectious condition (odds ratio: 3.86; $p < 0.001$).

Discussion: In our series there is a high utilization of BC, mostly in patients with diagnosis of infection. Nevertheless BC were performed in a fifth of discharged patients without infection. Although only in a small proportion of cases a single BC sample was collected, in the vast majority less than 3 samples were used. Further analysis on the individual BC results and its consequences in terms of therapeutic and other clinical attitudes from physicians may provide additional insight regarding the optimal number of BC samples per patient, since this is still a much debated matter. The reduced BC positivity rate in our study (11.2%) is in line with the

figures presented in other series where it ranges from 9% to 20% depending on the clinical setting (greater in intensive care units), but no major series on IM wards are available.

Conclusions: Our data leads us to consider that there may be inappropriate use of BC which warrants further studies to define the adequacy of BC requests since these represent a considerable cost. Given the broad utilization of BC in the setting of IM, the implementation of clear clinical guidelines for its appropriate use is crucial.

A-112
INFECTIVE ENDOCARDITIS: THE ROLE OF AGE AND RENAL STATUS

B. Castillo Fernández, J. Alzate Gallego, M. Bernardi, J. Troya, N. Muñoz Rivas, M. Méndez Bailón, P. Ryan Murua

Primary Care A Southeast. Department of Internal Medicine. Hospital Infanta Leonor. Vallecas (Madrid), Spain.

Objectives: To evaluate clinical features and prognosis of patients with Infective Endocarditis (IE) admitted to a recently opened institution (Infanta Leonor Hospital).

Material and method: A transversal and retrospective study was carried out using clinical records of patients with the diagnosis of IE between February 2008 and May 2012. Demographic, clinical, diagnostic, therapeutic and prognostic variables were taken from the patients clinical record. The presence of IE was confirmed by Duke´s Criteria and by echocardiography. A descriptive analysis of quantitative and qualitative variables was carried out. A univariant analysis was perfomed using Fisher test and U Mann Whitney to evaluate data regarding prognosis.

Results: Eighteen patients with IE were included. The average age was 68.67 years, of whom 56% had previous heart disease, 33% wore prosthetic valves and 17% had pacemakers. Regarding the ethiology of the IE: 47% was due to Staphilococcus aureus, 12% Staphilococcus epidermidis and 18% to Enterococcus. Heart failure was the most common complication and was significantly more frequent in patients that had a prosthetic valve compared to those without it (65% vs 37%) p = 0.032. Higher levels of creatitine in patients with IE (1.8 mg/dl vs 1.3; p = 0.348) were associated to been hospitalized in an intensive care unit, to the need of a replacement valve surgery and a higher risk of death. Mortality due to IE is related to elderly people (83 years vs 63 years; p = 0.059).

Conclusions: Regarding our findings, IE usually affects patients with heart disease that have a prosthetic valve. Prosthetic valve IE contributes to the development of heart failure, the patients transfer to Intensive Care Unit or to a Cardiovascular Surgery Unit, especially in patients with kidney failure. Elderly patients with IE have higher rates of mortality. These could be explained by the fact that these patients have different surgical issues.

A-113
PATIENTS WITH POSITIVE CULTURE FOR METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS (MRSA) ADMITTED TO AN INTERNAL MEDICINE SERVICE

N. Costa Rosell[1], A. Rivera Austrui[1], A. García Flores[1], A. García Hinojo[1], A. Zamora Cervantes[1], R. Massa Puig[1], N. Subirà Farré[1], C. Gallés[2]

[1]Department of Internal Medicine. Hospital comarcal de Blanes - Corporació de Salut del Maresme i la Selva. Blanes (Girona), Spain. [2]Department of Microbiology. Hospital Comarcal Sant Jaume De Calella. Barcelona, Spain.

Objectives: To describe the characteristics of patients admitted to the Internal Medicine Department of the Hospital Comarcal de Blanes (Blanes County Hospital) with a positive culture for MRSA during the period 2008-2011. Data obtained from the centre's Epidemiological Surveillance team have been used as source.

Material and method: A descriptive study of patients admitted between 2008-2011 in our department with positive culture for MRSA (infection or colonization). The data have been extracted from the centre's registry monitoring and control system. Demographic and clinical data have been analyzed.

Results: We analyzed 139 positive cultures for MRSA in samples from 72 patients admitted to Internal Medicine. Of these patients, 58 were isolated (in 45 cases only by contact and in 13 cases by contact and respiratory isolation). The mean age of patients was 79.3 years. Of the 72 patients, 36 patients were colonized, 35 infected and 1 indeterminate case. Samples were collected for screening in 50.3% of cases and the rest for signs of infection (49.7%). Provenance of the 139 samples were: wounds (5.75%), sputum (10.7%), nasal swabs (43.8%), ulcers (29.5%), blood culture (4.31%), urine (4.31%) and others (4.31%). The patients were admitted from acute hospitalization (3), home (27) and nursing home for the most part (42). 14 patients had previously known MRSA, unknown in 8 cases and negative in 50. Patients were admitted for different reasons: cardiac in 9 cases, neurologic (stroke/encephalopathy) in 4 cases, respiratory (pneumonia, chronic obstructive pulmonary disease) in 25 cases, thromboembolic disease (2 cases), ulcers and wounds (5 cases), fever in 11 cases and miscellaneous (14 cases). The mean stay of these patients was 13.76 days (17.6 days in those who met criteria for infection and 10.9 days in those colonized), compared with the total global mean stay in patients admitted to Internal Medicine during this period of 7.2 days. Patients were hospitalized a mean of 6.3 days before the establishment of isolation measures. Overall mortality in patients with MRSA was 17 patients (23.6%), directly attributable to the MRSA infection in only 3 cases. Overall mortality in the same period of patients admitted to Internal Medicine during this period was 6.5%.

Conclusions: MRSA infections are the leading cause of isolation in a county hospital. Our sample shows an association of infection or colonization by MRSA and a longer mean length of stay and with an increased overall mortality compared to patients in the same period. Our data shows a time lapse between the patient's admission and instauration of measures of isolation up to 6.3 days, which makes us consider that an increase in the suspicion and early detection is necessary in our centre.

A-114
UTILITY OF 18F-FDG PET-CT IN THE EVALUATION OF INFECTION SPREAD AND BACTERAEMIA

F. Alejandro[1], G. Llanos[1], F. Esther[2], D. Jordi[1], F. Albert[1], E. Montserrat[1], D. Anna[1], C. Jordi[2]

[1]Nuclear Medicine Department, [2]Department of Internal Medicine. Hospital de la Santa Creu i Sant Pau. Barcelona, Spain.

Objectives: To evaluate the utility of 18F-FDG PET-CT scan in detecting the spread of infection in patients with a known infection source and the source of infection in patients with bacteraemia.

Material and method: Twenty-four consecutive patients (mean age 73 y; range 44-88 y) were studied in order to assess the spread of infection from a known infection source (9 patients) and the infection source in patients with bacteraemia (15 patients). All patients had undergone radiological imaging exams with non-conclusive findings. In the 9 patients with known infection source, these were localized in: bone (3 patients with osteomyelitis or spondylodiscitis), 4 patients with endocarditis, 1 with septic

arthritis and 1 with pleuro pericarditis. Positive blood culture for: E. coli, S. aureus, S. epidermidis, Pseudomonae, Enterococcus faecalis, Klebsiella, Enterococcus and Serratia were found in the other group of patients. All patients underwent a whole-body PET-CT (Gemini TF hybrid tomography) scan.

Results: Four out of nine patients (45%) with a well-known infection source had new non-suspected septic spread to: spine, septic arthritis and pacemaker. In the group of patients with bacteraemia, infectious processes were found in 6/15 (40%) studies: prostate (2 patients), lung (3 patients) and vertebral osteosynthesis. These findings were clinically confirmed and patient's symptoms subsided after treatment. In 5 patients with negative PET-CT infectious foci in urinary tract and heart (endocarditis) were posteriorly detected after clinical follow-up.

Conclusions: 18F-FDG PET-CT has been able to demonstrate unsuspected spread from infectious sources and in localization of primary infection sources in patients with bacteraemia.

BACTERIAL BRAIN ABSCESS: EPIDEMIOLOGY, MICROBIOLOGY, TREATMENT AND PROGNOSIS

M. Ferrer Civeira, A. González Munera,
A. García-Espona Pancorbo, M. Clavero Olmos, E. Oliveros Acebes,
C. López González-Cobos, C. Pérez de Oteyza, M. Villalba García

Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: Brain abscesses are intraparenchymal collections of pus. Their incidence is approximately 1-2% in western countries. We wanted to analyze the characteristics of brain abscesses, as well as epidemiology, clinical findings, microbiology and treatment in our environment.

Material and method: We made a retrospective study of all the adults with diagnosis of bacterial brain abscesses admitted to our hospital from 2000 to 2010 and we collected epidemiological, diagnostic and microbiological facts. These data were analyzed with SPSS v. 18.0.

Results: There were 29 patients studied. We found 25 males (92.67%) and only 2 women. The mean age was 49.03 years (range 16-84). Of all the patients, 17 of them (60%) were immunosuppressed. The most frequently observed symptoms at diagnosis were neurological deficits (53.6%), where motor disturbances should be noted (24.1%). We also found a high rate of altered level of consciousness (50%), headache (42.9%) and fever (39.3%). Leucocytosis was observed in 18 patients (62.5%). Time elapsed from the onset of symptoms to the diagnosis was 9.75 days (range 0-90). All the patients were initially diagnosed using an image technique. The most common location for brain abscess was the frontal lobe (25%) although we found no differences between the hemispheres involved. When we analyzed the origin of the infection, 13 cases (44.4%) were associated to haematogenous spread and only 10 (33.3%) came from the extension from a contiguous infection. 23 patients had a positive microbiological culture, 20 of which (71.4%) were monomicrobial. Gram positive cocci were the most frequent isolated group, present in 14 cases (47.8%). Antibiotics were administered to all patients, while drainage was only necessary in 17 cases (60.7%). Complete remission was reported in 15 patients (75.9%). 6 patients died (20.7%) and there was only one recurrence.

Conclusions: Although brain abscesses are not a common disease, they still are a potentially fatal entity. This study shows that they are much more frequent in males and immunocompromised patients. Compared with literature, we should stand out how they are more frequently located in the frontal lobe and their haematogenous origin.

A-116
RETROSPECTIVE STUDY OF PATIENTS ADMITTED WITH LEPTOSPIROSIS AT DR. NEGRIN GENERAL HOSPITAL IN THE PERIOD 2000-2011

R. Castillo Rueda, A. Gil Díaz, N. Lorenzo, L. Salas Reinoso,
S. Santana Báez, S. Moreno Casas, S. Suárez Ortega,
P. Betancor León

Department of Internal Medicine. Hospital Universitario de Gran Canaria Dr. Negrín. Las Palmas de Gran Canaria (Las Palmas), Spain.

Objectives: To describe the clinical figures of patients diagnosed of leptopirosis and admitted in our hospital in the last 11 years, and analyse the factors related to bad prognosis.

Material and method: An observational and retrospective study of patients admitted in our hospital in the period 2000-2011 with signs and symptoms of leptospirosis as well as positive IgM ELISA test was conducted. Demographic variables, signs, symptoms, complications during the admission, laboratory and radiology tests, antibiotics received, average stay in the hospital and clinical evolution were also taken into consideration. A descriptive analysis of the sample was also made. Afterwards, a bivariate analysis was carried out in order to rule out predictive parameters related to bad prognosis. To accomplish this last goal, an independent Chi square test was used.

Results: Leptospirosis was diagnosed in 28 patients, 23 men (82.1%) and 5 women (17.9%). The mean age was 59.5 years (SD 15.4), being 64.3% of the patients from rural areas. Risky professions were identified in 32.1% of the cases and another 50% referred contact with animals. Alcohol intake was referred in 46.3% of patients. Outbreaks were not observed. Patients came to the hospital after an average 10.3 days onset of the symptoms. The most common signs were: abdominal pain (57.1%), asthenia (50%), myalgias (46.4%), vomiting (46.4%), nausea (42.9%) and diarrheas (32.1%). The most remarkable signs were: fever (85.7%), jaundice (64.3%), oligoanuria (60.7%), hepatomegaly (50%), coluria (42.9%) y dehydratation (39.3%). An abnormal chest X-ray on admission was found in 53.6% of the patients. Ceftriaxone was prescribed in 39.3% of the patients and doxycicline in 46.4% during around 13.3 days. Acute renal failure was found in 75% of the patients and hemodyalisis was indicated in 39.9% of them. Shock signs were presented in 64.3% of the patients, needing to be transferred to intensive care unit. Five patients (17.9%) died due to multiple organ failure. Signs of massive pulmonar hemorrhage were described in the autopsy performed in three of them. The mean hospital stay was 18.6 days (SD 17.4) Vomiting ($p = 0.02$), diarrheas ($p = 0.042$), abdominal pain ($p = 0.014$), jaundice ($p = 0.002$), coluria ($p = 0.04$), oligoanuria ($p = 0.006$), hypotension ($p = 0.001$), taquichardia ($p = 0.014$), taquipnea ($p = 0.004$), Hb < 10 gr/dl ($p = 0.02$), leukocytosis > 15400 ($p = 0.011$), low platelet account < 156000 ($p = 0.022$), Cr > 1.3 mg/dl ($p = 0.07$), CK > 40 ($p = 0.041$) and total hyperbilirrubinemia > 3 ($p = 0.01$) were found to be associated to severe cases who had to be transferred to the intensive care unit.

Discussion: In spite of having conducted the study for a period of 11 years, the sample was small so the results obtained should be carefully interpreted. Men over 60 years coming from rural areas prevailed in the sample without identifying an epidemiological antecedent in half of them. Typical signs and symptoms denoting multiple organ involvement and a significant percent of in-hospital complications were also found as described in other published studies.

Conclusions: Leptospirosis is not a common disease in our area but it is potentally letal. Signs and symptoms of leptospirosis must be well known so that a quick diagnosis and treatment may be done. Bad prognosis factors easily recognizable at the moment of admission were identified in our sample.

A-118
PROSPECTIVE STUDY OF CANDIDA BLOODSTREAM INFECTIONS IN A TERTIARY CARE HOSPITAL

S. Ragozzino[1], H. Ternavasio de la Vega[1], I. García García[2], G. Spalter Glicberg[1], M. Asensio Calle[2], F. Sauchelli[1], J. García Sánchez[2], M. Marcos Martín[1]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital Universitario de Salamanca. Hospital Clínico. Salamanca, Spain.

Objectives: To describe the epidemiology, risk factors, focus of infection and outcomes of candidaemia cases registered in a tertiary hospital.

Material and method: We performed a prospective analysis of all episodes of candidaemia between June 2011 and April 2012. We recorded clinical and epidemiological data (such as age, sex, underlying diseases that could predispose to infection, risk factors for candidaemia and focus of infection) as well as antifungal treatment and microbiological data. Patients were followed-up during admission to assess outcome of infection.

Results: During the study period we registered 31 episodes of candidaemia: 25 (80.6%) nosocomial infections (Oncology ward 7, Internal Medicine 4, Gastroenterology 2, Haematology 2, Intensive Care Unit [ICU] 2, and Surgery department 8), 5 (16.1%) health-care related and 1 (3.2%) community-acquired. Eighteen patients were male (58.1%) with a mean age (standard deviation) of 71.3 (13.1) years. Patients had multiple underlying diseases with a mean Charlson index of 4.9 (2.7). Most common comorbidities were solid tumors or haematologic malignancies (16 and 4 cases, respectively), heart diseases (7 patients with ischemic disease and 4 valvular disease), digestive diseases (11), diabetes mellitus (8), cognitive impairment or stroke (5), liver cirrhosis (2) and chronic kidney disease (2). Candida species isolated were: C. albicans (13; 41.9%), C. parapsilosis (9; 29.0%), C. tropicalis (5; 16.1%), C. glabrata (2; 6.5%), C. krusei (1; 3.2%), Candida spp. (1; 3.2%). The more prevalent risk factors were: prior antibiotic use (25; 80.6%), prior surgery (11; 35.5%), invasive procedures (23; 74.3%), prior ICU admission (2; 6.5%), urinary catheter (16; 51.5%), chemotherapy (9; 29.0%), transfusions (15; 48.4%), granulopenia (5; 16.1%), central venous catheter (17; 54.8%, of peripheral insertion in 7 cases), parenteral nutrition (20; 64.5%), corticoid treatment (3; 9.7%). The focus of infection was unknown in 12 cases (38.7%), abdominal in 12 (38.7%), catheter related in 6 (19.4%) and urinary in 1 (3.2%). Positive culture of the focus was identified in 8 cases (42.1%). Regarding outcomes, 5 patients required ICU admission and overall 30 day mortality rate was 31% (12 patients) with a median of 5 days between the documented infection and death.

Discussion: The typical patient with candidaemia in our setting is an elderly patient with multiple comorbidities and a central venous catheter, who has been receiving broad spectrum antibiotic therapy and has undergone surgery or other invasive procedures. The coexistence of multiple underlying diseases and risk factors usually makes very difficult the identification of the source of infection. Actually, it remained unknown in an important number of cases. As previously reported by other authors, we found that the most frequent focus of infection is abdominal. Regarding Candida species isolated, our results confirmed the trend showing an increase of non-albicans Candida species. Of special interest, C. parapsilosis represents the leading non-albicans species and its prevalence is higher when compared with other reports. Mortality rate in our setting is high and is similar to that showed in other series.

Conclusions: Candida species are important pathogens in hospitalized patients and are associated with significant mortality in our setting. The identification of risk factors has a key role for diagnosis and early treatment of candidaemia.

A-119
CLINICAL, ELECTROCARDIOGRAPHIC AND ECHOCARDIOGRAPHIC ABNORMALITIES IN LATIN AMERICAN IMMIGRANTS WITH NEWLY DIAGNOSED CHAGAS DISEASE IN SPAIN

C. Suárez Cuervo[1], M. Fernández Almira[1], M. Rodríguez Pérez[2], F. Pérez[2], O. Martínez Exposito[2], A. Rodríguez Guardado[1]

[1]Department of Internal Medicine, [2]Department of MIcrobiology. Hospital Universitario Central de Asturias. Oviedo (Asturias), Spain.

Objectives: Chagas disease is a zoonosis caused by the parasite Trypanosoma cruzi, a flagellated protozoa mainly transmitted to humans by the faeces of blood-sucking triatomine bugs (Triatoma infestans and others). The main objective of our study was to determine the presence of clinical, electrocardiografic (ECG) and echocardiographic abnormalities in a population of Latin American immigrants infected with Trypanosoma cruzi at the moment of diagnosis.

Material and method: Between 2008- 2011, we studied all consecutive adult patients newly diagnosed with Chagas infection at the Tropical Medicine Unit of Hospital Universitario Central de Asturias, in Spain. Exclusion criteria for the study were: (i) previously documented diagnosis of Chagas infection or antichagasic treatment, (ii) age less than 15 years, (iii) presence of hypertension, diabetes, coronary artery disease or other concurrent diseases associated with cardiomyopathy and, (iv) pregnancy. Individuals were considered as Chagas cases when two commercialised enzyme-linked immuno sorbent assay (ELISA)-based serological tests against crude and recombinant T. cruzi antigens were positive. In all cases we performed a polimerase chain reaction por T. cruzi. All newly-diagnosed Chagas patients underwent a clinical evaluation, including full medical history, physical examination, ECG with 30 seconds DII strip and a two-dimensional echocardiography. Patients were classified following the Brazilian Consensus Classification.

Results: We studied 22 adult patients (86% female, average age: 36 years old) with newly diagnosed Chagas infection positive for Chagas disease antibodies, which were confirmed in all cases. PCR was also positive in all cases. The countries of origin were: Bolivia (79%), Paraguay (11%), Brazil and Argentina (5% each). The average time of residence in Spain was 1335 days. Only one patient showed ECG and echocardiographic alterations (4.5%). ECG findings were ventricular extrasystoles (bigeminy and echocardiogram showed septal hypokinesia with barely normal systolic function). According to the Brazilian Consensus, this patient was on Stage B1, and the rest did not show cardiopathy signs.

Discussion: Chagas disease remains a neglected tropical disease and is as such recognised by World Health Organization. Following Latin American migration, Chagas disease has inevitably appeared in non-endemic countries in Europe and elsewhere. Acute Chagas disease is followed by a long asymptomatic period of latency (or chronic disease) characterised by the presence of antibodies against Trypanosoma cruzi. In this stage, clinical examination of the chest, oesophagus and colon may be normal; the 12-lead electrocardiogram (ECG) can show no irregularities or minor alterations.

Conclusions: ECG and echocardiographic alterations coherent with Chagas cardiomyopathy were found in a few proportion of newly diagnosed Latin American immigrants infected with T. cruzi. However, in the mid-term, Chagas disease might become an important cause of chronic cadiomyopathy in our attendance area. It should be considered in every Latin American patient with unexplained ECG abnormalities, cardiac symptoms or acute cardiovascular events. Both tests (serological test and polimerase chain reaction) should be routinely carried out at the moment of diagnosis.

A-120
INFECTION DUE TO STRONGYLOIDES STERCORALIS: COMPARATION BETWEEN HIV AND NON-HIV POSITIVE PATIENTS

C. Suárez Cuervo[1], M. Fernández Almira[1], M. Rodríguez Pérez[2], M. Martínez Sela[1], F. Pérez[2], O. Martínez Exposito[2], A. Rodríguez Guardado[1]

[1]Department of Internal Medicine, [2] Department of Microbiology. Hospital Universitario Central de Asturias. Oviedo (Asturias), Spain.

Objectives: Strongyloides stercoralis is a nematode parasite, which is endemic in tropical and subtropical regions. Infection usually remains asymptomatic, but in immunocompromised hosts severe and life-threatening manifestations such as hyperinfection syndrome and disseminated disease may occur. The aim of this work is to compare the characteristics of this infection for HIV and non-HIV infected patients.

Material and method: During the years 2008-2011 we conducted a prospective screening program of chronic strongyloidiasis in all immigrants patients attending in Tropical Medicine Unit of Hospital Central de Asturias. Combined examination of three concentrated stool samples, culture in blood agar and ELISA for serum anti–S. stercoralis antibodies was used as screening. We considered that infection existed if the microscopic visualization of larvae in stool sample and/or the ELISA was positive. In positive patients was discarded the presence of other nematodes or filarias. We performed an ELISA for serum anti-HIV antibodies in all patients. In positive patients we confirmed the infection by Western-Blot. Routine tests for determination of eosinophilia, CD4+ cell counts, and HIV load were performed simultaneously to serological studies. All positive patients were treated with ivermectin. All data was entered into a database and analyzed using SPSS 18.0 software package. Quantitative variables were analyzed with the Student t test or the Mann-Whitney test when appropriate. Qualitative variables were analyzed with the chi square test, with the Yates correction or Fischer's exact test (2-tailed) when necessary. All p values were 2-sided and values of 0.05 or less were considered statistically significant.

Results: Strongyloidiasis was diagnosed in 94 patients (34 men and 60 women). HIV infection was diagnosed in 13 patients (13.8%), with a median CD4 T cell count of 388 cells/mm^3.and median viral load of 275,163 RNA viral /ml. The average age was of 33 years for both groups. The mean time of permanence in Spain was 958 [892] days in HIV negative patients and 1164 [673] in HIV positive. There were not significant differences in sex, age, or time of permanence in Spain between both groups. The most frequents countries of origin were Equatorial Guinea (37%), Ecuador (16%), Spain (10%), Senegal (8.5%), Nigeria (6.5%), Ethiopia (5%) and others (17%). HIV patients were from Equatorial Guinea (8 vs 27 p = 0.05), 4 from Paraguay (4 vs 2 p = 0.02) and Colombia (1 vs 0, not significance). The most frequents symptoms in HIV negative patients were abdominal pain (28%), skin diseases (7.5%), diarrhea (8%) and the rest were asymptomatic. In HIV patients the most frequent symptoms were abdominal pain (15%) and the rest were asymptomatic (75% p = 0.0002 OR 7.92 [1.78-40.22]). Seventy-five non HIV patients had eosinophilia in blood (mean 1,263 [2,145] cells/mm^3) and twelve HIV patients (mean 722 [549] cells/mm3) without significant differences All patients showed positive serological test and in one patient the microscopic visualization was positive. All patients were treated with ivermectin. None patients developed hyperinfection syndrome. For all patients the serology became negative six months after the treatment. All patients survived.

Conclusions: The presence of infection for S. stercolaris is frequent in HIV positive patients although without symptoms. The infection is most frequent in sub-Saharan immigrants. To prevent potentially fatal hyperinfection syndrome, it is necessary realized screening with several stool examinations and serologic testing in this group of patients, and in infected ones instituted the treatment.

A-121
PSOAS ABSCESS: A HISTORICAL SERIES REVIEW

M. Alvarado Blasco, F. Teigell Muñoz, M.A. Duarte Borges, A. Coto López, M.A. Pérez-Jacoiste Asín, S. Prieto Rodríguez, N. García Pozuelo, C. Fernández-Miranda Parra

Department of Internal Medicine. Hospital 12 de Octubre. Madrid, Spain.

Objectives: Describe the clinical-epidemiological features, diagnosis methods, microbiology, treatment received and the evolution of a number of patients diagnosed with psoas abscesses.

Material and method: Patients diagnosed with psoas abscess at the "Hospital 12 de Octubre" between April 2008 and March 2012. Review of medical records, incorporation of the information obtained into a previously designed database, descriptive statistical analysis of the variables under study and comparison of our results with those obtained in other series of literature.

Results: In the period under study, 11 patients were diagnosed with psoas abscess. All of them were Caucasian, 82% were male and the average age at diagnosis was 66 years old. 54% of the diagnosed abscesses were the result of the extension of the infection from an adjacent source (usually gastrointestinal), 10% due to hematogenous spread and in 36% of the cases their pathogenesis could not be determined. In four cases the abscesses were bilateral; the unilateral ones developed most frequently on the right side. The most frequent symptoms were pain in the lumbo-sacro ipsilateral region (100%), fever (54%) and functional impotence (54%). Three of the 11 patients (27%) were associated to lumbar spondilodiscitis. All patients underwent at least one abdominal CT scan as a diagnostic test and abdominal MRI was necessary in three cases. The micro-organism responsible for the entire primary psoas abscess was S. aureus, while mixed aerobic and anaerobic flora was detected in samples of secondary abscesses. None of the cases was due to Mycobacterium. Most of the patients received combined treatment: seven of them, antibiotic and drainage by CT-guided puncture and three of them, antibiotic and drainage through open surgery; only a patient received, exclusively, antibiotic therapy. Out of the 27 patients, at least one suffered relapse of the abscess. One of the 11 patients had a fatal evolution.

Discussion: The psoas abscess (or the iliopsoas) is a rare process, although its incidence is rising in recent years due to aging of the population, the increase in immune compromised people and the increased use of CT and RM as diagnosis. Literature published so far is scarce, highlighting a number of 124 cases recently published by Navarro Lopez et al. The average age of presentation in our series is discreetly higher according to previous studies (66 years vs the average of 58), with a ratio of 85% being males, similar to the expected. Ten percent of abscesses were primary, and the most frequent cause was of secondary origin, as described. However, the most common secondary origin in our patients was gastrointestinal, unlike previously published (bone origin). The proportion of bilateral abscesses and spondylodiscitis was the expected one (up to a third of the cases approximately). The proportion of patients with pain and fever was also the expected (up to one third of the cases approximately). The proportion of patients with pain and fever was also the expected one. From the microbiological point of view it is confirmed the presence of Staphylococcus aureus as the most frequent microorganism in primary abscesses and of poly-microbial infections in the secondary, although the absence of isolations of E. coli, previously described as the most frequent agent at the primary gastrointestinal and urological sources is

appreciated. We have not found any case of tuberculosis, compared to 15-20 per cent of what was previously published in our country, which could be due to the absence of HIV patients or immune-suppressed in our series, factors previously associated with the germ. Also we cannot ignore that there is a selection bias in the encoding process. It is worthy to note that all described cases of recurrence had been treated with antibiotic therapy and percutaneous drainage versus none treated surgically. Even though our sampling is small, it supports what has been suggested in previous publications where it seems that there is a high rate of recurrence in patients not treated surgically. It has been described that age is a factor associated with mortality. Our only deceased patient in our series was 74 years old (older than the average), although his death cannot be attributed directly to the psoas abscess.

Conclusions: Incidence of the psoas abscess is rare although the frequency of its diagnosis has increased thanks to the use of the CT. Secondary abscesses are more frequent, usually by enteric bacteria, mixed infections and anaerobics. At present, the most responsible organism for the primary psoas abscesses is S. aureus. However, we must keep in mind that Mycobacterium tuberculosis is the causative agent in those patients from endemic areas, especially if associated with spondylodiscitis. The treatment of choice is the antibiotic therapy together with surgical or percutaneous drainage, although it is possible that this may result in a higher rate of recurrence.

A-122
GENERAL CHARACTERISTICS OF ESOPHAGEAL CANDIDIASIS UNRELATED TO HIV INFECTION

M. Raffo Márquez[1], A. Bejarano García[2], M. Pérez Trsitancho[2], J. Fajardo Pico [2, 3], A. Hidalgo[2], I. Suárez Lozano [2, 3]

[1]Department of Internal Medicine. Hospital Blanca Paloma. Huelva, Spain. [2]Department of Internal Medicine. Hospital Infanta Elena. Huelva, Spain. [3]Department of Internal Medicine-Enfermedades Infecciosas. ASOMEI. Huelva, Spain.

Objectives: Esophageal candidiasis is an infrequent illness in subjects without underlying immune-depression, while, it constitutes one of the more frequent opportunistic infections in HIV infected subjects and a sentinel disease that should alert us in patients not known to be infected with HIV. The objective of our study consists in describing the clinical and epidemiological characteristics of esophageal candidiasis in subjects not known to be infected with HIV.

Material and method: It is an observational and retrospective study carried out in a 285 bed hospital in a specific area of 168.401 inhabitants. The cases of esophageal candidiasis diagnosed between the years 2000-2011 via endoscopy and later confirmed anatomopathologically have been reviewed. The search for cases was realized via the Pathological Anatomy register, Endoscopy reports, Diagnosis in discharged hospital patients (CMBD). The information about serology against HIV was obtained from the register of the microbiology service.

Results: Initially 31 episodes were identified, of which 11 were excluded through the lack of serology against HIV, leaving a final sample of 20 patients, 14 male and 6 female. All 20 had suspected esophageal candidiasis via upper digestive endoscopy and later confirmed in the anatomopathological study. None of the subjects had previously suffered episodes of candidiasis, and the leukocyte recount was normal at the time of the diagnosis. The average age at the moment of diagnosis was 62 years (DE 14.5). The majority showed digestive symptoms when they were evaluated in the surgery, Dysphagia being the most common symptom, present in a total of seven patients (35%), four had heartburn (20%), two epigastralgia (10%), nausea and vomiting in one (5%). Four patients showed no symptoms whatsoever to suggest pathological esophageal at the time of diagnosis, carrying out the endoscopic assessment for other motives. The presence of oral thrush was not documented in any of the cases. With respect to the risk factor of developing esophageal candidiasis, the review of the clinical history of the diagnosed subjects showed that four of them were smokers (20%), three (15%) were habitual smokers and consumers of alcohol (daily consumption of more than 60 g of ethanol), and one patient (5%) consumer of alcohol exclusively. Ten of the cases that were studied didn't show any condition that, a priori, could be indicative of immune-depression. Four patients had mellitus diabetes, five had chronic renal disease, and three had a history of known neoplastic disease and in five the previous consumption of steroids for diverse pathologies. Eight patients were receiving proton ray treatment with inhibitors. No patients were, at the time of diagnosis, undergoing chemotherapy, radiotherapy or antimicrobial treatments. The neutrophil recount was normal in all the cases. All the cases were treated with fluconazol with disappearance of the symptoms, with no detection of posterior occurrence.

Conclusions: The existence of diverse illnesses and risk factors such as mellitus diabetes, underlying neoplastics, chronic renal disease or alcoholism, in which the appearance of certain digestive symptoms (disphagia, heartburn, etc.) should make us suspect the existence of esophageal candidiasis. Contrary to what happens in subjects infected with HIV, oral candidiasis is not associated or recurrent. In only 65% of the cases was the misleading of the HIV infection realized, resulting in esophageal candidiasis being an opportunistic event defining a case of aids.

A-123
PREVALENCE OF PERSISTENT PARASITIC INFECTIONS IN FOREIGN-BORN, HIV-INFECTED PATIENTS IN THE NORTH OF SPAIN

C. Suárez Cuervo[1], M. Fernández Almira[1], M. Rodríguez Pérez[2], M. Martínez Sela[1], F. Pérez[2], Ó. Martínez Expósito[2], A. Rodríguez Guardado[1]

[1]Department of Internal Medicine, [2]Department of Internal Microbiology. Hospital Universitario Central de Asturias. Oviedo (Asturias), Spain.

Objectives: Foreign-born, HIV-infected patients are at risk for sub-clinical parasitic infections acquired in their countries of origin. The long-term consequences of co-infections can be severe, yet few data exist on parasitic infection prevalence in this population. The Tropical Medicine Unit of Hospital Universitario Central de Asturias performed a systematic screening program of imported diseases in HIV positive immigrant population. This study presents the results of the first five years of this screening program.

Material and method: A prospective, descriptive study was designed to include all the immigrants patients diagnosed with HIV infection attending in Hospital Central de Asturias, Spain, from March 2006 to March 2011. We included demographic variables as age, sex, country of origin, months from arrival in Spain to first consultation, CD4+ cells count and viral load at time of diagnosed. Screening comprised blood count, biochemistry, basic urinalysis, hepatitis B virus (HBV), HCV, strongyloidiasis and schistosomiasis serologic analysis, stool parasites, blood test for filarias, PCR for malaria and Chagas disease serologic analysis (immunofluorescent antibody test, ELISA) and PCR in people from Latin America. Qualitative variables were compared using the χ^2 test, and the Fisher exact test when necessary. For quantitative variables, the Student t test for non paired variables or the Mann-Whitney U test were used. Significance was designated at $p < 0.05$. All tests were performed with the SPSS 15 software for Windows (SPSS Inc., Chicago, IL, USA).

Results: A total of 57 patients were analyzed: (51% female, mean age 29 years). 70% are immigrant subsaharan and the rest Latin American. The most frequent countries of origin were Equatorial Guinea (43%), Nigeria (10%), Senegal (9%), Colombia (9%), Paraguay and Morocco (4% each) and others (21%). Mean time in Spain: 1,061 days (3-9,876). Mean Cd4+ cells were 209 cells/mm^3. The average viral load was 47.000 RNA viral copies. Intestinal parasites was diagnosed in 27 of patients: T. trichuria (22%), strongyloidiasis (11%), amebiasis (7%), schistosomiasis (5%), G. intestinalis (4%). All infections by T. trichuria was diagnosed in Equatorial Guinea patients. Other parasite diseases were: filariasis by M. perstans (9%); malaria (9%, all from Equatorial Guinea) Chagas disease (4%), The 7% of patients had two or more parasites, more frequent in Sub-Saharan patients (p =,056). A total of 8 patients (14%) had chronic hepatitis B virus and 2 patients had HCV hepatitis. 19% of patients had latent syphilis significantly more frequent in Sub-Saharan patients (9 vs 2 p = 0.04). In 12 patients the screening did not show any disease.

Conclusions: Given the high prevalence of certain parasites infections and the potential lack of suggestive symptoms and signs, selected screening for strongyloidiasis and schistosomiasis or use of empiric antiparasitic therapy may be appropriate among foreign-born, HIV-infected patients. Identifying and treating helminth infections could prevent long term complications.

A-124
CAUSES OF ADMISSION AND DEATH IN HIV PATIENTS IN 2010 IN SANTA MARÍA DEL ROSELL HOSPITAL IN CARTAGENA

A. Jimeno Almazán, A. Rodríguez Pavía, B. Alcaraz Vidal, C. Albaladejo Ortiz, G. Tornel Sánchez, J. Vega Cervantes, A. Moreno Hernández, C. Smilg Nicolás

Departament of Medicine. Hospital General de Área Santa María del Rosell. Cartagena (Murcia), Spain.

Objectives: 1. To know the general characteristics of HIV population that requires hospital admission. 2. To describe admission and death causes in patients diagnosed of HIV. 3. To establish if hepatopathy is the main cause of death in our reference population.

Material and method: Descriptive and prospective analysis of all the HIV patient's admissions along 2010 (February 2010 to February 2011) in Cartagena, II Health Area of Murcia. Not only the Internal Medicine admissions were collected, but also other medical specialties admissions. Those excluded were: programmed admissions and those for non complicated obstetric cause (birth). Patient's data that were diagnosed for the first time of HIV on admission were included. Collected variables were: demographic characteristics, years from diagnosis, following of the disease, clinical and immunological condition, presence of hepatitis B virus and C virus co-infection, CD4 level, viral load, treatment, cause and days of admission and cause of death. All data were got from medical files during admissions. The statistical analysis was provided by computer programme SPPS v.18.

Results: 122 admissions on 82 patients were collected, that left an average of 1.5 admissions per year. 29% were readmissions. The median of hospital staying was 5 days. 70.4% were males and the mean age was 45. The predominant rout of transmission was intravenous drug use. Social problems were very frequent; as a matter of fact the 40% of our population were in this situation. Up to 69.7% were co infected with the hepatitis C virus. The CD4 median was 370/µL and viral load median 50 copies. 51% were on HAART. The three more frequent causes of admission were: non opportunistic infections (n: 29, 24.6%), those related to drug use and psicopathies (n: 22, 16.1%), and gastrointestinal (non-hepatic) alterations (n: 15, 12.7%). Mortality rate was 7.3% (n: 6). All the patients that died had less than 250 CD4 and the difference with those that survived was statistically significant (p: 0.01). Death causes were: 50% by hepatopathy decompensation and 50% by AIDS-defining illnesses (1 opportunistic infection, 1 AIDS wasting syndrome, and 1 AIDS-related cancer).

Discussion: With the use of highly active antiretroviral therapy (HAART) we have been witness to the change of admission and death causes in patients affected with HIV infection. Along the last decade it's been described a decrease of the diagnosis of clinical conditions that are considered AIDS criteria, and a rise of pathology related to the decompensation of hepatopathy due to hepatitis C virus. This one is nowadays the main death cause in population infected with HIV.

Conclusions: Admitted patients were frequently immuno-suppressed with uncontrolled viremia and remained without treatment. Non-opportunistic infections were the most frequent cause of admission, followed by drug-use and psychiatric related problems. These admissions reflect the high rate of social problems that these patients present. Hepatopathy decompensation is confirmed as the most frequent cause of death, with no detriment of opportunistic infections between those immunodepressed.

A-125
CLINICAL RELEVANCE OF MYCOBACTERIUM AVIUM -INTRACELLULARE ISOLATES OVER A PERIOD OF TEN YEARS

M. Rivas[1], S. Santos[1], H. Villar[2], M. Zarraga[1]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital San Agustín. Avilés (Asturias), Spain.

Objectives: The Mycobacterium avium-intracellulare complex (MAC) includes M. avium y M. intracellulare (MAI), slowly growing organisms genetically similar and generally not differentiated in the clinical microbiology laboratory. MAC can cause two mayor pulmonary diseases especially in older people with an underlying lung disease, disseminated disease in severely immunocompromised patients (those suffering from: AIDS, hematologic malignancy or with a history of immunosupressive therapy), and superficial lymphadentys especially in children. The aim of the present study is to analyze the clinical significance of MAI isolates over a period of ten years. Describe the number of isolates, the incidence of "colonization"/nfection, location of the samples, in addition to the clinical and epidemiological characteristics of those patients studied.

Material and method: Retrospective study of MAI isolates obtained from the Microbiology Service of San Agustin Hospital, from January 2001 to December 2010, by reviewing medical records. The identification was made using techniques for detecting nucleic acids Accuprobe Mycobacterium Avium Gen Probe Complex Culture Identification Test.

Results: We obtained 42 isolates of MAI (out of 485 NTM isolates (8.66%) belonging to 29 patients. The average age of patients was 64 ± 20 (median 71), 62% were male. In 28% of patients (n = 8) MAI was isolated in several episodes during the period of study, 86% of the isolates were of respiratory origin. With regards to the underlying disease and predisposing factors, (41%) of the patients were diagnosed with COPD, 25% had bronchiectasis, and 27% had a history of malignancy, 7% of patients had cystic fibrosis and a 14% had a previous history of tuberculosis. 14% of patients were HIV positive, of which 50% had disseminated infection. The incidence of infection was 31% (n = 9), 67% were immunocompromised patiens (44% VIH positive, 33% has history of malignancy) and 67% has MAI repeated isolates. Treatment was administered in 78% of the

infected patients, while 6 were cured, 1 case of relapse and 2 died.

Discussion: Sings and symptoms of NTM disease are variable and nonspecific. However, as these organisms are commonly found in nature, contamination of culture material or transient infection does occur, thus a single positive sputum culture, especially in asymptomatic patients with respiratory disease, was often not be treated. In this study 83% of the patients had radiological abnormalities (20% nodule-interstitial, 34% bronchiectasis).None of the patients which was decided not to treat immediately presented suggestive infection or radiological after the follow-up clinic.

Conclusions: MAI isolates are becoming increasingly frequent, and in our study most of them corresponded to "colonizations". However, it is necessary to evaluate their clinical significance as pathogens, when the isolation is made in HIV patients, lymphadenopathy in pediatric patients, immunosuppressed patients for malignancies or chemotherapy, and when repeated isolates are obtained from one or more locations.

A-126
PREVALENCE OF METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS IN THREE INTERNAL MEDICINE DEPARTMENTS

F. Castaño Romero[1], I. García García[2], A. Barbosa Ventura[1], G. Ternavasio de La Vega[1], S. Zhilina[1], J. García Sánchez[2], F. Laso Guzmán[1], M. Marcos[1]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital Universitario de Salamanca. Hospital Clínico. Salamanca, Spain.

Objectives: Methicillin-resistant Staphylococcus aureus (MRSA) is an important nosocomial pathogen, resistant to many antibiotic classes. Since the presence of this germ determines a worse prognosis in several infections, such as infective endocarditis our aim was to study the prevalence of MRSA in three Internal Medicine Departments of our hospital.

Material and method: Microbiological results from January 2010 to April 2012 were retrospectively reviewed in order to analyze S. aureus isolates from different sites. Basic demographic data and antibiogram pattern were recorded.

Results: A total number of 237 S. aureus were isolated and 72 of those were MRSA (30.4%, table). According to the site of isolation, 28 of 54 positive sputum cultures were MRSA (51.9%), 17 of 64 blood cultures (31.5%), 26 of 51 skin and soft tissue cultures (51.0%), and only one of 17 positive urine cultures (5.9%).

Discussion: In our study, we report that 37.5% of cultures were positive for MRSA and prevalence rate was around 50% in sputum and skin and soft tissue cultures. Other authors in Europe have shown different prevalence rates of MRSA, ranging from 54% in Portugal or 58% in Italy to 2% in the Netherlands. According to our results, MRSA isolates are increasing in our hospital and first line treatments for specific infections may need to be revised.

Conclusions: Our results show an overall prevalence of MRSA of 37.5% in 237 clinical specimens. Similar results were reported by other authors and highlight the risk of inadequate empirical antibiotic therapy in S. aureus infections.

A-127
DIFFERENCES IN MORTALITY CAUSES AMONG MEN AND WOMEN IN THE HIGHLY ACTIVE ANTIRETROVIRAL THERAPY (HAART) ERA PROSPECTIVE STUDY OF THE LAST 8 YEARS (2004-2011)

H. Azkune Galparsoro[1], F. Rodríguez-Arrondo[1], C. Sarasqueta[2], X. Camino[1], M. Goenaga[1], M. Bustinduy[1], M. Ibarguren[1], A. Fuertes[1], M. Elola[1]

[1]Department of Infectious Diseases. Donostia Unibertsitate Ospitala-Hospital Universitario Donostia. Donostia-San Sebastian (Guipúzcoa), Spain. [2]Epidemiology. BioDonostia. Donostia-San Sebastian (Guipúzcoa), Spain.

Objectives: Describe and compare mortality causes, clinical and demographic data among men (M) and women (W) of our HIV infected cohort in the HAART era.

Material and method: Prospective, observational study of our HIV infected cohort (n = 1399) from January 2004 to January 2011. Demographic features, HIV risk behaviours, mortality causes, immuno-virological and clinical situation, HAART adherence and follow up data were analyzed in each gender.

Results: (M and W) Overall deaths: 205 (78% vs 22%). Mean age (45 ± 8.5 vs 44 ± 9.5). Risk behaviours: IDU (66.9% vs 73.3%), sexual transmission (18.8% (MSM 50%) vs 17.8%), other/unknown (14.4% vs 8.9%). Main causes of deaths; AIDS defining illnesses (25.6% vs 8.9%), AIDS non defining illnesses (74.4% vs 91.1%) (p 0.015). Hepatic disease (23.1% vs 26.7%), non AIDS malignancies (13.8% vs 13.3%), non AIDS infections (10% vs 15.6%), unexpected/cardiovascular deaths (17.8% vs 28.9%), other causes (8.8% vs 6.7%). Patients in treatment with methadone (24.4% vs 42.2%) (p 0.025). Patients in HAART (> 1 month) (85.6% vs 95.6%), > 1 year of HAART (71.9% vs 88.6%) (p 0.025). LastVL < 50 copies/ml (56.2% vs 64.4%). Last Median CD4 account (224 vs 276 cell/ml) and last VL (49 copies/ml in both gender). Median CD4 NADIR(110 vs 132 cell/ml) (p 0.076).-Outpatient follow-up and HAART adherence: new diagnoses (11.9% vs 6.7%), bad follow-up/adherence (43% vs 37.8%), good follow-up/adherence (44.7% vs 55.6%) (p 0.35).

Conclusions: We notice significant differences among: Gender and cause of death (p 0.015). Men death of AIDS defining illnesses (25.6% vs 8.9%), women death of non AIDS defining illnesses (74.4% vs 91.1%), highlighting unexpected/cardiovascular deaths (17.8% vs 28.9%). Patients in treatment with methadone (24.4% vs 42.2%) (p 0.025). Percentage of patients in HAART (> 1 year, 85.6% vs 95.4%) (p 0.025).-CD4 NADIR was 110 cell/ml in men and 132 cell/ml in women (p 0.076)-We do not notice significant differences in median age (p 0.35), risk behaviours (p 0.59), percentage ofpatients with undetectable VL (p 0.39), follow-up/ART adherence (p 0.358), median last CD4 (p 0.258) and VL (p 0.945).

Table (A-126). MRSA frequency according to the site of isolation

Clinical specimen	Total number of S. aureus isolates	S. aureus	MRSA (n,%)	Percentage of the total
Sputum	54	26	28	12.0%
Blood	64	47	17	26.5%
Pressure or skin ulcer	51	25	26	51.0%
Urine	17	16	1	5.9%
Other sites	51	34	17	33.3%
Total	237	148	89	37.5%

A-128
MONOTHERAPY AMONG HIV-INFECTED PATIENTS: EFFECTIVE, SAFE AND CHEAP

M. Torralba González de Suso[1], S. Cuerda Coronel[2], E. Díaz Gómez[2], A. Espinosa Gimeno[1], S. Láinez[1], L. Sánchez[1], A. Lázaro López[2], M. Rodríguez Zapata[1]

[1]Department of Internal Medicine, [2]Department of Hospital Pharmacy. Hospital Universitario. Guadalajara, Spain.

Objectives: To analyze the short-term effectiveness of reducing treatment to a single agent with boosted Protease Inhibitor (PIs) by maintaining therapy after virologic suppression with a highly active antiretroviral therapy (three drugs) regimen for HIV-infected patients at our Hospital.

Material and method: Prospective study of patients who started monotherapy with lopinavir/ritonavir (LPV/r) or darunavir/ritonavir (DRV/r) after achieving plasma HIV viral load (VL) suppression < 50 copies/mL for at least 6 months with three active drugs. Variables included: age, gender of the patients, monotherapy starting date, serum lipids levels and renal function at baseline and then one, four and twelve months after the simplification. Rates of maintenance of HIV VL < 50 copies/mL and change in CD4 T-cell counts were calculated at these times too. The history of treatment failure to IPs and adherence level measurement 6 months before the beginning of the monotherapy regimen was also evaluated.

Results: Twenty-six patients were enrolled (18 male, 8 female), median age: 46. Twenty-two patients received DRV/r 800/100 mg once daily and 4 patients received LPV/r 400/100 mg twice daily. None had documented or suspected drug resistance. Six patients (1 of LPV/r arm, 5 of DRV/r arm) did not keep suppressing viral load < 50 copies/mL the 6 months before the monotherapy. Twenty subjects (2 of LPV/r arm, 18 of DRV/R arm) showed excellent adherence (> 90%) the previous 6 months to the simplification regimen. All the patients complete the first month of the monotherapy but only 15 (4 of LPV/r arm, 11 of DRV/r arm) achieved 4 months. Four patients (1 of LPV/r arm, 3 of DRV/r arm) concluded one year with the boosted IPs single treatment. At month 1, all the subjects of the LPV/r group and 14 of 15 patients (93%) of the DRV/r group whose laboratory parameters were monitorized had VL < 50 copies/mL. The four patients of LPV/r arm and the 7 of 10 DRV/r arm (one no monitorized) maintained viral suppression at the fourth month with monotherapy. Three patients (1 of LPV/r, 3 of DRV/r) completed twelve months with viral load below limits of assay detection. 5 virolgic blip were reported in 5 different subjects of DRV/r arm throughout the treatment (first month: 1, fourth month: 3, twelve month: 1). None was related to LPV/r group. There was no decline in CD4 cells nor a statistically significant rise in both strategies. No virological failure was documented, so there was no need to restart nucleosides. An initial upward trend in total cholesterol and triglycerides was observed in both arms, higher in the LPV/r (p = ns). Renal function was maintained stable in all patients (p = ns). No serious adverse events were reported.

Discussion: Our population sample and follow up are smaller than other studies published, nevertheless the short-term outcomes obtained showed a similar effectiveness. Although there were 5 blips in the follow-up, there was no need to restart nucleoside. No virologic failure was detected (VL > 1,000 copies) so these strategies seem to be safe and cheap.

Conclusions: Our short-term treatment outcomes of monotherapy indicate a similar efficacy and safety at a lower cost than the triple therapy; however, we need a long-term monitoring in a high proportion of patients to assess that monotherapy is as safe and efficacious as HAART.

A-130
CHARACTERISTICS OF INFECTIVE ENDOCARDITIS IN A TERTIARY HOSPITAL

A. Fuertes Rodríguez, M. Goenaga Sánchez, K. Reviejo Jaka, T. Etxeberria García, E. Gaminde Uriarte, H. Azkune Galpasoro, M. Bustinduy Odriozaola, A. Sáez Berbejillo

GAMEGI Group. Hospital Donostia. San Sebastián (Guipúzcoa), Spain.

Objectives: Infective endocarditis (IE) is a serious condition. Observational studies showed that the profile of this pathology significantly changed over the past decades. For this reason, we review the characteristics of diagnosed cases of IE in our hospital.

Material and method: A prospective population-based observational study was conducted in Donostia Hospital of all the diagnoses IE cases in the period March 2008 to April 2012. We show epidemiologic, etiologic and management data.

Results: In the period March 2008 to April 2012, 145 cases of IE diagnoses according to modified Duke criteria. A total of 99 cases (68.27%) were in men and 46 (31.73%) in women. The patients median age was 70 years (range, 32-92 years). Patients over 80 years: 24 (16.55%). Transthoracic echocardiography was performed for all patients. The distribution of the locations of IE was: 88 native valves (aortic: 35; mitral: 44; tricuspid: 8; pulmonary: 1); 44 prosthetic valves (aortic: 30; mitral: 13; tricuspid: 1); 12 intracardiac stimulation devices; the location of IE remained uncertain in 12 patients. Patients with involvement of two valves: 12; a valve and a device: 3; patients with involvement of all the valvular system: 1. Causative microorganisms were identified by blood cultures, valve culture, serology or by PCR of valve material. Eventually, 7 patients (4.82%) had no etiologic agent identified. Causative microorganisms were: 17 coagulase negative Staphylococci; 34 MSSA; 2 MRSA; 1 S. agalactiae; 26 S. viridans; 7 S. epidermidis; 2 S. neumoniae; 17 S. bovis; 17 group betahemolytic streptococci; 15 Enterococci; 3 HACEK; 2 Gemella; 2 Listeria; 2 C. parapsilosis; 1 T. whipelli; 1 Brucella; 1 Yersinia; 1 E.coli; 1 B. fragilis; 1 C. bytiricum; 1 P. acnes. Cardiac surgery was perform in 72 patients (49.65%), 57 of whom were men (79.1%). Median Euroescore was 24.22%. The mortality rate was 19.31% (28 patients); patients dead in Intensive Care Unit: 16 (11 of whom was performed cardiac surgery); in acute unit: 9; long-stay unit: 2; Hospital at Home: 1. The antibiotics administered were considered correct in all cases according to the group management support IE hospital. 62 patients (42.75%) received some treatment like outpatients.

Conclusions: IE is a prevalent disease that increasingly affects old people. It seems that there is a change in the etiology: Staphylococci being the most common etiologic agents. There are a significant number of outpatients treated at home. Despite the advances, the mortality of this entity continues to be important (in our series, intermediate described in the literature).

A-131
RELATIONSHIP BETWEEN CHIMERISM AND INFECTIOUS COMPLICATIONS IN LIVER TRANSPLANT: A PRELIMINARY STUDY

M. Alvarado[1], M. Fernández Ruiz[1], F. López Medrano[1], R. Ayala[2], C. Jiménez[3]

[1]Infectious Diseases Unit, [2]Hematology Service, [3]General Surgery and Abdominal Organ Trasplantation Service. Hospital 12 de Octubre. Madrid, Spain.

Objectives: To study if there is any kind of relationship between the chimerism and infectious complications in patients with liver transplants.

Material and method: 29 adult patients who received a hepatic transplant in our hospital between June 2001 and January 2005

have been studied. A total of 121 blood samples were obtained at different times following the transplant (median interval 6 months). The degree of chimerism was determined through a real time quantitative PCR technique. The results were measured in a percentage of the donor's DNA within the sample. Retrospectively, the cases of patients who suffered from severe infections and needed to be hospitalized within the first twelve months following the transplant were registered. We compared chimerism in function of different variables based on Mann-Whitney U test.

Results: Out of the 29 cases: 69% men, 34% hepatitis C positive and 50 years of age´s average. Every patient had at least one blood sample that presented chimerism (3% median, ranging from 0.01% to 98%). 28 out of 29 patients presented an infection (21 bacterial, 17 from Candida spp, 1 from filamentous fungus, 13 from Cytomegalovirus). The average of chimerism detected was 9%. The average of chimerism was significantly lower in those patients who developed infection by CMV (4.1% vs 12.9%) (p = 0.01). Nevertheless, the average of chimerism was greater in subjects with bacterial infections (10.0% vs 6.2%) even though the difference was not statistically relevant (p = 0.3). Also, the average of chimerism was higher in those subjects who developed some fungal infection (11.5% vs 5.3%) (p = 0.08). The degree of chimerism was lower in the patients who died during the procedure (1.7% vs 10.1%) (p = 0.1). No differences in chimerism were observed in those patients who developed neoplasias or those with transplant rejection.

Discussion: Chimerism is the presence of donor leukocytes in peripheral blood of transplant recipients. The liver is the solid transplanted organ where this phenomenon has been reported more frequently. In the past, chimerism was relationated to some immunological aspects: the higher percentage of chimerism, the more immunotolerance and the longer graft´s survival. There are no studies about the relationship between chimerism and infectious complications. We observed that those patients who suffered from Cytomegalovirus infection used to have low level of chimerism. We did not obtain any result statistically significant about the relationship between chimerism and fungal or bacterial infections. It is not clear the clinical relevance of these results. This study has been limited by its reduced sample rate.

Conclusions: In this study, It seems to exist a tendency of having less chimerism in those patients who developed an infection from Cytomegalovirus but we were not capable of proving a unidirectional or significant relationship between the percentage of the donor´s leukocyte chimerism and the development of infections in carriers of the hepatic transplant. It would be necessary a study with a larger sample size in order to show if this relationship really exists or not.

A-132
LISTERIOSIS: ANALYSIS OF 27 CASES IN A GENERAL HOSPITAL

G. Martínez[1], M. Roget[1], M. Andrés[1], H. Espejo[1], M. Morera[2], F. Bella[1], E. García[1]

[1]Department of Internal Medicine. Consorci Sanitari de Terrassa. Barcelona, Spain. [2]Department of Microbiology. CATLAB. Barcelona, Spain.

Objectives: The aim of the study was to analyse the co-morbidity, clinical presentation and prognosis of listeriosis at our hospital during the last 15 years.

Material and method: From January 1998 to April 2012 we retrospectively recorded 27 cases of listeriosis. Diagnosis of listeriosis was made by means of isolation of Listeria monocytogenes from a normally sterile site (blood culture, cerebrospinal fluid, ascites fluid, biliar fluid, amniotic fluid or placenta) in a patient with a clinical compatible illness. A case was considered pregnancy-associated if it involved a pregnant women, a miscarriage, a stillbirth or a newborn < 1 month old. The mother and her newborn were counted as a single case. In all cases demographic information, disease presentation, antimicrobial treatment and outcome data were recorded.

Results: Nine (33%) were pregnancy-associated cases. Among the 18 patients with no pregnancy-association listeriosis 10 were male (55.6%) and 8 were female (44.4%). Mean age in no pregnancy cases was 64.4 years (± 18.7) and 33.3% were aged > 75 years. According to clinical presentation, thirteen cases (48.1%) were primary bacteremia, most of them (76.9%) without clinical focus nor septic metastasis. Only in 2 cases bacteremia was associated with brain abscess and one case with cholecystitis. Blood cultures were obtained in seven of the pregnancy-associated cases and were positive in 5 of them (71.4%). Four patients (14.8%) presented with meningitis, one of them with bacteremia. One cirrhotic patient developed a bacterascites. In the bacteremic group all patients (100%) had underlying diseases (neoplastic, hematologic, diabetes, digestive autoimmune diseases or immunosuppressive conditions). Three patients had diabetes as the only underlying disease, one patient had HIV infection. Seven cases (53.8%) were under immunosupressive (steroid, methotrexate) or cytostatic therapy. Patients with meningitis had no predisposing conditions. In pregnant women, infection was developed during the third trimester of pregnancy in 8 cases (88.8%). The remaining case occurred in the second trimester and resolved in miscarriage. Sixteen patients (59.3%) were first treated with ampicillin monotherapy or aminoglucoside combination. In one case was initially used cefepime, and the rest of them received amoxicillin, piperacillin/tazobactam, cotrimoxazole or vancomycin. Finally two cases did not receive antimicrobial therapy because of the seriousness of the underlying condition. The whole pregnancy-associated cases resolved satisfactory for pregnant women, and so for her newborns except for the case occurred in the second trimester. Five patients died, 18.5% of mortality rate. In one case death was not directly related to infection by Listeria. All patients who died had bacteremia and severe underlying disease.

Discussion: Bacteremia and menignitis are the most common manifestations of listeriosis, in our study accounted for 70% (17/27) of the cases. Pregnancy-associated cases represented 33% of the patients. Mean age of the patients has increased along the years, 33.3% of the patients recruited in our series were aged > 75 years. Clinical outcome was favourable in pregnant- associated cases with good response to amoxicillin or ampicillin. More than 70% of cases of listeriosis occur in persons with recognized underlying diseases. In our study, 61.1% of the cases in the non pregnancy-associated patients had underlying disease, most of them in the bacteremic group. Successful treatment can be achieved with amoxicillin and ampicillin; in our case ampicillin monotherapy or aminoglucoside combination was administered as a first option in 59.3% of the cases. Fatality rate of listeriosis reported in the literature ranges from 20% to 40% for the majority of underlying conditions, we report an 18.5%. In our study mortality rate is higher in bacteremic listeriosis. All patients who died had bacteremia and severe underlying disease.

Conclusions: Bacteremia and meningitis are the most common manifestations of listeriosis in non pregnancy-associates cases. Mortality rate is higher in patients with bacteremic listeriosis and severe underlying disease.

A-133
MEDITERRANEAN SPOTTED FEVER: DIAGNOSIS AND PROGNOSIS IN A ENDEMIC COUNTRY

J.G. Batista[1], A. Faria[3], F. Louro[3], F. Aldomiro[2]

[1]Department of Infectious Diseases, [3]Department of Medicine I, [2]Department of Medicine II. Hospital Prof. Doutor Fernando da Fonseca. Amadora, Portugal.

Objectives: The rising number of rickettsial diseases is a public health concern in Portugal, where the most prevalent tick-borne disease is Mediterranean spotted fever (MSF). Although usually considered to have a benign evolution, it may be associated with high morbidity and mortality. Several studies have identified risk factors associated with a worse prognosis such as elder age, alcoholism, diabetes and glucose-6-phosphate dehydrogenase deficiency. High levels of clinical suspicion and the prompt initiation of treatment with tetracyclines are the keys to a favourable outcome. The authors discuss predisposing co-morbidities in MSF, its clinical and laboratorial presentation and the prognosis, in a country where MSF is endemic.

Material and method: The authors carried out a retrospective analysis of all admissions to 2 Medical Wards during a 5 year period (January 2007 to December 2011). All patients with a diagnosis of MSF were included and the characteristics evaluated were: age, sex, clinical presentation, medical history, laboratory tests, treatment and outcome.

Results: A total of 28 cases of MSF were diagnosed during this period. There was a higher prevalence of infection amongst males, and the average age was 52 years (17-79). Four cases had a history of alcoholism and 2 patients had a personal history of diabetes. Upon admission, 24 patients were febrile and 22 patients presented with a rash (maculo-papular in 20 of them); myalgia was present in 15 cases and headache in 9. Tache-noire was found in 11 of the patients. Laboratory tests revealed thrombocytopenia in 20 cases, hyponatremia in 21, acute renal failure in 7 cases and a rise in liver enzymes in 20 cases (mainly ALT). Serology for Rickettsia conorii was performed in 90% of the patients and was positive in 21.4% of these. All patients were treated with doxycycline and had a benign and uncomplicated evolution.

Discussion: Higher prevalence in male sex remains inconclusive as a real risk factor for MSF or a consequence of higher environmental exposure and, although elder age is associated with worse outcome, we didn't identify it as such in this sample. The authors observed higher prevalence of known risk factors for MSF like chronic alcoholism, diabetes and hypertension, but these weren't associated with a bad prognosis. Most patients presented with a febrile syndrome associated with maculopapular rash, and only 39% had a tache noire. We believe that in an endemic country these clinical features are clue to diagnosis and that tache noire may suggest it but surely doesn't exclude MSF when it's absent. Laboratory findings are relatively frequent but unspecific; when present, one should take in account dramatic alterations in their values, because these seem to predict unfavourable evolutions. Above all, uremia is associated with worse outcome, though multifactorial in the majority of patients, and should be tested frequently. To confirm diagnosis, serology with immunofluorescence was performed in 90% of the sample, and was only positive in 6 of them. According to this and other studies in MSF-endemic regions, we think serology must not delay initiation of proper therapy and that it isn't imperative to confirm diagnosis when typical clinical features are present and an appropriate answer to tetracyclines is observed.

Conclusions: MSF is still highly prevalent in Portugal, where it's considered endemic, even in urban areas, so high suspicion is advised if the epidemiological and personal history are suggestive of a tick-borne disease and typical clinical features are present. Diagnosing MSF may be easy, but predicting patient's prognosis is not and, most importantly, prompt initiation of proper antibiotherapy remains key to favourable outcome.

A-134
DESCRIPTIVE STUDY OF OPPORTUNISTIC INFECTIONS IN HIV PATIENTS ADMITTED TO THE INTERNAL MEDICINE DURING THE YEARS 2010-2011

D. Gudiño, S. Vicente Rodrigues, M. Hayek Peraza, M. Miguélez Morales, M. Linares Feria, P. Laynez Cerdeña

Department of Internal Medicine. Complejo Hospital Universitario Ntra. Sra. de Candelaria. Santa Cruz de Tenerife, Spain.

Objectives: This is a tertiary hospital covering an area of 500,000 habitants, the population of 1,400 patients cohort VIH. It is estimated that the prevalence of people living with HIV/AIDS in Spain is 120-150000 and although the diagnosis and treatment is free and confidential, there is a high number of infected (about 30%) who know their status so that many develop severe immunosuppression and AIDS without receiving antiretroviral therapy. Our hospital covers a population of 500000 inhabitants and the cohort of HIV in our hospital is approximately 1400 patients. The aim of this study was to describe the frequency of opportunistic infections and determine which is the most frequent in HIV + patients at the Hospital Our Lady of Candelaria during the period January 2010-December 2011.

Material and method: Retrospective descriptive study of HIV patients admitted to Internal Medicine during the period January 2010 to December 2011. We reviewed the medical records of patients admitted to the Internal Medicine service during this period.

Results: 151 objectified revenues and 22 readmissions. Of the total 45 (29.80%) patients were admitted for an opportunistic infection. Of these 6 (13.33%) were female and 39 (86.66%) were male. The mean age was 40.70 years. In relation to the mechanisms of transmission: 40% former IDUs, 40% and 20% heterosexual sex 34%. HCV co infection was 18% of patients. The most common opportunistic infections, Pneumocystis jirovecii Pneumonia 24.4%, recurrent pneumonia 11.11%, wasting syndrome 8.8%, 8.8% lymph node TB, pulmonary tuberculosis 8.8%, 8.8% cerebral toxoplasmosis, pneumonia CMV 4.4%, 4.4%, cryptococcal meningitis, cerebral lymphoma, esophageal candidiasis 4.4% 4.4% 15.5% other causes during the period of the study had 4 patient died (8.8%), most of whom from pneumonia jirovecii pneumonia and decompensated liver disease. Were newly diagnosed patients (42.2%), being the most common admission diagnosis constitutional syndrome and HIV 2 º Pneumocystis jirovecii pneumonia. 20% of patients were found 2 or more concurrent infections the most common CMV.

Conclusions: We conclude that infections accounted respiratory opportunistic infection common in HIV + patients and that the most common infectious agent is Pneumocystis jirovecii.

A-135
A DESCRIPTIVE STUDY OF HIV PATIENTS ADMITTED TO INTERNAL MEDICINE IN 2011

S. Vicente Rodrigues, D. Gudiño, M. Hayek Peraza, M. Miguélez Morales, M. Linares Feria, P. Laynez Cerdeña

Department of Internal Medicine. Complejo Hospital Universitario Ntra. Sra. de Candelaria. Santa Cruz de Tenerife, Spain.

Objectives: It is estimated that the number of people living with HIV/AIDS in Spain is between 120,000 and 150,000. Although testing, diagnosis and treatment are free and confidential, there are a high number of infected individuals (about 30%) who are not aware of their HIV status, and so many develop severe

immunosuppression and AIDS without receiving antiretroviral therapy. In 2008 it was reported that 30% of new diagnoses had a CD4 count of less than 200. Our aim is to analyse what happens in our catchment area (the south of the island of Tenerife) and describe the clinical and epidemiological characteristics of the study population. Our hospital is a tertiary hospital covering an area with 500,000 inhabitants, with a HIV population in our cohort of 1,400 patients.

Material and method: Retrospective descriptive study of HIV patients admitted to Internal Medicine in 2011. The medical records of patients admitted to Internal Medicine in 2011 were reviewed for this purpose.

Results: 88 objectified admissions of 74 patients, 14 readmissions. 26.13% of patients were female and 73.86% were male. The mean age was 41.55 years. The mean period since HIV diagnosis was 11.22 years. The mechanisms of transmission were: 54.7% from IVDU EX; 33.84% and 9.43% respectively from homosexual and heterosexual transmission; 2% from blood products. 54.71% were receiving HAART at the time of admission. It was noted that 33.96% of patients had a CD4 count of less than 200 on admission and 64.15% had a detectable viral load at admission. Of the patients studied 11.32% had social problems, 49% had poor adherence to treatment and 41.5% presented previous opportunistic infections. The HCV coinfection rate was 39.62%. 3.77% required ICU admission. The most frequent reasons for admission were respiratory infections (33.8%) and AIDS-defining illnesses (28%) of which tuberculosis was the most frequent. Liver disease was the reason for admission in eight patients (15% of total). During the year there were seven exitus admissions (13.2% of total), most of which were due to pneumonia jirovecii and de-compensated liver disease (28.57% each). There were nine newly-diagnosed patients (16.98% of total), the most common admission diagnosis being constitutional syndrome and HIV 2 º Pneumocystis jirovecii pneumonia. These new diagnoses were mostly from admissions to internal medicine, and most were at HIV stage C3. The most common transmission mechanism in new patients was sexual intercourse.

Conclusions: As in Southern Europe in our patients are predominately intravenous drug users, which largely explains the high prevalence HCV antibodies, which is the most prevalent chronic active infection in this population. An increased incidence of newly diagnosed patients was documented, most of whom present at an advanced stage of the disease at diagnosis. An increase in sexual transmission as a means of transmission was also seen in the patients, as is typical in Southern Europe.

A-136
CLINICAL FEATURES OF TUBERCULOSIS (TB) IN IMMIGRANTS, COMPARED TO SPANISH PATIENTS

I. Francisco[1], Á. Ballesteros[2], J. Oriol[3], S. Fernández[3], G. Beltran[3], D. Sánchez[3], F. García Bragado[1], A. Vinyes[1]

[1]Department of Internal Medicine. Hospital Universitari de Girona Dr. Josep Trueta. Girona, Spain. [2]Department of Internal Medicine, [3]Pneumology. HMB Badalona Serveis Assistencials. Badalona (Barcelona), Spain.

Objectives: We aimed to analyse the impact of immigration on TB in recent years in two Spanish hospitals, comparing the clinical features in such population with autochthonous patients.

Material and method: We analyzed epidemiological & clinical data of TB cases comparing immigrant vs autochthonous patients along the study period (2000-11). To check the consistency of data in different levels of health assistance, we studied databases from two hospitals: a general hospital "Dr. J. Trueta" in Girona [G] & a district hospital "HMB" in Badalona [B].

Results: N = 503 patients (358G/145B). Male 351 (69.8%). Age 40.8 ± 21.0 years. Immigrants 181 (36%), slightly higher proportion in general (G) 139 (38.8%) than in district (B) 42 (29.0%) hospital (p = 0.04): Sub-Saharan 50G + 5B (30.4%); Morocco 31 + 9 (22.1%); S. America 26 + 13 (21.5%); Asia 10 + 12 (12.2%); East Europe 20 + 3 (12.7%), Other 2 (1.1%) Immigrants were younger than autochthonous: 31.0 ± 11.6 vs 46.3 ± 23.0 years; p < 0.5, with similar gender distribution: 67'4% vs 71.1% males, respectively; p = 0.7. The immigrants/autochthonous ratio significantly increased from the 1st half (66/193) to the 2nd half (115/129) of the period (p < 0.05), even in each hospital separately. HIV was found equally frequent in both groups, while the remaining risk factors scarcely appeared in immigrants (in this population we also detected 4 cases of TB during pregnancy). Extrapulmonary TB in both groups did not reach significance: 72 (39.8%) immigrants vs 104 (32.3%) autochthonous; p = 0.09. The only greater significant manifestation was osteoarticular TB (21 vs 13 cases, respectively; p = 0.01). We didn't find differences in the median delay of diagnosis between immigrants 32 days [IQR 16-91] & autochthonous 33 [IQR 10-74] p = 0.2, regardless the kind of hospital (Girona 33 days [IQR 14-80] vs Badalona 30 [IQR 10-90] p = 0.9 or along the study period (1st half 33.5 days [IQR 10-81.5] vs 2nd half 31 days [IQR 10'7-90] p = 0.9. Number of bacilliferous in the 309 pulmonary cases was similar in both groups: 52 (53.6%) in immigrants vs 88 (43.8%) in autochthons p = 0.1 Description of resistances: autochthonous (3Z, 2H, 1HZ) & immigrants patients (1H, 2Z, 2S, 1 Ukrainian MDR-TB & 1 Russian XDR-TB). We reviewed 347 (69%) patients with registered follow-up: 140 (40.3%) immigrants & 207 (59.7%) autochthonous. They fulfilled treatment 89/140 (63.6%) in the former group & 164/207 (79.2%) in the last group; p < 0.05, although other 54(15.6%) patients, mainly immigrants (31), were controlled elsewhere. Death for any cause was slightly more frequent in autochthonous 17 (8.2%) than in immigrants 7 (5%); p = 0.3.

Discussion: Endemic TB is higher in Spain than in other parts of Europe. Immigration has slowed the decline of TB in Spain. So far, our universal and public health system may have helped a prompt diagnostic & treatment.

Conclusions: Immigration is a risk factor for TB. There's not delay in diagnostic during the study period in such population. A trend of extrapulmonary cases is observed, significant in osteoarticular manifestations. Multiresistant TB is a particular concern, especially in those people arriving from former soviet republics. Increase of TB in immigrants makes essential to keep sanitarian politics to control its raise.

A-137
OBSERVATIONAL STUDY ON ADHERENCE TO ANTIRETROVIRAL THERAPY IN HIV PATIENTS ADMITTED TO THE SERVICE OF INTERNAL MEDICINE FOR THE YEAR 2011

S. Vicente Rodrigues[1], D. Gudiño[1], P. Díaz Ruiz[2], G. Callejón Callejón[2], M. Hayek Peraza[1], M. Miguélez Morales[1], M. Linares Feria[1], P. Laynez Cerdeña[1]

[1]Department of Internal Medicine, [2]Department of Pharmacy. Complejo Hospital Universitario Ntra. Sra. de Candelaria. Santa Cruz de Tenerife, Spain.

Objectives: Adherence to antiretroviral therapy (HAART) is one of the key factors in the monitoring of patients infected with human immunodeficiency virus (HIV) since, in many cases, can determine the success or failure of therapy used. The emergence of new groups of antiretroviral drugs and the introduction of new treatment strategies improved the prognosis, evolution and quality of life of patients with HIV infection. However for that treatment is to inhibit viral replication is necessary to achieve very high rates of adhesion, which determines a highly demanding in proper making medicines. It is considered to adhere to taking at least 90-95% more doses. Besides the importance of this factor to avoid treatment failure

and, as happens in other groups of anti-infective drugs must not be forgotten that there is a risk of emergence of resistant strains. The complexity of the treatment regimen, which may have a high load of tablets including multiple daily doses and the frequency of side effects make HAART difficult to tolerate. The objective of this study was to determine adherence to antiretroviral treatment of HIV patients admitted to the Internal Medicine department of our hospital.

Material and method: Retrospective observational study of patients admitted to the Internal Medicine antiretroviral treatment at the Hospital Universitario Nuestra Señora de la Candelaria in the year of 2011. Adherence was determined by structured interview and collection of medication in the pharmacy department. For the calculation of adherence in pharmacy we use a formula that analyses the collection of medication. Upon detecting poor adherence by dispensing record is confirmed by survey SMAQ.

Results: We had 88 objectified income observed during 2011, 74 patients with 14 repeated admissions. 26.13% of patients were women and 73.86% were male. The mean age was 41.55 years. The mean time to diagnosis of HIV was of 11.22 years. Regarding adherence data collected in pharmacy: we found that 51 patients of those admitted had already pre-treatment and of these 61.17% had 2 daily doses of drugs and 41.37% had a daily intake of drugs. In relation to the number of drug taking: 60% were taking 2 drugs in their treatment, 31.1% were on 3 drugs and 8.8% were taking a drug. Analyzing adherence find that 51% of patients had poor adherence. Of those admitted 23 patients had new treatments, of which 73.9% started treatment with 3 drugs, and 26.5% with 2 drugs. In relation to the number of times take medication at day 60.8% had a daily intake, and 39.1% had 2 daily doses of drugs. Of the patients 17% presented new treatment poor adhesion.

Conclusions: There is no ideal method for measuring adherence to antiretroviral therapy. The easiest methods are simple to apply and the structured interview the patient and recording of dispensations made in the pharmacy. The interview is one of the most used, but there are several versions of the questionnaire based on that, even in some cases, they may provide different results when applied to a patient. The record of dispensations is a very easy to implement but does not guarantee the reliability of the results and to go regularly to pick up the medication is not synonymous with good compliance. The formula overestimates adherence, because, there are patients who can get along medication and not take it, those who take medication underinsured not take it (no). This means that their worst adhesion is detected by this method. Adherence is one of the most important factors to achieve optimal results in the treatment of HIV infection, so that simplification of treatment regimens, tailored to the personal schedules of each patient and their lifestyle, so as the ability to anticipate possible adverse effects, interactions and resistance in the number of tablets are the basic strategies for optimizing adherence to HAART.

A-138
PREDISPOSING CARDIOPATHIES IN INFECTIVE ENDOCARDITIS

P. Sánchez Junquera, G. Hérnandez Pérez, J. Soto Delgado, A. de la Vega Lanciego, E. Martínez Velado, M. Mateos Andrés, M. Chimeno Viñas, P. García Carbó

Department of Internal Medicine. Complejo Asistencial de Zamora. Zamora, Spain.

Objectives: To know the kind of predisposing cardiopathies in endocarditis and the time needed for diagnosis and treatment to improve the attention given to our patients.

Material and method: Retrospective and descriptive study where the records of patients with endocarditis are analized from January 1st 2000 to December 31st 2011. Evaluated data are: type of predisposing cardiopathy, length of stay until diagnosis, antibiotics used prior to diagnosis, number of admittances in the previous month, empirical antibiotics used, treatment duration, inhospital mortality and number of cases that required surgical treatment. Percentages and averages have been calculated with these results and they have been compared to those in the literature.

Results: Twenty seven patients have been studied, 16 males (59.3%) and 11 females (40.7%) with ages from 30 to 85 years (average 67). Time elapsed until diagnosis varied from 1 to 18 days (average 3). In 17 cases (62.9%) a predisposing cardiopathy was identified. Predisposing cardiopathies were: mechanical valve prosthesis, 5 cases (29.4%); mitral stenosis and/or insufficiency, 4 cases (23.5%); aortic stenosis and/or insufficiency, 4 cases (23.5%); mitral valve prolapse, 3 cases (17.6%); pacemaker, 1 case (5.9%). Excluding the patients with prothesis, 2 cases were due to rheumatic endocarditis (11.7%). Antibiotics were given before diagnosis in 12 patients (44.4%): ceftriaxone (4), vancomicyn (3), quinolones (4) and rifampicin (1). The number of patients that had a previous admittance were 5 (18.5%). The treatment prescribed was an association of antibiotics in 26 cases (96.3%) and the drugs used were: gentamycin, 19 cases (70.3%); third generation cephalosporins, 11 cases (40.7%); cloxacillin, 9 cases (33.3%); vancomicyn, 8 cases (29.6%); ampicillin 6 cases (22.2%); penicillin G, 4 cases (14.8%); rifampicin, 2 cases (7.4%); amikacin, 1 case (3.7%). Treatment duration among those who didn't require surgery and those who survived was: 6 weeks, 4 cases (26.6%); 5 weeks, 5 cases (33.3%); 4 weeks, 3 cases (20%); 3 weeks, 3 cases (20%). Death during admittance happened in 3 cases (11.1%). Replacement valve surgery was needed in 13 (48.1%).

Discussion: In our series, the percentage of endocarditis with a predisposing cardiopathy is similar to the one disclosed in the literature (20-40%). An 11.7% of cases occurred in relation to a rheumatic cardiopathy, which is slightly more frequent than compiled in the literature (8%). Valvulopathy was degenerative in 35.3% of cases, more frequent than in the literature (30%); probably because of the higher age of our patients. The percentage of prolapse of the mitral valve was also greater than in the literature (10%). Endocarditis happened on a prosthetic valve in 29.4% of cases (10-30% in the literature). The chosen antibiotic and the treatment duration were correct in all cases except for 2, that were diagnosed during the early years of the study. The percentage of patients that required valve replacement surgery was 48% (40% in the literature); probably related to the high percentage of endocarditis on prosthetic valves that we found. Mortality is similar to the one published in the literature (10-15%).

Conclusions: It is important to insist on giving antibiotic prophylaxis before any kind of manipulation (dental, urinary, etc) to all patients with any of the predisposing cardiopathies detailed above; this should be written specifically in all the reports. We emphasize on the necessity of performing blood cultures prior to starting the treatment of infectious processes of not well established cause. We also stress the need of maintaining the treatment for at least 4 to 6 weeks.

A-139
DIAGNOSING HIV IN UNEXPECTED PATIENTS: OUR EXPERIENCE IN A MEDICAL WARD

J.G. Batista[1], F. Aldomiro[2], P.C. Pacheco[1]

[1]Department of Infectious Diseases, [2]Department of Medicine II. Hospital Prof. Doutor Fernando da Fonseca. Amadora, Portugal.

Objectives: Infection with the human immunodeficiency virus (HIV) continues to be a public health problem on a world-wide scale. Amongst the general population, risk factors such as intravenous drug use (IVDU) and men who have sex with men (MSM) are

most frequently associated with this infection, but promiscuous heterosexual behaviour and not practicing safe sex are responsible for an increasingly larger number of new cases of HIV infection. The lack of preoccupation with the latter risk factors, and the belief that these behaviours do not place people at a greater risk for HIV infection often leads to late and unexpected diagnosis. The authors carried out a retrospective study of all the patients admitted to an Internal Medicine Ward with an initial diagnosis of HIV infection to determine risk factors, the presenting clinical situation and the immunological and virological status of these patients at the time of diagnosis.

Material and method: A retrospective study of all patients admitted to an Internal Medicine Ward between January 2006 and December of 2010 was carried out. All patients without a known diagnosis of HIV infection, but who presented with a positive serological test after admission were included. The following characteristics were evaluated: gender, race, age, diagnosis at the time of discharge, serology for HIV 1 and 2, CD4 count, viral load, serology for hepatitis B and C, length of stay in the ward and outcome.

Results: During this 5 year period an initial diagnosis of HIV infection was made in 50 patients, with an average age of 46.12 years (23-76). 63.3% were male, and 98% presented with a positive serology for HIV 1. The majority of the patients were heterosexual, and presented with advanced stages of the disease – an average CD4 count below 200 cells/mm^3 and an average viral load above 450 000 copies/ml, and 18 of them presented with AIDS-defining conditions. The length of stay was significantly greater than the average for the Ward. Although only 1 patient died before Hospital discharge, clinical file review after discharge revealed a mortality rate of 30%, mostly because of opportunistic infections.

Discussion: An initial diagnosis of HIV infection in patients admitted with unspecific clinical presentations was relatively frequent. This is particularly relevant when one takes into consideration that our Hospital has an Infectious Disease Ward and 4 Medical Wards, and these numbers represent the experience of only one of these Wards. The principal risk factor was promiscuous heterosexual behaviour, with no condom use. This conclusion seems to highlight the popular misconception that HIV infection is a problem that affects mainly IVDU and MSM. The majority of patients presented with advanced disease status and many presented with AIDS defining conditions.

Conclusions: HIV is a public health concern and isn't restricted to MSM and IVDU patients anymore. As clinicians, one should be aware of this; it is important to investigate risk factors in clinical history and to test patients presenting with unspecific manifestations and vague complaints in order to shorten time to diagnosis, reduce the number of late presenters and provide early access to antiretroviral therapy. We also feel that these results highlight the need for more efficient public campaigns, as the previous ones promoting the concepts of safe sex and condom use seem to have had limited success, and raise the discussion on public HIV screening, especially in regions with high HIV incidence. As for now, voluntary testing seems to be the clue to broaden the possibility of diagnosis to the general population.

A-140
SEROPREVALENCE OF TETANUS, DIPHTERIA, PERTUSSIS AND MEASLES IN TURKISH ADULTS: IMPLICATIONS FOR ADULT VACCINATION

M. Durusu Tanriover, C. Aycan, S. Ascioglu, S. Unal

Department of Internal Medicine. Hacettepe University Faculty of Medicine. Ankara, Turkey.

Objectives: Antibody levels against diseases covered by childhood immunization schedules diminish due to immune aging, indicating the need for an adult immunization schedule. The primary aim of the study was to investigate the prevalence of seropositivity against tetanus, diphteria, pertussis and measles in adult and elderly patients visiting the outpatient clinic of General Internal Medicine and Geriatrics Departments of Hacettepe University Faculty of Medicine. The second aim was to determine the need for booster vaccination with regard to predefined cut off antibody levels.

Material and method: Patients who were seen in the General Internal Medicine and Geriatrics outpatient clinics between May 2011 and December 2011, and who consented were enrolled to the study. Demographic characteristics and chronic diseases were recorded. Disease and vaccination history about tetanus, diphteria, pertussis and measles were obtained depending on the patients' declaration. Blood samples for tetanus, diphteria, pertussis and measles antitoxoid antibodies were obtained and centrifuged to keep the serum samples until they were collectively analyzed. Tetanus toxoid IgG, diphteria toxoid IgG, Bordatella pertussis toxin IgG, measles virus IgG levels were determined by using enzyme immunoassay (ELISA) method. Results were evaluated in terms of seropositivity, need for booster vaccination and protection with regard to recommended cut-off values.

Results: A total of 1367 patients consented, however 1,303 blood samples were available. Mean age of the patients was 57.1 ± 15.8 and 68% of them were female. Diabetes was the most prevalent chronic disease (23.5% of patients). Serum antibody levels were classified as protective or non-protective with regard to defined cut off values for each disease. Protective antibody levels were present for tetanus, diphteria, pertussis and measles in 31%, 34.8%, 9.7% and 98.8% of the patients respectively. Booster vaccine was indicated in 77.3%, 96.4%, 90.3% and 1.8% of the patients respectively.

Discussion: Adult vaccination coverage has been low, despite the increasing attention and constantly updated guidelines released by national and international authorities. Former epidemiological studies from Turkey revealed similar and even lower seropositivity rates for diphtheria, tetanus and pertussis. This study not only evaluated the antibody levels but also the presence of chronic diseases which themselves indicate the necessity of adult vaccination against certain infectious diseases. More than 75% of patients required a booster for tetanus, while more than 90% of them required a booster for diphtheria and pertussis with regard to antibody levels. Interestingly, only 2% of the study population was supposed to receive a measles vaccine, presumably due to the high rate of childhood infection as disclosed by the patients.

Conclusions: This study demonstrated that seropositivity is low for diphtheria, tetanus and especially for pertussis in adult and elderly patients. Booster vaccinations are required in adult life in accordance with national and international adult vaccination guidelines.

A-141
EVOLUTIONARY DIFFERENCES BETWEEN THE INFLUENZA A VIRUS SUBTYPE H1N1 AND INFLUENZA A VIRUS SUBTYPE H3N1 AMONG HOSPITALIZED PATIENTS IN THE COMPLEJO ASISTENCIAL UNIVERSITARIO DE BURGOS

A. Blanco[1], R. Cabo[1], S. Molinero[1], G. Megías[2], V. Portillo[1], C. Dueñas[1], E. Ojeda-Fernández[2], J. Lorenzo[1]

[1]Department of Internal Medicine, [2]Microbiology Department. Complejo Asistencial de Burgos. Burgos, Spain.

Objectives: To analyze the outcome evolution in patients infected by influenza A virus subtype H1N1 and influenza A virus subtype H3N1 since the beginning of their admission and during the treatment in a tertiary care hospital.

Material and method: This is a retrospective cohort study in which 107 patients were analyzed in the Internal Medicine and

Pulmonology departments in a tertiary care teaching hospital. Two groups were compared: the first sample consists of 30 patients affected by influenza A virus subtype H1N1 between October 2010 and April 2011, and the second sample consists of 77 patients affected by influenza A virus subtype H3N1 between October 2011 and April 2012. The diagnosis was confirmed using the PCR technique in nasopharyngeal aspiration and throat culture. A comparison was made connecting the complications and the response applied in both samples.

Results: In the sample of influenza A virus subtype H1N1, patients showed pneumonitis (56.7%) and bacteraemia (6.7%). Only one patient showed an ischemic attack, and another one showed myoclonus. A broad-spectrum antibiotic was applied in 89.7% of the patients, 71% received a corticosteroid treatment and in 65.5% oseltamivir before the first 48 hours. Just a patient was admitted to the Intensive Care Unit in order to use mechanical ventilation. The average stay in the hospital was 6.9 days. In the sample of influenza A virus subtype H3N1, 2.6% patients showed pneumonitis and bacteraemia (5.3%) and there was one case of viral pleuropericarditis. A broad-spectrum antibiotic was applied to the 89% of the patients, 80% used corticosteroids and oseltamivir was applied before the first 48 hours to 60% of the patients. None of the patients were admitted to the Intensive Care Unit and 3 patients died because of non-related causes. Their average stay in the hospital was 9.2 days.

Discussion: Influenza is usually a self-limited infection, though acutely debilitating. However, it is connected with increased morbidity and mortality in certain high-risk populations. If we initiate antiviral therapy without delay, it can shorten its symptoms from one up to three days; the benefit is even greatest when given it within the first 24 to 30 hours. In patients with fever, it has been demonstrated that there is almost no benefit when the treatment is initiated two days or more after the onset of uncomplicated influenza. Some studies have suggested that antiviral therapy has several benefits like the reduction of the severity and frequency of complications caused by influenza, the duration of hospitalization in patients with severe influenza, and influenza-associated mortality. Antibiotics are indicated only for bacterial complications of acute influenza such as bacterial pneumonia, otitis media, or sinusitis.

Conclusions: Pneumonitis and other cardiovascular problems are significantly associated with subtype H1N1. As it has been showed in other studies before, the beginning of the specific antiviral treatment in the first 48 hours implies a reduction of the average stay of the patients in the hospital, but it does not affect the mortality rate.

A-142
MANAGEMENT OF COMMUNNITY ACQUIRED PNEUMONIA IN A SHORT STAY UNIT

N. Felipe Pérez, J. Medina García, C. Hernández Carballo, J. del Arco Delgado, J. Romero Pérez, J. Delgado Casamayor, F. Martín Hernández, P. Laynez Cerdeña

Department of Internal Medicine. Complejo Hospital Universitario Ntra. Sra. de Candelaria. Santa Cruz de Tenerife, Spain.

Objectives: To describe the demographical and clinical characteristics of patients admitted into a SSU and their comorbidities. To analyse this unit's efficiency in terms of readmissions and appropriateness of therapeutical approaches implemented.

Material and method: Descriptive, prospective study in Hospital Universitario Nuestra Señora de la Candelaria's SSU selecting all patients with a discharge diagnosis of CAP (GRD) between February 2011 and February 2012. The following variables are analysed: age, gender, pluripathology according to broadly used criteria, pneumonia severity (Fine) index, basal treatment, stay (days), antibiotics on admission and on discharge and readmissions.

Results: A total of 34 consecutive patients were analysed. Mean age was 76 ± 10.42 years. 19% were male. 38% computed as pluripathological patients, meeting at least two criteria. 41.2% were classified as category IV according to Fine's classification criteria. The accrued frequency of mean length of stay of 4 days was 90.6%. There was a statistically significant correlation between the number of pluripathological categories and length of stay (Rho = 0.472; p = 0006). Length of safy also correlated with temperature on admission (Rho = 0.629; p = 0.021). 3 of the patients had to be readmitted for the same reason following 30 days after hospital discharge. Maximum length of stay was 5 days. No statistical significant differences were seen comparing groups above and below 4 days of stay.

Discussion: Community acquired pneumonia (CAP) is a highly prevalent infectious disease among elderly people, often requiring hospital admission. Short stay units (SSU) might be a useful tool able to provide enough warranties in terms of clinical management and could help reducing in-hospital length of stay, hence improving bed management efficiency and reducing comorbidity directly related to prolonged in-hospital stay.

Conclusions: SSU can be an efficient and safe alternative to conventional treatment of CAP, can help reducing mean length of stay without playing any role on readmissions. Moreover, in our experience, the patient profile is an elderly, pluripathological, physically or socially dependent patient that is also chooseable for this modality of treatment.

A-143
AMEBIASIS, AN EMERGING PATHOLOGY IN DEVELOPED COUNTRIES?

C. Salas Pelayo, L. Corral Nieri, F. Arnaiz de ñas Revillas Almajano, A. Sánchez González, C. Valero Díaz de Lamadrid, F. Ortiz Flores

Department of Internal Medicine. Hospital Valdecilla. Santander (Cantabria), Spain.

Objectives: Describe the epidemiological and clinical features of patients with intestinal or invasive amebiasis, for the last 10 years in our center.

Material and method: From January 2002 to January 2012, ten reported cases of amebiasis (70% male) were diagnosed at our hospital. Risk factors (travel or source of endemic area, HIV infection and unsafe sex), service income, clinical presentation and relevant data of physical examination were collected. Invasive disease was defined as extraintestinal, involving liver, lungs or brain. Imported cases were those from endemic areas or with history of travel to these areas, considering the rest as native. Laboratory tests determined the presence of eosinophilia (500 cells/dL), anemia (Hb 12 g/dL), elevated erithrocyte sedimentation rate (ESR) (15 mm/h), elevated C-Reactive Protein (C-RP) (0.5 mg/dL), altered transaminases (AST 37 U/L or ALT 40 U/L), elevated total bilirubin (1.2 mg/dL) and Entamoeba histolytic serology (indirect hemagglutination antibody detection), defined as positive titer from 1/320 and high titer from 1/1280. Parasite detection was performed by microscopic examination of stools or aspirated fluid from the abscess puncture and polymerase chain reaction (PCR). Data were collected from abdominal ultrasound, abdominal computerized tomography (CT scan) and colonoscopy. Type of treatment (medical, surgical or both), complications and mortality were also analyzed.

Results: The mean age was 38 years (27 SD10 in women and 43 SD13 in men). 40% of the cases were native and 60% imported. 60% had an invasive disease (all of them with liver abscess). There was no pulmonary neither cerebral disease in our series. Only two cases were HIV-positive and just one case has had unsafe sexual practices.

80% were admitted in internal medicine service, 3 of them in digestive diseases section. 40% of the cases presented diarrhea, 30% fever and 20% weight loss. Hepathomegaly was found in 50% of patients. Laboratory tests revealed that almost two thirds had elevated values of ESR and C-RP. 40% had eosinophilia, 60% anemia, half of the cases had high levels of transaminases and only two patients had elevated bilirubine. Six out of 9 cases we performed serological test, resulted positive. Five of them were highly positive. Microscopic examination of stools (80% of cases) and aspirated fluid of abscess (40%) was made, resulting positive in just two and none of the cases, respectively. In just one case, a PCR of the abscess fluid was applied, being highly positive. In 70%, an abdominal ultrasound was performed and in five of them, also a CT scan. The mean size of the abscess diameter was around 5.5 cm. In addition, four of them were multiple. 50% of the patients underwent colonoscopy (in 3 of them mucosa ulcerations were found and in the rest the result was normal). 9 of the patients were treated with metronidazole 750 mg po tid, and a pregnant patient, with paromomycin. In 3 cases (30%), a surgical drainage of the liver abscess was performed, without finding a common criteria for this aptitude. There were no deaths in our series.

Discussion: The prevalence of amebic infection is higher than expected in our environment, not only in imported cases, but also in natives (40% of the cases). It is remarkable how common liver involvement is. It seems that surgical drainage of liver abscess does not provide a clear benefit in evolution. It is considered useful to provide an adequate management of this patients, according to an accurate collection of risk factors, and guidance of diagnostically tests, specially serological supported by imaging techniques, being the profitability of the ultrasound similar to the CT scan.

Conclusions: Native amebiasis appears to be more common than expected in developed countries. It must be considered as a cause of diarrhea and fever in young men, even if they have not travelled to endemic areas.

A-144
SEPSIS CAUSED BY GROUP A STREPTOCOCCUS, S. PYOGENES, IN ADULT POPULATION. RETROSPECTIVE STUDY 2005-2011 IN A TERTIARY HOSPITAL

P. Martínez Olaizola[1], M. San Martín Díez[1], A. Burzaco Sánchez[1], J. Sanz Prieto[3], M. Martínez Ortiz de Zárate[1], R. Cisterna Cáncer[2], M. Varona Peinador[1], B. Cobanera Echebarria[1]

[1]Emergency Department, [2]Department of Microbiology. Hospital Universitario Basurto. Bilbao (Vizcaya), Spain. [3]Primary Care. Comarca Interior. Amorebieta (Vizcaya), Spain.

Objectives: The Group A Streptococcus (GAS), Streptococcus pyogenes, is a grammpositive aerobic coccus which is associated with a variety of suppurative infections. Most frequently it causes pharyngitis and skin infections, usually with a good clinical outcome with the appropriate medical treatment. In rare occasions Streptococcus pyogenes causes invasive infections, with high morbidity and mortality even after a suitable and early treatment is administered. The invasive GAS infections only represents 0.6% of the adult bacteremia To describe the invasive GAS infections/sepsis incidence, during a 6 year period (2005-2011) we conducted a descriptive study with respect to the epidemiological, microbiological and morbimortality clinic characteristics.

Material and method: We examined the Group A Streptococcus (GAS) isolations in our medical center throughout the 2005-2011 period and we obtained 223 cases, of which 27 patients satisfied invasive GAS infection/sepsis criteria.

Results: From our sample of 27 patients with an invasive GAS infection/ sepsis diagnostic from group A Streptococcus, Streptococcus pyogenes, 63% were males and 37% were females. When analyzing patients, comorbidity cardiac disease was detected in 29.6% of the cases, kidney disease in 22.2%, pulmonary disease in 18.5%, diabetes mellitus in 11.1%, liver disease in 11.1%, alcoholism in 7.4% and peripheral vascular disease in 3.7%. In the patient/year distribution there is a remarkable increase in the number of cases throughout 2010 and 2011. Of our sample, 25.9% of the patients suffered a previous skin disease as a primary site of infection. Patients presented evidence of the following symptoms: fever (88.9%), soft tissue (63%), joint (22.2%), gastrointestinal (22.2%), respiratory (18.5%), pharyngitis and amygdalitis (14.8%), and urinary (11.1%). The establishment of the clinic was sudden and devastating in a 22, 2% of the patients, with a less than 12 hour range since the first symptom until the establishment of the invasive GAS infection/sepsis. C reactive protein was determined in 21 patients. In 76% of the cases, the value was 10 times higher than the referenced one. Procalcitonin was determined for 44, 4% of the patients, obtaining values higher than 10 ng/ml in a 41% of the cases. The Group A Streptococcus (GAS), Streptococcus pyogenes, was isolated in 59.3% of the blood cultures, in 40.7% of the skin and soft tissues cultures, in 11.1% of synovial fluid cultures, in 7.4% of throat cultures, in 3.7% of bronchial aspirate cultures and in 3.7% of cerebrospinal fluid cultures. The microorganism was isolated simultaneously in blood cultures and in cultures of other locations in the 22% of the patients. In the emergency department, the patients were treated with antibiotic therapy according to the guidelines of sepsis severe, and then according to the antibimicrobial susceptibility testing. Debridement surgical techniques were used on a 33% of the patients. 44.4% of the patients were admitted to the intensive care unit with a 25.9% of mortality. Long-tem effects were observed in an 11.1% of the patients.

Conclusions: The invasive GAS infections/sepsis, as in others studies, has a high mortality. The average age is wide. 96.2% were immunocompetent, in contrast to previous decades, when invasive GAS infections were associated with immunocompromised patients older than 60 years. Throughout our study the predisposing factors involved were cardiac and kidney disease; unlike others series in which predisposing factors has been frequently associated with diabetes mellitus and alcoholism. We haven't recorded any case of association with previous chickenpox. Neither have we detected events associated with postpartum or gynecological surgery described extensively in medical literature. This study has shown how an apparently trivial skin infection can lead to severe ones associated with high mortality. In our sample 22% of the patients had a very quick development of the invasive GAS infection/ sepsis, fact that proves the need of an early medical/surgical treatment.

A-145
MALARIA IN A NON-ENDEMIC AREA

J. Paz, L. González, S. Rodríguez, H. Enríquez, A. Arca, A. Sanjurjo, P. Sánchez, J. de la Fuente

Department of Internal Medicine. Hospital Povisa. Vigo (Pontevedra), Spain.

Objectives: Knowing the main features of malaria cases diagnosed in our health area, located in a remote region of migration flows and with a strong marine character and whether some characteristic epidemiological, clinical, analytical or treatment was related to increased mortality.

Material and method: We propose a retrospective observational descriptive study of all patients admitted over 15 years from January 1976 to April 2012.

Results: During this period there were diagnosed 102 cases in 99 patients (97 males) with a median age of 36 years. The mean period of hospital stay was 11.2 days. The time to diagnosis ranged

from 1 to 60 days with an average of 13 days and the time of defervescence of 2.3 days. Regarding to occupation almost all of them were sailors or worked in related tasks to fishing or on ships goods. Only one patient had no relation with navigation but had been working on Ivory Coast. Of the 2 females,1 had a recent vacation trip to Kenia and the other worked as a volunteer on an endemic zone. Only 15 patients had taken chemoprophylaxis (14.7%) and 21 (20.5%) have had malaria previously. The 78% (80) were Spanish citizens. The most frequent zones of contagion were: West Africa coast 73.5% (mainly Equatorial Guinea) and east Africa coast 11.7%.We had an autochthonous case in a patient who was infected due to the use of parental drugs and sharing needles with an infected person with malaria. The most frequent specie was P. falciparum: 58%. Respect to symptoms: fever (100%), chill (47%), vomiting (41%), profuse sweating (41%) and signs splenomegaly (34.3%), hepatomegaly (27.8%) and jaundice (19.6%). The blood test most important findings were: anemia (50%), increased level of liver enzymes (50.5%), thrombocytopenia (43%) and leukopenia (36.2%). Renal function failure occured in 15.6%, severe anemia that required red blood cells transfusion in 11.8% and central nervous system afection in 3 patients. Regarding to evolution, 3 patients died all from Equatorial Africa: 2 of them with parasitemia 100% died in the first 24hs of treatment. Note that all severe patients had not prophylaxis, had not had malaria previously, and the species involved was P. falciparum. The most frequent treatment administrated were chloroquine 48.4% and the combination of quinine sulfate and doxycycline or sulfadoxine-pyrimethamine in the 37.2% of the cases.

Discussion: Due to the nature of our hospital, all male patients diagnosed they were for professional reasons, whether related to fishing well with shipping goods which sets us apart from other series published in Spain. It seems important to note that significant differences in terms of average stay for patients treated before 2000 (12.29 days)-hydroxychloroquine-treated mostly with respect to those treated later (6.3 days)-mostly treated with quinine plus doxycycline-having found no such differences when comparing treatment regimens, which seems to show that improving the quality of care could be related to these differences.14.7% of patients received chemoprophylaxis, a percentage significantly lower than that estimated for Spain (20-43%). Yet this fact was not associated with increased mortality. Within the criteria of severe malaria by WHO in 2000 we only found a relationship with mortality shock he suffered.

Conclusions: The typical profile of a patient suffering from malaria in our area is that of a young man, sailor, to stay in sub-Saharan waters and has not taken prophylaxis. There was no increase in the number of patients who received chemoprophylaxis in recent years for greater access to information, so we must focus our efforts on prevention programs targeted to populations at risk. Mortality was associated with falciparum species, with the absence of chemoprophylaxis and a clinical picture compatible with shock. There was no association between diagnostic delay and increased mortality. It is the only study where all the male patients were engaged in work related to the sea.

A-146
STAPHYLOCOCCUS AUREUS BLOODSTREAM INFECTIONS

M. González García[1], M. González Gómez[1], E. Gaspar García[1], P. Mellado Delgado[2], G. García García[1], M. García Morales[1], O. González Casas[1], E. Pardo Magro[1]

[1]Department of Internal Medicine, [2]Department of Cardiology. Complejo Hospitalario Universitario de Badajoz. Badajoz, Spain.

Objectives: Bacteraemia caused by Staphylococcus aureus is associated with high morbidity and mortality. The aim of the study was to analize the clinical characteristics from patients admitted to our Hospital who had bacteraemia by Staphyloccocus aureus and compare about the differences between methicillin-resistant and methicillin-susceptible Staphyloccocus aureus.

Material and method: We reviewed the medical records of 86 patients admitted to Badajoz University Hospital who had bacteraemia by Staphyloccocus aureus (positive blood cultures registered by Microbiology department), during the period of 1 January 2010 through 30 April 2012. The pediatric population was excluded. Statistical analyses were performed by use of SPSS program (version 18.0). In the first time we conducted a descriptive study about the clinical characteristics from the 86 patients. On the second time we conducted a cohort study with two groups: patients with bacteraemia by methicillin-resistant Staphyloccocus aureus and patients with bacteraemia by methicillin-susceptible Staphyloccocus aureus.

Results: The average age of patients was 63 years (standard deviation 16.8). There were 53 male and 33 female. The results about personal history studied were: 13 patients had drug allergy history, 40 patients were immunocompromised (the most had diabetes mellitus, followed by neoplasms and immunosupressive therapy), 21 had valvular disease, 13 had permanent catheter or arteriovenous fistula and 4 patients resided in community center. All patients had risk factors except one. The most frequent risk factor was "take antibiotic before bacteraemia" (94.2%), followed by peripheral line (93%), "stay longer than 7 days" (70.9%), "urinary catheter during admission" (60.5%), "central line during admission" (59.1%), blood transfusion (19.8%), "surgical site infection" (5.8%) and bed sore (5.8%). We found a secondary focus of bacteraemia in 77 patients, and in 9 cases was primary bacteraemia. The most frequent origin in secondary bacteraemia were: venous access (39.5%), lung (22.1%), urinary (15.1%); less important were surgical site infection, skin, bone, fluid peritoneal or cerebrospinal. Blood cultures in 25 cases were positive to methicillin-resistant Staphyloccocus aureus and 61 to methicilin-susceptible Staphyloccocus aureus. In 26 patients infection was acquired in community (positive blood culture in the first 72 hours of admission). We performed echocardiogram in 37 patients, and we found infective endocarditis in 16.2% of cases. The most used antibiotics were: cloxacilin (10 patients), linezolid (10), vancomycin (9), daptomycin (4) and cotrimoxazol (4). Input focus (urinary catheter, peripheral o central line…) was removed in 85.1% of cases. 44% of patients presented factors associated with poor prognosis, 35 patients needed intensive cares and 13 were exitus. In the cohort study we found significant differences only in valvular disease: it was more frequent in the methicillin-resistant Staphyloccocus aureus group (with a p value lower than 0.05).In the other analyzed variables we didn't find significant differences between both groups.

Discussion: Our study results: the personal history characteristics, risk factors and type of infection (community, primary or secondary), were similar to the literature. However we didn´t find significant statistical difference in mortality between methicillin-resistant Staphyloccocus aureus and methicillin-susceptible Staphyloccocus aureus ("comparison of mortality associated with methicillin-resistant and methicillin-susceptible Staphylococcus aureus bacteraemia: A meta-analysis"), maybe because the patient sample was too small.

Conclusions: Despite the advancement of antibiotic treatment and microbiology procedures, the Staphyloccocus aureus bacteraemia is yet associated to a high morbidity (endocarditis in the 16% of patients who were realized echocardiogram) and high mortality (15.1% of patients were exitus).

A-147
TREATMENT OF INFECTIVE ENDOCARDITIS AT HOME. 16 YEARS EXPERIENCE

A. Fuertes Rodríguez, M. Goenaga Sánchez, C. Garde Orbaiz, P. Idígoras Viedma, J. Mendiola Arza, A. Izaguirre Yarza, J. Mendiola Yarza, I. Arruabarrena Echeverría

GAMEGI Group. Hospital Donostia. San Sebastián (Guipúzcoa), Spain.

Objectives: Outpatient parenteral antibiotic therapy (OPAT) is increasingly used; in case of Infective Endocarditis (IE) is not common because of its severity. The guidelines about OPAT are conservatives. The objective of this review is to present our experience in this field for a period of 16 years.

Material and method: A prospective population-based observational study was conducted in Hospital Donostia of all IE cases diagnoses in the period 1996 to March 2012 treated in Hospital at Home. Diagnosis was performed according to modified Duke criteria. We collected data about Epidemiological, etiological and management characteristics.

Results: In a period of 16 years, 110 cases of IE were treated by OPAT. According to modified Duke criteria, 73 cases were classified as definitive cases and 37 as probable cases. Sex distribution: 83 (75.5%) men and 27 (24.5%) women. The patients´ mean age was 66 years (range, 26-92 years). Patients over 60 years: 77 (70%); patients over 80: 18 (16.36%). The distribution of the location of IE was: 66 native valves (aortic: 26; mitral: 32; tricuspid: 6; pulmonary: 2); 26 prosthetic valves (aortic:17; mitral: 9); 11 intracardiac stimulation devices; the location of IE remained uncertain in 11 patients. 6 patients had two valves affected and only one patient had all the valvular system involved; Causative microorganisms were: 20 (18.2%) coagulasa negative Staphylococci; 11 (10%) MSSA; 48 (43.6%) S. viridans; 7 (6.4%) other Staphylococci and Streptococci; 11 Enterococci (10%); 3 (2.7%) anaerobic germens; 5 (4.5%) another Gram negative germens (2 HACEK); 5 patients (4.5%) had no etiologic agent identified. The antibiotic regimen used was: ceftriaxone 38 cases (plus aminoglycoside 16); ampicilin 19 cases (plus aminoglycoside 10; plus ceftriaxone 2); cloxaciline 17 cases; daptomycin or vancomicyn: 10 cases; penicillin G 6 cases; piperacilin-tazobactan: 2 cases. Median of the days of hospital treatment was: 16.20 (range 0-59 days); days of treatment in Hospital at Home were 21.57 (range 1-125 days). Patients were referred from: Infected Disease Unit (49 cases); Internal Medicine Service (44 cases); other services (8 cases). Patients with any type of infuser electronic device for treatment: 43 (39%). Patients who completed the antibiotic cycle at home: 88 (80%). There were 22 readmissions (20%). The causes of readmission were: fever, vascular access problems, neurological symptoms and others. Median de day of the readmission: 18 days. The mortality rate was 0.90% (1 case).

Conclusions: OPAT is an alternative to treatment of IE. In our series, affected valve and etiologic agent don´t determine the outcome. The choise of this treatment modality requires close monitoring. It is necessary a trained team to establish OPAT and to coordinate the services implicated in this programme.

A-148
TUBERCULOSIS REGISTER: A 9-YEARS STUDY AT FUENLABRADA UNIVERSITY HOSPITAL

R. Calderón Hernáiz, E. Madroñal Cerezo, N. Cabello Clotet, D. Rejas Velasquez, M. Fernández López, J. San Martín López, A. Barrios Blandino, A. Zapatero Gaviria

Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: Tuberculosis (TB) is a major public health problem all aronund the world. In Spain, rates triple those of other European Union countries, especially among immigrants. The percentage of immigrants in our area is 15.7% (2011). We describe all cases of TB diagnosed at Fuenlabrada University Hospital (FUH) during 9 years, analyzing epidemiological, clinical, microbiological and therapeutic factors.

Material and method: Descriptive prospective study of all cases of TB diagnosed at FUH, in south-east area of Madrid, from June 2004 to December 2011. Patients were collected from consults and during hospital admissions. We made a systematic review of electronic clinic history. χ^2 was used for categorical variables (or exact Fisher test when indicated) and U-Mann-Whitney or t-Student for continuous variables. p significance was < 0.05 for all statistical analysis, using the SPSS 18.0 version.

Results: During this period we diagnosed 288 cases of TB: most of them were pulmonary cases (193/288 (67.01%)) followed by lymphatic (31 (10.7%)) and pleural (30 (10.4%)). There was an increased incidence of new diagnoses between the 2005-2008 years, with 60.7% of cases diagnosed in this time frame, later it descends. Most were male (183:107) with a mean age of 39.33 years ± 20.2 (36) (0-89). The 44.4% (128/288) were immigrants, mainly from Arab countries (28.9%), Sub-Saharans (28.1%), Latin America (21.09%) and from Eastern Europe (18.75%). Immigrants patients with TB were significantly younger than the Spanish, in our series ((33 ± 13.5 (31) versus 44 ± 3.4 (40) years (p < 0.05)). The 22.41% were immunosupressed, especialy due to HIV infection (14/288). The 15.9% had been in contact with other patients previously diagnosed of TB and up to 7% had a history of inadequately treated TB. Only 113 patients had positive Mantoux. The symptoms were variable depending on the location, but fever was present in 47.2%. Acute phase reactants were slightly elevated (mean CRP 3.69 mg/dl ± 6.71) and most of patients had not leukocytosis. Anemia was present in 26.2% of cases. Lobar infiltrate was the most frequent radiological pattern (28.3%) followed by cavitation (19.7%). Normal chest radiography was seen in 64 patients. Microbiologycal diagnosis was achieved in 191 cases. We made 60 histological diagnosis with demonstration of necrotizing granulomas and, finally, just 37 patients had clinical diagnosis. We detected 19 cases of resistance to TB drugs (6.59%), within which there were 10 multi-drug resistant TB patients. Almost half of patients (47.2%) received treatment with three drugs and the other half (44.8%) with four; the rest received second-line treatments. The mean treatment time was 6 months (± 3.47). Treatment toxicity was low: hepatotoxicity was the most frequent (6.2%) followed by skin toxicity (2.8%). Only 7 patients required Intensive Care Unit admission. The outcome was generally favorable but there were 48 losses of follow up, mainly in the group of Sub-Saharan and Arab patients (p < 0.05). Mortality was very low in our series (2.41%).

Conclusions: About half of diagnosis of tuberculosis made in our area tend to be in immigrants, mostly from Arab or Sub-Saharan countries and Latin America and they are younger than the Spanish patients. The most common finding is fever with or without respiratory symptoms. Acute phase reactants are sightly elevated, most cases have not leukocytosis and up to a quarter of patients may have anemia. We detect more than 6% of resistant tuberculosis. There is poor adherence to treatment and monitoring in sub-Saharan and Arab patients.

A-149
INCIDENCE, RISK FACTORS AND PROGNOSIS OF BACTERIAL INFECTIONS IN CIRRHOTIC HOSPITALIZED PATIENTS

M. Bucar Barjud[1], T. Revuelto Artigas[2], Y. Arguedas Lázaro[2], A. Lue[2], M. Serrano Herrero[1], M. Navarro Aguilar[1], T. Serrano Aulló[2], S. Lorente Pérez[2]

[1]Department of Internal Medicine, [2]Department of Gastroenterology and Hepatology. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: Bacterial infections are a frequent complication in patients with advanced liver cirrhosis (LC). They occur in 20-60% of patients admitted for decompensate disease. Although its prognosis has improved in recent decades, mortality associated with severe infections is still high, reaching 50-60% in patients who develop septic shock. Changes in the epidemiology of infections in these patients have been reported such as increased incidence of nosocomial infections which are mainly caused by gram-positive cocci. As a consequence of these changes it would appear that currently recommended regimens for empirical therapy for these infections were ineffective with hospitalized patients. OBJECTIVE: Determining actual incidence of infection in patients with CH who were admitted to hospital and being able to objectify etiology, risk factors and their impact on mortality.

Material and method: A prospective study of patients with CH who were admitted to our department from March 2010 until August 2011 was used. All patients underwent ascitic fluid cultures, blood and urine tests and were taken a chest radiography at admission in order to search for any kind of active infection. Tests were repeated if they showed symptoms or signs of infection and/or decompensated cirrhosis during their hospital stay. All data relating to liver disease, performing invasive procedures and the results were collected and entered into a database. Data were analyzed using SPSS 17.0.

Results: 423 admissions of 209 patients with CH were analyzed. We detected a total of 248 episodes of infection, with an infection rate of 58.6% of which 60.8% were acquired in the community and the rest were considered hospital acquired. Most (40%) were caused by gram-positive cocci. The most frequent infections were urinary (19.5%), respiratory (14.6%) spontaneous bacterial peritonitis (8.2%) and primary bacteremia (8.2%). A third of the infectious episodes were asymptomatic and detected thanks to a screening study. In the multivariate analysis, the presence of infection was associated only with the Pugh Child (CP) stage C and cholesterol levels ($p < 0.001$). Analyzing only hospital-acquired infections, the only independent risk factor was the development of invasive techniques ($p < 0.001$). Hospital mortality was significantly higher in cirrhotic patients with infection than those without infection (23.6% vs 8.6%) $p < 0.001$. In multivariate analysis the presence of infection and the CP stage were the only factors independently associated with hospital mortality.

Discussion: The frequency of infection in cirrhotic patients admitted to our hospital is similar to that described in literature which is about 60% and with the severity of liver disease, one of the major determinants of hospital mortality of these patients. The incidence of nosocomial infections is high and is clearly related to the performance of invasive procedures. Nearly half of all nosocomial infections were caused by Gram-positive cocci, suggesting that empirical treatment guidelines currently accepted should be modified and readjusted to the epidemiological profile of each environment.

Conclusions: Infections in hospitalized patients with CH are highly prevalent in our environment and they have high risk of mortality. As they are often asymptomatic they should be kept in mind in order to diagnose and treat them.

A-150
MORTALITY RISK FACTORS IN PATIENTS WITH ACINETOBACTER BAUMANNII BACTEREMIA: CASE CONTROL STUDY

M. Fernández Almira[1], C. Suárez Cuervo[1], S. Rojo Alba[2], A. Blanco[3], M. Martínez Sela[1], F. Pérez[2], A. Rodríguez Guardado[4]

[1]Department of Internal Medicine, [2]Department of Microbiology, [3]UVI, [4]Infectious Diseases Unit. Hospital Nuestra Señora de Covadonga. Oviedo (Asturias), Spain.

Objectives: Bacteremia caused by Acinetobacter baumannii has contributed to high mortality rate, prolonged stays in the intensive care unit, and rapid development of antimicrobial resistance to commonly used antimicrobials. This study sought to determine predictors of mortality for patients with A. baumannii bacteremia.

Material and method: We retrospectively reviewed 99 adult patients with A. baumannii bacteremia, between 2000 and 2010; the 50 (50.5%) who survived were categorized as the survivor group (group 1), and the 49 (49.5%) who died as the mortality group (group 2). Cure was achieved when clinical signs of infection were absent. To assess survival, patients were followed-up until they died in the hospital or were discharged. Continuous values were expressed as means and compared using Student's t-test or the Mann–Whitney U-test. Categorical values were expressed as absolute and relative frequencies and were compared using Fisher's exact test or χ^2 test. A P value less than 0.05 was considered as statistically significant. A binary logistic regression analysis using a stepwise (Wald) approach to determine the factors influencing the mortality of the infection was performed.

Results: We reviewed 99 bacteremias by A. baumannii in 99 patients Cure of the infection was reported in 50 cases, and the remaining 49 patients died as a direct consequence of the infection. There were no significant statistically differences in sex, age, service of precedence, mean stay in hospital or presence of central venous catheter, mechanic ventilation or bladder catheter. The presence of diabetes (2 in group 1 vs 10 in group 2, $p = 0.028$, OR 5.4 [1.103-26.443]), was significantly associated with higher mortality. Significantly higher mortality was found in abdominal origin of infection (5 cases in group 1 vs 13 cases in group 2 $p = 0.040$; OR = 3.250 [1.060-9.967]). The presence of septic shock (24 in group 1 vs 42 in group 2 $p = 0.0001$), distress respiratory (11 in group 1 vs 35 in group 2 $p = 0.000$) and renal failure (13 in group 1 vs 32 in group 2 $p = 0.000$) was associated with higher mortality. Twenty patients in survivor group showed carbapenem resistant and 37 in mortality group ($p = 0.003$ OR 3.42 [1.38-8.59]). Thirty-seven patients were treated with colistin, 31 with carbapenems, 15 with only aminoglycosides, and the rest with other treatments. Mortality was lower in patients treated with carbapenems (21 group 1 vs 10 group 2, $p = 0.047$, OR = 2.49 [0.92-6.87] and higher in aminoglycosides group (2 in group 1 vs 13 in group 2, $p = 0.0006$,) Seven patient died before the instauration of a definitive treatment. In the multivariate analysis, mortality was only influenced by treatment, and carbapenem resistant.

Conclusions: Mortality of bacteraemia by A. baumannii is higher. Treatment with only aminoglycosides, and carbapenem-resistant, were independent risk factors associated with higher mortality rates for A. baumannii bacteremia.

A-151
THE COMBINED EFFECT OF COLISTIN WITH RIFAMPICINE OR TIGECYCLINE IN THE IN VITRO RESISTANCE TO COLISTIN IN ACINETOBACTER BAUMANNII

J. Praena Segovia[1], R. López Rojas[2], J. Domínguez Herrera[2], J. Pachón Díaz[2]

[1]Department of Internal Medicine. Hospital Virgen del Rocío. Sevilla, Spain. [2]Clinical Unit for Infectious Diseases, Microbiology and Prev. Biomedical Institute of Seville, IBIS/ University Hospital Virgen del Rocío/University of Seville/ CSIC. Sevilla, Spain.

Objectives: Acinetobacter baumannii appears ever more frequently as the cause of serious intra-hospital infections with high morbi-mortality, showing high rates of resistance to the anti-microbians used in clinical practice. Colistin (COL) is one of the most recent therapeutic alternatives available, with sensitivity rates close to 100%. Due to the every growing use of COL, there have been outbreaks from COL-resistant strains, which, although sporadic, are more and more frequent. Our objective is to study the prevention of resistance to COL in A. baumannii by using a combination of COL with rifampicine (RIF) or tigecycline (TIG).

Material and method: A standard A. baumannii ATCC 19606 strain was used. Minimum inhibitory concentrations (CMI) and bactericide concentrations (CMB) for COL, RIF and TIG were determined according to the micro-dilution in broth method by Clinical Laboratory Standard Institute. The selection of COL-resistant colonies were studied using fatality curves, performed by duplicity (primary and secondary curves) where the initial A. baumannii (5×10^5 ufc/ml) was inoculated; it was incubated with COL only and in combination with RIF or TIG at a concentration equal to 1xCMI and at the maximum concentration (Cmax) reached in saline solution in humans with standard therapeutic dosage. The bacterial concentration was quantified after 0, 24, 48 and 72 hours in agar-blood plates and in plates with COL (4 µg/ml) to select the COL-resistant colonies. The stability of these resistant colonies was assessed by means of streaking in series in the agar-block plates free of antibiotics during five (5) consecutive days.

Results: CMIs/CMBs (mg/l): COL 0.25/0.25; RIF 2/4; TIG 0.12/0.12. Selection of colonies resistant to COL: at a concentration of COL at 1xCMI, resistant colonies were observed in the plates after 24, 48 and 72 hours. When combined with 1xCMI of RIF, no resistant colonies were selected and the initial inoculant was eradicated. The combination with 1xCMI TIG failed to generate resistant colonies, but the inoculant was not eradicated in within 72 hours. With a concentration of COL equal to Cmax in humans, no resistant colonies appeared and the initial inoculate was eradicated. The combinations of COL plus RIF or COL plus TIG at a concentration equal to the Cmax obtained in humans failed to generate resistance while the inoculate was eradicated in 72 hours. In the study for the stability of the resistance to COL in the resistant colonies, there was a loss of resistance to COL in the colonies obtained in the primary fatality curve after five streaks in the plate without antibiotic pressure, while for those obtained in the second curve, the resistance to COL remained stable.

Conclusions: Our results show that the appearance of in vitro resistance to colistin in Acinetobacter baumannii may be avoided by using colistin in combination with rifampicine or tigecycline. These results authorize us to assess said combinations in animal infection models.

A-152
A 5-YEAR REVIEW OF ASPERGILLOSIS CASES IN A PORTUGUESE TERTIARY HOSPITAL

D. Fidalgo Batista, M. Escarigo, M. Amaro, M. Delerue

Department of Medicine 1. Hospital García de Orta. Almada, Portugal.

Objectives: The pulmonary form of aspergillosis goes from the simple aspergilloma to the invasive aspergillosis, that has emerged as one of the most common and most feared opportunistic infections in immunocompromised patients; mortality in patients with full-blown aspergillosis exceeds 50%. The authors objective is to characterize the aspergillosis profile in their clinical environment.

Material and method: Retrospective analysis of the case files, patient past medical history and treatment options in patients with the diagnostic of Aspergillosis.

Results: 8 patients were identified, 50% male, with an overall average age of 63 years and 45 days of hospitalization. The dominant symptoms were fever, cough (75%) and shortness of breath (62.5%). The main risk factor identified was a prior pulmonary tuberculosis (87.5%), with only one chronic immunosuppressed patient enrolled. 87.5% presented imagiologic changes suggestive of Aspergillosis. The diagnostic accuracy due to other diagnostic test was 50%. The pharmacologic treatment was 87.5% done with voriconazol and the mortality observed was 12.5%.

Discussion: In our environment, the preexisting structural lung disease presents the leading role in predisposing host factors associated with invasive pulmonary aspergillosis. There was a good correlation between imagiology and diagnostic accuracy, and a low rate of Aspergillus isolations.

Conclusions: The length of stay (LoS) represents an significant economic burden to the health system. The low mortality in our sample is mainly due to the non-immunosuppressed pattern of the subjects. The risks for disease and the type of disease that occurs are the combined result of multiple cellular functions that impact in conidial clearance, production of inflammation, and killing of invasive forms. The use of voriconazole has become common for the management of aspergillosis and in our patients presented a high response rate to treatment.

A-153
INFECTIOUS AND THROMBOTIC COMPLICATIONS LINKED TO IMPLANTED PORT-A-CATH CENTRAL VENOUS DEVICES IN CHEMOTHERAPY OF MULTIPLE MYELOMA: A COHORT OF 142 PATIENTS

J. Alonso Alonso, G. Barreiro García, A. Cánovas Fernández

Department of Internal Medicine. Hospital Universitario de Cruces-Osakidetza.UPV. Baracaldo (Vizcaya), Spain.

Objectives: We aimed to evaluate the infectious and thrombotic complications of totally implanted devices, Port-a-Cath (PAC), used for chemotherapy in MM patients.

Material and method: Prospective observational study of MM patients treated with chemotherapy through PAC in our department (1995-2007). Antibiotic prophylaxis with cefazoline was prescribed before PAC implantation. The device was maintained indefinitely during treatment, unless complications requiring its removal occurred (infection, thrombosis or dysfunction). Primary thromboprophylaxis was not routinely prescribed. The diagnosis of PAC infection was based on in differential growth blood cultures taken from PAC versus peripheral vein, when PAC culture was positive two or more hours earlier than the peripheral culture, or a positive culture of exudate from the pocket was obtained. Associated thrombosis was diagnosed by ultrasound or computerised tomography scan. Upon diagnosis of PAC infection, systemic

antibiotherapy and antibiotic lock was prescribed and PAC maintained unless clinical deterioration of the patient or pocket infection occurred, making removal of the device necessary. Statistical methods: Fisher exact test, Student t, log-rank test, Kaplan-Meier survival tables and Cox regression multivariate binary logistic model.

Results: 155 implanted PAC in 142 patients (55% male and 45% female) were included for analysis. Median age was 67 years (27-84). Subtype of monoclonal immunoglobulin: G in 46.5%, A in 27.7%, and D or light chain in 25.8%. The median duration of each PAC was 20.9 months (0.5-108) and the median duration of chemotherapy by PAC 9 months (0.3-42). Twenty nine infections of PAC (27 bacteremia and 2 pocket infections) were detected in 25 patients (0.2/1,000 days). Coagulase negative Staphylococcus (CNS) (43.7%) was the most frequently isolated microorganism, followed by Gram negative rods (25%) and other Gram positive cocci (14.3%). Antibiotic lock along with systemic antibiotics was prescribed in 18 infections (62%), achieving the maintenance of the device in 17 (94%). PAC associated thrombosis was detected in three patients (0.02/1,000 days). The device was removed in 31 patients (20%): in 13 patients (8.3%) because of infection and in the remaining because of dysfunction or end of treatment. The assessment of prognostic variables only showed a significant association between longer duration of chemotherapy and risk of infection (Student t: 3.08; p = 0.002), and between infection and the risk of removal of the device (chi^2: 17.2, p = 0.00004).

Discussion: There are few references to the complications associated with totally implanted devices for chemotherapy in patients with multiple myeloma (MM). The necessity to maintain prolonged treatment may involve more frequent complications, particularly infections (0.2/1,000 days, in the usual references) and thrombosis (risk of 0.02 to 0.92/1,000 days). The usually poor condition of these patients makes it desirable to avoid surgical manipulations and maintain devices. Our observations indicate that prolonged use of PAC devices in these patients do not carry an increased risk of complications and that infectious complications can be usually controlled without removal of the devices.

Conclusions: The registered frequency of PAC infection and thrombosis in our patients is similar to that described in other clinical settings (i.e, non myeloma patients), as well as the aetiology of infections, being CNS the most frequently implied. Antibiotic lock was remarkably efficacious to avoid removal of PAC devices. Consequently, PAC devices appear to be safe in the chemotherapy of MM patients, without involving a higher risk of infection or thrombosis than that observed in different clinical settings, despite the usually longer time of use of the devices in these patients.

A-154
INFECTION DUE TO STRONGYLOIDES STERCORALIS IN HIV PATIENTS

M. Fernández Almira[1], C. Suárez Cuervo[1], S. Rojo Alba[2], M. Rodríguez[2], M. Martínez Sela[1], F. Pérez[2], A. Rodríguez Guardado[3]

[1]Department of Internal Medicine, [2]Department of Microbiology, [3]Infectious Diseases Unit. Hospital Nuestra Señora de Covadonga. Oviedo (Asturias), Spain.

Objectives: Strongyloides stercoralis is a nematode parasite, which is endemic in tropical and subtropical regions. Distinctive characteristics of this parasite are its ability to persist and replicate within a host for decades and its potential to cause life-threatening infection in an immunocompromised host. The goals of this study were two fold: i) to determine the frequency of imported strongyloidiasis in HIV patients ii) to describe epidemiological, laboratorial and clinical features of imported strongyloidiasis in this group of patients.

Material and method: During the years 2008-2011 we conducted a prospective screening program of chronic strongyloidiasis in all HIV positive immigrant patients attending in Tropical Medicine Unit of Hospital Central de Asturias. Combined examination of three concentrated stool samples, culture in blood agar and ELISA for serum anti–S. stercoralis antibodies was used as screening. We considered that infection existed if the microscopic visualization of larvae in stool sample and/or the ELISA was positive. In positive patients was discarded the presence of other nematodes or filarias. We performed an ELISA for serum anti-HIV antibodies in all patients. Positive patients were confirmed by Western-Blot. Routine tests for determination of eosinophilia, CD4+ cell counts, and HIV load were performed simultaneously to serological studies. All positive patients were treated with ivermectin. All data were entered into a database and analyzed using SPSS 18.0 software package. Quantitative variables were analyzed with the Student t test or the Mann-Whitney test when appropriate. Qualitative variables were analyzed with the chi square test with the Yates correction or Fischer's exact test (2-tailed) when necessary. All p values were 2-sided and values of 0.05 or less were considered statistically significant.

Results: we screened 39 patients, 13 of them (36%) had a strongyloidiasis. No significant differences in sex and age were found between both groups. The most frequent countries of origin in patients with strongyloidiasis were: Equatorial Guinea (26%), Senegal (20%), Ecuador (13%), and Bolivia (7%). The average time in Spain was significantly higher in strongyloidiasis patients (1,164 [673] days vs 443 [715], p = 0.025). No significant differences between median CD4 cell count (388 [218] cells/mm^3 vs 378 [252]) and median viral load (275,163 [445,980] vs 529,933 [1,241,602] RNA viral/ml) were found All patients showed positive serological test and in two patients the microscopic visualization was positive. The countries of origin were: Equatorial Guinea (8 cases), Paraguay (4 cases) and Colombia (one case). The most frequent symptoms in positive patients were abdominal pain (2 cases), skin disease (1 case), and the rest were asymptomatic.

Conclusions: The presence of infection for S. stercolaris is frequent in HIV infection patients, especially whose from Equatorial Guinea, although without symptoms.. There is no relation with CD4 cell count or viral load. To prevent potentially fatal hyperinfection syndrome, it is necessary to carry out screening with several stool examinations and serologic testing in risk groups, especially in immigrant population, and in infected ones instituted the treatment.

A-155
A DESCRIPTIVE AND RETROSPECTIVE STUDY OF THE DISTRIBUTION OF HIV SUBTYPES IN AN INFECTIOUS DISEASES CONSULTATION

H. Fernandes[1], C. Ângela[1], I. Apolinario[1], T. Pimentel[1], F. Branca[2], A. Carvalho[1]

[1]Department of Internal Medicine, [2]Department of Clinical Pathology. Hospital de Braga. Braga, Portugal.

Objectives: HIV is characterized by a high degree of genetic variability. Worldwide the predominant HIV-1 is classified into three groups, M responsible for current global epidemic, O and N. The group M includes 9 pure subtypes identified by the letters A, B, C, D, F, G, H, J, K and 43 recombinant forms. In Europe, subtype B is the most prevalent, but infection with non-B subtypes has become more frequent due to migratory flows from Africa and Asia. In 2000 a molecular epidemiological study in Portugal showed that subtype G has assumed a predominant position compared to other subtypes, constituting a unique case in Europe. Objective: Observational, descriptive and retrospective study of the distribution of HIV subtypes in an infectious diseases consultation.

Material and method: Consultation of individual data of 293 patients infected with HIV 1, followed in an outpatient clinic between 1996 and 2011 regarding the variable HIV-1 subtype, sex, age, nationality, country/origin of probable infection, way of transmission, stage at admission, time between admission and the initiation of treatment.

Results: We analyzed data from 293 patients with HIV-1, 225 males, mean age 42 years. Of these 32.4% were subtype B, 30.7% subtype G, 14% subtype C, 6.5% subtype F, 2.4% subtype A, 1% subtype D, recombinant forms representing 12.4%, being the most common BG (4.8%), AG (2.7%) and AE (1.7%). 80% of patients were born in Portugal, 2.7% in Brazil, 1.7% in Mozambique and less than 1% in other countries. The contagion occurred most likely in Portugal (93.2%). The transmission categories were heterosexual (49.5%), drug-addict (34.5%), homosexual (9.6%) and transfusion (0.7%). Of the 90 patients with subtype B, 49% were heterosexual, 24% drug-addict and 21% homosexual; of subtype G, 55.5% heterosexual, 40% drug-addict and 1% homosexual; and of the subtype C, 58.5% drug-addict, 32% heterosexual, 4.8% homosexual (chi-square, $p < 0.05$). At the time of diagnosis, 39.2% of patients were asymptomatic; the mean CD4 counts were 300/mm^3. Currently 74.1% of the patients are under treatment.

Conclusions: In our population we detected a predominance of subtype G that differentiates us from other European populations, which may be relevant to the infection course and in future treatment management.

A-156
NEUROLOGICAL SYMPTOMS IN INFECTIVE ENDOCARDITIS

A. Fuertes Rodríguez, M. Goenaga Sánchez, E. Gaminde Uriarte, K. Reviejo Jaka, T. Etxeberría García, P. Idígoras Viedma, J. Jiménez Alfaro, M. Vaquero Valencia

GAMEGI Group. Hospital Donostia. San Sebastián (Guipúzcoa), Spain.

Objectives: Infective endocarditis (IE) debut may mimic different disease as neurological pathology. This diversity may complicate the diagnosis and delay treatment. Because of that, we decided to analyze the characteristics of EI with neurological symptoms that have been presented to our hospital.

Material and method: A prospective population-based observational study was conducted in Hospital Donostia. We collected all the IE cases diagnosed between March 2008 to April 2012. We reviewed cases which presented with neurological signs, defined as neurologic focality, depressed level of consciousness or a new headache. We present epidemiologic, etiologic and management data.

Results: In the period March 2008 to April 2012, 145 cases of IE were diagnosed according to modified Duke criteria. A total of 30 cases (20.68%) presented neurological symptoms. 19 men and 11 women. The patient´s mean age was 67 years (70 in global series). The distribution of the locations of IE was: 19 native valves (aortic: 7; mitral: 11; tricuspid: 1); 10 prosthetic valves (aortic:6; mitral: 3; tricuspid: 1); the location of IE remained uncertain in 1 patient. 1 patient with involvement of two valves and another, a valve and a device. Causative microorganisms were: 5 coagulasa negative Staphylococci; 11 MSSA and 1 MRSA (40%; in general series: 24.82%); 6 S. viridans; 1 S. pneumoniae; 2 S. bovis; 1 Enterococci; 1 L. monocytogenes; 1 C. parapsilosis.. Eventually, 1 patient had no etiologic agent identified. Cardiac surgery was performed in 10 patients (33.33%), 7 of whom were men (49.65% in global series). Median Euroescore was 32.08% (24.22% in global series). The mortality rate was 46.6% (14 patients) (19.31% in global series); in the 50% of them, the causative agent was MSSA or MRSA. The administered antibiotics were appropriated in all cases according to the IE management support group.

Conclusions: The presence of neurological symptoms may mimic the diagnosis of IE.-Some causative microorganisms, like MSSA or MRSA, are associated to neurological manifestations. In our series, the neurological signs and MSSA or MRSA are associated to a worse prognosis and increased mortality.

A-157
TRICHURIS TRICHURIA A COMMON CAUSE OF CHRONIC IRON DEFICIENCY ANEMIA IN IMMIGRANT ADULTS

M. Fernández Almira[1], C. Suárez Cuervo[1], S. Rojo Alba[2], M. Martínez Sela[1], F. Pérez[2], A. Rodríguez Guardado[3]

[1]Department of Internal Medicine, [2]Department of Microbiology, [3]Infectious Diseases Unit. Hospital Nuestra Señora de Covadonga. Oviedo (Asturias), Spain.

Objectives: Anaemia is a major global public health problem especially in developing countries, frequently due to iron deficiency. One of the principal risk factors for iron-deficiency anaemia are parasite infections such as hookworms (Necator americanus and Ancylostoma duodenale) and whipworms (Trichuris trichiura Therefore, the objectives of our study were to study the association between Trichuris infection and presence of anaemia in immigrant population.

Material and method: We retrospectively analyzed the characteristics of T. trichuria infection in 45 patients, who attended in the Tropical Medicine Unit of Hospital Universitario Central de Asturias, Spain, between 2007-2011. Examination of three concentrated stool samples was used as screening. Eosinophilia and anaemia in blood test were studied in all patients. Anaemia was defined as a hemoglobin level below 11 g/dL. All positive patients were treated with mebendazole.

Results: The study included 23 women and 22 men with an average age of 35 years. The mean time of permanence in Spain was 316 [489] days. The most frequent countries of origin were Equatorial Guinea (75.6%), Senegal (11%), Ecuador, Ivory Coast and Morocco (4.4% each), The most frequent symptoms were abdominal pain (31%), skin diseases (5%), diarrhea (5%), and anaemia (3%). Other parasites were Hookworm (18%), Strongyloides stercolaris (13.3%), Schistosomas spp and g. intestinalis (11% each), Ascaris lumbricoides (9%,) and Entamoeba histolytica (4.5%). Thirty patients have anaemia (mean 10.75 mg/dL [2]). HIV co-infection was present in 9% patients The presence of anaemia was significantly more frequent in HIV positive patients (3 vs 1 $p = 0.088$).All patients were treated with mebendazol and iron supplement, successfully.

Conclusions: Trichuris trichuria infection should be considered in all patients in endemic areas with chronic iron deficiency anemia and/or occult blood loss even in asymptomatic patients.

A-158
CHARACTERISTICS OF PATIENTS WITH NEUROCYSTICERCOSIS IN A TERCIARY HOSPITAL

R. Montejano Sánchez, R. Micán Rivera, A. Quesada Simón, F. Arnalich Fernández

Department of Internal Medicine. Hospital Universitario La Paz. Madrid, Spain.

Objectives: The neurocysticercosis is an endemic parasitosis with a high prevalence in South and Central America. Recently, an increase in its prevalence has been described. The aim of this study is to describe the characteristic of these patients.

Material and method: The study population consisted of patients admitted to internal medicine or neurology for the last 6 years, diagnosed of neurocysticercosis by computerized scan (CT) and /or magnetic resonance imaging (MRI), to confirm the diagnosis and

identify the phase. We analyse age, gender, home country, recent travel, personal history, symptoms, CT and MRI findings, serological tests, treatments and follow up. Data were analysed with SSPS statistical programme, version 17.0. Quantitative variables were described as mean and standard deviation and frequencies for qualitative variables.

Results: A total of 23 patients were included, 15 (65.2%) female and 8 (34.8%) male. The mean age was 45.26 years old (24-91). All patients, except three patients, were from Central and South America: Ecuador 56.5%, other countries were Peru, Colombia and Bolivia. The onset symptom was headache in 10 patients (43.5%), with ocular alterations (13.4%), sensitive alterations (21.2%) or seizures (13.04%). In the electroencephalography, epileptic activity was found in 6 patients (26.1%). In the CT scan findings, the most frequent were: multiple calcified nodules (34.9%), and hypodensity contrast-enhancing lesions (21.7%) and perilesional edema in 9 patients (39.1%). In MRI findings, we observed vesicular stage (21.7%), enhancing nodular lesion (21.7%) and intraventricular cysts (13%). In the patients that a radiology test was performed in the follow up, calcific lesions were found in 9 patients (39.1%). None of the patients presented intestinal alterations. Serological test were positive in 8 patients (34.8%). Treatments more frequently prescribed were combination of prednisone and albendazole (30.4%) and dexamethasone and albendazole (21.7%). Antiepileptic drugs were needed in 7 patients (30.4%), carbamazepine was the most frequent used.

Discussion: The prevalence of this disease has increased for the last years in our country. It could be related with the high level of immigrated population, as it is more frequent in them. All the patients except one were foreign people. The main symptom found was the headache, with or without ocular symptoms (photophobia, diplopia) partial or generalised seizures, sensitive alterations or motor alterations. They are similar findings to previous researches. All these symptoms were related to the larva´s phase, location and the number of parasites.

Conclusions: The neurocysticercosis' prevalence has risen in our country related to the increase of population from endemic countries. There were no differences in clinical events or evolution respect to cases described in endemic zones. Headache was the most frequent symptom, sometimes with another neurological symptoms. It could be an under-diagnosed disease so many of the patients are oligosymptomatic. This entity should be rule out in immigrant patients with neurological symptoms.

POSITIVES BLOOD CULTURES

A. Fernández Pantiga[1], V. Arenas García[1], D. Blanco Suárez[1], V. Díaz Fernández[1], A. Arenas Iglesias[1], M. Fernández Prada[1], J. Ferreiro Celeiro[1], G. Castaño de las Pozas[2]

[1]Department of Internal Medicine, [2]Respiratory Department. San Agustín Hospital. Aviles (Asturias), Spain.

Objectives: The aim of our study was to find out how bacteremia is managed in our hospital, using epidemiological and ethiological data, in order to assess the appropriateness of antibiotic treatment.

Material and method: Data collection was performed retrospectively during 2010 being 66.1% in spring; 19.1% in summer, 10.2% autumn and 3.4% winter. It should be noted also that were analyzed as defining factors of bacteraemia associated with health care the presence of any of the following factors: Home-based Hospital in the last month, Residence in social health center, urinary catheter; wounds in the 30 days prior to admission; chronic haemodialysis or peritoneal dialysis; chemotherapy administration 30 days prior income in acute-care unit 2 or more days in the 90 days preceding. The assessment of the severity of the bacteremia was performed according to the criteria published by up to date 2012. The empiric antibiotic treatment was considered successful when the organism isolated in vitro was sensitive to the antibiotic. The analysis of the data was carried out through the SPSS program 1.8.

Results: We collected a total of 118 positive blood cultures (66.1% spring, from a sample of patients with a mean age of 71.07 years; of which 43 (36.4%) were positive for a germ which was interpretated as a contaminant. In the 75 remaining, the most frequent source as the origin of bacteremia was the urinary (29.3%), followed by digestive (20%), unkown source (14.7%), respiratory (13.3%) and a group known as miscellaneous (wound surgical, catheter...; 22.7%). The most common bacteremia was the comunitary one (49.3%), followed by health care associated (33.3%), and last one, nosocomial (17.3%). The bacteria most frequently isolated was Gram-positive cocci (40%), followed by enterobacteria (36%) and polymicrobial (10.7%). Sepsis was the most frequent clinical manifestation (45.3%), followed by simple bacteremia (25.3%), septic shock (14.7%) and severe sepsis (12%) The overall mortality was 16.2%, being higher in the group of nosocomial (30.6%), followed by health care (20.83%) and communitary (8.1%). Analyzing mortality according to the source we find catheter (50%), followed by unknown (45.45%), urinary (14.28%), digestive (6.6%), and respiratory (0%) One of every three patients who received empirical antibiotic therapy is not appropriate was what meant double the percentage of mortality. Also when the antibiotherapy was adequate there was a statistically significant decrease of 8 days of average stay.

Conclusions: In our environment, the most common type of bacteremia is communitary. It's significant, the high prevalence of Gram-positive cocci among the etiologic agents, being urinary the most frequent source Highlights the high proportion of bacteremia associated with health care causing a significantly mortality, perhaps influenced of being elderly people. In our hospital the lower mortality occurs when origin of bacteraemia is respiratory.

A-160
TOSCANA VIRUS MENINGITIS IN THE NORTH OF THE GRANADA PROVINCE(SPAIN), OVER THE LAST 5 YEARS

A. Benavente Fernández[1], J. Moreno Quirós[2], I. Pedrosa Corral[3]

[1]Department of Internal Medicine, [2]Department of Family and Community Medicine. Hospital General Básico de Baza. Baza (Granada), Spain. [3]Servicio de Microbiología. Complejo Hospitalario Virgen de las Nieves. Granada, Spain.

Objectives: In the north of the Granada province, exists a swamp area (Negratín), habitat of the Phlebotomus spp sandflies; transmitter vector of the Toscana virus, which can cause aseptic meningitis and meningoencephalitis. We analyzed the clinical and epidemiological data of 4 cases of meningitis due to Toscana virus diagnosed in our hospital over the last 5 years.

Material and method: For 5 years, we have consistently included PCR determination for Toscana virus, in the processing of all cerebrospinal fluid samples of patients with suspected aseptic and/or lymphocytic meningitis, among the other usual determinations. 78 cerebrospinal fluid samples of patients with suspected aseptic/lymphocytic meningitis were processed for virus isolation in cell culture. The medical records of patients with Toscana virus isolation were analyzed.

Results: Toscana virus was isolated in cerebrospinal fluid of 4 patients from a total of 78 (5.13% of viral isolates). The first case was diagnosed in August 2008 and the last in July 2011. The mean age was 38.75 years, range 29-49 years.3 of the 4 patients lives in villages adjacent to the swamp. One of the patients had direct epidemiological data regarding the habitat of the vector, the sandfly, as he works on the Negratin swamp beach. The predominant

symptoms were headache, 4/4, associated with neck stiffness in 3/4, mild fever; interval Temperature: 37.1 ºC-38.5 ºC and nausea-vomiting 2/4. All cases occurred in the summer months between June and August, with predominance in the month of August, 2/4. The outcome was favorable in all cases, with an average hospital stay of 7.25 days; range 4 to 11 days.

Discussion: Toscana virus receives its name due to the area where it was first isolated; the Italian region of Toscana. Even though, it has been described to affect all the Mediterranean area, representing an important emerging pathogen. In the interior zone of the north of the Granada province, there is a big sandy swamp area (Negratín), much like the Mediterranean, where the Sandfly has settled down. Our study closely resembles previous studies of Toscana virus meningitis in Spain (José María Navarro, Concepción Fernández-Roldán, Mercedes Pérez-Ruiz, Sara Sanbonmatsu, Manuel de la Rosa y M. Paz Sánchez-Seco. Meningitis por el virus Toscana en España: descripción de 17 casos. Med Clin (Barc). 2004;122(11):420-2; Sanbonmatsu-Gámez S, Pérez-Ruiz M, Collao X, Sánchez-Seco MP, Morillas-Márquez F, de la Rosa-Fraile M, et al. Toscana virus in Spain. Emerg Infect Dis. 2005 Nov) which enforces our results, despite the small number of cases.

Conclusions: As a emerging pathogen, Toscana virus should be considered among the causative agents of lymphocytic meningitis in the north of the Granada province, especially in the summer months, due to the presence of the Negratín swamp, habitat of the Phlebotomus spp sandflies.

A-161
COMORBIDITY IN HIV-INFECTED PATIENTS

A. Fuertes Rodríguez, L. Pascual Tomé, X. Camino Ortiz de Barrón, M. Bustinduy Odriozola, M. Von Wichmann de Miguel, M. Goenaga Sánchez, H. Azkune Galpasoro, J. Iribarren Loyarte

Infection Diseases Unit. Hospital Donostia. San Sebastian (Guipúzcoa), Spain.

Objectives: To identify the comorbidities that HIV patients present nowdays. To evaluate the usefulness of a nursering guiated unit for it.

Material and method: Systematic pilot study in HIV patients who are controlled as outpatient. We collected the followinginformation: blood pressure (BP), smoking, alcohol and other drugs, methadone program membership, BMI, diabetes, dyslipidemia, hepatitis coinfection, history suggestive of COPD, other diagnoses, received treatments. We gave outpatients the opportunity to be followed and to be advised in nursing unit. Data collection by nursering with medical support.

Results: In the period June 2011 to December 2011 218 patients were evaluated. Baseline characteristics: 126 men, 92 women. The mean age was 48 years (range 21-81). Way of acquisition of HIV: Substance Abuse IV: 51.8% (15% in the methadone program), 25.7% heterosexual, MSM 16%, others or unknown 6.4%. All of them on HAART, most good immune status (CD4 693/µl average, only 4 patients with CD4 < 200) and a good virological control (192 -88.1% -, 18 -8.2% -; 8 to 3.7% - with viral load < 20; between 20 and 50, between 50 and 400 respectively). Comorbidity: Co-infection with HCV, 120 patients (55%), HBV 3 (1.4%), both 4 (1.83%). Previous cardiovascular event in 17 patients (7.8%) with 15 episodes of ischemic heart disease, 1 stroke and 1 intermittent claudication. Concerning toxic habits: 108 (49.5%) patients were active smokers with average consumption of 14 packs/year, and 28 (12.8%) were former smokers. 31% of men and 19.6% of women have an excessive alcohol consume (more than 60 g/day and 40 g/day, 39 men and 18 women respectively). Recognize marijuana usually 24 (11%). Have been detected 21 patients (9.63%) with high BP (≥ 140/90, 3 times); Was unknown in 14. Mean body mass index: 23.52 (range: 16.1 to 37.93). In routine analysis, 7 patients (3.21%) presented altered fasting glucose (110-125 mg/dl). 115 patients had dyslipidemia (52.75%), being in treatment and 86 (74.78%) while the 84.88% of them continued to have high levels. Cardiovascular risk by Framingham score: 20% in 6 patients, between 10-20% in 54. Met criteria for chronic bronchitis 8 patients being known only 2 of the 6 patients.Patients taking HAART treatments other than to 104, with a mean of 1.5 tablets (range of 1-15 tablets).

Conclusions: HIV patients have significant comorbidity, at least in part, may go unnoticed. This pilot study shows that a structured query can be an excellent tool for identifying comorbidity. It provides the basis for the design of a larger study, which also analyze the involved factors and potential early interventions to improve the prognosis of future patients.

A-162
BONE MINERALIZATION DENSITY IN HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTED PATIENTS

R. Montejano Sánchez, R. Micán Rivera, A. Quesada Simón, F. Arnalich Fernández

Department of Internal Medicine. Hospital Universitario La Paz. Madrid, Spain.

Objectives: Long-term complications of HIV, such as metabolic complications cardiovascular disease and bone alterations have increased as a result of the improvement in high activity antiretroviral therapy (HAART) and longer survival times. Bone alterations, osteopenia and osteoporosis, are common in HIV-1-infected individuals. Osteoporosis is common in HIV-infected with prevalence estimates approximately 3-fold higher than non–HIV-infected individuals. Mechanisms of alteration of bone turnover are still unclear and it is thought to be multifactorial. The aims of our study were to supply some information on bone loss and to determine the incidence of bone alterations in HIV infected patients in our hospital.

Material and method: Study populations and evaluations: It is a retrospective observational study. A total of 118 HIV-infected subjects were analysed between December 2009 and August 2010. A Dual-Energy X-ray Absorptiometry (DEXA) was performed to them, asked by their habitual specialists. Epidemiological data, risk factor for osteopenia and osteoporosis, underlying diseases, typical HIV-related variables (viral load, CD4 cells, High active antiretroviral treatment (HAART) history…), and other treatments were evaluated. -Statistics analysis: Data were analysed with SSPS statistical programme, version 9.0. Quantitative variables were described as mean and standard deviation and median and interquartile range, according their distribution. Qualitative variables were considered as absolute and relatives frequencies.

Results: A total of 118 patients were included in the analysis, 61 (51.7%) female and 57 (48.3%) male. The mean age was 47.5 years old. Co-infection with hepatitis C virus (HCV) were detected in 54 patients (45.6%) and with chronic hepatitis B virus (HBV) was detected in 32 patients (27.1%). The 89.3% of the patients were Caucasian. We analyse risk factor for osteoporosis such as methadone (93%), smoker (44.1%), active alcoholism (5.7%), menopause (26.1%). Data relative to HIV infection: media time from the diagnosis 14.16 ± 7.45 years, AIDS event (46.6%), mean of nadir CD4 cells 144, mean CD4 cells 559, non detectable viral load (80.5%). HAART treatments: R5 co-receptor inhibitor 3.4%, fusion inhibitor 5.9%, integrase inhibitor 8.5%, protease inhibitor 49.2%, booster protease inhibitor 65.3%, no analogous retro-transcriptase inverse 62.7%, analogous retro-transcriptase inverse 94.9%, disoproxil fumarato tenofovir 58.5%. Bone Mineral density was normal in 16.1%, osteopenia was found 46.6% and osteoporosis in 37.3%. When analyse bone density separately in HIV patients and coinfected HCV patients, osteopenia was more frequent in monoinfected patients (54.7%) and osteoporosis in coinfected patients (46.3%).

Discussion: Presence of altered bone mineral density is frequent in HIV patients. There are many factors related to bone density loss, some of them are more frequently described in HIV patients, related to its treatment and secondary comorbidities. No sufficient evidence has been described to attribute some role to the HIV infection, although more researches are needed. Many others factors have been associated making difficult to prevent the development of new cases.

Conclusions: Bone mineral density alterations are frequently described in HIV patients with or without associated hepatopathy. Osteopenia is more frequently found in HIV patients while osteoporosis is more frequent in HCV co-infected patients. The differences in the bone density we described could be related to multiple risk factors. HIV and its treatments and its secondary comorbidities could be related with bone mineral density alterations.

A-163
FEATURES OF HIP PROSTHESIS INFECTIONS AT ZAMORA'S HEALTH CARE COMPLEX. YEARS 2008-2011

E. Martínez Velado[1], A. Chocarro Martínez[1], C. Martín Gómez[1], F. Alvarez Navia[1], M. Chimeno Viñas[1], J. Soto Delgado[1], D. Aranguran Rodríguez[2], A. Fernández Prieto[2]

[1]Department of Internal Medicine, [2] Department of Traumatology. Complejo Asistencial de Zamora. Zamora, Spain.

Objectives: To know the number of cases diagnosed of hip prosthesis infections between years 2008-2011, together with their features, causal organism and therapy as well as evolution after diagnosis.

Material and method: Descriptive, observational and retrospective assessment of 34 patients diagnosed of hip prosthesis infection during the period between years 2008 thru 2011. Clinical records of patients with that diagnosis were reviewed, and the following parameters were assessed: gender, age, kind of infection, model of prosthesis implanted, main symptom at diagnosis, prevalence of infections according to different years assessed, cultures obtained and organisms found, therapies adopted and their time length as well as follow-up in an Internal Medicine outpatient setting after discharge.

Results: From a total amount of 34 cases documented for those years assessed, there were six intramedullar nails and 28 complete hip prosthesis. Slight rise in number of women affected (53%), distribution according to localization was equal for both sides, mean age at presentation was 77.5 years, 70% of cases represented late infections, pain was the main symptom in 47% of cases and distant illness was present in 14% of individuals recruited; cultures became positive in 29 patients with Staphylococcus aureus as organism most frequently found, in 14 cases. 23% of infections (eight patients) presented multi-drug resistant germs. Prosthesis replacement was performed in 38% of patients. Rifampicin was the antibiotic most frequently used (82% of cases) and mean length of therapy was 23.7 weeks with mode of 24 weeks. After discharge the follow-up was done in an Internal Medicine outpatient setting in 68% of patients, while three individuals died during inpatient therapy.

Discussion: Prosthesis infections represent one of chief and feared complications at Orthopedic Surgery and Traumatology Departments due to their economical impact as well as surgery failure leading to sequels and therapies undergone by patients. According to several assessments a crude hip prosthesis infection rate around 4% is estimated, and a lower percentage is observed in our series standing at 1.8%. On the other hand, different series report organism identified in about 50% of cases, rising up to 85% in our Institution, thus leading to better match of antibiotic therapy trying to optimize available resources. Our series shows a higher number of late-onset prosthesis infections, while other reports have diagnosis of infection predominantly during the first month after prosthesis implantation.

Conclusions: Lower crude hip prosthesis infection rate in our series. Pain as main warning symptom. Staphylococcus aureus was the organism most frequently found at positive cultures. Significant rise of multi-drug resistant microorganisms. Rifampicin-based antibiotic regimens were mostly used. Significant percentage of patients with infected prosthesis material removed.

A-164
FEATURES OF KNEE PROSTHESIS INFECTIONS AT ZAMORA'S HEALTH CARE COMPLEX. YEARS 2008-2011

E. Martínez Velado[1], C. Martín Gómez[1], A. Chocarro Martínez[1], F. Alvarez Navia[1], M. Chimeno Viñas[1], M. Mateos Andrés[1], L. Mustapha Abadie[1], J. Blanco Sanchón[2]

[1]Department of Internal Medicine, [2]Department of Traumatology. Complejo Asistencial de Zamora. Zamora, Spain.

Objectives: To know the number of cases diagnosed of knee prosthesis infections between years 2008-2011, together with their features, causal organism and therapy as well as evolution after diagnosis.

Material and method: Descriptive, observational and retrospective assessment of 26 patients diagnosed of knee prosthesis infection during the period between years 2008 thru 2011. Clinical records of patients with that diagnosis were reviewed, and the following parameters were assessed: gender, age, kind of infection, model of prosthesis implanted, main sign at diagnosis, prevalence of infections according to different years assessed, cultures obtained and organisms found, therapies adopted and their time length as well as follow-up in an Internal Medicine outpatient setting after discharge.

Results: From a total amount of 26 cases documented for those years assessed, a slight rise was present in number of women affected (69%), distribution according to localization was equal for both sides, mean age at presentation was 72.4 years, 69% of cases represented late infections, exudate was the main sign in 50% of cases; cultures became positive in 25 patients with Staphylococcus epidermidis as organism most frequently found, in 54% of cases. No multi-drug resistant germs were isolated. Prosthesis replacement was performed in 50% of patients. Rifampicin was the antibiotic most frequently used (84% of cases) and mean length of therapy was 24.5 weeks with mode of 24 weeks. After discharge the follow-up was done in an Internal Medicine outpatient setting in 77% of patients.

Discussion: Prosthesis infections represent one of chief and feared complications at Orthopedic Surgery and Traumatology Departments due to their economical impact as well as surgery failure leading to sequels and therapies undergone by patients. According to several assessments a crude knee prosthesis infection rate around 2.1% is estimated, and a higher percentage is observed in our series standing at 2.3%. On the other hand, different series report organism identified in about 40% of cases, rising up to 96% in our Institution. Our series shows a higher number of late-onset prosthesis infections, while other reports have diagnosis of infection predominantly during the first month after prosthesis implantation.

Conclusions: Slightly higher crude knee prosthesis infection rate in our series. Exudate at surgical wound as main warning sign. Staphylococcus epidermidis was the organism most frequently found at positive cultures. No multi-drug resistant microorganisms isolated in our series. Rifampicin-based antibiotic regimens were mostly used. Significant percentage of patients with infected prosthesis material removed.

A-165
PNEUMOCYSTIS JIROVECII COLONIZATION IN LUNG TRANSPLANT RECIPIENTS WITH CYSTIC FIBROSIS

R. Terán Redondo[1], V. Friaza[2], A. Calzada Valle[1], E. Campano[2], R. Morillo de la Osa[2], I. Martín[1], E. Quintana[3], E. Calderón[1]

[1]Department of Internal Medicine and CIBER de Epidemiología y Salud Pública, [2]IBIs/CSIC/Seville University y CIBER de Epidemiología y SP, [3]Cystic Fibrosis Unit. Complejo Hospitalario Regional Virgen del Rocío. Sevilla, Spain.

Objectives: Pneumocystis jirovecii is an atypical opportunistic fungus with lung tropism and worldwide distribution that causes pneumonia (PcP) in immunosuppressed individuals. The development of sensitive molecular techniques has led to the recognition of a colonization or carrier state of P. jirovecii, in which low levels of the organism are detected in persons who do not have PcP. Pneumocystis colonization has been described in patients with various lung diseases, including individuals with cystic fibrosis who have prevalence ranges from 1.3% to 21.6%. Cystic fibrosis is one of the most common indications for lung transplantation worldwide and certainly the most common indication for all pediatric lung transplants and for bilateral lung transplantation irrespective of age. P. jirovecii is a major cause of fatal pneumonia in immunosuppressed lung transplant patients. However, there is no data about P. jirovecii colonization in lung transplant recipients with cystic fibrosis. The aim of this study was to analyze the frequency and dynamic evolution of P. jirovecii colonization among patients with Cystic fibrosis after lung transplantation.

Material and method: The study included 11 cases (3 males, 8 females; median age 21.9 ± 6.9 years, range 13–32 years) who attended a specialized Cystic fibrosis unit. All of them received chemoprophylaxis with trimethoprim-sulfamethoxazole. Patients were followed for a 1-year period and underwent a clinical and biological examination every 6 months in conjunction with use of a standardized questionnaire. A patient colonized with P. jirovecii was defined as an individual, with no symptoms or thorax radiography signs of PcP, whose respiratory specimen contained P. jirovecii DNA detectable by nested PCR.

Results: At baseline, P. jirovecii colonization was detected in five (45.5%) patients, but everyone except for one were colonized sometime during the follow-up period. Molecular identification of P. jirovecii polymorphisms in the mt LSU rRNA gene was determined by direct sequencing. Three different genotypes were detected: 10% genotype 1 (85C/248C); 20% genotype 2 (85A/248C) and 70% genotype 3 (85T/248C). Plasma samples from patients were assayed for β-D-glucan, with standard assay reference values defining > 80 pg/mL as positive for PcP. Median β-D-glucan was 87.6 ± 37.7 pg/mL in P. jirovecii colonized patients, compared with 80 ± 29.3 pg/mL in patients without colonization (p = 0.59).

Conclusions: Our results demonstrate that P. jirovecii colonization is common and may appear at any time after lung transplantation in patients with Cystic fibrosis despite use of chemoprophylaxis. Serum level of β-D-glucan is not useful for detecting P. jirovecii colonization in cystic fibrosis patients. Therefore, frequent monitoring of these patients using molecular techniques is thus necessary for detecting P. jirovecii colonization.

This work was supported by the Spanish Ministry of Science and Innovation (FIS-PS09/00957).

A-166
LEVEL OF PARASITEMIA, COMPLICATIONS AND COINFECTIONS OF MALARIA IN AREA 3 OF MADRID

P. Cuadros Tito[1], A. Elena González[1], M. Rubio Olivares[1], J. Ramírez Peñaherrera[1], J. Pino Gil[1], G. Esteban Gutiérrez[2], J. Cuadros González[3], G. Rojo Marcos[1]

[1]Department of Internal Medicine, [2]Emergency Department, [3]Department of Microbiology and Clinical Parasitology. Hospital Universitario Príncipe de Asturias. Alcalá de Henares (Madrid), Spain.

Objectives: Malaria is the most important parasitic disease in the world for its morbidity and mortality. In the last 20 years there has been an increase in the diagnosis of imported malaria in developed countries due to migration and travelling. The aim of this report is to analyse the level of parasitemia, the rates of complicated malaria and the most frequent coinfections in patients diagnosed of malaria in our center over the past 5 years.

Material and method: The Príncipe de Asturias University Hospital is located in Alcalá de Henares (Madrid) and has 600 beds. It provides health service to 363.809 inhabitants with a high proportion of immigrants (20%) particularly from Sub-Saharan area. All medical reports with the diagnosis of malaria from January 2006 to December 2011 were reviewed retrospectively. Epidemiological, microbiological and clinical data were collected and put into an Excel database. Statistical analyses were performed.

Results: Between 2006 and 2011, 164 cases of malaria were diagnosed. The mean age was 28.6 years old, 37 were younger than fifteen. 97% were of black ethnicity. 44.5% were females and 12 pregnants. Species distribution was P. falciparum 86.6%, P. ovale 7.9% and mixed infection 3.6%. Low parasitemia was the most frequent (Table 1). As expected by the origin of the patients, coinfections were found (Table 2). The rate of severe malaria related complications was low: 5 severe anemia with Hb < 7 g/l

Table 1 (A-166). Parasitemia

	N	%
Only PCR positive	26	15.9
Low (< 1% or < 20,000)	94	57.3
Moderate (1-5% or 20-50,000)	27	16.5
High (> 5% or > 50,000)	17	10.4

Table 2 (A-166). Coinfections

	Positives	Total tested	%
HIV	19	88	21
HCV	5	54	9.2
HBV	12	74	16.2
Filariasis	11		
Intestinal parasites	10		

(3%), 2 ARDS (1.2%) and 1 abortion in an eight-week pregnant woman (0.6%). 2 HIV patients died from opportunistic infections not related with malaria. The treatment of choice was atovaquone-proguanil (55.5%) followed by the combination of quinine and clindamycin (13.4%).

Discussion: P. falciparum infection with low parasitemia in young African patients remains the main feature in our sample, similar to our previous experience and the reports from other centers in our country. Our review shows a very significant rate of co-infection with HIV (21%). Also stands out other co-infections such as HBV (16.2%) and HCV (9.2%), filariasis and intestinal parasites. The malaria related complication rate was low (4.8%). The main causes were severe anemia and ADRS and there were no deaths related with malaria.

A-167
ACTINOMYCOSIS. RETROSPECTIVE STUDY IN THE TOLEDO HOSPITAL COMPLEX

J. Gonzáles Carhuancho, J. Largo Pau, M. Arrabal Arrabal, M. Flores Chacartegui, A. Piqueras Martínez, M. Martín-Toledano Lucas, R. Rubio Díaz

Department of Internal Medicine. Complejo Hospitalario de Toledo. Toledo, Spain.

Objectives: Clinical characterization of patients diagnosed with actinomycosis in the last 10 years at the Toledo Hospital Complex.

Material and method: Patients were identified by searching computer databases in the patient record and the Pathology Service of our center, using the term "actinomycosis and/or actinomyces" during the period from January 1, 2002 to the December 31, 2011. The diagnostic criteria were microbiological and/or histological, in clinical settings supported. We performed retrospective analysis of epidemiological, clinical and evolution data.

Results: 12 patients. Sex: 8 men and 4 women. Mean age 59 years (42-79 years). Factors predisposing: cancer (2), chronic alcoholism (2), COPD (2), DM (1), HIV infection (1), malnutrition (1), previous surgery (1), none (2). Clinical forms: 6 oral-cervicofacial (1 chronic dacryocystitis, 2 nasal, 1 chronic sinusitis, 1 pharynx, 1 mandibular osteomyelitis), 3 thoracic (2 bronchial stenosis, 1 pulmonary abscess), 2 abdominal (1 esophageal, 1 gastric) and 1 CNS (brain abscess). Histology was positive in all cases, 7 surgical specimens and 5 endoscopic biopsy (3 bronchoscopy and 2 gastroscopy), the culture was performed at 6, being in all negative. 10 patients received antibiotic treatment (6 intravenously and orally 4) and surgery was performed in 7 patients. Outcome was assessable in all cases.

Discussion: The genus Actinomyces is formed by Gram+ anaerobic filamentous bacteria that colonize mouth, colon and vagina. Are less virulent and cause disease only when altering mucosal barriers. Actinomycosis induce a chronic, insidious and slowly progressive, suppurative and granulomatous inflammation with formation of abscesses and fistulas with typical sulfur granules. Actinomycosis is a rare and simulating disease usually not taken into account, which affects delays in diagnosis and need for surgery. Our series is consistent with the literature in peak-incidence in the mid-decades and the predominance of males. Most patients have predisposing factors. Also most common sites are the oral-cervicofacial and digestive, although in our series are represented uncommon sites (brain abscess) and rare (gastric). The culture is achieved in a minority of cases, due to be nutritionally demanding and require strict anaerobic cultures affected by previous antimicrobial therapy. Our series there were no positive culture. Histology is the most useful diagnostic method in our series all cases. It is generally recommended antibiotic prolonged therapy at high doses, individualized to penicillin and in some cases in combination with surgery. In our series 2 patients were treated with surgery alone and other 5 with surgery and antibiotics. The response was positive in all cases.

Conclusions: 1. Actinomycosis remains a challenge for the skilled clinician, since most cases are diagnosed after surgery. 2. It should be suspected in patients with predisposing factors, disruption of mucosal barriers, chronic course, presence of tumors and refractory or recurrent infections. 3. Histology is still the most useful test for diagnosis. 4. Treatment of choice remains penicillin, with high doses for a prolonged time, with good response, requiring surgery on occasion.

A-168
LACTATE IN CEREBROSPINAL FLUID. IS IT A GOOD TEST FOR DIAGNOSING ACUTE BACTERIAL MENINGITIS?

P. Chacón Téstor[1], A. Espinosa Gimeno[1], M. Torralba González de Suso[1], J. Hergueta González[1], P. Salas Gómez-Pablos[2], M. Rodríguez Zapata[1]

[1]Department of Internal Medicine, [2]Department of Clinical Analysis. Hospital Universitario. Guadalajara, Spain.

Objectives: To study whether there are significant differences between the values of lactate in the CSF of bacterial meningitis, lymphocytic (viral and aseptic) and noninfectious CNS processes and establish a cutoff point that would serve to differentiate bacterial meningitis from aseptic or viral meningitis.

Material and method: Design: Cross-sectional study. We included lumbar punctures performed last year (2011) at our Hospital. Biochemical and microbiological data were studied. Lactate was assessed in people with abnormal CSF. The final clinical diagnosis when the patients were discharged from the Hospital was the gold standard. Patients who were taking antibiotics before lumbar puncture were analyzed. We assessed sensitivity, specificity, and positive and negative likelihood ratios.

Results: Three hundred and five lumbar punctures were made in 2011 at our Hospital. 29.18% (89) were pathological (more than 6 cells in the CSF cell count). Twenty six of these (29.21%) were associated with acute bacterial meningitis, 32 (35.95%) were non-infectious processes of the CNS. We excluded in the analysis 31 (34.83%) lumbar punctures performed in children under 5 years old. The median age was 49 (IQR 31-77) and 50% were men. We found 8 acute bacterial meningitis, 17 viral meningitis and 33 non-infectious CNS disorders. The median lactate value was 2.2 in viral meningitis, 7.5 in bacterial meningitis and 2.3 in other SNC disorders. With a cutoff of 4.4 mmol/L sensitivity and specificity was 100% to differentiate bacterial from viral meningitis. With a cutoff of 4.4 mmol/L, sensitivity was 100% and specificity was 93% to discriminate bacterial meningitis from viral or others CNS disorders. Positive likelihood ratio was 11.5 and negative likelihood ratio was < 0.0001. We have to point out that 6 out of 8 people with acute bacterial meningitis had been administered antibiotics before the lumbar puncture. The lactate indicates the likelihood of presenting a bacterial meningitis (OR: 4.22; CL95%: 1.56-11.44; p = 0.005).

Discussion: Lactate in CSF can be helpful in the diagnosis of bacterial meningitis. The 4.4 mmol/L cutoff helps to avoid using antibiotics in patients with virtually no possibility of presenting bacterial meningitis. However, our study has a very small sample size and the confidence level of the sensitivity and specificity is wide. Some studies suggest that lactate is affected by certain processes such as subarachnoid hemorrhage, tumors, seizures and generally any condition causing cerebral anoxia.

Conclusions: Lactate is elevated in patients with bacterial meningitis. The proposed cutoff point (4.4 mmol/L) could help differentiate bacterial meningitis from viral meningitis or other processes affecting the CNS (bleeding, seizures, tumors). Prospective studies with larger sample sizes are needed to incorporate this test into clinical practice.

A-169
NOCARDIOSIS. EXPERIENCE AT A TERCIARY CENTER

R. Mayayo Alvira, V. Hontañón Antoñana, C. García Cerrada, M. Lizarriturry Beltrán de Heredia, F. Montoya Lozano, F. Arnalich Fernández

Department of Internal Medicine Service. Hospital Univerditario La Paz. Madrid, Spain.

Objectives: Nocardiosis is an uncommon infection caused by the genus Nocardia, which has increased in the last years. The principal outcome of this study was to investigate the prevalence of this infection in our hospital and the main characteristics of the patients and also the prevalence in immunocompetents.

Material and method: We retrospectively reviewed all the cases of Nocardiosis diagnosed at Hospital Universitario La Paz in Madrid between January 2010 and January 2012. The following clinical data were collected: age, sex, diabetes mellitus, alcoholism, chronic obstructive pulmonary disease, as well as tumoral disease, immunosuppressive therapy (including corticoids), concomitant infections (TB, HIV, etc.) and organ transplantation. Other data were the Nocardia species, the clinical manifestations, the diagnosis method, the therapy and its duration and the possibility of a disseminated infection.

Results: In our study fourteen patients with Nocardiosis were diagnosed. Five of them had several infections by different Nocardia species. Five different species were isolated, being the most frequent the Nocardia farcinica (42.8%). A total of eleven (78.6%) were male and only one was immunocompetent. Out of the thirteen immunocompromised patients eleven (84.6%) were treated with corticoids (inhale 9/11 or systemic 2/11), eight (61.5%) had an oncologic or hematologic disease, one was a renal transplant recipient and one was HIV-positive. The most common presentation is pulmonary and skin disease, so the main diagnosis was made by the isolation of Nocardia in the sputum culture, the bronchoalveolar lavage, the bronchoalveolar aspiration and the skin biopsy. Only eight (57.1%) patients were treated: seven with trimethoprim-sulfametoxazole for six months and one with meropenem during ten days. The rest of the cases were assumed as colonized and did not receive any kind of treatment. No disseminated infection was detected although it was only studied in nine cases. More than 80% presented and improvement with infection resolution and only two patients died (renal carcinoma progression and respiratory sepsis).

Discussion: Nocardiosis is an uncommon infection caused by gram-positive bacteria from the anaerobic actinomycetes in the genus Nocardia. At least 33 species cause disease in humans but the most common is N. farcinica (as it can be seen in our study), being as well the most virulent and the most resistant to antimicrobials. It has been regarded as an opportunistic infection even though approximately one-third of the patients are immunocompetent. In this review more than 90% of the patients were immunocompromised. It is characterized by being a disseminated infection affecting specially the lung, the skin and the central nervous system with a tendency to relapse and progress despite appropriate therapy and with a predomination in male hosts. In our study relapse was observed in five patients, although in some cases the reinfection was produced by different species. The susceptibility varies among different species and areas with a high susceptibility to cotrimoxazole in our environment, used as the treatment of choice, as it can be seen in this study.

Conclusions: Despite the fact that Nocardiosis is not frequent, the number of cases detected has been sufficient to make us interested. The majority of patients are immunosuppressed, considering inhaled corticoid therapy as an important risk factor that contributes to the pulmonary infection (the most frequent in our hospital). We have notice the existence of relapse and infection by different species of Nocardia in the same patient; that is considered as colonization in one-third of the cases. No cases of disseminated infection have been detected, although it has been only studied in 60% of the patients. This might be due to lack of knowledge or because it has been considered as a non-infective disease. The standard therapy in our environment is cotrimoxazole with great results.

A-170
REVIEW OF CASES OF INFECTIOUS SPONDYLODISCITIS DIAGNOSED BETWEEN 2004 AND 2010 IN A TERTIARY CARE CENTER

M. Ibarguren, M. Bustinduy, A. Fuertes, N. Pérez, M. Elola, U. Errasti, H. Azkune, J. Iribarren

Infectious Diseases Unit. Hospital Universitario Donostia. San Sebastián-Donostia (Guipúzcoa), Spain.

Objectives: To analyze the epidemiological and microbiological characteristics of infectious spondylodiscitis in a tertiary care center To evaluate the diagnostic and therapeutic management of infectious spondylodiscitis in our unit.

Material and method: We reviewed a retrospective cohort including all infectious spondylodiscitis assessed in the Infectious Diseases Unit of our hospital between 2004 and 2010. We analyze their demographic, microbiological, diagnostic and therapeutic characteristics and their clinical evolution.

Results: We report 59 cases of infectious spondylodiscitis diagnosed between 2004 and 2010; 59.3% were male, with a median age of 66 years. The diagnosis from the onset of symptoms was delayed a median of 34 days (0-802 days). The major clinical manifestation was pain (96.6%) whereas 66.1% of the patients had fever and 27.1% of them neurological involvement. In 45.8% of cases the location was lumbar. The most probably spread of infection was hematogenous in 49.2%, post-surgery in 15.3%, contiguous spread in 3.4% and unknown in the remaining 32.2% of cases. For the microbiological diagnosis, blood cultures were obtained in 42 of the 59 cases (57.1% were positives), but biopsy was required in most cases (needle biopsy by CT guidance in 29 cases and open biopsy in 22 patients, from whom culture were positive respectively in 41.4% and 72.7%). Gram positive bacteria were the most frequently infecting organism (45.8% of cases, mainly Staphylococcus aureus) while 10.2% of cases were secondary to Gram negative infection, 8.5% were tuberculous spondylodiscitis, 8.5% were fungal infections and in the remaining 28.8% no microbiological diagnosis was reached. Antituberculous therapy was administered in 18 of the 59 cases, although there were only 5 confirmed cases of tuberculous spondylodiscitis. The median duration of treatment was globally 120 days (23-616), and 77 (36-371) excluding cases in which antituberculous treatment was administrated. Surgery was necessary in 49.2% of patients, with diagnostic or therapeutic purpose. Regarding the prognosis, 30.5% recovered without sequelae, residual symptoms occurred in 49.1% of cases, whereas 20.1% died.

Conclusions: Infectious spondylodiscitis it´s a severe disease which is frequently diagnosed late and requires long treatment. Microbiological diagnosis is often difficult; in our study, we reached it in 71.2% of cases. The long term outcome is poor, with functional sequelae and high mortality.

A-171
CLOSTRIDIUM DIFICCILE INFECTION. DESCRIPTIVE STUDY IN A SECONDARY HOSPITAL

P. Parra Rosado, M. Ruiz-Ruigómez, R. Gálvez López, J. Badiola González, F. Anguita Santos, A. Adamuz Jiménez, A. Lluna Carrascosa, D. Sánchez Rico

Department of Internal Medicine. Hospital de Especialidades San Cecilio. Granada, Spain.

Objectives: Our aim was to compare the risk factors for nosocomial clostridium infection in our hospital with the ones that had been published in other series including last reviews.

Material and method: We analyzed all patients admitted at San Cecilio Universitary Hospital in the last year, including admissions in medical and surgical hospitalization units from January 2011 to January 2012 and to whom Clostridium difficcile toxins had been analyzed in faeces. We included all patients with one positive outcome in the group of infected even though previous results had been negative. We excluded results from external office request. We used faeces samples for investigation of clostridium A and B toxins. And we analyzed results with SPSS 17.0 program.

Results: We analyzed a total of 149 patients including positive and negative outcomes. 13 of them had positive results, for this group the average age was 65, up to 85.7% had been treated with a proton pump inhibitor, specifically with omeprazol. 76, 9% of these patients had been under antibiotic therapy, 53, 8% of them with previous use and 23, 1% were under this treatment by the time clostridium infection was confirmed. When analyzing the antibiotic used, b-lactamics were the most popular for 40% of the patients undergoing antibiotic treatment, followed by quinolones and meropenem (30%). 23.1% had parenteral nutrition and none had undergo enterogastric surgery. 7.7% had a diagnosis of cancer and all of these were receiving quimiotherapy.

Conclusions: Comparing the obtained results with the ones that have been recently published, we have found relation between the risk factors previously described and the ones presents in our group. We would like to underline the close relation between clostridium infection and proton pump inhibitor chronic use. We feel that further studies with a bigger sample will be needed.

A-172
EXTRAPULMONARY TUBERCULOSIS DIAGNOSED BY BIOPSY IN THE PAST 11 YEARS AT THE COMPLEJO HOSPITALARIO DE NAVARRA (CHN) - SECTION A

E. Martínez Litago[1], I. Rodríguez Pérez[2], I. Villar García[1], S. Pérez Ricarte[1], M. León Rosique[1], J. Oteiza Olaso[1], T. Rubio Vela[1], C. García Labairu[1]

[1]Department of Internal Medicine, [2]Department of Pathological Anatomy. Hospital de Navarra. Pamplona/Iruña (Navarra), Spain.

Objectives: 1. Descriptive analysis of patients diagnosed with extrapulmonary tuberculosis (TB) by biopsy in the last 11years in the Department of Internal Medicine (IM). 2. Comparative study on patients diagnosed with extrapulmonary tuberculosis in other hospital services.

Material and method: Retrospective study which reviewed the medical records of patients diagnosed by biopsy of extrapulmonary tuberculosis in the CHN - Section A. They were collected demographic variables, biopsy report, Mantoux test, chest radiograph, clinical manifestation, treatment, risk factors, microbiological analysis of the simple from the hospital service that makes the diagnosis.

Results: They were obtained 10 cases of extrapulmonary tuberculosis diagnosed by biopsy in Internal Medicine. The mean age at diagnosis was 60.5 years with 70% female. Only one patient was of foreign origin (Angola). The reason for consultation was for a study of adenopathies in 80% of patients, whit cervical location in 60%. In all cases the biopsy report described caseous necrosis tuberculoid type granuloma with or without Langerhans cells, showing acid-fast bacilli with Zhiel-Nielsen technique in 5 cases. Regarding that 7 patients were Mantoux positive ≥ 13 mm. 60% of patients had abnormalities in the chest radiograph. TB treatment was received in a 100% of patients with a good performance. Regarding the 14 cases of TB diagnosed in other specialties (6 services) subject of study is more variable, predominantly pleural involvement, 9 patients presented radiological abnormalities being the most common pleural effusion. Patients had more risk factors for TB (from foreign origin 2/14 and HIV 3/14). Only 4 cases were described Mantoux reading. With respect to other variables (demographics, additional studies and medical treatment) the information is not collected in the medical record review. Overall 8 biopsy samples were sent (4 IM) to obtain Microbiology, 7 cultures were positive for Mycobacterium tuberculosis. In another 4 cases with pleural effusion the fluid was sent for culture and resulted positive.

Discussion: In the sample high yield is observed in additional studies to biopsy, such as performing a chest radiograph, Mantoux test and mycobacterial culture. Yet in both groups it highlights the lack of samples sent to Microbiology. Only 16% of patients in the sample were of foreign origin, and 12.5% HIV. All patients were treated with three drugs except two patients with quadruple therapy, with good results in 100% of cases and only one patient was not treated because the diagnosis was at necropsy. Comparing the diagnostic M.I. with other specialties it highlights the striking difference in the subject of study (80% adenopathy in MI) and risk factors (1 for 3 in the other services). The systematic study in IM is more complete regarding the conduct of the clinical history and laboratory tests in the rest of the services.

Conclusions: The most frequent form of diagnosis of extrapulmonary tuberculosis was pathologically lymph nodes proceeding in most of the cases from IM, the second most common sample from the pleural effusion biopsy by the department of pneumology. In Suspected TB its highly profitable the application of Mantoux test, chest radiography and culture. In the biopsy study it must be specified the request for the culture of mycobacteria due to its high profitability. TBC ruling must be followed despite not having risk factors (immunosuppression, foreign origin) in lymphadenopathy and pleural effusion.

A-173
SPONTANEOUS BACTERIAL SPONDYLODISCITIS: A 5-YEAR RETROSPECTIVE STUDY

D. Stoimenis, C. Spyridonidou, E. Lazoudi, A. Lalia, N. Papaioannou

1st. Department Internal Medicine. Genaral Hospital G. Papanikolaou. Thessaloniki, Greece.

Objectives: We conducted a retrospective case study over a 5-year period in order to evaluate the clinical features, laboratory findings, management and outcome of patients with bacterial spondylodiscitis.

Material and method: Ten patients (7 men, 3 women; age range 48-85 years, median 67) were identified. Demographic characteristics, underlying diseases, clinical signs and symptoms, laboratory findings, radiologic imaging, isolated microorganisms, treatment and outcome were recorded.

Results: All patients presented with gradually deteriorating back pain and fever (over 38 ºC). Neurological symptoms were found in 6/10. The duration of symptoms varied from 25 to 90 days. No common predisposing factor was recognized except for immunodeficiency and diabetes mellitus in some patients. Laboratory tests revealed in all cases normocytic anaemia and

elevated inflammatory markers (ESR, CRP, leukocytosis). Blood cultures were positive (100%); Staphylococcus aureus was the most frequent isolate (50%). Biopsy of the spine was performed in 2 patients. All patients had undergone MRI scan of the spine, which established the diagnosis. The initial MRI revealed 11 anatomical levels. The most common site of infection was the lumbar spine (O2-O5, 70%). 7/10 patients had multiple occurrences at different levels and 6/10 had also accompanying epidural or paravertebral expansion and psoas abscess. All patients were managed conservatively with parenteral, followed by oral, antibiotic therapy for a mean duration of 3 months. Nine patients regained normal ambulatory status; poor outcome was recorded in only one patient associated with neurological deficits.

Discussion: Back pain was the hallmark clinical manifestation of the disease (100%) accompanied by fever and marked acute phase response (elevated ESR, CRP and leukocytosis) in almost all of our patients at presentation. Positive blood cultures (100%), radiographic imaging and spinal biopsy confirmed the diagnosis. MRI is considered to be the modality of choice both for defining the lesions in spine, epidural or paravertebral expansion or psoas abscess and for follow-up. Conservative treatment resulted in positive outcome in most of our patients. Empirical antimicrobial agents followed by deescalation therapy, after the blood culture results obtained, were administered intravenously for 1-2 months. Outpatient parenteral antimicrobial therapy has been reported to be used for long-term management of the disease, but our patients received oral antibiotics for another 1-2 months after their discharge. In addition, all patients had been immobilized for at least 2 weeks after diagnosis. Inflammatory markers decrease promptly and are used for monitoring, while radiographic lesions restore late in the course of the disease. No surgical intervention was required. Surgical therapy should be considered when treatment failure occurs and persistent clinical symptoms, neurologic deficits, spinal cord instability or deformation are present.

Conclusions: The diagnosis of pyogenic spinal infection should be considered in any patient with acute or subacute back pain, fever and increased inflammatory markers. Early diagnosis and treatment prevent the need for surgical intervention. A long duration of follow-up is required to determine relapse of the disease.

A-174
A COMPARISON BETWEEN THREE MOST COMMONLY USED SCALES AS PREDICTORS OF MORTALITY IN PATIENTS WITH PNEUMONIA IN THE HOSPITAL EL BIERZO FROM JANUARY 1ST TO DECEMBER 31TH 2011

D. Alexis, C. Prada González, N. Ramos Vicente, T. Khaliulina, A. Castañón López, P. Dos Santos Gallego, J. Hernando García, L. Corral Gudino

Department of Internal Medicine. Hospital el Bierzo. Ponferrada (León), Spain.

Objectives: Many groups have been explored factors that predict mortality in hospitalized patients with pneumonia. The CURB 65 score, the Pneumonia Severity Index (PSI) and the Severe Community-Acquired Pneumonia Score (SCAP) are the most commonly used scoring systems. Aim to compare the value of the three scales in patients with suspected pneumonia without an infiltrate on chest X-ray (non-pneumonia) or in patients with aspiration pneumonia (aspiration).

Material and method: CURB-65, PSI and SCAP were retrospectively assessed on consecutive patients hospitalized for respiratory infection in the internal medicine ward of our Hospital from the January 1st to December 31th 2011. The discriminatory value of the three indexes, as predictors of mortality in hospitalized patients. Their value for discrimination on readmission and length of hospital stay were also assessed.

Results: 326 patients were recruited. 56 (17.2%) died in-hospital and 89 (33%) of the 270 survivors were readmitted within one year of discharge. 189 patients were diagnosed as pneumonia (58% males, 82y), 111 as non-pneumonia (66% males, 81y) and 26 as aspiration pneumonia (58% males, 83y). Mortality was significantly higher in patients with aspiration pneumonia (35% vs 15% in non-pneumonia and 16% in pneumonia, p = 0.05). CURB-65 (> 3) was the better discriminator of mortality. The areas under the ROC curves for CURB-65 > 3, PSI and SCAP > 10 for predicting in-hospital mortality were 0.64 (p = 0.00), 0.57 (p = 0.11), and 0.57 (p = 0.14), respectively. Mortality rates according CURB-65 values (< 3 vs > 3) were 10 vs 50% in aspiration (p = 0.09), 6 vs 30% in non-pneumonia (p = 0.00) and 11 vs 22% in pneumonia (p = 0.05). None of the three indexes were related with hospital readmission or in-hospital length of stay.

Discussion: When CURB 65 is greater or equal to three, mortality increases fivefold in patients with respiratory infection without pneumonia and reaches a fifty percent in those with aspiration, which means one in two patients dies. However in patients with pneumonia mortality increases twice.

Conclusions: According to the results of the study carried out the CURB 65 is the most reliable scale as an indicator of mortality.

A-176
EXPERIENCE IN THE TREATMENT OF RESISTANT TUBERCULOSIS

E. Madroñal Cerezo, R. Calderón Hernaiz, N. Cabello Clotet, R. Martín Díaz, A. Castro Gordón, J. San Martín, J. Hinojosa, A. Zapatero Gaviria

Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: To analyze the epidemiology of TB cases with resistance pattern treated at our hospital. We have classified resistant TB cases according to the 2006 WHO definition. Mono-resistant TB: resistance to one 1st line drugs. Poly-resistant TB: resistance to 1st line drugs other than isoniazid (H) and rifampicin (R). Multidrug-resistant TB (MDR-TB): resistance to H and R. Extremely resistant TB: resistance to H, R, fluoroquinolones (FQ) and injectable drugs (capreomycin, kanamycin, and amikacin).

Material and method: Prospective study of all TB cases diagnosed at the Hospital de Fuenlabrada, Madrid (southwest area), Spain. Study period: from June 1, 2004 to December 31, 2011. The study of resistance was performed on all strains of mycobacteria isolated in the Tuberculostatic National Reference Center. We have review all the medical records of patients admitted in Internal Medicine, Neumonology or other hospital services.

Results: We have analyzed 288 cases of TB. The diagnosis was confirmed by microbiological culture of Mycobacterium tuberculosis complex in 186 (64.6%). The study of resistance was performed in 163 samples (56.6%). The incidence of resistance was 6.6%. Pattern of resistance: H (5.5%), MDR-TB (2.8%), isolated H resistance (2.4%), one case of resistance to I + P, Ethambutol 1.4%; these four patients have also resistant to other 1st line drugs and some injection drugs. There was no resistance to FQ. Resistance to other 2nd line drugs 2.8%. The risk of drug-resistant tuberculosis was higher in male (9% vs 1.9%, P 0.042) and immigrants (12.5% vs 1.8%, P 0.005). There was higher incidence of resistance in HIV positive and diabetics, but not in other groups of immunosuppression (chronic treatment with steroids, cancer, renal or liver failure). Previous TB had a higher prevalence of developing MDR-TB (10% vs 2.3%, p 0.042) and R resistance (20% vs 2.3%, p 0.042). There was higher risk of drug-resistant TB if patients were living in overcrowded conditions (25% vs 6%) although not statistically significant (p 0.18). 7 patients required ICU admission, but only one of them had drug-resistance pattern. Smear-positive 52.6%. The number of cases with a

resistance pattern was similar every year, with an incidence around 2 cases/year. A family microepidemic by a strain resistant to H and ethionamide. Treatment: 48% 2nd line drugs, 47% 4 drugs (1st line), 5% (3 drugs 1st line). The mean time of treatment was 12.5 months, except MDR-TB (24 months). One patient with MDR-TB needed also surgical treatment (pulmonary cavern) and the use of a permanent catheter for injectable drugs. The rate of adverse events was high (47.37%), especially when 2nd line drugs were used. There weren't cases of hepatotoxicity or skin lesions. Evolution: Cure 52.63%, one death (HIV C3 admitted to the UCI). All cases were included in a program of Directly Observed Treatment (DOT), in spite of which, four of them (21%) did not return to the hospital.

Discussion: The immigrant population has increased over the last decade in Spain. This fact may increase new cases of tuberculosis and especially may increase the incidence of tuberculostatic resistance. We have an important problem due to immigrant patients used to discontinue treatment, even though their inclusion in DOT programs.

Conclusions: 1. Male immigrant and immunocompromised (HIV) are the population at greatest risk for resistant tuberculosis.2. The rate of resistance tuberculosis-drugs is high (> 5% H resistance and almost 4% MDR-TB). 3. MDR-TB is observed in pulmonary and extrapulmonary disease. 4. Treatment toxicity was low, appearing mainly when 2nd line is required. 5. A significant number of cases loss the follow up, whit a significant risk to public health. 6. The management of resistant tuberculosis is difficult and a multidisciplinary approach is need (medical and social activities).

A-177
THE PREVALENCE OF FUNGI INFECTIONS IN PATIENTS IN RURAL AREAS AND THE SURVIVAL RATE OF IMPAIRED FUNGAL INFECTIONS (IFI) IN GENERAL HOSPITAL

G. Chosnis, A. Rachioti, P. Roumelis, A. Loidoris, P. Karamitrou, E. Kalavri, E. Zaronakis, M. Rapti

Department of Internal Medicine. General Hospital of Livadeia. Livadeia, Greece.

Objectives: The environmental spread of Fungi in a rural area with animal farms and systemic agriculture of cotton and yeast. The risk assessment and prognosis of mold-related disease is important for pre-emptive therapy in neutropenic patients.

Material and method: 92 patients, 40 females and 52 males, within the period 2009-2011 detected: 35 with DM (15 hepatic, 20 renal impairments) 25 unspecific symptoms (fever, dyspnoea, haemoptysis) 20 pulmonary fibrosis 4 rabdomyolysis (risk factor) Empeiric therapy with caspofungin, fluconazole, posoconazol, voriconazol 14 (15%) disseminated infection in the hospital.

Results: Table.

Conclusions: Early diagnosis and survival are highly connected-DM is considered a critically-ill non-neutropenic patient. The optimal dose is critically important for effective therapy-IFD is difficult to detect and diagnose due to unspecific symptoms, high cost of serum antigen and drugrelated false positive results (cross reaction). Monitoring of local epidemiology is crucial-Arbitrary use of MIC and PCR. Culture diagnosis is time consuming, leading to pre-emptive therapy.

A-178
TUBERCULOUS PERITONITIS: A REPORT OF 10 CASES

I. Etxaburu[1], S. Estrada[1], I. Aizpurua[1], J. Urkijo[1], M. Blanco[1], J. Cazallas[2]

[1]Department of Internal Medicine, [2]Infectious Diseases Unit. Hospital Galdakao-Usansolo. Vizcaya, Spain.

Objectives: To present a retrospective study of ten consecutive cases of tuberculous peritonitis observed in our hospital during the last ten years.

Material and method: Retrospective study of all the cases with tuberculous peritonitis registered in the last ten years. We considered confirmed diagnosis positive culture for mycobacterium on ascites fluid or a peritoneal biopsy and probable those who had lymphocytic ascites with ADA > 39 U/L or TBC on another organ. We included epidemiological, clinical, analytical, radiological and evolutionary information.

Results: We gathered ten patients with a 59 years old age average, 70% of them were men. In all cases, except one, the symptoms lasted at least for one month. With regards to the risk factors, 3 out of the ten patients were HIV carriers, 4 were HBV (one of them HCV and two others were cirrhotic), one had a renal insufficiency treated with peritoneal dialysis and another one suffered from neoplasia; there were no risks factor in 5 of the patients (50%). 30% of the total number of patients were from African origin. Main symptoms were ascites (80%), fever (60%) and abdominal pain (30%), occasionally constipation, weight loss or abdominal tenderness. One patient was asymptomatic. Most frequent analysis results were anemia and increased of acute phase reactants. Mantoux was only tested into 8 patients, 5 were positive (62.5%). We studied the chest X-ray of 9 cases, with no abnormalities in 8 cases and residual signs in another one. The abdominal CT showed ascites in 8 cases, peritoneal thickening in 7, peritoneal implants on 4 and mesenteric lymphadenopathy. Just one patient went into laparoscopy, where peritoneal implants were found (histopathology: granuloma). Ascetic fluid was analysed in 6 cases, where 4 of them (66.6%) had increased levels of ADA (39 UI/L); among the rest, in 2 cases active TB was found in another organ. On one case laparoscopy was performed and on the other one urgent surgery was required due to intestinal occlusion. In 5 cases possible TB was diagnosed (lymphocytic ascites with increased ADA (3) or TB in another organ (2), in 4 cases we reached to definitive diagnosis (mycobacterium culture

Table (A-177). Results

Groups	Survival rates
15 allergic bronchopulmonary and chronic lung diseases	10 (9%)
Immunocompromised	
35 DM Ketosidosis	30 (27%)
2 SOT (solid organ transplant)	1 (0.9%)
haematological malignancies (chaemotherapy)	5 (4.6%)
15 critically ill & contaminated disease	3 (2.7)
3 HIV	0
Skin infections	
5 infected wounds	5 (4.6%)
2 Disseminated & painful cellulitis & onychomycosis	2 (1.8%)

positive in peritoneal fluid (3) or biopsy (1)); in 1 case urgent surgery was followed by anti-tuberculosis treatment reaching complete cure. Antibiotic treatment included isoniazid and rifampicin in all cases (2 cases required to change rifampicin to levofloxacin due to hepatotoxicity), ethambutol in 2 cases (1 cirrhotic) and pyrazinamide in 8; there were only 2 cases of cytolysis and low cholestasis, solved thanks to levofloxacin inclusion; in all cases cure was reached.

Discussion: Tuberculous peritonitis is an uncommon site of extrapulmonary infection. The risk is increased in patients with cirrhosis, HIV infection, diabetes mellitus, underlying malignancy, anti-tumor necrosis factor agents treatment, patients undergoing continuous ambulatory peritoneal dialysis and in western countries, immigration is also associated. The most common clinical features are ascites, abdominal pain and fever. 70% of patients have symptoms for more than four months before the diagnosis is established. Should be considered on all patients presenting with unexplained lymphocitic ascites with a serum-ascites albumin gradient of < 1.1 g/dl. The gold-standard for diagnosis is culture growth of Mycobacterium on ascites fluid or a peritoneal biopsy. Selection of treatment is based upon the same principles as the selection for pulmonary tuberculosis. Prognosis is variable, depending on the underlying condition, comorbidities and early diagnosis.

Conclusions: Tuberculous peritonitis should be included in the differential diagnosis patients with lymphocytic ascites and fever or serum-ascites albumin gradient of < 1.1 g/dl. Its incidence is increasing with the immigration and the HIV infection. Invasive diagnostic tests should be reserved for those cases where we cannot achieve certain diagnosis or we have serious doubts between tuberculous peritonitis and peritoneal carcinomatosis.

A-179
RISK FACTORS OF QUINOLONE-RESISTANT ESCHERICHIA COLI IN COMPLICATED URINARY TRACT INFECTIONS

M. Balaguer, A. Esparcia, A. Artero, M. Madrazo, M. Carmona

Department of Internal Medicine. Hospital Universitario Dr. Peset. Valencia, Spain.

Objectives: Resistance to fluoroquinolone drugs is increasing among Escherichia coli causing complicated acquired urinary tract infections (UTI). The aim of this study was to know the demographic and clinical risk factors of quinolone-resistant E. coli in patients admitted to the hospital with urinary tract infections.

Material and method: A prospective study of patients admitted to the Department of Internal Medicine of a university hospital with community acquired UTI was performed, during a four-year period. Clinical and microbiological characteristics of quinolone-resistant and quinolone non-resistant E. coli cases were compared. Statistical analysis was done by SPSS 18.0.

Results: Two hundred and twenty-five patients with E. coli UTI, 76 men and 149 women, with a mean age of 78.13 ± 14.18 years old were included. Eighty six (38.2%) and 139 (61.8%) cases were caused by quinolone resistant and non-resistant E. coli, respectively. By univariate analysis quinolone-resistant E. coli was associated to McCabe Index > 2 (OR, 0.51; 95%CI, 0.33-0.79), nursing home residents (OR, 3.05; 95%CI, 1.27-7.32), dementia (OR, 2.03; 95%CI, 1.16-3.54), recurrent UTI (OR, 4.36; 95%CI, 2.37-8.03), previous hospitalization (OR, 5.64; 95%CI, 3.13-10.17), urinary catheter (OR, 4.11; 95%CI, 2.07- 8.16), health-care related infection (OR, 6.72; 95%CI, 3.60-12.55), and antibiotic use within previous 3 months (OR, 7.41; 95%CI, 4.05-13.55). By multivariate analysis only the previous use of antibiotics was related to quinolone-resistant E. coli (OR, 4.17; 95%CI, 1.71-10.17). However, empirical treatment with quinolones is not even recommended in patients without previous use of antibiotics, as the proportion of quinolone-resistant in these patients was 19.69%.

Conclusions: Previous use of antibiotics is the only predictive factor of quinolone-resistant E. coli in complicated urinary tract infections. However, the high proportion of quinolone-resistant E. coli in our setting makes the empirical use of quinolones in complicated UTI not recommended under any circumstances.

A-180
DYSLIPIDEMIA AND ANTIRETROVIRAL THERAPY IN PATIENTS WITH HIV INFECTION. HOW MANY PATIENTS DO WE TREAT WITH LIPID LOWERING DRUGS?

M. Torralba González de Suso[1], G. Hernando Benito[1], L. Engonga Obono[1], P. Chacón Testor[1], L. Abejón López[1], B. Rodríguez Llansola[2], M. Rodríguez Zapata[1]

[1]Department of Internal Medicine, [2]Department of Hospital Pharmacy. Hospital Universitario. Guadalajara, Spain.

Objectives: Our objective was to assess the prevalence of dyslipidemia and its relationship to antiretroviral treatment and to study lipid-lowering drug use in this population.

Material and method: Design: Cross sectional study. All HIV infected patients seen at the HIV unit with at least one full lipid profile were included. We studied the prescription of lipid-lowering drugs (statins, fibrates or ezetimibe) at the time the lipid profile was assessed.

Results: 336 were studied with a median age of 43 years (IQR: 37-48 years) Of which 68% were males. 32.8% were HCV + and 3% were HBsAg +. 78.1% had a VL < 50 copies/ml and median CD4 was: 530 cells/mcL (IQR: 380-672). 56.5% were using one NNRTI and PI 43.5%. 82.5% used the tenofovir and abacavir 9%. 30.1% of patients had cholesterol above 200 mg/dl and 33% had hypertriglyceridemia over 150 mg/dl. 14.9% had LDL above 160 mg/dl. 29.6% had a low HDL and total cholesterol/HDL was higher than normal limits in 14.8%. Statins were used in 7.4% of patients, 0.6% fibrates and 0.6% ezetimibe. There was less hypercholesterolemia with DRV/r than ATV/r (p = 0.049) and ATV/r than LPV/r but without being statistically significant. There was less hypercholesterolemia with NEV than with EFV and with TDF than with ABC, although the differences were not statistically significant. NNRTIs had higher HDL (p = 0.011) and lower total cholesterol/HDL that IP (p = 0.001). The DRV/r showed less hypertriglyceridemia and lower total cholesterol/HDL than ATV/r (p = 0.006 and < 0.0001 respectively). HCV patients had less cholesterol levels (p < 0.001) and LDL (p < 0.006). Neither CD4 nor CV was associated with a worse lipid profile. Substantial variability was observed among physicians when prescribing statins although each doctor conducted a similar percentage of dyslipidemia (p = 0.028).

Discussion: Although dyslipidemia is high in our population, few patients are being treated with statins. There are still no good clinical trials to evaluate the best strategy for dyslipidemia (adding statins or modifying antiretroviral treatment). In our studies we were surprised to find the Darunavir/r better lipid profile, as against Atazanavir/r. These drugs have been compared in a small clinical trial without any observable differences (i.e Metabolic clinical trial).

Conclusions: The prevalence of dyslipidemia is substantial in people with HIV infection. Despite a high prevalence of dyslipidemia, statin use in this population is infrequent. NNRTIs and DRV/r are seen as antiretrovirals with more favorable lipid profile.

A-181
RETROSPECTIVE STUDY OF PNEUMONIAS IN THE AREA OF THE BIERZO: MORTALITY, READMISSION AND HOSPITAL STAY IN 2011

N. Ramos Vicente, C. Prada González, D. Alexis, T. Khaliulina, M. Cimas Valencia, S. Sandomingo Freire, C. Teijo Núñez, L. Corral Gudino

Department of Internal Medicine. Hospital El Bierzo. Ponferrada (León), Spain.

Objectives: Respiratory infections such as pneumonia are a major cause of admission in internal medicine services. In our retrospective study we analyze the causes that increase the mortality of our patients.

Material and method: Patients hospitalized for respiratory infection in the internal medicine ward of Hospital El Bierzo from the January 1st to December 31th 2011 were selected. Several demographic, signs, symptoms, comorbidity, laboratory, X-ray and microbiology data were analyzed and related with in-hospital mortality, length of in-hospital stay and readmission in the year before discharge.

Results: 326 patients were recruited. 56 (17.2%) died in-hospital and 89 (33%) of the 270 survivors were readmitted within one year of discharge. Mortality rates were higher in patients with hospital-acquired pneumonia (33%) and "healthcare-associated pneumonia"/ nursing homes (20%) than in patients with Community-acquired pneumonia (7.4%, p = 0.00). Also mortality rates were higher in aspiration pneumonia (35 vs 15% p = 0.05), pulmonary fibrosis (50 vs 17% p = 0.03), renal failure (24 vs 15% p = 0.05), history of stroke (30 vs 14% p = 0.01), dependency in activities of daily living (20 vs 10% p = 0.02), altered mental status at admission (30 vs 5% p = 0.00), tachypnea at admission (41 vs 7% p = 0.00) and bilateral consolidation in X-ray (30 vs 13% p = 0.04). Blood cultures were done in 96 patients (29%) with 11% positive. Sputum culture was done in 115 (35%) with 33% positive. Urinary antigen was done in 109 (33%) with 8% positive for S. pneumoniae. The positive result of blood cultures and urinary antigen were associated with higher mortality (36 vs 7% p = 0.00 and 22 vs 4% p = 0.02 respectively). Hypertension, ambulatory oxygen therapy, long-term corticoids schemes, active alcoholism, renal failure and altered mental status at admission were related with higher rates of readmissions. Patients with hospital-acquired pneumonias have longer in-hospital stays.

Discussion: Pneumonia is a disease that is growing and generating significant morbidity and mortality with frequent hospital admissions and healthcare costs. The retrospective chart review may be useful to detect defects in the operation of our service and improve the quality of care for our patients.

Conclusions: 1. Within three types of pneumonia, which has a higher mortality rate is the Hospital acquired pneumonia. 2. We have analyzed other clinical factors, laboratory and radiological also increase mortality as: aspiration pneumonia, pulmonary fibrosis, renal failure, history of stroke, dependency in activities of daily living, altered mental status at admission, tachypnea at admission, bilateral consolidation in X-ray and the positive result of blood cultures and urinary antigen. 3. Chronic diseases such as hypertension, renal failure or altered mental status and chronic treatment with oxygen or steroids were due to higher readmission rate. 4. The hospital stay was longer in hospital-acquired pneumonias that Community-acquired pneumonia or healthcare-associated pneumonia.

A-182
ANALYSIS OF 111 CASES OF EXTRA PULMONAR TUBERCULOSIS

E. Madroñal Cerezo, R. Calderón Hernaiz, N. Cabello Clotet, D. Rejas Velasquez, R. Martín Díaz, J. Ruiz Giardín, A. Barrios Blandino, A. Zapatero Gaviria

Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: To analyze the clinical features, epidemiology, risk factors and outcome of patients with extra pulmonary tuberculosis (EPTB). To assess the differences observed regarding cases of pulmonary tuberculosis (PTB).

Material and method: Prospective study of cases of tuberculosis (TB) diagnosed at the Hospital de Fuenlabrada, Madrid (southwest area), Spain. Study period: from June 1, 2004 to December 31, 2012. Variables analyzed: epidemiological risk factors for tuberculosis, clinical, radiological and laboratory findings, diagnosis, treatment and outcome.

Results: 288 cases of TB. 111 (38.54%) cases of EPTB. The mean age of patients with EPTB was 42.72 years (SD 20.5) vs 37.30 years (SD 19.9) for patients with PTB, without significant association (p 0.059). Males and smokers had frequently pulmonary disease (p < 0.05). Immigrants were similar in both groups. Patients with immunosuppression, especially HIV had extra pulmonar disease. Patients with pulmonary TB had respiratory, systemic symptoms and low weight more often than no pulmonar disease (p < 0.05). There were no differences about laboratory abnormalities (elevated CRP, leukocytosis or anemia). Extra pulmonar disease was diagnosed mainly by histology (p < 0.05) while pulmonary disease was diagnosed by microbiological techniques (p < 0.05). There were no differences in the clinical suspicion. Seven patients required admission to the ICU. Four of them were patients with no pulmonary tuberculosis and the other three had pulmonary disease. There wasn't a significant association of risk (p = 0.306). Multidrug resistance was higher in the group of EPTB (4.8% vs 3.5%), although not statistically significant. Resistance to isoniazid was the primary resistance most frequently observed (2.25% PTB and 1.8% EPTB).

Discussion: In our study we have found most frequently lymph node involvement than others reports. No pulmonary tuberculosis has low profitability of microbiological diagnosis. That's why we need a predictive model based on demographic, clinical, radiological and laboratory test to confirm or exclude the disease.

Conclusions: 1. Younger patients with immunosuppression have more often no pulmonary tuberculosis. 2. There are no differences about gender or nationality. 3. Pulmonar tuberculosis predominates in young male smokers. 4. EPTB cases are concentrated in younger patients, no differences in gender or nationality, unlike TBP predominates in young male smokers. 5. Systemic symptoms are frequently found in cases of PTB. 6. There`s high incidence of multidrug resistance in cases of EPTB, in spite of that evolution is favorable with a very low incidence of recurrence or death.

A-183
REVIEW OF CASES OF CHAGAS DISEASE IN HEALTH AREA OF TOLEDO

C. Navarro Osuna, R. Rubio Díaz, A. Piqueras Martínez, T. Núñez Gómez-Alvarez, P. Toledano Sierra, C. Vélez Pérez, A. Lizcano Lizcano, M. Rodríguez Cola

Department of Internal Medicine. Complejo Hospitalario de Toledo. Toledo, Spain.

Objectives: Review of epidemiology, initial approach and/or early treatment of Chagas disease in the health area of Toledo.

Material and method: Retrospective review of cases of Chagas disease diagnosed in the period between 0 1/01/2009 and 15/05/2012, collected from all over the health area of Toledo, including cases with positive serology for Trypanosoma cruzi (ELISA and IFI.).

Results: This is a descriptive study, accomplished through the digitized search in medical records in the Hospital Virgen de la Salud de Toledo, with data analyzed by SPSS, with the total sample n = 12, 50% women, 50% male, mean age at diagnosis 33.58 years, with a standard deviation of 14.06 years. All subjects are from Bolivia. The reason for initiating the study was, in 33.33% of cases by family history of Chagas disease, 33.33% was due to place of origin, 16.66% started by screening for donation and 16.66% by screening during pregnancy In 100% of cases were diagnosed in chronic and indeterminate phase of disease. The percentage of missing cases was 41.7% and 58.3% remained, of whom 28.5% started treatment, performing PCR for Trypanosoma cruzi prior to treatment. Only 14% continued treatment, now presenting cutaneous hypersensitivity. In 75% of patients underwent echocardiography, with mean LVEF at baseline of 63.50%, without changes in contractility, aneurysms or intracavitary thrombus in any of the cases.

Discussion: Chagas disease is a zoonosis endemic in America, caused by the protozoan Trypanosoma cruzi. This is an emerging disease in our environment due to migration from Latin America to non-endemic countries. The most common means of transmission in endemic countries is the vector, but the vector does not exist in Spain, being the horizontal route the most common way of transmission (for organ donation or blood transfusion; carried out, by law, a screening), and less frequent the vertical way. It consists of an acute phase, the most common in children, 50% asymptomatic, which if untreated, becomes a chronic phase, which presents symptoms occasionally (20-30% of cases) with cardiac disease (blockages, arrhythmias) and digestive (megasyndromes). Chronic cases are the most frequently detected, encompassing pregnant in endemic areas, the rest of population from endemic area and reactivation in immunocompromised individuals. This diagnosis is made with direct or indirect techniques (ELISA and IFI) and PCR, being also chosen to follow. The treatment of choice is benznidazole; beginning in acute states, children, immunosuppressed, transplant recipients and chronic individual cases. Of the 12 cases analyzed, 100% were from endemic areas, identified by family history, origin, and screening in pregnant women and donor. All patients were asymptomatic, being in chronic undetermined phase. Were treated 2 of 12 patients, being present only one of them.

Conclusions: Chagas disease is an infrequent infection underdiagnosed and with poor follow-up given the high percentage of patients who leave the study for demographic reasons. The reason for the emerging interest is the increase of immigrants from endemic areas with chronic illness, pregnant women and blood and organs donations.

A-184
DEVELOPMENT OF TUBERCULOSIS IN HIV-INFECTED PATIENTS RECEIVING SUCCESSFUL ANTIRETROVIRAL THERAPY

E. Martín-Echevarria[1], M. Torralba[1], A. Pereira Julia[1], B. Martínez[1], J. Machín[1], A. Moreno[2], M. Rodríguez Zapata[1], S. Moreno[2]

[1]Department of Internal Medicine. Hospital Universitario. Guadalajara, Spain. [2]Infectious Service. Hospital Universitario Ramón y Cajal. Madrid, Spain.

Objectives: The risk of developing TB is markedly reduced in HIV-infected patients receiving HAART, but the incidence is still significantly higher than that in the non-HIV-infected population. Our aim is to evaluate if the residual risk of developing TB in patients treated with HAART is related to an inadequate immunovirological response.

Material and method: Observational, cohort study in a single institution. Patients were included in the analysis if they had received HAART (a combination of at least 3 antiretroviral drugs) at any time in the course of HIV infection. TB was diagnosed only if microbiologically proven. Univariate and multivariate analyses were performed to identify risk factors associated with the development of TB.

Results: This study included 1,824 patients, followed for a median 473 days. Most patients (59%) had acquired HIV-infection through intravenous drug use. After initiation of HAART, 45 patients developed TB during the follow-up. The development of TB was directly related with the increase in CD4 count [OR (95%CI): 0.683 (0.522-0.894) by increases of 100 CD4/µL over baseline]. The maximal protection was reached in patients increasing ≥ 150 cel/µL after 12 months of therapy [OR (95%CI): 0.29 (0.11-0.8)] or ≥ 300 cel/µL after 24 months of therapy [OR (95%CI): 0.73 (0.71-0.75)]. However, there was still a measurable residual risk in patients with successful HAART. There was no association between achieving HIV RNA < 50 copies/mL and the development of TB [OR (95%CI): 1.43 (0.68-2.49)].

Conclusions: The risk of developing TB in patients on HAART is related with the immunological response, as measured by the absolute CD4 count, and not with the virological response. The significant residual risk of developing TB in patients receiving otherwise successful HAART, emphasizes the need of adjunctive strategies in order to minimize this risk.

A-185
SHOULDER ARTHROPLASTY (SA) INFECTION: EXPERIENCE WITH SIX CASES

E. Mozos de la Fuente[1], E. Madroñal Cerezo[2], A. Sáenz Gutiérrez[3], M. Beseguer Peinado[5], J. Almodovar Delgado[6], J. Cobo Reinoso[4]

[1]Department of Internal Medicine. Hospital San Pedro. Logroño (La Rioja), Spain. [2]Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain. [3]Department of Internal Medicine. Complejo Hospitalario de Ciudad Real. Ciudad Real, Spain. [5]Department of Microbiology, [6]Department of Traumatology, [4]Department of Infectious Diseases. Hospital Ramón y Cajal. Madrid, Spain.

Objectives: To review PSI in our institution in order to describe clinical, microbiological and therapeutic features.

Material and method: In our institution almost all prosthetic joint infections (PJI) are evaluated and followed by the Infectious Diseases Service. We selected all PSI from the cohort of patients with PJI followed by the infectious diseases service during the period 2007-2012. The diagnosis of infection was defined as the presence of at least one of the following four criteria: isolation of the same microorganism from two cultures of joint aspirates or intraoperative periprosthetic tissue specimens; presence of acute inflammation on histopathological examination of periprosthetic tissue; sinus tract communicating with the prosthesis; or purulence in a joint space. We classified PSI according to the classification of Tsukayama in four types. I: positive intraoperative culture; II: early postoperative infection (< 1 month after implantation); III: acute hematogenous and IV: late-chronic (> 1 month after implantation).

Results: During the study period 172 PJI were followed by the infectious diseases service. Only 6 (3.5%) were PSI. The average age was 75.3 years. 50% was female. According with Tsukayama classification, 2 PSI were diagnosed as type II, and 4 PSI as type IV. Among these four cases the average since the placement of the prosthesis to the diagnosis of late chronic infection was 23.5 months. Clinically all patients presented with local signs (erythema, purulent drainage, wound infection) without systemic signs or symptoms. Staphylococcus epidermidis was isolated in all the cases,

Propionibacterium acnes in 3, Staphylococcus auricularis in 1 and Corynebacterium in 1. Three of the cases presented polimicrobial infections. Only 1 of the 4 type IV cases was treated with the standard two-stage procedure of prosthesis exchange; in the other 3 patients a conservative approach of debridement, prosthesis retention and "suppressive" antibiotic therapy was elected in order to preserve the function of the implant. Two early PJI were managed with debridement and prosthesis retention. All the patient remain free of symptoms of infection after a mean follow-up of 16 (2-29) months, and last C-reactive protein remain in normal range in five (one case still on therapy for an early PJI).

Discussion: Shoulder arthroplasties represent a very small percentage of the performed joint replacements. In fact, prosthesis registers are usually limited to hip and knee implants, and do not include shoulder prosthesis. In accordance with this, there is a limited experience with SA infections. Although it is assumed that the general principles of management for knee and hip prosthetic joint infections (PJI) should be applied to prosthetic shoulder infections (PSI) functional and anatomical differences could influence a more conservative approach.

Conclusions: All microorganisms isolated were gram-positive bacteria, and in half of the cases P. acnes was implicated. The diagnosis should be suspected always in presence of wound infection or local signs. We found a more conservative approach than in hip and knee PJI, probably because shoulder is not a loading joint and its function could be sometimes preserved in spite of infection.

A-186
STREPTOCOCCUS BOVIS BACTERAEMIA: CLINICAL AND MICROBIOLOGICAL CORRELATES IN A SERIES OF 26 PATIENTS

I. Muñoz Roldán, M. Martín Puig, M. Clavero Olmos, C. Recarte García-Andrade, A. González Munera, D. Salor Moral, M. Villalba García, C. López González-Cobos

Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: To characterise the clinical features, associations and outcome in a series of patients with Streptococcus bovis bacteraemia.

Material and method: Retrospective analysis of all episodes of Streptococcus bovis bacteraemia at a University Hospital from Spain between January 2004 and November 2010 was performed. The hospital records of these patients were reviewed to assess their demographic and clinical features.

Results: During the study period 26 evaluable episodes of Streptococcus bovis bacteraemia were identified (20 males; mean age 69.6 years). The most important underlying predisposing conditions were: Chronic liver disease 26.9%, history of malignancy 23%, valvular heart disease 42.3%. Presumed sources of SBB were: biliary tract infection 3 patients, primary bacteraemia 9 patients and infective endocarditis 13 patients. Overall, 19 patients (73%) underwent colonic evaluation. Some form of gastrointestinal pathology was present in 17 patients examined. A diagnosis of colorectal carcinoma was made in 1 patient. 23 of the bacteraemia episodes (88.4%) were caused by S. bovis biotype I and the remaining 3 patients by S. bovis biotype II species. Gender distribution did not differ between the two groups, whereas the mean age in patients with bacteraemia caused by S. bovis biotype II (60 years) was lower than those with S. bovis biotype I bacteraemia (70 years). Infective endocarditis was significantly more common among patients with S. bovis biotype I infection. At the end of the observation period, none of patients had deceased.

Conclusions: Isolation of S. bovis from blood cultures should lead to prompt investigation of infective endocarditis. The high incidence of primary bacteraemia has been relevant.

A-187
UROPATHOGENS IN PATIENTS ADMITTED TO AN INTERNAL MEDICINE SERVICE; RELATIONSHIP WITH COMORBIDITY, RISK FACTORS AND ORIGIN

S. Sanz Baena[1], V. Delgado Cirerol[1], G. Pérez Martín[1], E. Berrocal Valencia[1], M. Moro Álvarez[1], G. Ramírez Olivencia[2], J. Lacasa Marzo[1]

[1]Department of Internal Medicine. Hospital Central de la Cruz Roja, San José y Santa Adela. Madrid, Spain. [2]Department of Infectious Diseases. Hospital Carlos III. Madrid, Spain.

Objectives: The wide use of antibiotics has led to changes in antimicrobial sensitivity and emergence of acquired resistance in urinary pathogens. There is no universally accepted definition of "multiresistence", but the suspicion of its existence is crucial to choose an appropriate empirical antibiotic treatment. The aim of this study is trying to relate specific clinical characteristics (origin, risk factors and comorbidity) with the presence of a germ-resistant in the urine culture.

Material and method: A total of 100 samples were taken from patients admitted to the Internal Medicine Department of the Hospital de la Cruz Roja (Madrid; Spain) for any reason, from January 2011 to April 2012. Were considered multiresistant microorganisms (MMR) those in which there was high or intermediate resistance to more than one family or group of commonly used antimicrobials, in addition to those, who by their clinical significance or epidemiological deserved to be considered. Clinical characteristics of the source patient, theoretical place of pathogen acquisition, risk factors for presence of urinary tract infection, and patient's comorbidity according to Charlson index were analysed. The risk factors for urinary infection was: 1) presence of urinary catheter, 2) manipulation of the urinary tract the previous week, 3) the month before hospitalization, 4) use of antibiotics in the previous month, 5) more than two episodes of urinary infection in the past year; 6) diabetes mellitus, 7) chronic renal insufficiency (creatinine > 1.3 mg/dL), and 8) use of steroids (more than 5 mg. for more than 3 weeks). The processing and statistical analysis of data was performed using SPSS 15.0.

Results: Clinical characteristics of source patients were: age 82.74 (SD 9.6), male sex 38%. 12% of them were institutionalized and 53% had some degree of dependency. 77% of patients had, at least, one risk factor for urinary tract infection, the most prevalent was diabetes mellitus (30%), followed by the presence of urinary catheter (26%) and the use of antibiotics in the previous month (23%). The community-acquired was considered by 79%, hospital-acquired 13% and institution-acquired 8%. The mean Charlson index of patients was 2.94 (range 0-11, SD 2.05). E. coli was the most frequent pathogen founded (45 positive cultures), followed by Klebsiella and Enterococcus sp. 77% (77) of the isolated organisms were multiresistant (MMR). The 81.1% of the cultures with MMR germs came from patients with at least one risk factor, compared with 60.9% of no MMR who came from the same kind of patients ($p = 0.036$). There was no statistical significance between the source of acquisition of the urine culture (community, institution or hospital) or Charlson index (though there was a tendency that suggests that this significance is not reached due to the small sample size).

Conclusions: One or more risk factors presence for urinary infection correlates a priori, with the possibility of finding a multiresistant germ in the urine culture. The isolation of multiresistant bacteria has no exclusive nosocomial origin, but it is widely spread by the institutions and, more worryingly, in the community. More studies are needed to correlate rates of comorbidity (such as Charlson index) and the presence of multiresistant bacteria in urine.

A-188
STUDY OF PNEUMOCOCCAL INFECTION AT FUENLABRADA HOSPITAL'S AREA

D. Rejas[1], M. Tojo[1], E. Madroñal[1], R. Martín[1], R. Calderón[1], N. Cabello[1], J. Jaqueti[2], A. Zapatero[1]

[1]Department of Internal Medicine, Department of Microbiology. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: Streptococcus pneumoniae infection is the most common cause of community-acquired pneumonia and the most frequent cause of pneumonia hospitalization. In Spain is estimated between 5 and 11 cases per 1000 inhabitants/year. Urine antigens determination is a rapid and highly sensitive for the diagnosis of this infection.

To determine the number of isolates positive for Pneumococcus in the urine in the period between November 2010 to February 2011 and November 2011 to February 2012. Analyze the clinical and epidemiological characteristics of patients, and pneumococcal prophylaxis indication.

Material and method: Descriptive study of pneumococcal urinary antigen registers requested by the Departments of Internal Medicine, Pneumology, Oncology and Emergency, during the winter months of 2010, 2011 and 2012, analyzing the prevalence of various comorbidities that are associated to pneumococcal infection: Diabetes mellitus (DM), heart disease, chronic lung disease, chronic kidney disease (CKD), liver disease, immunosuppression, and splenectomy. Also determine the percentage of patients vaccinated for pneumonia among all patients, and those who fulfill criteria of vaccination without being, by using the HORUS (computer network connecting primary care with the specialist). The study analysis was performed using SPSS 18.0.

Results: During the first period studied there were 24 positive pneumococcal urinary antigen made a total of 379 (6.3%). In the second period there were 34 positive urinary antigen of 419 (8.1%) requested. Of the total of confirmed pneumococcal infection (58), 48% were women and 52% male, mean age 68 years ± SD 20 (range between 16 and 95). In 61% of patients the definitive diagnosis was obtained during the first three days after his arrival in the ED. In 52% of patients initial antibiotic therapy was modified after the definitive diagnosis. 7% of the patients died during admission being only one case directly related to pneumococcal infection. 41% of patients suffered at least one diagnosed chronic lung disease, 41% had some form of heart disease, 26% of DM, 12% of patients had some degree of immunosuppression, 10% had CKD, and 10% liver. From all of patients 73% fulfilled criteria for prophylaxis, among them, only 14% were vaccinated.

Conclusions: Our study shows the low vaccination coverage in patients at high risk of pneumococcal infection (over 65 years with one comorbidity), however, mortality from pneumonia is very low in our series. The definitive diagnosis was made in most cases so early in the first 3 days and led to the modification of the antibiotic in more than half of cases. The most common comorbidities related in our series, with pneumococcal infection are chronic lung diseases, heart disease and diabetes.

A-189
USE OF EMPIRICAL ANTIBIOTIC THERAPY IN DEPARTMENTS OF INTERNAL MEDICINE OF THE EMILIA ROMAGNA REGION (ITALY): DIFFERENCES BETWEEN MANAGEMENT OF SEVERE INFECTIONS IN HOSPITALS OF LARGE AND SMALL DIMENSIONS

G. Pedretti[1], G. Cioni[2], P. Giuri[3], G. Gussoni[6], M. Giorgi-Pierfranceschi[4], G. Civardi[5], on behalf of FADOI Emilia Romagna

[1]Department of Internal Medicine Department. Ospedale di Fidenza, AUSL Parma. Italy. [2]Department of Internal Medicine Department. Ospedale di Pavullo nel Frignano, AUSL Modena. Italy. [3]Department of Internal Medicine Department. Ospedale di Castelnovo Monti, AUSL Reggio Emilia. Italy. [4]Emergency Department. Ospedale di Piacenza, AUSL di Piacenza. Italy. [5]Department of Internal Medicine Department. Ospedale di Fiorenzuola, AUSL di Piacenza. Italy. [6]Fondazione FADOI. Centro de Studi FADOI. Milano, Italy.

Objectives: In the peripheral hospitals, where often infectious disease specialists lack, the internists are involved to start the empirical antibiotic treatment for serious infections requiring hospitalization. Indeed in severe infections adherence to guidelines, the appropriate use of resources, the timing of onset, the correct dose and the right choice of antibiotics are of extreme importance for patients' outcome. The aim of this study was to know the practice about the use of starting empirical antibiotic therapy in severe infectious disease requiring hospitalization in all the 70 Internal Medicine Units of Emilia Romagna Region (Italy), and to analyze the difference between hospitals with more than (big) and with less than (small) 250 beds.

Material and method: A questionnaire of 55 questions was administered to all 70 teams of Internal Medicine of the Emilia Romagna Region (Italy). Statistical analysis of collected data was performed using Chi square test by splitting into 2 groups the units who responded to the questionnaire based on hospital size (with more than or less than 250 beds) to evaluate a statistically significant difference ($p < 0.05$) with regard to adherence to the main guidelines of scientific societies in the field of infectious diseases and the administration of empirical antibiotic starting therapy for serious infections requiring admission to hospital.

Results: Replies to the questionnaire were received from 53 departments contacted on 70 (75.7%) with a good representation of all the Internal Medicine Units of the provincial region. Statistical analysis revealed some interesting data from hospitals of large and small dimensions, as regards the management of serious infections by internists. In small hospitals were required more consulting ($p < 0.05$) from emergency department for patients with acute infections than in big hospitals, this result appears to be strongly influenced by the existence of a Department of Infectious Diseases. For the same reason it was found that in small hospitals internists were called for consulting in surgical wards for patients with acute infectious disease ($p < 0.05$) more frequently than in larger hospitals. In hospitals with more than 250 beds were prescribed more recent drugs such as linezolid and daptomycin for infections by Gram + MRSA instead of the glycopeptides ($p < 0.05$), this data is to be referred to more consuetude in treating infections sustained by MDR bacteria by the units of Internal Medicine of the larger hospitals. And finally in small hospitals seems to be more attention to data collection with computerized programs and to measure therapeutic efficacy and use of resources.

Conclusions: In Emilia Romagna Region the units of internal medicine have become aware of the serious problem of severe infections, but there are still major disparities in the management of the empirical treatment of these diseases, both in terms of the appropriateness of high cost antibiotic prescriptions as for the use of resources and the measurement of outcomes. The purpose of our scientific society (FADOI) is to standardize the management of serious infections through a training program for professionals and peer audit.

A-190
TUBERCULOSIS PLEURAL EFFUSION IN CASTILLA-LEON Y CANTABRIA

A. Blanco[1], C. Dueñas[1], A. Ginés[2], E. González[2], M. Fernández[3], J. Hernández[3], P. de Dios[4], E. Fernández[4]

[1]Department of Internal Medicine. Complejo Asistencial de Burgos. Burgos, Spain. [2]Department of Internal Medicine. Hospital Clínico Universitario de Valladolid. Valladolid, Spain. [3]Department of Internal Medicine. Hospital Valdecilla. Santander (Cantabria), Spain. [4]Department of Internal Medicine. Complejo Asistencial de León. León, Spain.

Objectives: To evaluate the bacteriology, clinical course, characteristics of the pleural effusion and outcome of patients with tuberculosis thoracic empyema.

Material and method: We have retrospectively reviewed the charts of all patients with a hospital discharge diagnosis of tuberculosis empyema in 14 hospitals from Castilla y León and Cantabria between January 2005 and December 2009. The diagnosis was confirmed by the positivity of the Lowenstein culture in pleural fluid. We compared the results with the characteristics of non-tuberculosis thoracic empyema recorded in the same time and hospitals.

Results: From 459 empyemas register during the time of study, only12 patients were identified as having tuberculosis empyema. The group included 11 males (91.7%) and one female (8.3%) with an average of 40.83 years. Nobody of the patients death during the study and all of them were discharged from the hospital. Only one predominant co-morbidity was found: diabetes mellitus. All the patients had symptoms attributable to their empyema with cough and purulent sputum being the most common symptoms in a 58.3%. of the cases. Other symptoms included: fever (50%), with chest pain, dyspnea and hemoptisis in less than 10% of the patients. The pleural fluid had a serofibrinous macroscopic aspect in 91.7% versus an 8.3% of purulent fluid. In all the cases, the pleural fluid contain a great number of lymphocytes with an ADA elevated. Only in one patient, the Ziehl tintion of pleural fluid was positive. The 12 cases received appropriate treatment with tuberculostatic therapy, 2 patients were treated by drainage and 1 requiring decortication. Only one complication was recorded: pyopneumothorax.

Conclusions: In our series, tuberculosis thoracic empyema seems rare. Male patients predominated with a male patient/female patient ratio of about 10:1 and great average tan other series. These patients had less co-morbidities and factor leading to infection. No mortality attributable to the disease was found. The clinical course is nonspecific and less expressive tan in other bacterial empyemas. The diagnosis was confirmed in all the cases by pleural fluid Lowenstein culture. In the pleural fluid, the predominant is a serofibrinous aspect with elevated ADA and negative Ziehl. The best approach is the appropriate treatment with tuberculostatic therapy with less thoracic drainage.

A-191
THORACIC EMPYEMA IN HIV-INFECTED PATIENTS

R. Cabo[1], C. Dueñas[1], P. García[2], M. Chimeno[2], J. Da Cruz[3], A. Morán[3], M. Morán[1], J. Quispe[4]

[1]Department of Internal Medicine. Complejo Asistencial de Burgos. Burgos, Spain. [2]Department of Internal Medicine. Complejo Asistencial de Zamora. Zamora, Spain. [3]Department of Internal Medicine. Complejo Asistencial de Palencia. Palencia, Spain. [4]Department of Internal Medicine. Hospital Universitario Río Hortega. Valladolid, Spain.

Objectives: To evaluate the bacteriology, clinical course, characteristics of the pleural effusion and outcome of HIV-infected patients with thoracic empyema.

Material and method: We have retrospectively reviewed the charts of all HIV-infected patients with a hospital discharge diagnosis of empyema in 14 hospitals from Castilla y León and Cantabria between January 2005 and December 2009. The diagnosis was confirmed by one of the following criteria: pleural fluid culture or Gram´s stain showing organism, documentation of gross purulent fluid at thoracentesis or biochemical evidence of empyema defined as pH < 7.10, and either lactate dehydrogenase level > 1,000 IU/l or glucose level < 40 mg/dl.

Results: 6 patients were identified as having empyema during the period of study. The group included 5 males (83.3%) and one female (6.7%) with an average of 55.16 years. Length of hospitalization average was 10.5 days. The cultures of pleural fluid were positive in 3 cases (50%) with no bacteria predominant isolates. All patients had symptoms attributable to their empyema with chest pain and fever being the most common symptoms (66%). Other symptoms included purulent sputum (50%), cough (50%) and dyspnea (33%). The pleural fluid had a purulent aspect in 5 cases (83.3%) containing great numbers of polymorph nuclear leukocytes. No predominant factor leading to infection or co-morbidity was found. The 6 cases received appropriate antibiotic. 3 cases were treated by drainage and 2 requiring decortication. All the patients survived and were discharged from the hospital.

Conclusions: In our series, thoracic empyema seems rare in adults HIV-related diseases, compared to general population. Male patients predominated with a male patient/female patient ratio of about 5:1 and less average than in other series. No predominant microbiology of the pleural fluids was recorded. All patients had symptoms attributable to their empyema with fever and chest pain being the most commons. The best approach to treatment is a prompt drainage of the infected pleural cavity and appropriate antibiotic treatment, since a favorable outcome is expected.

A-192
PYOGENIC LIVER ABSCESS: ANALYSIS OF THE CLINICAL CHARACTERISTICS, ETIOLOGY AND OUTCOME

M. Asensio[1], S. Barbero[1], J. Pérez[1], F. Pedro de Lelis[1], I. Abad[2]

[1]Department of Internal Medicine, [2]Clinic Documentation Unit. Consorcio Hospital General Universitario de Valencia. Valencia, Spain.

Objectives: Pyogenic liver abscess is a potentially life-threatening condition. Knowledge of etiology and related risk factors play an important role in the successful therapy. In this study our intention is to investigate the clinical characteristics, underlying diseases, etiology, outcome, and prognostic factors related to mortality of the pyogenic liver abscess.

Material and method: The medical records of all patients admitted to the hospital with a diagnosis of liver abscess during the period 2000 to 2012 were reviewed. This hospital serves to a population of 400.000 habitants. A retrospective, descriptive study was conducted. Categorical variables were analyzed by χ^2 test and the difference between means of continuous variables with t test.

Results: A total of 71 patients (45 men and 26 women; mean age 65.5 years; SD 16.98) with a diagnosis of liver abscess were studied. Mortality rate was 15%. Associated medical conditions were: High blood pressure 43.7%, Diabetes mellitus 26.8%, liver disease 16.9%, malignancy14.1%. The median Charlson score on admission was 3.94 (SD 2.76). The higher values were associated with higher mortality rate (p = 0.014). The predominant source of infection was the biliary system 44%: biliary duct obstruction 6 cases, cholecystistis 11, cholangitis 14. Abcesses in 19 patients were of unknown origin despite thorough investigation (26%). The most common symptoms were fever and/or chills (77.5%), abdominal pain (67.6%) and vomiting (25%). Leukocytosis (defined as WBC > 11,000 cells/mm^3) was observed in 43 patients (60.6%).

Total bilirubin was elevated in 19 patients (26.8%). A significant difference in mortality rate was found in relation to higher levels of bilirubin (p = 0.04), deceased patients had a mean bilirubin of 3.44 and survivors 1.16. Blood cultures were carried out for 50 (70%) patients with 26 (52%) yielding a positive result. Abscess cultures (obtained by image-guided percutaneous needle aspiration) were carried out for 46 patients (64%) of which 29(63%) yielded isolates. Microbiological findings: 18 (25.4%) of the infections were polymicrobial. E. coli was the most common isolated 15 cases (21.1%), followed by Klebsiella spp 13 cases (18.3%), Streptococci spp 11 cases (15.5%). Klebsiella spp was isolated more frequently in diabetic patients than non-diabetic patients (p = 0.019). Eighteen patients develop complications (25´45), relapse occurred in 9 patients (12´7%) and 11 patients died (15.5%). Among patients who suffered relapse of the abscess the median time of treatment was 24.44 days compared to 53.46 days in the group which did not relapse (p = 0.03).

Discussion: In the present study the annual incidence (1.45 cases per 100,000 hab) and mortality rate 15% indicates that this intraabdominal infection represents an important disease to be consider. Yield of the abscess cultures was higher than that of blood cultures, therefore it is important to obtain culture of the abscess material in order to identify the causative organism of the liver abscesses.

Conclusions: This study shows that biliary-related origin is the main etiology of pyogenic liver abscesses, most of them were polymicrobial, and among those with just only one bacterium the most frequent were E. coli and Klebsiella spp. Liver abscess has a relatively high mortality rate, which is associated with high score in Charlson scale, and hyperbilirubinemia.

A-193
PREVALENCE AND CHARACTERISTICS OF COMPLICATED COMMUNITY-ACQUIRED PSEUDOMONAS AERUGINOSA URINARY TRACT INFECTIONS

A. Faus[1], A. Artero[1], A. Esparcia[1], M. Madrazo[1], M. Balaguer[1], J. Alberola[2]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital Universitario Dr. Peset. Valencia, Spain.

Objectives: Pseudomonas aeruginosa is primarily encountered as a nosocomial pathogen. However, as the characteristics of patients admitted to hospitals have changed there appears to be increasing recognition of P. aeruginosa as a cause of community acquired infections. The aims of this study are to identify the prevalence and the clinical and epidemiological characteristics of complicated community-acquired P. aeruginosa urinary tract infections (UTIs).

Material and method: Study of a prospective series of patients over a four-year period admitted to a Department of Internal Medicine of a university hospital with community acquired UTI. The prevalence of P. aeruginosa was determined and their epidemiological and clinical characteristics were collected by chart review and compared to UTIs caused by other pathogens. SPSS 18.0 was used for statistical analysis.

Results: Eleven cases (3.7%) from a total of 300 UTIs with a pathogen isolated in urine were caused by P. aeruginosa. The mean age of patients with P. aeruginosa UTIs was 77.8 ± 14.2 years; 63.6% were male; a history of recurrent UTIs was found in 36.4% of cases; previous use of antibiotics was recorded in 72.7%; severe sepsis and septic shock were present in 27.3% and 9.1%, respectively; Mc Cabe index was ?2 in 63.6%. None of these characteristics were statistically different between the groups of P. aeruginosa and non-P. aeruginosa UTIs. A history of recent hospitalization (72.7% for P. aeruginosa vs 42.2% for non-P. aeruginosa, p = 0.045), permanent urethral catheter (54.6% for P. aeruginosa vs 23.5% for non-P. aeruginosa, p = 0.019), UTI related to health care (90.9% for P. aeruginosa vs 57.4% for non-P. aeruginosa, p = 0.027) and inadequate empirical antimicrobial treatment (54.5% for P. aeruginosa vs 24% for non-P. aeruginosa, p = 0.028) were more frequent in the group of P. aeruginosa UTIs.

Conclusions: P. aeruginosa is an infrequent cause of UTIs in patients admitted to the hospital from the community (3.7%). The prevalence of P. aeruginosa in patients with no health care associated infections is so low in our setting (0.5%) that empirical antimicrobial treatment against P. aeruginosa for community UTIs is unnecessary.

A-194
RELATIONSHIP BETWEEN SERUM RESISTIN CONCENTRATIONS AND INSULIN RESISTANCE IN PATIENTS WITH CHRONIC HEPATITIS C

G. Enache[1], E. Rusu[2], M. Jinga[4], S. Ateia[6], F. Rusu[5], V. Jinga[3], G. Radulian[2]

[1]Department of Internal Medicine-Diabetes. Clinical Emergency Hospital Constanta. Constanta, Romania. [2]Diabetes II Clinic. National Institute of Diabetes, Nutrition and Metabolic Diseases Prof. N. Paulescu. Bucharest, Romania. [4]Gastroenterology Clinic, [5]Urology Clinic. Emergency Military Hospital "Carol Davila". Bucharest, Romania. [6]Medas Clinic. Medas Clinic. Bucharest, Romania. [3]Department of Urology. University of Medicine "Carol Davila". Bucharest, Romania.

Objectives: Resistin is a protein secreted by preadipocite in the process of differentiation into mature adipocytes and has a strong pro-inflammatory action. Resistin is linked to the development of insulin resistance (IR), but information on the direct relationship of resistin levels in humans with chronic hepatitis C (CHC), and their effect on the histological severity, are few. The aim of the current study was to determine the circulating resistin levels obtained from patients with CHC and to correlate them with insulin resistance and hepatic histological features.

Material and method: We included 172 patients with chronic hepatitis C virus, 60 patients with NASH (certified ultrasound) and 60 patients representing healthy control group. IR was determined using Homeostasis model assessment (HOMA-IR). All patients with CHC underwent liver biopsy and the liver specimens were evaluated with the Ishak scoring system for viral liver disease. Body mass index (BMI) was calculated for all subjects, and serum insulin, C-peptide, and lipoprotein levels were also measured.

Results: Resistin level was higher in patients with CHC (23.1 ± 14 ng/ml in patients with CHC and 23.4 ± 16.5 ng/ml in patients with CHC and diabetes) and in those with SHNA (20.7 ± 13.09 ng/dl) and lower in patients in the control group (9.3 ± 3.6 ng/ml) (p = 0.0001). In patients with CHC, serum resistin levels increased parallel with increasing body mass index (from 18.4 ± 12.12 ng/ml in normal weight patients to 24.5 ± 12.2 ng/ml in patients with grade I obesity and 20.3 ± 40.08 ng/ml in patients with grade II obesity (p = 0.001)). Resistin correlated positively with BMI (r = 0.288, p = 0.003) and HOMA-IR (r = 0.36, p = 0.0001). In patients with CHC increased level of resistin was risk factor for SH (OR = 5.4, 95%CI 1.9-14.9, p = 0.001). Resistin level was higher in patients who have more severe liver inflammation (30.3 ± 20.2 ng/dl versus 30.2 ± 11.6 ng/ml, p = 0.042). Resistin was correlated with histological activity, increasing with its increase (p = 0.038) and fibrosis (p = 0.0001).

Conclusions: This study demonstrated the relationship between resistin and IR and resistin and hepatic steatosis in obese patients with CHC. These data suggest increased resistin levels in CHC patients which are related to histological severity of the disease. There is an explanation for this finding, as resistin is related to IR, it may contribute to hepatic steatosis by promoting IR and insulin signal changes in hepatocytes.

A-195
CLINICAL IMPACT OF BACTEREMIA IN ESCHERICHIA COLI COMPLICATED URINARY TRACT INFECTIONS

M. Madrazo, A. Esparcia, M. Candel, M. Balaguer, A. Artero

Department of Internal Medicine. Hospital Universitario Dr. Peset. Valencia, Spain.

Objectives: Escherichia coli is the primary cause of urinary tract infections (UTIs). Routine performance of blood cultures is not recommended in patients with uncomplicated UTIs and they are mainly reserved for complicated infections. The goal of this study is to determine whether E. coli complicated UTIs with positive blood cultures (PBC) have a worse prognosis than those with negative blood cultures (NBC).

Material and method: A retrospective study of cases with complicated community-acquired UTIs caused by E. coli admitted to a Department of Internal Medicine of a university hospital, from October 2007 to March 2011. Clinical and microbiological variables were collected by chart review. Outcomes were compared between cases with positive and negative blood cultures. SPSS 18.0 was used for statistical analysis.

Results: Blood cultures were obtained in 95 cases (42.2%) of 225 cases with E. coli complicated community-acquired UTIs. Blood cultures were positive in 54 cases (55.6%), and in every case E. coli was isolated in concordance with urine cultures. Therefore, no single case required a change in antimicrobial treatment based on blood culture results. Age 76.7 ± 11.36 PBC vs 74.14 ± 19.49 NBC, p = 0.420), male sex (31.4% PBC vs 39.5% NBC, p = 0.409), previous use of antibiotics (40.7 PBC% vs 34.8% NBC, p = 0.555), a history of recent hospitalization (27.7% PBC vs 39.5% NBC, p = 0.221), health care related infection (42.59 PBC% vs 51.16% NBC, p = 0.4), APACHE II (12.89 ± 4.53 PBC vs 11.67 ± NBC, p = 0.181) and severe sepsis or septic shock (46.29% PBC vs 30.23% NBC, p = 0.107) were not different between bacteremic and non-bacteremic cases. Length of stay in hospital (7.57 ± 4.50 vs 8.86 ± 8.80, p = 0.352), global hospital mortality (3.7% PBC vs 2.32% NBC, p = 0.697) and hospital mortality related to infection (1.85% PBC vs 0% NBP, p = 0.370) were not different between groups with positive and negative blood cultures.

Conclusions: In our study bacteremia in patients with E. coli complicated urinary tract infections was neither associated with more severe infections nor had any influence on outcomes.

A-196
LYME DISEASE PRESENTATION OF SIXTEEN PATIENTS AND REVIEW THE LITERATURE

D. Cuervo Blanco[1], E. Fonseca Aizpuru[1], M. García Alcalde[1], R. Fernández Madera[1], I. Arias Miranda[2], E. Rodríguez Avila[2], A. del Valle Prieto[3], J. Morís de la Tassa[1]

[1]Department of Internal Medicine, [3]Department of Microbiology. Hospital de Cabueñes. Gijón (Asturias), Spain. [2]Department of Internal Medicine. Hospital de Valle del Nalón. Riaño. Asturias, Spain.

Objectives: Analize clinical features, epidemiology, treatment and outcome in a series of patients diagnosed of Lyme disease (LD) in our hospital between August 2008 and December 2011.

Material and method: We conducted a descriptive and retrospective study of a sample of patients diagnosed of LD in Cabueñes Hospital (with a population of 300.000 inhabitants). Microbiology department reported all the suspected cases with positive Borrelia burgdoferi serology. When a positive serology (Elisa & Immunoblot), IgM, and/or IgG seroconversion, and compatible clinical symptoms, the diagnosis of "active" Lyme disease was done. Statistical Package for the Social Sciences (SPSS) was used for the analysis.

Results: Sixteen patients were diagnosed. Thirteen (81, 3%) were males and three (18, 8%) were females. The mean age was 48+/-18 years. Nine (60%) of then live in the rural area, and six (40%) in the urban one. There was a tick bite in 10 (62.5%) cases. The main clinical features were erythema migrans (EM) in 12 (75%), influenza-like symptoms, fever and fatigue in 2 (12.5%), and neurological symptoms -radiculopathies in 2 (12.5%). One patient develop a complete atrioventricular block, and another one knee arthritis. Laboratory test were unremarkable, highlighting slight elevation of erytrocite sedimentation rate (ESR) and liver function test (TGO, TGP). Arthrocentesis was performed in one patient resulting in inflammatory fluid. Fifteen patients underwent antibiotics treatment, mainly with oral doxycycline –in 10 (62.5%), oral amoxicillin clavulanic – in 2 (12.5%), and intravenous ceftriaxone in 3 (18.8%) patients because of neurologic or cardiac symptoms. Antibiotic treatment was maintained an average of 22 ± 7 days (10-30). The outcome was favorable in 100% of patients -10 (62.5%) attending review.

Discussion: Lyme disease (LD) is caused by spirochaetes of the Borrelia burgdorferi spp, which are transmitted by Ixodes spp ticks. The epidemiological characteristics and clinical features are similar to those previously published. The signs and symptoms of LD are diverse. LD is evident in three stages, the first of which includes erytema migrans (EM). Cardiac involvement is an uncommon manifestation ocurring in up to 8% of patients. Arthralgias and arthritis of the knee may be evident. Radiculopathies have rather nonespecific symptoms, and may cause asymmetric pain in the limbs. Microbiological or serological confirmation of LD is needed for all manifestation of the disease -except for EM. The criteria for serological diagnoses are not standardised, seropositivity due to past infection may be included, and the diagnosis of some chronic forms of LD is currently controversial. There are patients with positive IgG serology for years, and many of them have received proper antibiotic therapy. It has been suggested that the overdiagnosis and overtreatment may be an important problem. Antibiotic treatment depends on the LD stage. Early and localized stages are usually treated with oral doxycycline or amoxicillin. In more advanced stages, treatment with parenteral ceftriaxone or cefotaxime are recommended. Symptomatic patients with cardiac Lyme borreliosis with high grade atrioventricular block should be closely monitored, and temporary cardiac pacing might be necessary.

Conclusions: 1. The epidemiological characteristics, age, sex, and clinical features are similar to literature. 2. A positive serological test does not mean that a patient necessarily has "active" Lyme borreliosis, it would be advisable not routinely treat asymptomatic patients or adequately treated patients.

A-198
HOME CARE FOLLOW-UP OF SEVERELY NEUTROPENIC PATIENTS WITH ACUTE MIELOBLASTIC LEUKEMIA

P. Sanroma[1], D. García[1], A. Bermúdez[2], S. González[1], A. Aguilera[1], C. González[1], M. Pajarón[1], C. Escalada[1]

[1]Home Care Unit, [2]Department of Hematology and Hemotherapy. Hospital Valdecilla. Santander (Cantabria), Spain.

Objectives: To evaluate the clinical evolution, demand for assistance and complications arising during the home care follow-up of patients with acute mieloblastic leukemia (AML) in aplasia phase following chemotherapy treatment.

Material and method: Prospective descriptive study of patients with neutropenia following AML chemotherapy treatment admitted to our Home Care Unit (HCU) from 1997 to 2012. We use specific protocols of mucositis and neutropenic fever according to haemathology service.

Results: We analyze 35 neutropenic episodes in 20 patients with AML, 13 males/7 females. The median age was 66 years (15-91).

Patients were referred from ambulatory consultation and hospitalization in 17 and 18 cases. The median of previous hospitalization days was 9 (3-17). All patients required central or peripheral venous access (31 and 4 cases). 32 patients (91.42%) received oral prophylactic antibiotherapy. The median of days below 100, 500 and 1,000 PMN/ml were 6 (0-19), 13 (2-25), and 17 (3-32). Neutropenic fever was developed in 22 cases. First episode of neutropenic fever was developed on 4th day (1-28) following home care admittance and 6th day of neutropenia (1-28). Neutropenic fever had clinical documentation in 12 cases (54.44%) and 8 episodes (36.36%) had microbiological documentation. In these cases, the isolated germs were: 3 negative coagulase Staphylococcus, 2 Escherichia coli, 1 Streptococcus mitis, 1 Enterobacter cloacae and 1 Aspergillus fumigatus. Blood cultures were the main source of isolation in 7 cases. Epidermidis sthaphylococcus was the main germ related with catheter infection. No multiresistant germ was isolated. Cephalosporins where used as initial empirical antibiotherapy in 14 episodes (63.63%) and carbapenems in 5 (22.72%). Teicoplanin combined with other antibiotics was used in 18 cases (81.81%) and antifungal therapy was added in 5 cases. In 7/22 episodes the treatment was modified according to the bacteriological results or clinical evolution. Only in 3 cases (8.57%), patients needed to be admitted to inpatient care, (two of them after medullar recovery): 2 due to poor evolution of fever and 1 due to urologic pain not controlled at home. No patient died during neutropenia period. The median days of hospitalization in HCU was 22 days (3-50). In 91% of cases, patients were treated at home in the phase of neutropenia and were discharged after haematological recovery. The median of visits were 27 for nurses (9-52) and 15 for doctors (1-33). Family collaboration was considered good in all cases.

Conclusions: Our study shows that the treatment of neutropenia in patients with AML supervised by an expert medical team with standardized procedures and protocols is an effective and safe alternative. The hospital readmission was very low and no patients died during neutropenic period. It is important to emphasize that no multiresistant germs were isolated. No patients died from causes related to neutropenia.

A-199
MALARIA: A 10-YEAR RETROSPECTIVE STUDY AT A CENTRAL HOSPITAL

M. Monteiro[1], A. Vilaça[1], T. Pimentel[1], F. Gonçalves[1], A. Mesquita[2], A. Estrada[2]

[1]Department of Internal Medicine, [2]Department of Clinical Pathology. Braga Hospital. Braga, Portugal.

Objectives: Malaria is the most important parasitic disease of humans, causing hundreds of millions of illnesses and probably over a million deaths each year. Travelers, who are generally nonimmune, are at high risk for severe disease from falciparum malaria at any age. Although some patients with uncomplicated Plasmodium falciparum malaria can be treated successfully in an outpatient setting, patients with no immunity against the disease are at increased risk for sudden development of severe complications. With this casuistic we pretend to characterize the patients with diagnose of malaria, in a central hospital, during 10 years and 5 months (January 2002-May 2012).

Material and method: After obtaining the cases with malaria from Maxdata, we analyze every patients' clinical files.

Results: We analyzed 36 cases of malaria. Thirty five patients had positive peripheral-blood smears and one patient had positive plasmodium DNA. Males were more commonly affected (80% of cases) and the mean age was 36.5 years [6-70 years]. Approximately 60% (21 patients) had arrived from Angola and most of them lived in our country (83%). Five patients completed correct prophylaxis and 13 already had malaria in the past. Almost all patients had fever (94%) and the rest complained about gastrointestinal symptoms (67%), headache (47%) and myalgias (42%). The commonest laboratory findings were elevated erythrocyte sedimentation rate or C-reactive protein (92% of patients), thrombocytopenia (86% of patients) and liver function abnormalities (86% of patients). Others laboratory findings include anemia (61% of patients) and low leukocyte counts (33% of patients). Fourteen patients had clinical and laboratory criteria for severe malaria. Only 4 patients were treated as outpatients. Thirty two patients required hospitalization, 10 of them in an intensive unit care. The mean length of stay in hospital were 8.6 days [2-45 days]. The most common treatment was the combination of quinine plus doxycycline (72% of patients). One patient died.

Discussion: Although almost of the patients had no immunity against the disease, with the prompt diagnose and appropriately treatment all of them, except one, had a favorable evolution.

Conclusions: Malaria is an infrequent diagnosis in our hospital and was always acquired in a malaric-endemic country by a returning traveler or emigrant (most of them from chloroquine resistant areas).

A-200
EVOLUTION OF BIOCHEMICAL AND VIROLOGIC PARAMETERS AFTER SIMPLIFICATION TO ETRAVIRINE (ETV) IN PRE-TREATED HIV PATIENTS

L. García-Fraile Fraile, I. Santos Gil, J. Sanz Sanz, A. Salas Aparicio, C. Sarriá Cepeda

Department of Internal Medicine. Hospital Universitario de la Princesa. Madrid, Spain.

Objectives: ETV has shown a good lipidic profile and low hepatotoxicity at randomized studies. However, there is little data about the evolution of lipids and transaminases in HIV patients who have switched to ETV from a previous regimen.

Material and method: Prospective observational study, of pretreated HIV patients in our hospital, who changed to ETV from a previous antiretroviral treatment for any reason. HCV prevalence (with positive PCR-HCV) and fibroscan results in coinfected patients, are registered. Triglycerides (TG), total cholesterol (TC), LDL-cholesterol (LDL-c), HDL-cholesterol (HDL-c), AST/GOT and ALT/GPT are compared at the 6th and 12th month after switching; CD4+ lymphocytes and viral loads are compared at these moments as well.

Results: Overall, 48 patients were included. Changing regimens were based on NNRTI (NNRTI 27%, efavirenz 17%, nevirapine 10%), PIs (PIs 62%, lopinavir 27%, atazanavir 15%, saquinavir 6%, fosamprenavir 4%, darunavir 4%, other PIs 6%), or triple therapy with NRTI (11%). The reasons for changing were dislipemia and lipodystrophy (17% and 12% respectively), hepatotoxicity (12%), digestive disorders (10%) and inespecific asthenia (10%). Baseline CD4+ lymphocyte count was 555 cells/ml (range width 110-2195), and 69% of patients had an undetectable baseline HIV VL (< 40 copies/ml). HCV coinfection was found in 26 patients (54%); fibroscan was performed in 20 of them, 42% showed significant fibrosis (F ≥ 2). At 6th and 12th month, mean TC levels evolved from 195 to 174 and 179 mg/dL respectively; LDL-c decreased from 98 to 93 and 96 mg/dL; and TG dropped from 174 to 133 and 121 mg/dL. No significant clinical change was found in AST and ALT levels; but in 3 patients whose transaminases levels were over 100 mg/dL (two of the HCV+), these parameters came down to normal levels within the next 6 months. CD4+ lymphocytes mean went from 555 to 567 and 513 (in 6th and 12th month respectively). The proportion of patients with undetectable VL at 6th and 12th month was 80% and 85% respectively.

Conclusions: Switching to an etravirine-containing HAART is safe, improving lipid parameters in general, without hepatotoxicity even

in HCV coinfected patients. In our study, hepatic disorders produced by other antiretroviral chemicals improved. Also we found increasing efficacy as it gets a higher proportion of undetectable VL.

A-202
DESCRIPTIVE REVIEW OF 14 MALARIA INFECTIONS IN TOLEDO AREA

M. Rodríguez Cola[1], A. Lizcano Lizcano[1], C. Navarro Osuna[1], R. Rubio Díaz[1], J. Cardenas[2], C. Velez Pérez[1]

[1]Department of Internal Medicine, [2]Department of Medical Oncology. Complejo Hospitalario de Toledo. Toledo, Spain.

Objectives: Review of epidemiology, clinical manifestations, laboratory and treatment of malaria cases diagnosed from 01/01/2005 to 30/04/2012.

Material and method: Search in digital files (e-docs) of the Hospital Virgen de la Salud (HVS) using the search parameters "malaria" and "paludismo". The cases included were diagnosed both by serology and identification of the parasite in blood. We collected age, sex, nationality, history of recent travel to endemic areas, implementation of prophylaxis, clinical and examination findings and treatment performed.

Results: Of the 19 cases found analyzed 14 that meet the parameters we search. 78.4% of patients were men, mean age 26 years and 6 months, 50% were immigrants from endemic regions with recent travel to their country of origin. 85.7% of cases made trip to endemic region, being the most frequent Mali, 14.3% being immigrants from endemic country, without achieving establish whether they had traveled recently. No patient received appropriate prophylaxis (0%). Patients had fever (100%), asthenia (50%), gastrointestinal symptoms (50%) and musculoskeletal (42.9%) and malaise (28.6%) as more frequent symptoms. 21.7% of patients no signs on physical examination. 35.7% had hepatomegaly and splenomegaly, 14.3% had hepatomegaly isolated and 14.3% had hepatomegaly with splenomegaly and jaundice. Two patients (1.4%) developed severe forms of the disease. The hemoglobin sample mean was 10,878, with standard deviation of 3,181. The mean bilirubin was 1.30, with standard deviation of 1,126. In 85.7% of individuals identified the parasite by microscopic analysis. 78.6% was identified Plasmodium falciparum and 14.3% Plasmodium vivax. As a treatment, 42.9% were performed with Atovaquone-Proguanil for 3 days; 21.4% with quinine-doxycycline and 21.4% with different combinations of antimalarial drugs.

Discussion: Malaria was officially eradicated in Spain in 1964. However, at the present time, hundreds of imported cases are registered in our country each year. Malaria is endemic throughout most of the tropics, predominate in Asia, Africa and some regions of South America. Approximately three billion people living in 108 countries who are exposed. Malaria is caused by parasites of the genus Plasmodium (P), with more than 150 species; being the most frequent P. falciparum and P. vivax, acting as a vector of the disease several species of the genus Anopheles mosquito. The incubation period for P. falciparum infection is about 12-14 days, and for P. vivax and P. ovale is also about two weeks. Groups at highest risk include young children (6-36 months), pregnant women, and travelers to malarious areas that usually have not had prior exposure to malaria parasites or have lost their immunity. Malaria should be suspected in patients with any febrile illness if they have had exposure to a region where malaria is endemic. The initial clinical manifestations are nonspecific, with fever, as the main symptom. They can also appear gastrointestinal symptoms, headache and musculoskeletal symptoms, varying depending on the species of Plasmodium parasite, parasite load and immunologic status of the patient. Diagnosis is made by microscopic examination of blood (blood smear). No method of malaria prevention is fully effective and it is always possible to get infected despite taking prophylactic medications properly. There are several types of antimalarial drugs, so the drug of choice depends on the geographic area to be visited, according to resistance pattern and species of Plasmodium.

Conclusions: Malaria should be suspected in patients with fever and history of travel to endemic regions. P. falciparum usually produces the most severe forms. It is very important to continue anti-mosquito measures and complete successfully prophylaxis, remembering that it is not fully effective.

A-203
EARLY SWITCH FROM INTRAVENOUS TO ORAL ANTIBIOTICS IN HOSPITALIZED PATIENTS WITH COMMUNITY-ACQUIRED PNEUMONIA: A RETROSPECTIVE STUDY

M. Mariano, H. Martíns, I. Baptista

Department of Internal Medicine. U.F 1.2 Hospital de São Jose. Lisboa, Portugal.

Objectives: Community acquired pneumonia (CAP) is a common and serious illness with high healthcare costs, usually treated in hospitalized patients with intravenous antibiotics to provide optimal serum levels. The duration of intravenous treatment is an important determinant of length of hospital stay. An early switch from intravenous to oral antibiotics (switch therapy) in hospitalized patients, with evidence of clinical improvement and stability, may allow early discharge, decreased of length of hospital stay, reduced drug costs and adequate patient satisfaction. Objectives: (1) characterize the population hospitalized with the diagnosis of CAP treated initially with a regimen of intravenous antibiotics, (2) assess the patients with clinical stability at day 4 and how many were submitted to switch therapy and (3) compare the clinical cure and length of hospital stay in both groups.

Material and method: Design: Retrospective study of the clinical records of patients hospitalized with CAP in a general medicine ward during 6 months (October 2001 until March 2012).

Results: From the total of 92 hospitalized patients with CAP, 86 fulfilled the study requirements, 46 were female and the mean age was 67.9 ± 3.5. The mean pneumonia severity index (PSI) score was 121.8 (class I 3.5%, II 10.5%, III 30%, IV 43%, V 13%); 59 patients had ≥ 1 comorbidities, such include chronic obstructive lung disease (37.3%), diabetes mellitus (25.4%), congestive heart failure (28.8%), malignancy (6.8%) and chronic neurologic disease (13.6%). The pathogens were identified in 18 patients (sputum 16.7%, blood 38.9%, urine antigens 44.4%) and the most common was Streptococcus pneumoniae (72.2%). Most patients received empirical amoxicillin/clavulanic acid (52%) or a cephalosporin (20%) plus macrolid. At day 4, 54 patients (62.8%) had reached clinical stability criteria (decrease in fever and respiratory rate, acceptable oxygen saturation and blood pressure), but only 11 (20.3%) were submited to switch therapy at that time. In the group of patients with clinical stability criteria that maintained intravenous therapy after day 4, 23 had PSI class IV or V, 17 patients had ≥ 2 comorbidities and 9 (17.3%) underwent a switch from intravenous to oral antibiotic subsequently, being the mean time day 6.8. The mean length of hospital stay was 7.2 days in the switch therapy patients and 11.6 days in patients with intravenous therapy. The mortality was 0% in the early switch therapy group and 4% in the others.

Conclusions: In this study, although limited by a small number of patients, early switch from intravenous to oral antibiotics in patients with CAP, clinically stable, appears to be as effective as continuous intravenous treatment and results in shorter hospital stay. The possible physician relutance to switch, seems to be related with the severity of initial presentation and comorbilities.

A-204
RADIOLOGICAL CHARACTERISTICS OF SEVERE PNEUMONIA AND COMPARISON OF EVALUATIONS BY EMERGENCY PHYSICIANS AND RADIOLOGISTS

O. Torres[1], E. Gil[1], A. Giménez[2], T. Franquet[2], S. Alfonso[2], C. Pacho[1], M. Mateo[3], D. Ruiz[1]

[1]Department of Internal Medicine, [2]Department of Radiology, [3]Emergencies Department. Hospital de la Santa Creu i Sant Pau. Barcelona, Spain.

Objectives: To assess the radiological characteristics of severe pneumonia and to compare evaluations made by emergency physicians and radiologists.

Material and method: X-rays from patients with severe pneumonia (hospital admission and CURB-65 ≥ 2) were selected from a prospective cohort of 171 adults diagnosed of pneumonia by emergency clinicians (December 2009 to May 2011). The X-rays were reevaluated by two radiologists who were blind to clinical data. Patients with Barthel Index < 60 were excluded because of concerns about poor X-ray quality and poor prognosis unrelated to pneumonia. Presence, location and resolution of pulmonary infiltrates and pleural effusion on X-rays and computed tomography (CT) were recorded. An interrater reliability analysis using the Kappa statistic was performed.

Results: A total of 75 patients met the inclusion criteria. Four of 75 X-rays considered as radiologically-confirmed pneumonias by the emergency physicians were not verified by radiologists: 2 because of poor quality X-rays, 1 lobar collapse and 1 pachypleuritis. Characteristics of the 71 patients included in the study were: age 79.3 ± 12.9 years old, 71.8% males and Fine Index 128 ± 34.8. A third of patients had healthcare-associated pneumonia. Risk factors for aspiration were recorded in 21.1% patients. Etiologic diagnosis was obtained in 57.6% patients: pneumococci in 11.3%, legionella 5.6%, P. aeruginosa 4.2%, rhinovirus 4.2% and miscellanea in 11.2%. Ten percent of patients died in hospital. The most frequent locations of infiltrates were: multifocal bilateral 32.4%, multifocal unilateral 19.7% and right lower lobe 22.5%. Radiologists reported pleural effusion in 53.5% compared to 16.9% by emergency physicians (interrater reliability: Kappa = 0.14, p = 0.123). CT was performed in 10 (14.1%) patients. Pleural effusion was right-sided in 23.9%, bilateral 18.3% and left-sided in 9.9%. Cavitations were observed in 1/71 X-rays and 1/10 CTs. Radiologic resolution was confirmed in 54.9% p within 3 months of diagnosis. Radiological findings were not associated with the type of pneumonia, a specific pathogen, or mortality.

Conclusions: Almost all severe pneumonias diagnosed by emergency physicians were confirmed by radiologists. The multifocal radiologic pattern was that most frequently observed in severe pneumonias. Pleural effusion was poorly reported by the physicians but was detected by the radiologists in more than half the severe pneumonias.

A-205
CHRONIC OBSTRUCTIVE PULMONARY DISEASE IN PATIENTS WITH COMMUNITY ACQUIRED PNEUMONIA

A. Rodrigues, J. Sequeira, F. San Martín, C. Teotónio, R. Amorim

Department of Internal Medicine. Hospital Caldas da Rainha. Caldas da Rainha, Portugal.

Objectives: The aim of the present study was to evaluate the impact of COPD as a comorbid condition on length of hospitalization, mortality during hospitalization and 30-day mortality in patients hospitalized with the diagnosis of Community Acquired Pneumonia (CAP) during the period of 2010-2011.

Material and method: The study was a retrospective study of hospitalized patients with CAP in a secondary care hospital -A protocol was elaborated based on the latest Guidelines of the Portuguese Respiratory Society, which comprised demographic variables, the proposed clinical outcomes (length of stay; death during hospitalization and 30-day mortality), stratification risk of Pneumonia through score CURB65 and PSI (Pneumonia Severity Index).

Results: Among 285 patients with CAP, 52.6% men, 47.4% women, with a mean age of 77.72 ± 12.77. About 63 had a comorbid diagnosis of COPD and 222 did not have COPD. The median length of stay was similar between the two groups 9 ± 6. Applying the PSI score, 98.6% belonged to a class > III. Applying CURB65, 95% had a score > 2, with a mean score of 3.37 ± 1.08. Etiological diagnosis could only be obtained in 22% of patients. Hospitalized patients with COPD showed more infections with Pseudomonas aeruginosa. There were 52 deaths during hospitalization, 12 cases among patients with COPD. The 30-day mortality however was superior in patients with COPD 8% versus 10% (p = 0.01).

Discussion: In the present study we found no statistically significant correlation between mortality during hospitalization and the existing comorbidity condition of COPD, as in the PORT Cohort study from which PSI derived. Nevertheless, 30-day mortality was more frequent in the group of patients with COPD. There was no correlation between the length of stay and the presence of COPD, which is probably due to the existence of other interfering variables such as age and the presence of other severe co-morbid conditions.

Conclusions: There was no statistically significant difference in mortality during hospitalization in patients with or without COPD. However, 30-day mortality was significantly superior in COPD patients. There was also no statistical difference between the length of stay, another clinical outcome evaluated. There was a statistically significant correlation between score CURB65 and the existence of COPD as a comorbidity once applying Chi-square Test (p = 0.005), which was not true for PSI (p = 0.4).

A-206
LUNG ABSCESSES IN AN INTERNAL MEDICINE DEPARTMENT

V. Romão, J. Tavares, P. Crespo, S. Calretas, R. Marques dos Santos, J. Nascimento Costa

Department of Internal Medicine. Hospitais da Universidade de Coimbra - CHUC, EPE. Coimbra, Portugal.

Objectives: Lung abscesses (AP) are necrotic parenchymal lung cavitations caused by microbial agents. It's rare and associated to a variable mortality, between 5 and 75% depending on the pathophysiology of underlying diseases. Objective: To characterize patients with lung abscesses admitted in an Internal Medicine Department between January 1, 2000 and June 30, 2011.

Material and method: A retrospective study of clinical consultation and statistical analysis.

Results: 23 patients with lung abscesses were included: 52% were men; 57% were admitted between 2009-11, 39% between 2005-08. Mean age was 72 years [27-97], 61% over 75 years. 43% came from institutions. Main diagnosis at admission time: 65% of pneumonia [43% community acquired, 13% healthcare associated and 9% nosocomial], 17% resulting from aspiration, 5% with empyema, 5% with squamous cell carcinoma, 5% of dental caries and declared alcohol, 5% of chronic obstructive pulmonary disease. Almost 78% of patients presented with more than 2 risk factors and other comorbidities, corresponding to 70% of cardiovascular diseases, 43% presented sequelaes of stroke and other neurological disorders, 22% with diabetes, and 17% had

smoking habits. 86% presented with acute manifestations. Anatomical position of abscesses: 43% at right lower lobe, 30% at right upper lobe, 24% at lower left. The agents more often found were (N = 21): 33% S. aureus methicillin-resistant (MR), 14% P. aeruginosa, 10% K pneumoniae, 10% E. coli MR, 10% with origin on oropharynx flora and 33% didn't present any isolated agent. Antibiotics: 52% were treated with piperacillin + tazobactam (PT), 48% with metronidazole (M), 29% with meropenem/imipenem, 24% of vancomycin, 19% with clindamycin, 14% and 10% with levofloxacin and ceftriaxone. The association PT + M was preferred in 29% of patients. Average duration of antibiotic therapy: 18.8 days [8-34]. Good response to therapy (apyrexia up to 7 days of antibiotic therapy) achieved in 81%. Average duration of hospitalization: 45.9 days [12-256]. Mortality was 4%.

Discussion: Although pulmonary abscess is uncommon, there has been an incidence increase in the last years. The primaries are the majority, which is according with literature (however, not resulting from aspiration pneumonia). Although the isolated agents are associated with worse prognosis, there was a good response in 79% of cases, with 96% survival rate - a good result according to the literature. All of them were prior submitted to antibiotics, which influenced the microbial results. Costs related with these admissions are high (exams, antibiotics, and length of hospital too long).

Conclusions: The incidence of pulmonary abscess increased in our sample. The characteristics of the Internal Medicine Department patients has been changing along the last years: older patients (highly dependent) and more resistant agents envolved in nosocomial infections. These are associated with worst prognosis. New discoveries and uses of antibiotic have allowed good outcomes through the last decade. On the other hand, resistant microbial agents are also consequence of misuse of these therapies. These results challenge us to plan an extensive study in order to obtain new epidemiological findings and reflect about therapeutic practice.

A-207
SERUM LEVELS OF VITAMIN D IN HIV-INFECTED PATIENTS

A. Arca[1], M. Camba[1], L. Novoa[1], J. Lorenzo[2], S. Araujo[1], H. Enríquez[1], J. Paz[1], J. de la Fuente[1]

[1]Department of Internal Medicine, [2]Department of Endocrinology. POVISA Hospital. Vigo (Pontevedra), Spain.

Objectives: Vitamin D deficiency has reported to be high prevalent in HIV-infected patients. Detectable HIV viremia, HAART therapy and ethnicity were significantly associated with vitamin D deficiency. To determine the prevalence of vitamin D (25(OH)D) in HIV-infected patients and to compare with that of HIV-negative patients.

Material and method: We performed a descriptive study in which 176 patients were included, 81 with HIV infection followed up in the office of Internal Medicine and 95 non-HIV patients, who attended the consultation of Endocrinology in a tertiary hospital in Vigo, Spain (latitude 42 ºN). Serum levels of 25(OH)D were determined by immunoassay. Vitamin D status was defined as the following: deficiency as 25(OH)D < 10 ng/mL and insufficiency as 25(OH)D 10-30 ng/mL.

Results: The average age of HIV patients was similar to non-HIV (50.4 ± 9.8 vs 48.6 ± 13.5 years). The proportion of males was significantly higher in HIV (76.5% vs 23.1%, p < 0.005). The body mass index (BMI) in HIV was 26.55 ± 4.66 Kg/m^2 and 28.52 ± 5.808 Kg/m^2 (p = NS) in HIV-negative. The median CD4 lymphocyte count was 524.16 cell/mL and 88.89% had an undetectable viral load. Median levels of serum 25(OH)D did not differ between seropositive and controls [21.5 ± 10.03 ng/ml (range 3-51) vs 23.7 ± 9.5 (range 7-55) respectively. The prevalence of deficit of 25(OH)D was higher in HIV (13.6% vs 7.4%), while insufficiency was similar (67.9% vs 69.5% p = NS). It was observed a significant inverse correlation BMI and levels of 25(OH)D in seronegative patients. Serum levels of vitamin D and the degree of deficiency were not associated with HAART.

Conclusions: HIV- infected patients have a high prevalence of 25(OH)D deficiency that does not differ significantly from seronegative controls. There were not apparent relationship between HAART therapy and serum levels of 25(OH)D.

A-208
DESCRIPTIVE STUDY OF MICROBIOLOGICAL ISOLATES IN INTERNAL MEDICINE, UNIVERSITY HOSPITAL OUR LADY OF CANDELARIA DURING THE YEARS 2010 AND 2011

S. Vicente Rodrigues[1], D. Gudiño[1], D. García[2], M. Padilla[1], L. Abella[1], J. Ode[2], P. Laynez Cerdeña[1]

[1]Department of Internal Medicine, [2]Department of Microbiology. Complejo Hospital Universitario Ntra. Sra. de Candelaria. Santa Cruz de Tenerife, Spain.

Objectives: Infectious diseases are a major problem for health services, both in economic terms (direct and indirect costs) and in terms of patients' health. The infection rate depends on each ward, the procedures performed, which antibiotics are prescribed and the local hospital microbial flora. Empirical treatment indicated for these infections depends in part on epidemiological studies of the environment in which they are found, and their antimicrobial sensitivity profiles. Objective: to study microbiological isolates in the department of Internal Medicine, Our Lady of Candelaria University Hospital for the years 2010 and 2011, and describe the antibiotic sensitivity of these isolates.

Material and method: Retrospective descriptive study of microbiological isolates from the Department of Internal Medicine, Our Lady of Candelaria University Hospital for the years 2010 and 2011, and analysis of their sensitivity profiles to commonly-used antimicrobials.

Results: In 2010, 616 isolates were obtained, the most frequent of which being Pseudomonas aeruginosa (20.8%), followed by Escherichia coli (17.5%) and Staphylococcus aureus (17.1%). In 2011, 605 isolates were obtained. The most common microorganism was Pseudomonas aeruginosa (24.42%), followed by Escherichia coli (13.2%) and Staphylococcus aureus (11.91%). In relation to the antibiotic sensitivity of different isolates, Escherichia coli had a sensitivity to carbapenems and tigecycline of 100%, a rate of quinolone resistance of 50%. There was a decrease in the resistance phenotype ESBL (extended spectrum beta-lactamase) from 19.4% to 8%. The genus Klebsiella showed a 100% sensitivity to carbapenems and tigecycline and 30-40% of resistance to quinolones. The percentage of ESBL remained stable at around 20%. Furthermore, Pseudomonas aeruginosa had a sensitivity of around 60% to the antimicrobials used empirically against this bacteria (piperacillin-tazobactam, cefepime and ceftazidime), with imipenem showing some benefit (70%). It also showed a high sensitivity to colistin (95%). Staphylococcus aureus showed 100% sensitivity to linezolid, 99% to glycopeptides (teicoplanin resistant to an isolate), a sensitivity to cotrimoxazole of 99% and an improvement in the percentage of methicillin-resistant S. aureus (MRSA) from 76% to 37%.

Conclusions: The number of isolates and the percentage distribution of different bacterial species over the two years of the study was similar. The bacteria most frequently isolated were Pseudomonas aeruginosa and Escherichia coli. Total ESBL and MRSA

decreased. These studies of epidemiology and susceptibility profiles in our area should be considered when establishing correct empirical antibiotic therapy protocols. The microbiological monitoring of infections is essential for the proper management of antibiotic therapy for the patient.

A-209
TUBERCULOUS MENINGITIS: A DESCRIPTIVE AND COMPARATIVE STUDY WITH OTHER FORMS OF TUBERCULOSIS IN VIGO (NW OF SPAIN)

J. Montes Santiago, B. Machado, V. Rodil, J. Álvarez, J. López Otero, R. Pérez Álvarez, G. Rey-García

Department of Internal Medicine. Complejo Universitario de Vigo. Vigo (Pontevedra), Spain.

Objectives: Tuberculosis remains an important health care problem in Galicia, the area with highest prevalence in Spain. The aim of this study was to describe the clinical characteristics of tuberculous meningitis (TBM) in a Healthcare Area in South Pontevedra (Vigo, NW of Spain).

Material and method: A retrospective study was performed of all patients with diagnosis of TBM in Meixoeiro Hospital, covering an urban and rural area with a population reference of 167,000 inhabitants > 14 years in the South of Pontevedra. Cases of TBM were retrieved in the period 1996-2011 from the Minimum Basic Data Set at hospital discharge (Diagnostic code 013.0 of the International Classification of Diseases 9th ed, ICD-9CM). For a purpose of comparison cases of TBM+ and without meningitis discharged at Internal Medicine Service between 2001 and 2011 were used.

Results: Thirty-two cases of TBM were studied. Clinical data are shown in table 1. We compared also 23 of these patients with TBM+ and 83 discharged in Internal Medicine without meningitis (TBM-) (2001-2011). Age [50 ± 18 (TBM+), 51 ± 21 (TBM-)] and sex [men, 61% (TBM+), 60% (TBM) were similar. VIH coinfection was higher for TBM (26% (TBM+) vs 7% (TBM-), $p < 0.05$). Mortality also was higher in TBM but that not reach statistical significance [13.0% (TBM+) vs 4.8% (TBM-); $p = 0.352$]. In the whole period 1996-2011 microbiological diagnosis was obtained only in a third of cases in CSF and in another quarter there was a sputum culture +. In this period 4 antituberculous drugs were used in 87%, corticoids in 47%, adherence was good in 75% and the global mortality was 13%.

Discussion: MTB is often difficult to diagnosis and a combination of clinical, radiological, analytical and microbiological data can afford the diagnosis. This is important because the mortality (13%) remain high, although it seems lower than other historical series (nearly 21%; Azuaje et al. Enferm Infecc Microbiol Clin. 2006;24:245-50).

Conclusions: Tuberculous meningitis is not uncommon in our healthcare area. It is often difficult to diagnose and a combination of clinical and complementary data can offer a reasonable suspicion of the diagnosis.

Table (A-209)

Nº Cases	32
Age < 65 years (%)	88
Sex (men)(%)	56
HIV + (%)	28
ADA CSF (> 6 U/l)(%)	84
CSF culture + (%)	31
PCR + (in 25)(%)	28
Death (%)	13

A-210
REVIEW OF 97 CASES OF INFECTION BY S BOVIS

K. Goenaga Pareja[1], S. Molinero Abad[2], M. Pedromingo Kus[3], M. León Téllez[4], A. Morán Bécares[1], C. Dueñas Gutiérrez[2], V. del Villar Sordo[4], J. Barragán Casas[3]

[1]Department of Internal Medicine. Hospital San Telmo. Palencia, Spain. [2]Department of Internal Medicine. Complejo Asistencial de Burgos. Burgos, Spain. [3]Department of Internal Medicine. Complejo Asistencial de Ávila. Ávila, Spain. [4]Department of Internal Medicine. Hospital Santa Bárbara. Soria, Spain.

Objectives: Streptococcus bovis is an important cause of bacteremia, infective endocarditis (IE) and septic shock in adults. We report causes of S. bovis infection in a series of patients.

Material and method: We report 97 cases of S. bovis infection amongst a range of hospitals (Ávila, Burgos, Soria, Palencia) in a region of Spain (Castilla y León). The study was conducted from 2007 through 2009.

Results: Ninety-seven subjects were included in the study. Men: 41 (mean ± SD, age = 71.6 ± 19.4). Women: 56 (mean ± SD, age 71.2 ± 15.9). Bacteremia occurred in 48 patients (pts) (49.5%); source of bacteremia was: IE (5 pts), surgical/non-surgical site infection (4 pts), peritoneal fluid (3 pts), biliary tract (1 pt), perianal abscess (1 pt), lung (1 pt), urinary tract (1 pt) and isolated bacteremia (32 pts). No bacteremia was found in 49 pts (51.5%); in these 49 cases, infection sources were: urinary tract (16 pts), surgical site infection (11 pts), non-surgical site infection (8 pts), biliary tract (6 pts), peritoneal fluid (3 pts), pleural fluid (1), synovial fluid (1 pt), ocular (1 pt), bronchial lavage (1 pt) and vaginal fluid (1 pt). Antibiogram became available in 91 patients: 90/91 (99%) were susceptible to penicillin. Our isolates showed most commonly resistance to ciprofloxacin (17/91, 18.7%) and clindamycin (10/91, 11%). Gastrointestinal cancer (cancer history or detected during the study period) was found in 22 pts (22.7%); other cancers appeared in 16 pts. Overall mortality was 21.6% (21 pts): among them, bacteremia was found in 10 cases (11 pts without bacteremia). S. bovis-related mortality was 28.6% (6/21) (all of them with bacteremia, one of them with IE). Other causes of mortality accounted for 71.4% (15/21).

Conclusions: In our study, S. bovis-infection did not predispose toward bacteremia (49.5 versus 51.5%). The most frequent origin of infection was the surgical/non-surgical site of infection (23/97: 23.7%) followed by the urinary tract (17/97: 17.5%). IE-frequency was low (5/97: 5.2%). Most S. bovis isolated were susceptible to penicillin (99%). Resistance to ciprofloxacin was 18.7%. Overall mortality was 21.6% (21/97). S. bovis-related mortality was 28.6% (6/21) (all of them with bacteremia).

A-211
REVIEW OF SHYPHILIS CASES IN A COMMUNITY HOSPITAL OVER THREE YEARS

M. Barragán González[1], P. Alonso González[2], I. Arias Miranda[1], M. Taboada Martínez[1], E. Martín Roces[1], L. Tamargo Chamorro[1], J. Alfonso Megido[1]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital Valle del Nalón. Langreo (Asturias), Spain.

Objectives: To estimate the incidence of shyphilis in our area. Make a demographic analysis, describe the main symptoms, complementary studies performed, treatment and follow-up was done.

Material and method: Retrospective and descriptive analysis made from the systematic review of medical records of patients with positive serologic test for shyphilis; non-treponemal-test

Table 1 (A-211). Age distribution

Number of cases	1	6	4	3	2	0	1
Age (years)	< 20	20-30	31-40	41-50	51-60	61-70	> 70

Table 2 (A-211). Symptom guide to diagnosis

Bone lesion	Visual disturbance	Genital ulcers	HIV protocol	Risk sexual contact	Neurological symtpom	Skin lesion
1	1	2	2	3	3	5

(Veneral Disease Research Laboratory; VDRL/ rapid plasma reagin;RPR) and treponemal-specific tests (Treponema Pallidum Haemagglutination; TPHA) between the years 2009 to 2011 in a community hospital.

Results: We found 17 patients with reaginic and no reaginic positive serology for shyphilis in our area in the three years. The annual incidence was 8.75 cases/100,000 hab in 2009, 5 cases/100,000 hab in 2010 and 7.5 cases/100,000 hab in 2011. The distribution was: 15 males and 2 females, the highest prevalence is observed between 20 and 50 years old, cutaneous manifestations are the predominant symptom leading to diagnosis. Human immunodeficiency virus (HIV) serology is requested for all patients but not hepatitis B virus (VHB) serology although both share the same pathway of transmission. Lumbar puncture is performed to rule out neurosyphilis in 7 patients (only 1 case positive). After diagnosis 10 patients were untreated (3 had been treated, 3 were treated by their primary care physician and 1 patient was followed up). All patients were treated with penicillin. 9 patients failed to follow up. Of the 8 patients followed up only 1 patient had no reduction in non-reaginic antibody titers.

Discussion: The incidence of syphilis in our area is higher than average incidence in our country. The clinical presentation is highly variable but ulcer or chancre at the infection site at onset of illness and maculo-palular skin lesions on the trunk, palms and soles in the secondary phase are characteristic. Differential diagnosis with other sexually transmitted diseases is required and screening for gonorrhoea, chlamydia, hepatitis B, and HIV is mandated. The most common diagnosis is serological; treponemal tests are more specific and usually remain positive for years, non-treponemal test are used to monitor disease activity and treatment efficacy, also is performed in cerebrospinal fluid to rule out neurosyphilis. All new diagnosis of syphilis should be treated, penicillin is still the treatment of choice for all stages. Monitoring should be done to rule out treatment failures.

Conclusions: Syphilis incidence is rising all around the world since 2000 due to increase of unsafe sex practices. The clinical presentation is heterogeneous and Physicians in all specialties need to be able to recognise the signs and symptoms of a disease that was believed close to disappear.

A-212
HIGH RATE OF EXTENDED-SPECTRUM BETA LACTAMASE-PRODUCING IN BACILLI GRAM-NEGATIVE BACTERAEMIAS

A. Sousa Domínguez[1], M. Pérez Rodríguez[1], R. Longueira Suárez[1], A. Argibay Filgueira[1], A. Martínez Vidal[1], A. Rodríguez Gómez[1], L. Martínez Lamas[2], C. Martínez Vázquez[1]

[1]Department of Internal Medicine Department. Infectious Disease Unit, [2]Microbiology Department. Complejo Universitario de Vigo. Vigo (Pontevedra), Spain.

Objectives: Gram-negative bacilli (GNB) are the second most frequent group of microorganisms isolated in blood cultures. The aims of the study were to determine the clinical, therapeutics and microbiological characteristics of GNB isolated in blood cultures and to identify mortality-associated risk factors.

Material and method: GNB bacteraemias, in patients older than 15-year-old, were prospectively gathered between January and December 2011. Epidemiological characteristics, source of infection, empirical treatment as well as appropriate antibiotic and evolution were reviewed. Bloodstream infections were classified as community-acquired bacteraemia (CAB), nosocomial bacteraemia (NB) or health-care associated bacteraemia (HCAB).

Results: Two hundred and three GNB bacteraemia were identified during the study period. They were classified as CAB 46%, NB 33% and HCAB 21%. The mean age of the patients was 65 ± 17.0 years in NB, 74 ± 16.8 years in CAB and 69 ± 14.2 years in HCAB p = 0.0001) and 50% were male. Most frequent sources of infection in CAB were urinary (25% NB, 59% CAB, 41% HCAB, p = 0.0001) and biliary tract (9% NB, 20% CAB, 2% HCAB, p = 0.012) and catheter-related bloodstream infection (CRBSI) in NB and HCAB (28% NB, 1% CAB, 21% HCAB, p = 0.0001). No differences were found in abdominal source of infection prevalence between the three groups (22% NB, 13% CAB, 19% HCAB, p = 0.37). The most common empirical treatment was beta-lactam antibiotics, especially in CAB group (37% NB, 75% CAB 50% HCAB, p = 0.0001), followed by carbapenems in NB (54% NB, 16% CAB, 38% HCAB, p = 0.001) and quinolones (8% NB, 13% CAB, 15% HCAB, p = 0.44). Antipseudomonal antibiotics were used in 56% of cases (75% NB, 33% CAB, 65% HCAB, p = 0.0001). Empirical treatment was inappropriate in 17% of cases (22% NB, 13% CAB, 22% HCAB, p = 0.32). Microorganisms isolated were E. coli (59%, 39% NB, 79% CAB, 48% HCAB, p = 0.0001), E. cloacae (7%; 6% NB, 3% CAB, 18% HCAB, p = 0.007), K. pneumoniae (6%), S. marcescens (4%), P. aeruginosa (4%), A. baumannii (3%), P. mirabilis (3%). The 20% of isolated GNB were quinolone-resistant (24% NB, 15% CAB, 23% HCAB, p = 0.34) and 3% carbapenems-resistant (all of these were NB: 2 P. aeruginosa, 4 A. baumannii, and 1 B. cepacia). Eleven GNB were multidrug-resistant (9% NB, 2% CAB, 7% HCAB, p = 0.16). From a total of 120 E. coli, 18 (15%) were extended-spectrum beta-lactamase producing (ESBL) (27% NB, 11% CAB, 14% HCAB, p = 0.15). Risk factors for ESBL E. coli were prior antibiotic (OR 3.6, IC 1.3-10.2) and prior quinolone therapy (OR 7, CI 1.6-31.2). Among these patient inappropriate antibiotic was more frequent (47% vs 8%, p = 0.001), however mortality rate was similar (17% vs 12%, p = 0.7). Thirty three of patients died (16%), with a high rate among NB and HCAB (22% NB, 9% CAB, 23% HCAB, p = 0.03). Risk factors associated with mortality were ICU-stay (OR 4.5, CI 1.81-11.19) and prior antibiotic therapy (OR 2.4, CI 1.15-5.2). Nevertheless, association between mortality and inappropriate empirical treatment could not be demonstrated (27% vs 17%, p = 0.31).

Conclusions: High rate of ESBL E. coli bloodstream infections was detected, especially in nosocomial bacteraemia. Risk factors for ESBLE were prior antibiotic and prior quinolone therapy. Inappropriate therapy rate was elevated in patients with ESBLE, although this was not associated with higher mortality.

A-213
EPIDEMIOLOGY, CLINICAL AND ANALYTICAL CHARACTERISTICS OF AN OUTBREAK OF TRICHINOSIS IN THE AREA OF TOLEDO

M. Fernández, A. Gallegos, M. de Vicente, L. de Matias, M. Vázquez, J. Magallanes, K. Marin, F. Marcos

Department of Internal Medicine. Hospital Ntra. Sra. del Prado. Talavera de la Reina (Toledo), Spain.

Objectives: To analyze the clinical, analytical and epidemiological characteristics of patients of an outbreak of Trichinella spiralis in Toledo (Spain), in February 2012.

Material and method: All the potential patients were identified based on a list of all the Trichinella's serology tests requested in our area during February and March 2012. We reviewed the symptoms and indications taken from the medical histories, both of Primary Care and the Hospital (admissions to the Hospital, visits to the Emergency Department and visits to the Internal Medicine outpatient clinic). We collected the values of the liver function tests, the presence of eosinophyilia and the results of the serologic tests of each patient. Every patient was classified as a confirmed case (epidemiological contact, compatible clinical symptoms and/or laboratory results, and a positive serology), or a probable case (negative serology) depending on the results. Treatments were compared with the standard recommendations and the response to those therapies was analyzed.

Results: Among the 39 patients to whom serology tests were requested, two were excluded from the study because there was no clinical history recorded. Among the remaining 37, there were 21 men and 16 women, with ages between 7 and 84. They all had the same epidemiological contact: ingestion of meat of a wild boar during a family celebration. The most frequent symptoms were fever (43.24%), myalgias (37.83%) and facial edema (29.72%). Nine of the 37 patients were asymptomatic (only 2 with positive serology). Three patients were admitted to the Hospital; one due to exacerbation of severe COPD in relation with the polymyositis produced by T. spiralis, and two due to severe polymyositis and fever in relation to trichinosis. There were no cases of myocarditis or encephalitis nor of death. 32.5% of the cases had eosinophilia and 51% had an increased CK and/or AST/ALT. We identified 11 cases as confirmed and 13 as probable. Not all probable cases had a second serologic determination performed. The remaining 13 cases, although having had epidemiological contact, did not present any symptoms, abnormal laboratory results or a positive serology. The most commonly used anti-parasitic drug was mebendazol. 78% of the confirmed cases received anti-parasitic treatment (5% with corticosteroids). In 2 cases the specific treatment received was not recorded. Among the probable cases, 53% were treated and only one received corticosteroids.

Discussion: Compared with other published series, the type of predominant symptoms is similar with the exception of migraine that was only present in one of the patients of our study. We have not measured the time from the epidemiological contact to the appearance of symptoms because, in most cases, it had not been registered by Primary Care. On the other hand, the clinical evolution with or without treatment has been favorable in all cases regardless of the treatment chosen. No relation between the severity of symptoms and the title of antibodies has been documented. Two cases that were admitted into the Hospital due to trichinosis, corticotherapy was used for more than five days. The third case, an exacerbation of COPD, could be discharged without having received any anti-parasitic treatment. On the other hand, it's presumable that if a second normalized serology test had been performed to all patients, many of the probable cases could have been confirmed and probably some of them in which the diagnosis of trichinosis was discarded would also have had positive serology.

Conclusions: Preventive measures both in animals of farm and in meat obtained hunting to avoid the consumption of contaminated meat, are very effective to avoid new outbreaks of trichinosis and are customarily performed in our country. The current economic situation of our country favors poaching in many rural areas as ours, which turns an economic problem into a public health problem.

A-214
MEASUREMENT OF SCD14, IL-6, HIGH SENSITIVE CRP, CHITOTHYROSDASE AND PROCALCITONIN LEVELS IN PATIENTS WITH DIABETIC FOOT AND EFFECTS OF HBO THERAPY ON THESE MARKERS

E. Arslan[1], A. Karakas[2], S. Demirbas[1], H. Yaman[3], Ö. Coskun[2], S. Yildiz[4]

[1]Department of Internal Medicine, [2]Department of Infectious Diseases, [3]Department of Clinical Chemistry, [4]Department of Undersea and Hyperbaric Medicine. Gülhane Military Medical Academy. Ankara, Turkey.

Objectives: Foot infections in patients with diabetes are common and are associated with high morbidity, risk of lower extremity amputation and the length of hospitalization as well. Diabetic foot infection is often a clinical diagnosis. Systemic symptoms are not always on the foreground. In this study, we aimed to measure levels of SCD14, IL-6, high sensitive CRP (hsCRP), chitothyrosdase and procalcitonin in patients with diabetic foot and to investigate the effects of HBO therapy on these inflammatory markers.

Material and method: The study was designed retrospectively. 30 patients admitted with complaints of leg ulcers, pain, swelling, increased heat, and discharge from wound and diagnosed as diabetic foot infection (DFI) were included in the study. Of these patients, at baseline (prior to antibiotic therapy and HBO), on 15th and 30 days (10th and 20th sessions) blood samples were taken for sCD14, IL-6, hsCRP, chitothyrosdase and procalcitonin levels. Patients received a total of 20 HBO therapy sessions. Sessions were conducted in a 120-minute 5 days per week program at 2.4 ATA. sCD14, procalcitonin, and I-L6 levels were studied by ELISA. Analyses were performed for serum CHT enzyme activity according to the method described by Tunc et al. The measurements of hsCRP were performed by using CRP latex kit with an Olympus AU 600 auto-analyzer and reagent from Beckman Coulter (Brea, CA, USA). The data were evaluated with SPSS 15.0 software. In identification of data, mean ± SD, median, and quarters (1-3 quarters) were used. Friedman test was used for comparing multiple measures within the group, and a Bonferroni corrected Wilcoxon test was used for posthoc comparisons. $p < 0.05$ was accepted as statistically significant.

Results: Mean ages of patients were 29-80 years (mean ± SD, 61.97 ± 11.70). 22 patients were male and eight were female. Diabetes age of patients ranged between 4-30 (17.63 ± 5.73). Most patients (13 people) had Wagner third degree wounds. Serially obtained measurements of sCD14, IL-6, hsCRP, chitothyrosdase and procalcitonin were shown in Table 1. There was a statistically significant difference between baseline and at the result of treatment IL-6 levels ($p = 0.041$).

Conclusions: HBO therapy added to appropriate antibiotic therapy significantly reduced IL6 levels on 15th and 30th days. Although no significant change in hsCRP occurred, at 15th and 30th days, a reduction in accordance with the days of treatment were observed. All these data suggest that appropriate antibiotic therapy, with additional HBO therapy can reduce inflammation.

Table 1 (A-214). SCD14, IL-6, hsCRP, chitothyrosdase and procalcitonin levels measured in diabetic foot patients

	Before HBO		15th day		30th day		
	Orl ± ss	Median (1st-3rd)	Orl ± ss	Median (1st-3rd)	Orl ± ss	Median (1st-3rd)	p*

PNEUMOCYSTIS JIROVECII IN ACUTE INTERSTITIAL PNEUMONIA

M. Martínez-Rísquez[1], B. Herrera Hueso[1], M. Calero Bernal[1], R. Terán Redondo[1], A. Calzada Valle[1], R. García Contreras[1], J. Varela Aguilar[1], N. Respaldiza Salas[2]

[1]Department of Internal Medicine, [2]CIBER of Epidemiology and Public Health. Hospital Virgen del Rocío. Sevilla, Spain.

Objectives: Acute interstitial pneumonia (AIP) is a rare and fulminant form of diffuse lung injury. It is characterized by the presence of diffuse alveolar damage and rapid progression to severe respiratory failure, which leads to the need of mechanical ventilation in most cases. AIP etiology is unknown, although it has been proposed that infectious agents act as the trigger of the process. Also, recently it has been shown the presence of P. jirovecii colonization in a high percentage of patients with idiopathic interstitial lung diseases; however the presence of this pathogen in AIP remains still unknown. Therefore, this study aims to investigate the presence of P. jirovecii in AIP patients.

Material and method: We identified all cases of biopsy-confirmed AIP treated in our hospital during the last 10 years with available samples of bronchoalveolar lavage (BAL). The presence of P. jirovecii was studied by PCR, using primers for the large mitochondrial subunit gene of this organism. Positive and negative controls in each case were used together with a direct sequencing for establishing the genotype.

Results: We identified 5 cases of AIP (only one female) aged between 48 and 75 years. In 4 cases the symptoms developed in less than a week and all of them suffer from severe respiratory failure without hypercapnia. In all cases admission was required into the intensive care unit and mechanical ventilation. One patient had previous history of "Sicca syndrome" and focal segmental glomerulonephritis treated with oral corticosteroids. The female patient had a breast adenocarcinoma five years prior to the study, treated with radiotherapy plus tamoxifen and was in complete remission when AIP occurred. There were no cases of HIV infection and microbiological culture of BAL samples were negative in all cases. The presence of P. jirovecii DNA was indentified in all 5 cases. Two of them corresponded to the genotype 1 and two to the genotype 3. For the remaining one no amplification was achieved sufficiently for sequencing. Only two of the patients received empirical treatment with cotrimoxazole, one of them was the only survivor to the episode of AIP.

Conclusions: Our data suggest a possible role of P. jirovecii in the development of AIP. However, additional studies are necessary in order to unravel the role of P. jirovecii infection in the pathophysiology of AIP that allow us to design rational strategies for prevention and treatment.

A-216
EMPIRICAL ANTIBIOTICS TREATMENT IN SEVERE SEPSIS

C. Sánchez Marcos[1], J. González del Castillo[2], V. Isernia[1], G. Sotres[1], M. Nuñez Orantos[1], F. Martín-Sánchez[2]

[1]Department of Internal Medicine III, [2]Emergency Department. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: Study the factors which determine empirical antibiotics prescription in patients with severe sepsis at a hospital.

Material and method: We performed an observational, retrospective, non interventionist, cohort analysis in patients who were admitted to emergency room with severe sepsis (infectious fever with systolic blood pressure < 90 mmHg). All the data concerning about geographic variation, coexisting conditions, medications, risks factors of an infection with multidrug –resistant organisms and the results of microbiological diagnostic procedure and hospital mortality were obtained from the clinical charts of emergency room.

Results: 51 patients were included. The mean age was 69 years. Patients with 2 or more chronic disease were 13 (25.5%); 34(66.7%) had one risk factor for multidrug-resistant organisms. The respiratory tract was the most frequent infection (46%), following Urinary tract infection (18%). Patients with organic dysfunction were 16 (31.5%). In relation with the initial approach with empirical antibiotic treatment for communitary microorganism, multidrug-resistant organisms and specific microorganism was 32 (63%), 18 (35%) and 1 (2%), respectively. The total number of blood cultures obtained in emergency room were 47 (94%). The cases of isolation microorganisms were 32 (62.7%); 6 (11.8%) were multidrug-resistant organisms. The antibiotic was change in 22 patients (51%) when they were admitted for hospitalization floor. When we evaluated the reasons to receive the empiric antibiotic in emergency department, we concluded that the organic failure was the most important factor (p = 0.032) regardless other risk factor. There was a trend toward statistically significance between death and multidrug-resistant organism (p = 0.002). It occurred independently of organic dysfunction.

Discussion: Several prospective cohort studies in patients with bacteremia, both community and nosocomial infections, have shown the inadequacy of antibiotic therapy (AB) substantially increases mortality in seriously ill patients. Previous dose of AB, severity of infection and bacteremia are described in literature as independent risk factors of inadequacy. Inappropriate treatment delays the onset of effective therapy, increasing mortality and morbidity. Treatment guidelines for dealing with sepsis patients advise to establish a broad-spectrum antibiotic treatment in patients with septic shock. The presented study shows that prescription of empirical antibiotic treatment in emergency department is essentially based on the severity of the process in which case guidelines advise to expand the antimicrobial spectrum. In our series, cephalosporins (26.76%) and carbapenems (21.13%) are broad-spectrum antibiotics commonly used. It is interesting to

highlight that hospital mortality was associated with isolation of a multi-resistant pathogen. Despite establishing broad-spectrum empirical treatment in the most serious ill patients, 19.6% of the patients died (10) by multi-resistant pathogens. It was found a statistically significant association between hospital mortality and the presence in isolation of a microorganism multi-resistant (p = 0.002) regardless of the data of organ failure. We want to highlight that AB empirical treatment was changed in a large percentage of patients, although this change was made once culture results were known, what showed up that doctors from different units (Emergency and Internal Medicine) had the same initial criterion in the antimicrobial selection.

Conclusions: In our study, the choice of empirical antibiotic treatment at admission to emergency room of patients affected of severe sepsis is based upon data of organic dysfunction without taking into account the site of infection, comorbilities or risk of an infection with multidrug –resistant organisms. This point is important considering the currents reports talking about hospital mortality and the isolated multidrug-resistant organisms.

A-217
NUMBER CASES CAUSED OF FATAL PNEUMONIA CAUSED BY STREPTOCOCCUS PYOGENES (SP) DURING WINTER OF 2012 IN A SPECIALIZED HOSPITAL FROM SAS

V. Manzano Román, G. Ruiz Villena, S. Romero Salado, R. Aranda Blázquez, V. Lechuga Flores, M. Guzmán García, E. Sánchez Relinque, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: Infections caused by SP can be fatal and even became to death in a short time. Our goal is to know the clinical profile and development of patients (pt) with severe SP pneumonia in our Centre.

Material and method: Patients hospitalized with SP pneumonia from January-March were included. Variables studied: age, sex, admission department, comorbidity, symptoms, treatment and clinical develop. Data were analyzed using descriptive study.

Results: 4 patients with fatal SP pneumonia requiring ICU admission were analyzed. 4 patients (50% men) between 11 to 64 years old. 100% referred from Emergency department. Symptoms: 100% fever, 75% cough, 75% hypotension, 50% chest pain and brokenness, and individual clinical: diarrhea, hemoptysis and epistaxis. Comorbidity: a patient treated with MTX for psoriasis, two patients with cardiovascular risk factors (HTN, DM, dyslipidemia), and the youngest without known risk. Treatment initiated: Pt 11 years old: piperacillin/tazobactam as empirical therapy, it was subsequently replaced by ampicillin, gentamicin, cloxacillin. Pt 41 years old was treated first with ceftriaxone and levofloxacin; being afterword clindamycin specific therapy. Pt 42 years old was treated first with levofloxacin, ceftriaxone, linezolid and fluconazole. Due torpid develop ceftriaxone was retired and clindamycin and meropenem were included. Finally specific therapy was piperacillin/tazobactam. Pt 64 years was empirical treatment with clindamycin and ceftriaxone, he had good evolution clinical. The average time spent on ICU was 19 days on 75% of patients. Develop: three of them had slow but favorable course (two Pt required MV and pleural drainage); the youngest died.

Discussion: The 4 SP bacteremia case patients referred from Emergency service showed similar sex distribution with 39 years old as average age. Main symptoms: 100% fever, 75% cough and hypotension, 50% chest pain and brokenness. First-line empirical antibiotic therapy was ceftriaxone + levofloxacin in 50% of cases; in 25% was decided to chosen piperacillin/tazobactam and the rest of them were clindamycin + ceftriaxone. Develop was slow but favorable in 75% and 25% died.

Conclusions: It is very important to know the initial clinical of fatal SP pneumonia consistent in fever, chest pain and cough. It has quick and sever course with respiratory and systemic symptoms. Pneumonia complications may include: 75% pleural drainage, 50% toxic shock syndrome and 25% death. The X-rays is very characteristic: shows pneumonic infiltrate on lower lobes (LL) and pleural effusion. Therefore in patient with pneumonia in LL and sudden development of pleural effusions should be suspected SP infection. The mortality rate remains very high despite with antibiotic therapy rapid and appropriate.

A-218
PYOMYOSITIS (PM): THE THREE LEAVES OF A CLOVER

M. Pedromingo Kus, C. Machado Pérez, O. Abdallaoui Ellachoub, M. Álvarez Moya, M. Martín Casado, J. Barragán Casas, J. Molina Puente, D. Sánchez Fuentes

Department of Internal Medicine. Hospital Nuestra Señora de Sonsoles. Ávila, Spain.

Objectives: PM is a suppurative infection of the skeletal muscle; it mainly presents as pain and swelling of the involved muscles, with or without fever. Complications may occur. PM has good prognosis if treated properly. The mainstay of treatment is antibiotics and drainage of the abscess. We review three cases of complicated PM.

Material and method: We describe three patients with community-acquired PM caused by methicillin-sensitive S. aureus (MSSA) who presented to our hospital with joint pain, myalgias and/or fever. MSSA bacteremia was in all cases associated. Complete recovery was finally obtained under antibiotic treatment. In patient 1, a 76-year-old-woman with no medical history, the diagnosis of PM, septic pulmonary embolisms and osteomyelitis led us to the discovery of an underlying primary immunodeficiency disease. Patient 2 was an 18-year-old man who had presented to the emergency room with low back pain 5 days before the final diagnosis was established and treatment initiated. His medical records only revealed a dental procedure a month ago with periodontal abscess formation; no antibiotic intake was initially prescribed. He developed bilateral iliopsoas abscesses and septic shock. Patient 3 was a 66-year-old retired farmer-man with no medical problems apart from an anal fistulotomy 30 years ago. He had had pain and swelling in both shoulders for one week, and fever. Imaging studies revealed C6-C7 spondylodiscitis with right prevertebral abscess. A right gluteal abscess appeared after an intramuscular injection during medical care.

Results: Diagnosis and complications in all patients were studied, making use of imaging and laboratory studies. In all three patients blood cultures grew MSSA and muscle involvement was found. In one patient, IgG-kappa monoclonal gammapathy diagnosis was made. Another patient had a dental procedure history. The last patient did not refer any medical records. All patients cured under systemic antibiotic treatment. Only one patient needed drainage. No patient died in our report.

Discussion: PM rarely presents as a primary condition in immunocompetent patients, where the diagnosis is usually delayed. Many other factors increase the risk of developing this condition. Regarding our patients, only one of them was found to be immunocompromised, another one had a portal of entry and the other one had no risk factors. S. aureus is the most common organism isolated. Our review found MSSA infection in all cases. In two of our cases diagnosis was delayed. Any muscle can be affected; in all of our cases, extensive multifocal fluid collections were demonstrated. MRI is considered the gold standard in the

diagnosis of PM, as it was conducted in all of our patients. Ultrasound is helpful in the suppurative phase as demonstrated in our patients. Incision and drainage of the involved muscles, although essential in the vast majority of reported cases, was only performed in one of our patients, with successful and complete illness recovery in all of them. The three of our patients developed complications as described in previous clinical reports. Although mortality is described as high as 10%, no patient in our report deceased.

Conclusions: PM should be nowadays kept in mind in every patient attending for muscle pain, swelling and/or fever, regardless the risk factors. We propose correct and early staging of the illness using imaging and laboratory studies. Early antibiotic treatment should always be initiated.

A-219
EXTENDED-SPECTRUM BETA-LACTAMASE-PRODUCING ENTEROBACTERIACEAE: RISK FACTORS FOR INFECTION

N. Cubino Bóveda, A. Romero Alegría, E. Puerto Pérez, J. Martín Oterino, P. Miramontes González

Department of Internal Medicine. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca, Spain.

Objectives: To identify risk factors for infection with ESBL-producing Escherichia coli and Klebsiella pneumoniae and to determine whether clinical outcomes differed among patients with infections caused by resistant organisms and other patients with infections caused by susceptible organisms.

Material and method: This is a retrospective review of all extended-spectrum betalactamase-producing Eschericha coli insolated in our department (Internal Medicine in Universitary Hospital of Salamanca) for two years. All patients for whom culture results were positive for ESBL-producing E. coli from January, 1st 2010 to December, 31th 2011 were eligible for inclusion in the study. Potential risk factors for ESBL-producing E. coli infection were ascertained by means of a review of medical records. Data obtained included age, sex, number of hospital and ICU days prior to infection, and severity of illness, as calculated by means of the Acute Physiological and Chronic Health Evaluation (APACHE) II score. The presence of a central venous or arterial catheter, urinary catheter, or mechanical ventilation was also assessed. Finally, all antimicrobial therapy that was administered in the 30 days prior to admission was documented.

Results: There were 51 cases, 35.29% (18) women and 64.70% (33) males; the mean age was 81.1 years. The average stay in hospital was 25 days (in our hospital is 12.4 days). The 23.5% had arterial or venous central catheter and 76.4% the urinary catheter. Only 5.88% had required ICU admission and mechanical ventilation. 64.7% had received prior antibiotic treatment with amoxicillin and/or quinolones. The average APACHE II score was 12.52 points. The 76.47% of the patients were institutionalized.

Discussion: ESBL-producing Enterobacteriaceae have been reported worldwide, most often in hospital specimens but also in samples from the community. Generally they have been isolated in older people older than 80. Risk factors for ESBL-producing E. coli infection were catheterized bladder, being institutionalized and having received prior antibiotic treatment.

Conclusions: ESBL-producing Enterobacteriaceae are becoming a public health problem, with high economic cost because it increases the hospitalization and use of broad spectrum antibiotics. The age of patients, the presence of urinary catheter and taking antibiotics often seem the most determinant risk factors for these infections, and they should be considered for the choice of empirical antibiotic therapy in severe infections.

A-220
EPIDURAL ABSCESS: RETROSPECTIVE STUDY IN HOSPITAL DEL MAR BARCELONA IN THE PERIOD BETWEEN 2001-2011

S. Herrera, R. Soriano, E. Esteve, L. Vilaplana, M. Yagüe, R. Peccorelli, D. Molina

Department of Internal Medicine. Hospital del Mar. Barcelona, Spain.

Objectives: Primary: To analyse the frequency, clinical and microbiological features of epidural abscess in Hospital del Mar de Barcelona. Secondary: To analyse the etiopathogenic mechanism, incidence of neurological deficits at discharge and mortality of epidural abscess.

Material and method: Retrospective study of patients with the diagnosis of epidural abscess (spinal o intracraneal). Clinical records of all patients that have been coded for epidural abscess by the ICD.6 CM during the period between January 1st 2001 and 31st December 31st 2010 have been reviewed.

Results: Nine cases were included (6 women and 3 men, mean age 59, range 25-82). The average time between onset of symptomatology and first consult was 6 days. The average hospital stay was of 54.8 days (5-286). Four patients had back pain, 5 fever and 4 neurological deficit. There were no deaths but 1 case still had neurologic deficit at discharge. The first image technique used was MRI in 8/9, CT 1/9. The microbiological agent was recovered by CSF culture in two cases, direct puncture of the abscess in one case and the rest by surgery. The ethiological agent was S. aureus in 6 cases (of which one methicilin-resistent), Staph schleiferi in one case, and in two cases no germ was identified. In 6 cases treatment with betalactamics was initiated. The mean duration of the treatment was 7 weeks. The origin of the infection was previous spine surgery in 3 patients local instrumentation in 2 and 4 had concomitant infections. The location of the abscess was in the cervical spine in 4 cases (C2-D2), 2 lumbar (L2-S1), 2 intracranial and 1 dorsal (D4-D5). The mean of segments affected was four. Seven patients suffered complications (1 fistulization, 1 meningeal affection, 1 spodylodiscitis, 1 septic bone affectation, 2 infections of surgical wound, 1 osteomielitis, 1 pleural effusion).

Discussion: Epidural abscess is a rare but severe entity. In our series the typical clinical trial was infrequent and the diagnosis was made by image techniques. The most common germ was S. aureus related with previous surgery in half of the cases. In our series there were no deaths, and the time-to-diagnosis and length of antimicrobial treatment shorter than what is reported in the literature. This is probably because the post surgery/instrumentation origin in 5 out of 9 cases and the high rate of germen identification. Both location and extension were as usually described. There were no deaths due to epidural abscess in our series, even though high number of complications and large hospital stay have been observed.

Conclusions: Epidural abscess is a rare but severe entity. Early diagnosis and treatment are key for improving the prognosis and reducing the long-term consequences.

A-221
SIGNIFICANCE OF EOSINOPHILIA IN IMMIGRANTS IN THE NORTH METROPOLITAN AREA OF BARCELONA

A. Ballesteros[1], S. Roure[2], T. Falgueras[3], A. Calderón[3], R. Benítez[1], J. Vila[1], L. Valerio[2]

[1]Department of Internal Medicine, [3]Department of Microbiology. Badalona Serveis Assistencials. Badalona (Barcelona), Spain. [2]International Health Unit Metropolitan North. Institut Català de la Salut. Barcelona, Spain.

Objectives: To assess the incidence of eosinophilia in our experience and to describe the illnesses with which it is associated.

To check the efficacy of our diagnostic protocol & the benefits of the therapeutical approach.

Material and method: A retrospective review from database of patients with eosinophilia (2 determinations > 450 Eos/µl) detected between 2008-2011 at International Health centers, in the Northern Barcelona metropolitan area. The diagnostic protocol included a minimum of 3 stool samples (specific culture for Strongyloides), parasite urine examination, IgE & parasitic serology according geographical origin. Time interval since their arrival to Europe, final diagnose & efficacy of treatment were analyzed.

Results: We visited 727 patients [mean age 35.4 (SD 13.2); male 389(53.5%)]. Origin: South America 290 (39.9%), Africa 255 (35.1%), Asia 160 (22%), Europe 18 (2.5%), Oceania 3 (0.4%), North America 1 (0.1%). Eosinophilia was detected in 58 (8.0%): South America (28), Africa (13), Asia (16) & Europe (1). -Three patients showed high eosinophilia (> 3,000 Eos/µl): 2 Pakistanian with Ancylostoma duodenale (1 normalized & 1 lowered eosinophils after treatment); 1 HIV Dominican woman with lack of adherence & control, affected by an endomyocardial thrombus and stroke (possibly consequence of the very high level of eosinophilia) in which empirical treatment with ivermectine was uneffective. Other 32 patients showed moderated eosinophilia (1,000-3,000 Eos/µl): helmintiasis was detected in 22 of them (15 Strongyloides, 1 Schistosoma spp, 3 Uncinariasis, 1 Toxocara, 1 Ascaris lumbricoides, 4 Mansonella pertans) of which 11 normalized (50%), 5 lowered, 1 persisted eosinophilia & 5 missed follow-up; 2 patients with asthma normalized after exacerbations; 1 case with tuberculosis; 7 cases with no specific etiology of which 6 missed follow-up. -The remaining 23 patients had low levels of eosinophilia (< 1,000 Eos/µl): parasitic infection was found in 11people (5 Strongyloides, 3 Dientamoeba fragilis, 1 Schistosoma spp, 1 Hymenolepis nana, 1 Echinococcus granulosus, 1 Ascaris lumbricoides, 1 Mansonella pertans) of which all normalized after treatment except 2 follow-up losses; 1 had asthma, 1 urticaria, 1 coincidental tuberculosis, all 3 with resolved eosinophilia; from 9 patients without a justifiable cause in 6/9 eosinophils normalized spontaneously. Overall, from the 35 cases with parasitic infection, 20 (55.5%) normalized eosinophilia after etiological treatment, 7 (20%) still had levels above normal range and the remaining 8 (22.9%) missed follow-up. 29 people have lived in Spain for > 5 years and 30 migrated more recently. Degree of eosinophilia was slightly higher in the last group, without reaching significance (1,201.1 vs 1,697.3, respectively; p = 0.07). Although diagnostic efficacy was similar (75.8% and 71.0%), in recently arrived patients the cause of eosinophilia was usually related to parasitic infection, while in longer staying people asthma, urticaria and tuberculosis were the only alternative cause in 17.2%.

Discussion: Eosinophilia is a frequent challenge for physicians dealing with foreign population. An appropriate assessment is required for detection of potentially harmful pathologies. As follow-up of immigrants is sometimes difficult, a quick evaluation is needed.

Conclusions: A systematic approach to eosinophilia in immigrants is helpful. Recently arrived immigrants displayed slightly higher levels of eosinophilia. With higher levels of eosinophilia is more likely to achieve a specific diagnostic. Parasitic infection can be present in recently arrived or in long stay foreigners. Low eosinophilia might normalize spontaneously.

A-222
MODIFICATIONS OF LIPIDS FRACTIONS OR THE CREATININE CONCENTRATION IN HIV-INFECTED PATIENTS TREATED WITH MONOTHERAPY

I. Ríos Holgado, A. Fernández Rodríguez, A. Martín Aspas, F. Brun Romero, R. Pérez Cano, F. Guerrero, M. Márquez, J. Girón González

Department of Infectious Diseases. Hospital Universitario Puerta del Mar. Cádiz, Spain.

Objectives: Protease inhibitor monotherapy is a recognized option in the treatment of human immunodeficiency virus (HIV) infection, either because of simplification of triple therapy, either by secondary effects induced by nucleoside analogues inhibitors of the reverse transcriptase. The objective was the analysis of the modifications of lipids fractions or the creatinine concentration in a sample of HIV-infected patients, treated with monotherapy.

Material and method: Forty six HIV-patients (median age, 47, interquartile range (IQR) 42-51 years; male sex 34 patients (74%); drug users as risk factor, 19 (41%), time from HIV diagnosis, median 20, IQR 10-24 years; hepatitis C virus coinfection, 32 patients (70%), CDC stage C 16 (35%) in monotherapy treatment with either ritonavir-potentiated lopinavir (16, 35%) or darunavir (30 patients, 65%) were studied. Causes of change to monotherapy treatment were simplification (27 cases, 59%) or nucleoside analogues secondary effects (19, 41%). All of them showed undetectable HIV load at the moment of change to monotherapy. Total cholesterol, HDL- and LDL-cholesterol and creatinine serum concentrations as well as HIV load and CD4 T cell counts were analyzed at the beginning of monotherapy and at the end of follow-up (median follow-up, 10 months, range 2-26 months). Data are showed as the median (IQR) of the calculated annual increase of these variables.

Results: Every one of the patients maintained the undetectable HIV load at the end of the follow-up. At the end of the follow-up CD4 T cell count decreased by a median of 35 cells/mm^3 (IQR, -165, +30). Serum concentrations of the cholesterol fractions showed no significant changes during the follow-up (total cholesterol, median +1.50 mg/dl (IQR, -37, +36); HDL-cholesterol, median +0.7 mg/dl (IQR, -5, +23), LDL-cholesterol, median -7.20 mg/dl (IQR, -49, +13). Finally, serum creatinine concentration showed similar values at the beginning and at the end of the study (median change, 0.0 mg/dl (IQR, -0.1, +0.2). No significant differences were detected when patients in lopinavir- or darunavir-based monotherapy were compared.

Conclusions: Monotherapy with either lopinavir or darunavir is a safe alternative in patients with previously suppressed HIV replication. However, no beneficial effects of lipid fractions or renal function was detected when conventional therapy (based in three drugs combination) was changed to monotherapy.

A-223
CONTINUED IMPROVEMENT OF LIVER FIBROSIS AFTER SUSTAINED VIROLOGICAL RESPONSE TO ANTI-HEPATITIS C (HCV) TREATMENT IN HIV-COINFECTED PATIENTS

I. Ríos Holgado[1], F. Téllez[2], F. Brun Romero[1], M. Soto Cárdenas[1], E. Sifuentes Díaz[1], M. Cornejo Saucedo[1], L. Vela Manzano[1], J. Girón González[1]

[1]Department of Infectious Diseases. Hospital Universitario Puerta del Mar. Cádiz, Spain. [2]Department of Infectious Diseases. Hospital del S.A.S. La Línea de la Concepción. La Línea de la Concepción (Cádiz), Spain.

Objectives: Progression of liver fibrosis to cirrhosis follows an accelerated course in HCV-infected patients with HIV coinfection. An improvement of liver fibrosis has been described in HCV-monoinfectedpatients after anti-HCV therapy. Data about HIV-HCV

coinfected patients are limited. The objective of this work is to evaluate the changes in liver rigidity in HIV-HCV coinfected patients with chronic hepatopathies after anti-HCV therapy.

Material and method: One hundred and nine HIV-HCV patients were prospectively studied. All of them showed undetectable serum HIV load due to antiretroviral treatment. Anti-HCV therapy with pegylated interferon alpha2a, 180 micrograms/week, and ribavirin (weight-adjusted doses) was administered. Liver rigidity was evaluated by transient elastography at the beginning of the treatment, twelve months after the beginning (end of the therapy) and twelve months after finishing the treatment. Modification of liver rigidity was the dependent variable. The main independent variable was the attainment of a sustained virological response to anti-HCV therapy (SVR). Data are provided as median (interquartile range) or as absolute number (percentage). Wilcoxon's test was performed to analyze differences in the liver rigidity between two different time points.

Results: Characteristics of the patients were: age, 44 (IQR 41-47) years; male sex, 88 patients (81%); evolution of HIV-HCV infection, 21 (16-24) years; baseline CD4+ T cells, 433/mm^3 (IQR 314-651); infection by HCV genotype 1 or 4, 73 patients (67%); liver cirrhosis, 46 patients (42%). A 42% of patients (n = 46) attained a SVR. Characteristics independently associated with this response were the infection by an HCV genotype 2 or 3 and the absence of cirrhosis; interleukin 28B polymorphism CC approaches to statistical significance. Patients with a SVR showed an improvement of liver rigidity at the end of the therapy (baseline liver rigidity, 9.8 kPa (IQR 8.3-17.4); liver rigidity at the end of therapy 8.6 kPa (IQR 6.8-20.8), p = 0.015). Interestingly, liver fibrosis continues improving twelve months after finishing the anti-HCV treatment (7.3 kPa (IQR 4.9-13.2), comparing with baseline, p = 0.000; comparing with the end of therapy, p = 0.003). Changes in liver rigidity were not significant in patients without SVR.

Conclusions: Liver fibrosis improves with the treatment of HCV infection in HIV-coinfected patients with SVR. This improvement continues after finishing this therapy.

A-224
PROGRESSIVE MULTIFOCAL LEUKOENCEPHALOPATHY IN HIV PATIENTS IN HOSPITAL UNIVERSITARIO INSULAR DE GRAN CANARIA

N. Jaén Sánchez[2], N. Moya-Notario[2], E. Pisos Alamo[1], M. Hernández Cabrera[1], A. Francès Urmeneta[1], J. Pérez Arellano[1]

[2]Department of Internal Medicine Service, [1]Infectious Diseases and Tropical Medicine Unit. Internal Medicine. Complejo Hospitalario Universitario Insular-Materno Infantil. Las Palmas, Spain.

Objectives: Progressive multifocal leukoencephalopathy (PML) is a severe central nervous system infection due to John Cunningham virus (JCV), a pathogen member of the polyomavirus family. This demyelinating disease appears to occur, mostly, in patients with impairment of the immune system, including that with advanced HIV infection and low CD4 counts, that´s why, PML is considered one of the AIDS defining event. Though the use of highly active antiretroviral therapy (HAART) has decreased the incidence of PML, the prognosis is still poor. OBJECTIVES: To determine the epidemiological features of the HIV-infected patients with PML in the HUIGC: sex, age, clinical manifestations, CD4 count and viral load at the diagnostic moment and their survival.

Material and method: Retrospective analysis of the HIV-infected patients who were hospitalized with neurological manifestations between 2006 and 2011 in the Infectious Diseases Unit of the HUIGC and have positive polymerase chain reaction (PCR) for JC virus in cerebrospinal fluid (CSF) samples. The statistical analysis was made with the SPSS software version 19.

Results: Six patients were enrolled. The mean age was 40 ± 9 years and 83.3% were males. The prevalent neurological disturbances were: mental status impairment (83.3%), motor deficits (50%), cerebellar symptoms (33.3%) and epileptic seizures (16.7%). 66.7% had discontinued treatment before the PML diagnosis. CD4 count at the diagnostic moment of the PML was made in all of them. 5 patients (83.3%) had less than 100/mm^3 and only one of them had CD4 300/mm^3 and undetectable viral load in the prior 2 years. From the patients with CD4 < 100/mm^3, one developed the disease within the first month after initiating HAART, being diagnosed of immune reconstitution inflammatory syndrome (IRIS) and two, who already had MPL, presented worsening of the neurological symptoms because of the IRIS developed with the HAART. All the patients with positive JCV-PCR had bilateral multifocal lesions involving white matter in the MRI. The median survival was 10 weeks, only one is still alive.

Conclusions: 1. Within the clinical features, the mental status impairment was more frequent than the motor deficits.2. PML can exist in patients with a good virological and immunological control.3. Only one of them had CD4 300/mm^3 and undetectable viral load in the prior two years.4. 50% of the patient with PML had IRIS.5. Despite of the HAART, PML prognosis is still poor.6. PML treatment is still a challenge in the HIV-infected patient.

A-225
INFLUENCE FACTORS FOR HEPATIC STEATOSIS AND STEATOHEPATITIS IN VIRUS C INFECTED PATIENTS

J. López Prieto, E. González Reimers, F. Armas González, R. Alemán Valls, O. Pérez Hernández, R. Pelazas González, F. Santolaria Fernández, J. Gómez Sirvent

Department of Internal Medicine. Hospital Universitario de Canarias. San Cristóbal de La Laguna (Santa Cruz de Tenerife), Spain.

Objectives: Chronic hepatitis C virus (HCV) infection is an increasingly common form of non-alcoholic steatohepatitis, in which fat laden hepatocytes trigger an inflammatory response which may evolve to liver cirrhosis and even hepatocarcinoma. The aim of the present study is to analyse the factors related to the presence and/or intensity of liver steatosis and inflammation in patients affected by HCV infection.

Material and method: Eighty four patients were included. Histological evaluation was histomorphometrically assessed (proportion of fat and fibrosis in liver biopsy) and by Knodell and Metavir index. Adipokines (adiponectin, resistin, leptin, TGF-beta, TIMP-1), proinflammatory cytokines (TNF-alpha, IL-6), hormones (insulin, IGF-1, cortisol), malondialdehyde (MDA) and Th-1 and Th-2 cytokines were measured in serum samples. Whole body densitometry was also performed.

Results: In 15 patients, no steatosis at all was observed. Median value was 0.36%, but 14 patients showed more than 5% of fat (% of area) in their biopsies. Patients with marked steatosis (over the median) showed a higher trunk fat mass (T = 2.45; p = 0.017) and left arm fat mass (T = 2.01; p = 0.048), but a nearly significant trend (p < 0.1) was observed with all the fat parameters. Patients with negligible steatosis showed less fat both at right and left arms than patients with steatosis (p < 0.025 in both cases), and also, lower trunk mass (T = 2.12; p = 0.038). Patients with more marked steatosis showed higher cortisol (T = 1.99; p = 0.05), TNF-alfa values (Z = 2.01; p = 0.048), insulin (Z = 2.17; p = 0.03), HOMA index (T = 2.43; p = 0.015) and TIMP-1 (t = 2.44; p = 0.018) levels. Histological activity showed a significant relation with IL-4 (Z = 2.83; p < 0.01) and MDA (T = 2.1; p = 0.04) levels. Patients infected by genotype 3 showed significantly more fat deposits in the liver and a significant trend to have more trunk fat (p = 0.08).

Discussion: Hepatic steatosis and steatohepatitis is a common finding in hepatitis C infected patients. It is known that patients with more adipose tissue release more molecules that could mobilizate free fatty acids from visceral adipose tissue to the liver. On the other hand, hepatitis C virus could damage itself hepatocytes and leading typical histologic alterations such as steatosis, especially in the genotype 3 case. We have found in our study that patients with more marked steatosis showed more adipose tissue (specially trunk fat, that include visceral fat), higher levels of hormones relationated with movilization of free fatty acids from adipose tissue to the liver and higher level of TNF-alpha. It was interesting to find higher level of TIMP-1, a known hepatic fibrosis marker, in patients with more marked steatosis, which could suggest a rol in the leading of steatosis in these patients. There was in this way correlation between histological alterations with higher quantity of adipose tissue and higher levels of some molecules released by the same.

Conclusions: Patients with marked steatosis (more than 5% of liver fat) showed a higher trunk and arms fat mass, higher levels of insulin, HOMA index, cortisol, TNF-alpha and TIMP-1. Patients with genotype 3 showed too more hepatic steatosis that patients with other genotypes. Results of this study are in accordance with the two-hit hypothesis: insulin-resistance, in relation with altered adipokine secretion, is related to liver steatosis, whereas cytokines and increased lipid peroxidation account for the shift to steatohepatitis. We could not disclose a direct cytopathic effect of genotype 3 HC virus neither discard it.

A-226
EFFECT OF ALCOHOL, CANNABIS AND TOBACCO CONSUMPTION ON LIVER STIFFNESS IN HIV/HCV COINFECTED PATIENTS WITH ACTIVE HCV REPLICATION

J. López, J. Tor, A. Jou, R. Sanmartín, L. Llobera, R. Muga, B. Clotet, C. Tural

Department of Internal Medicine. Hospital Universitari Germans Trias i Pujol. Badalona (Barcelona), Spain.

Objectives: To assess the effect of cannabis, tobacco and alcohol consumption in co-HIV/HCV individuals. To determine the prevalence of these habits in this population.

Material and method: Liver stiffness (LS) was measured by Fibroscan from 01/2011 to 01/2012 in 306 consecutive individuals on active HCV replication (69 and 31% males and females; median age 47 years; body mass index: 23 kg/m^2, 73 and 27 naïve and non-responders to HCV therapy; HCV genotype 1 or 4: 83%; HCV RNA > 500.000 IU/ml: 70% median CD4: 557 cells/mm^3; HIV RNA bellow detection in 96%). Alcohol, cannabis and tobacco consumption was self-reported at time of LS measurement. Advanced liver fibrosis (ALF) and cirrhosis were defined by a LS > 9.5 Kpa, > 12.6 Kpa and 14 Kpa respectively. Univariate and multivariate statistical methods were used.

Results: Median LS was 7.8 Kpa (success rate > 60%: 96%; Interquartile range < 30%: 86%). The proportion of ALF was 40% and cirrhosis 17.3 and 12%. Alcohol, cannabis and tobacco consumption were reported in 23, 32 and 73% respectively. Heavy alcohol, defined by > 20 g/day in women and > 40 g/day in men, daily cannabis and more than 20 cigarettes/day were reported in 5, 23 and 27% respectively. There was no association between LS and age, gender, BMI, CD4, HIV RNA, HCV genotype, HCV treatment experience, Triglycerides, total and LDL and HDL cholesterol, alcohol, cannabis or tobacco consumption. There was a strong association between tobacco, alcohol and cannabis consumption (cannabis-tobacco: $p < 0.0001$, cannabis-alcohol: $p = 0.056$; alcohol-tobacco: $p < 0.0001$).

Discussion: We have not observed the deleterious effect of alcohol and cannabis consumption on liver fibrosis observed in other studies in HCV monoinfected individuals. The low frequency of alcohol intake and also the association between these habits have to be taken into account when interpreting our results. The use of the self reporting system method at time of LS measure to assess the real drug consumption could have biased our conclusions.

Conclusions: There is no association between alcohol, cannabis and tobacco consumption and LS in HIV/HCV-co individuals with stable HIV infection and active HCV replication. There is a low prevalence of self-reporting heavy alcohol intake but high prevalence of cannabis and tobacco consumption in this population.

A-227
RELATION BETWEEN DIABETES MELLITUS TYPE 2 AND HELICOBACTER PYLORI INFECTION AND CORRELATION BETWEEN HELICOBACTER PYLORI DETECTION WITH BREATH TEST OR ANTIGENS IN FAECES

A. Serrano Morte[1], C. Rodríguez Martín[1], S. Miranda Riaño[1], P. Mújica Addimandi[1], M. López de Juan[1], E. González Sarmiento[2], M. Cruz Moreno[3]

[1]Department of Internal Medicine, [3]Research Unit. Hospital Clínico Universitario de Valladolid. Valladolid, Spain. [2]Facultad de Medicina. Instituto de Endocrinología y Nutrición. Valladolid.

Objectives: Helicobacter pylori infection (HP) and diabetes mellitus type 2 (DM) are related with gastrointestinal manifestations. Specifically, in DM those manifestations can be caused by neuropathy or by HP infection. The aim of our study was to establish the frequency of HP infection in patients with DM using simultaneously two different techniques, breath test and antigens in faeces test. We also wanted to correlate the results obtained by these two techniques using the breath test as gold standard.

Material and method: Observational prospective study during two years in hospitalzed patients and outpatient. We collected anthropometric, analytic and comorbidity information of our patients excluding those who were under proton-pump inhibitor treatment as well as those who received antibiotic therapy the previous week. Then, they were conducted both breath test and antigens in faeces test.

Results: We studied 53 patients (17 females, 36 males). The average of age was 72.1 years (standard deviation [SD] = 3.66). Middleweight was 78.26 Kg (SD = 12.97), the average of size was 1.64 cm (SD = 0.08) and the body mass index (BMI) 28.702 (SD = 4.19). 22.6% patients suffered from DM for less than 5 years and the remaining 60.4% for more than 5 years. Regarding the DM treatment, 86.8% were treated with oral antidiabetic agents, and 24.5% with insulin. From the total, 66.03% were well controlled (HbA1c < 7%). Patients referred neither dyspepsia nor gastrointestinal disruption for about 76.9% and 77.4% respectively. The microvascular complications study showed that 13.2% patients suffered from retinopathy, and the remaining 13.2% and 5.7% from neuropathy and microalbuminuria respectively. On the other hand, we collected information about comorbidity and it was obtained that 45.3% of patients had hypertension and 35.8% dyslipemia. Tests were positive for 70.6% by breath test and 43.2% by antigens in faeces. Both trials had a weak agreement (Kappa Index 0.390, $p < 0.001$). Antigen in faeces had a specifity of 93.33% (CI = 95% [77.37-100]) and a sensitivity of 55.82% (95%CI [37.72-74.04].

Discussion: In this study we found that the detection of HP infection in diabetic patients was more than 70% using breath test but 43.1% by antigens in faeces test. The correlation between two

tests was weak and we found out that antigens in faces had a high specifity but low sensitivity.

Conclusions: It is possible to determinate that there is a connection between DM and HP infection. The percentage of diabetic patients with HP infection is high in this study (70.6%), as it was showed in other studies previously. According to our study, it would be better to use the breath test for detection of HP infection, owning to the fact that it is more sensitive.

A-228
COMPLICATIONS OF PATIENTS HOSPITALIZED FOR MALARIA IN THE INTERNAL MEDICINE DEPARTMENT OF A GENERAL HOSPITAL

P. Sánchez López, A. García Peña, B. Hernández Sierra, A.J. Corrales Torres, I. Reche Molina, S. Domingo Roa, C. Maldonado Úbeda, F. Díez García

Department of Internal Medicine. Complejo Hospitalario Torrecárdenas. Almería, Spain.

Objectives: To analyze the complications and epidemiological characteristics of patients hospitalized for malaria in the Internal Medicine Department of a General Hospital.

Material and method: We performed a retrospective study of patients admitted in the period between March 2004 and May 2011 in the Internal Medicine department with suspected malaria with further confirmation. We analyze the complications and epidemiological, clinical and laboratory characteristics in infected patients.

Results: During the study period, 16 patients were admitted with a diagnosis of Malaria, being mostly male (11 men, 68.8%/5 women, 31.3%). Previous history of malaria had 37.5% of cases, but only 6.3% of patients took pre-exposure prophylaxis. Parasitaemia was less than 5% in 56.3% between 5 and 10%: 6.3% and more than 10%: 12.5%. The mean length of hospital stay was 6 days. Clinical characteristics: fever in 75% of cases, gastrointestinal symptoms 68.8%, muscle 56.3%, headache 50%, jaundice 18.8%, hepatomegaly 18.8%, encephalopathy 6.3% and pruritus 6.3%. Laboratory parameters showed thrombocytopenia: 75%, hyperbilirubinemia: 43.8%, anemia: 37.5%, hypertransaminasemia: 25%, renal insufficiency (creatinine > 1.5 mg/dl): 12.5%, leukocytosis: 12.5% and eosinophilia: 6.3%. There were no cases with coagulation disorder. The acute phase reactants were elevated in 68.8% of cases. 12.5% of cases were positive for HIV, 12.5% positive for HBV and found no cases of HCV and tuberculosis. No one needed intensive care and one patient needed dialysis. Respect to other characteristics: the region where infected was 81.3% of cases in sub-Saharan Africa, 18.8% Europe, 6.3% Central American and 6.3% South America. The season in the country of infection was summer in 50% of cases. The diagnosis was confirmed by thick smear in 56.3% of cases, with PCR in 6.3% and 37.5% in both. In 31.3% of the patients was positive for P. falciparum and in other cases was negative or not performed. 81.3% were treated with quinine + doxycycline and atovaquone 18.8% with proguanil. Treatment was well tolerated in 93.8% of cases.

Conclusions: Of all patients admitted to our department with malaria, 37.5% of cases had previous history of malaria, but only 6.3% received malaria prophylaxis preexposure to the trip. Fever and clinical gastrointestinal symptoms were more frequent. The analytical parameters were found most frequently thrombocytopenia (75%), increased acute phase reactants (68.8%), hyperbilirubinemia (43.8%) and anemia (37.5%). Most patients had good outcome without major complications. Treatment was well tolerated in 93.8% of cases.

A-230
PATIENTS WITH HIV/AIDS INFECTION ADMITTED IN A INFECTIOUS UNIT OF A GENERAL HOSPITAL

P. Sánchez López, B. Hernández Sierra, G. Parra García, M. Esteban Moreno, C. Maldonado Úbeda, S. Domingo Roa, F. Laynez Bretones, F. Díez García

Department of Internal Medicine. Complejo Hospitalario Torrecárdenas. Almería, Spain.

Objectives: To know the epidemiological and clinical characteristics of patients admitted to medical units of a General Hospital the last year and knowing the reasons for admission, their immune and virological situation and the course and treatment at discharge.

Material and method: We performed a retrospective study in patients admitted with HIV/AIDS infection in an Infectious Unit of a Internal Medicine Service in the year 2.011. We analyzed the epidemiological, clinical, prognostic and therapeutic variables most relevant. Data were analyzed in SPSS database 17.

Results: We analyzed 55 patients, 68% of them were male and 15% of foreign origin. HIV infection was diagnosed in admission in 11% of the cases. In the other cases the previous HIV clinical stage was: A: 18%; B: 27% and C: 44%). The CD4 counts were below 200/uL in 24% of patients and 52% of them were taking HAART, with good compliance in 40%. The COMBO most used was the combination of tenofovir and emtricitabine (61%), associated with efavirenz (38%) or a protease inhibitor (31%). The reason for admission was an AIDS-defining illness in 50% of cases: tuberculosis (pulmonary 18%, disseminated 9%, extrapulmonary 4.5%), Burkitt lymphoma (31%) and recurrent pneumonia (18%) were the most prevalent diagnosis, Other concomitant comorbid diseases were: hypertension 22%, smoking 41%, hypercholesterolemia 6%, type 2 diabetes mellitus 10%, anemia 30%, heart failure 10%, cerebrovascular disease 10%, COPD 10%, malnutrition/cachexia 16%, thrombocytopenia 14% HBV infection 12.2% and HCV infection, 43%. 87.8% of patients were discharged and 6% died. In 70% of patients more than 5 drugs prescribed at discharge.

Conclusions: Thirty years after the beginning of the HIV/AIDS epidemic, the patients admitted to a hospital have advanced disease stage (mainly C3 stage, CD4 counts below 200/uL). Hepatotropic virus coinfection is very frequently and can influence the prognosis. There are increasing comorbidity with chronic diseases like COPD, heart failure and cardiovascular risk factors.

A-231
MICROBIOLOGICAL ISOLATION OF NONTUBERCULOUS MYCOBACTERIA IN THE PROVINCE OF ALMERÍA (SPAIN)

F. Díez García[1], M. Martínez Lirola[2], P. Sánchez López[1], W. Sánchez-Yebra Romera[2], F. Laynez Bretones[1], M. Morales Torres[2], M. Gálvez Contreras[1], A. Collado Romacho[1]

[1]Department of Internal Medicine, [2]Biotechnology Unit. Complejo Hospitalario Torrecárdenas. Almería, Spain.

Objectives: Nontuberculous mycobacteria (NTM) are environmental bacteria that behave as opportunistic pathogens. Its isolation is not always associated with disease. The incidence, anatomic location and distribution of species are very variable in each territory. The study aimed to describe the distribution of NTM species isolated microbiologically in the province of Almería (Spain) over the past 5 years (2007-2011).

Material and method: Design: Retrospective and observational study. Period: 2007-2011. Center: Torrecárdenas Hospital (Almería, Spain). Source: Database of mycobacteria laboratory in Almeria, which collects all NTMT provincial health network. Molecular identification using GenoType® Mycobacterium CM/AS. Outcome

measure: Interannual variation among isolates. Statistics: Anova.

Results: The isolation of an NTM occurred in 33.2% (n = 254) of patients with positive cultures for mycobacteria, with significant interannual variations (Anova: 0.012). The slow-growing mycobacteria (250/379, 66%) and the species included in the Runion sub-group III (N: 152, 40%) were the most frequent isolates. The isolate was respiratory in 89% (n = 362) of the cases and the gastrointestinal tract was the most frequent location for non-respiratory isolates (23/46 cases, 50%). The most common species isolated were: M.gordonae (n = 65), M. intracellulare (n = 60), M. avium (n = 57) M. fortuitum (n = 49) and M. abscessus (n = 43). The species with clinical significance most frequently isolated in the respiratory tract were: M. avium (12/20, 60%), M. abscessus (9/17, 52.9%) and M. intracellulare (14/27, 51.9%).

Conclusions: The isolation of NTM is common in the province of Almeria and it assumes 1/3 of all isolates of mycobacterias. We need a profound epidemiological study and a specific following of the patients with isolates of NTM for knowing the true clinical implications of this phenomenon.

A-232
RETROSPECTIVE STUDY OF HYDATID DISEASE IN AN INTERNAL MEDICINE DEPARTMENT IN A SECONDARY HOSPITAL

E. Escobar[1], C. Sobrino[1], G. Eroles[1], E. Labrada[1], A. Vergara[2], J. Jusdado[1]

[1]Department of Internal Medicine, [2]Department of Traumatology. Hospital Severo Ochoa. Leganés (Madrid), Spain.

Objectives: To describe the presentation, radiological findings and evolution of the hydatid disease in our center.

Material and method: We conducted a retrospective medical chart review of 104 patients diagnosed with hydatid disease from 1984 to 2008. Variables recorded were age and gender, occupation, date of diagnosis, chief complaint (abdominal pain, fever, jaundice, vomica etc), serology (considered as diagnostic if titer > 1:64, uncertain if titer was 1:64 to 1:32, and negative with titer < 1:32), and radiological studies (Chest and abdominal X-ray and CT, abdominal ultrasound) to assess cyst location. All data was analysed with SPSS version 16.0.

Results: We included 104 patients, 48.1% male and 51.9% female. Age distribution was 4 patients (3.8%) under 30 years old, 23 patients (22.1%) between 30 and 50, 38 patients (36.5%) between 50 and 70 and 39 patients (37.5%) over 70 years old. Patient's profession could not be recorded in 48.1% of the cases. The most frequent occupation was housewife (32.7%) followed by construction worker (5.8%). The most frequent reason for consultation was abdominal pain in 29 patients (27.9%) followed by fever in 5 patients (4.8%). 10 patients (9.6%) had other presenting symptoms such as jaundice, asthenia, vomica, back pain or anaphylactic shock. Serological tests were conducted in 57 patients (54.8%), being diagnostic for hydatid disease in 68.4% of these cases, uncertain in 8.8% and negative in 22.8%. Chest X-ray was performed in 91 cases, being the cyst visible in 14 of them (15.4%). From the abdominal x-rays recorded in 17 patients, 6 were considered pathological (35.3%). 68 abdominal ultrasound studies were conducted, being able to detect a cyst in 61 cases 89.7%. Abdominal CT scan was diagnostic for hydatid disease in 85 of 87 cases (97.7%). Regarding location of the cysts, 101 patients (97.1%) had liver cysts, 4 peritoneal cysts (3.8%) and 2 patients pulmonary cyst (1.9%). 79% of them were calcified. 12 patients (11.5%) had a complication: 2 compression after cyst growth, 3 infection, 2 cholangitis, 2 hepatopulmonary transit, 1 extrahepatic cholestasis, 1 anaphylactic shock and 1 acute abdomen after rupture of the cyst. There were not differences between genders concerning complications, and they were not more frequent in the patients over 70 years old. The most frequent initial symptom in this group of patients was abdominal pain in 10 cases. 50 patients were treated. Surgery as the only treatment modality was performed in 37 cases (74%) with a mean hospital stay of 18.4 ± 12.04 days. 12 patients (24%) had combined medical-surgical treatment while 1 patient (2%) had medical treatment as the only therapeutic modality. Regarding treatment outcome, 43 patients (41.3%) were cured of the disease, 36 of them with surgery (83.7%), 6 with combined treatment (14%) and 1 with medical treatment exclusively. 58 patients (55.8%) had a persistent disease whereas 2 patients (1.9%) recurred in the follow-up.

Discussion: 104 patients were diagnosed of hydatid disease in the study time, being the liver the most frequently affected organ. Age distribution of cases among groups over 30 years was homogeneous, without any significant differences between genders as well. Abdominal pain was the most frequent chief complaint. Serology was performed in 54.8% of the cases, being diagnostic for 68.4% of them. 97.7% of the 87 abdominal TC performed were pathologic versus 89.7% of the 68 abdominal ultrasound studies. 48.1% of the patients were treated, being surgery as a single modality the most frequent treatment, in 98% of the cases with a mean hospital stay of 18.4 ± 12.04 days. The disease was cured in 41.3% of the patients while it persisted in 55.8%.

Conclusions: Hydatid disease typically affects abdominal organs, with a homogeneous age and gender distribution. Abdominal pain and fever are the most common presenting symptoms. Our study concludes that abdominal TC is the most sensitive diagnosis test and that surgery is the most effective treatment modality, with or without medical adjuvant treatment.

A-233
EPIDEMIOLOGIC DESCRIPTION OF PATIENTS DIAGNOSED OF HIV INFECTION IN A UNIVERSITY HOSPITAL IN THE PERIOD 2007 – 2012

L. Fernández de Orueta, J. Martínez Carrilero, G. Vicente Sánchez, R. Regajo Gallego, M. Pérez Fernández, H. Aichner, J. Esteban Fernández, G. Gaspar Alonso Vega

Department of Internal Medicine. Hospital Universitario de Getafe. Getafe (Madrid), Spain.

Objectives: Risk behaviors and transmission routes of HIV infection have changed strikingly since the decade of 80s, when this disease was discovered. After adopting the specific socio-sanitary measures, new diagnoses per year has considerably decreased over the years. The aim of this study is describe the clinical and epidemiological characteristics of the newly diagnosed HIV patients in our hospital.

Material and method: We selected all the patients newly diagnosed of HIV infection from January 1, 2007 to March 29, 2012 in our hospital, a community hospital from Madrid. The total were 143 patients. Frequencies had been used to describe the qualitative variables and the mean for quantitative variables. We used the statistical program SPSS version 17.0 for data analysis, using as statistics the p of Pearson chi-square.

Results: 68.5% are male and 31.5% are women. The mean age was 40.07 year (from 21 to 73, and SD 10.41 years). Of these, 51.7% are Spanish and the other immigrants (48.3%): 23.1% from America, 16.1% from Africa, 8.4% from Europe (excluding Spain) and only 0.7% from Asia. The most common route of transmission is heterosexual (51%), followed by homosexual in 36.4% of causes, and only 4.9% intravenous-drug-users. There were no cases of transfusions or vertical transmissions. Analyzed the mode of transmission by countries, we found that heterosexual transmission was statistically significant more frequent in Africa and Europe (excluded Spain), than in Spain and America (p 0.000). HIV infection prevalence is higher among men in Europe, America and Asia, while

it is higher in women in the case of Africa (p 0.005), data that reach statistical significance. The mean viral load at diagnosis was of 116.966 copies per mililiter, and the mean CD4 count at diagnosis was of 409 cells. According to CDC classification, 63% of patients were asymptomatic at diagnosis (stage A) and 27.9% were presented with one of AIDS-defining diseases (stage C). Only the 17.5% of patients were diagnosis during primary infection period because it was symptomatic. 9.8% of HIV patients were coinfected with HCV versus 88.1% who were HCV negative. Only 0.7% had HBV positive serology compared with 97.2% who were HBV negative. HCV coinfection was statistically significant more frequent in Spanish people compared to other regions studied (p 0.003) and found no significant differences with respect to HBV. Antirretroviral treatment was initiated at diagnosis in 76.2% of patients newly diagnosed of HIV infection, and was postponed in 23.8% of patients because they did not met clinical or/and microbiological criteria for this.

Conclusions: The model of patient newly diagnosed with HIV infection in the last 5 years is a heterosexual male, 40 years old, who presents a good immune status but with high viral loads. In our sample is rare HCV coinfection and anecdotal in the HBV coinfection. Following the recommendations of clinical guidelines for HIV infection in adults, we advocate early initiation of antiretroviral therapy.

A-234
IDENTIFICATION OF LENGTH OF HOSPITAL STAY-ASSOCIATED RISK FACTORS IN PATIENTS WITH PNEUMONIA

N. Gago, A. Pellicer, G. Llerena, F. González, A. Cózar, M. Asensio, I. Díaz, F. Pedro

Department of Internal Medicine. Hospital General Universitario de Valencia. Valencia, Spain.

Objectives: To identify which factors have an influence on the length of hospital stay of patients admitted to an Internal Medicine Unit due to a respiratory infection.

Material and method: Descriptive, prospective study in every patient diagnosed of inferior airway infection, between November 2011 and April 2012, in the Internal Medicine Unit in Hospital General Universitario de Valencia. 490 variables were analyzed, from 111 patients, including demography data, personal medical records, functional scales, clinical, radiological and laboratory findings, prognostic scales, antibiotic therapy and clinical progress.

Results: 56.8% from 111 analyzed patients were women; average age was 83.55 years old, with a middle punctuation on Barthel scale of 30.97 (median of 10), a Charlson index with a median of 7, and a performance status average of 2.95. 57.7% were healthcare-associated pneumonias, 32.4% were community acquired pneumonias (CAP), and 12.6% were hospital acquired ones. Most common medical records were any grade of dementia (56.8%), congestive heart failure (31.5%), cerebrovascular disease (31.5%), diabetes mellitus (31.5%), COPD (19.8%), nephropathy (16.2%), neoplasia (15.3%), coronary disease (12.6%) and peptic ulcer disease (12.6%). 39.5% presented any grade of dysphagia. 75.3% had been treated previously with gastric secretion inhibitors and 47.7% with oral antibiotherapy. It was observed radiological lung condensation in 80% of patients. It was observed that 97.2% patients presented a PSI class of 4-5 (average punctuation 145). CURB-65 average punctuation was 2.83 with a median of 3. ATS criteria defined severe pneumonia in 47.7%. It was observed an increased length of hospital stay in men (p = 0.07) and a reduced in CAP (p = 0.17), both of them not significant. Patients with history of diabetes mellitus with organ damage (p = 0.022), previous pneumonia (p < 0.01) and dysphagia (p = 0.014) had an increased length of hospital stay. It was observed an increased hospital stay length in patients with increased bronchial secretion (p = 0.034) and patients with productive sputum (p = 0.17). Other findings that were not significant were systolic blood pressure lower than 90 mmHg and pO_2 lower than 60 mmHg (p = 0.07 and p = 0.12) respectively. Multiple lobe infiltrates (p = 0.12) and urea levels higher than 40 mg/dl (p = 0.15). ATS criteria of leukopenia and thrombocytopenia had a significant association (p = 0.02 and p < 0.01 respectively). Patients with hypotension that did not require vasoactive drugs (p < 0.01) and severe pneumonias defined by ATS criteria (p = 0.035) were associated with an increased length of hospital. Hospital stay in patients with infectious complications (p < 0.01) like pleural effusion (p < 0.01) and septic shock (p < 0.01) was significantly longer. Another complications that were associated with an increased length of hospital stay were pressure ulcers (p < 0.01), ADRS (p < 0.01) and impairment of renal function (p = 0.05). Patients with a Barthel scale score lower than 25 (p = 0.016), and a PSI index score of 5 (p = 0.04) had an increased length of stay hospital that was significant. Patients with CURB-65 score of 4 or 5 had not statistically significant differences.

Conclusions: All of prognostic scales detected patients with severe pneumonias. ATS criteria were the best scale if we attend to our results, although CURB-65 scale is easier to use. Infectious and non infectious complications were associated with an increased length of hospital stay, so efforts in order to early diagnosis and adequate treatment is recommendable. Medical history and biological findings that have not been initially associated with mortality such as diabetes mellitus with organ damage, hypotension, hypoxemia and multiple lobe infiltrates complete the risk factors related to an increase in length of hospital stay.

A-235
IDENTIFICATION OF MORTALITY-ASSOCIATED RISK FACTORS IN PATIENTS WITH PNEUMONIA

A. Pellicer, N. Gago, G. Llerena, A. Dragoi, F. González, F. Pedro

Department of Internal Medicine. Hospital General Universitario de Valencia. Valencia, Spain.

Objectives: To identify which epidemiological features of Internal Medicine admitted patients due to pneumonia are associated with an increase on mortality.

Material and method: Descriptive, prospective study in every patient diagnosed of inferior airway infection, between November 2011 and April 2012, in the Internal Medicine Unit in Hospital General Universitario de Valencia. 490 variables were analyzed, from 111 patients, including demography data, personal medical records, functional scales, clinical, radiological and laboratory findings, prognostic scales, antibiotic therapy and clinical progress.

Results: 56.8% from 111 analyzed patients were women; average age was 83.55 years old, with a middle punctuation on Barthel scale of 30.97 (median of 10), a Charlson index with a median of 7, and a Performance Status average of 2.95. 54.1% were healthcare-associated pneumonias, 33.3% were community acquired pneumonias (CAP), and 12.6% were hospital acquired ones. Most common medical records were any grade of dementia (56.8%), congestive heart failure (31.5%), cerebrovascular disease (31.5%), diabetes mellitus (31.5%), COPD (19.8%), nephropathy (16.2%), neoplasia (15.3%), coronary disease (12.6%) and peptic ulcer disease (12.6%). 47.7% presented any grade of dysphagia. 75.3% was been treated previously with gastric secretion inhibitors and 47.7% with oral antibiotherapy. Most common symptom was dyspnea (90%), followed by cough (74%) and alterations of conscious state (62%). The last one is associated with an increase on mortality (p = 0.016). Medians of breathing rate, creatinine and C Reactive Protein were 28.8 respirations per minute, 1.05 mg/dL and 12.8 respectively.

31.5% presented infectious complications; most frequently pleural effusion (11.7%). Between the non-infectious complications, the most frequent was the respiratory failure (68.5%). It has been seen a descent in expected mortality in CAP patients (p = 0.17) and an increase in hospital-acquired pneumonias (p = 0.15). There were no differences related to mortality in healthcare-associated pneumonias. It was observed an increase on mortality in patients with a Charlson index higher than 7 (p = 0.048), a Barthel < 25 (p = 0.013) and in patients with history of dysfhagia (p = 0'01) and renal disease (p < 0'01) that were the most statistically significant ones. No statistically significant relation was found in patients with previous pneumonias (p = 0.1), dementia (p = 0.13) and age (p = 0.18). Higher mortality associated clinical features were increase of bronchial secretions (p < 0.01) and delirium (p < 0.016). Biological data with more associated mortality were urea (p < 0.01), creatinine (p < 0.01), and a respiratory rate upper than 30 breathings per minute (p < 0.01). Infectious complications associated also a statistically significant higher mortality (p = 0.011). It has been observed that there is a statistically significant correlation between every analyzed prognostic scale and mortality (p = 0.01) CURB-65, PSI index (p = 0.034) and ATS scale (p < 0.01).

Discussion: It has been observed that there is a trend towards a higher mortality in some parameters between the different pneumonia groups that could be verified with a bigger study population. They stand out some factors that are not usually recorded at the initial clinical history, but which can determine the prognosis of our patients, like swallowing ability, previous pneumonias and a breathing rate upper than 30 breathings per minute. At the same time, renal failure has a strong relation with mortality and it should have a very special role in the integrative view of the patient with pneumonia. Every prognostic scale detected significantly the most severely ill patients, being ATS the one who showed more correlation. Infectious complications and, less importantly, non infectious complications, were related to a higher mortality. Therefore, an early detection and appropriate therapy would be an advisable clinical practise.

A-236
EPIDEMIOLOGICAL CHARACTERISTICS OF A COHORT OF HIV-CHV COINFECTED PATIENTS IN A COMMUNITY HOSPITAL

J. Martínez Carrilero, H. Aichner, L. Fernández de Orueta, R. Regajo Gallego, G. Vicente Sánchez, M. Pérez Fernández, G. Pérez Caballero, A. Monereo Alonso

Department of Internal Medicine. Hospital Universitario de Getafe. Getafe (Madrid), Spain.

Objectives: The first cases of acquired immunodeficiency syndrome (AIDS) were reported in 1981-1982, the etiologic agent was identified in 1983 and set of diagnostic tests was possible in 1984. HIV and HCV share similar transmission routes; the prevalence of coinfection with both viruses is about 25-33% (up to 50% for intravenous drug users -IDU- and 10% in homosexual people.) The current antiretroviral therapy has reduced the mortality associated with AIDS so, in the current moment, begin to take importance the non-AIDS events which involve increased mortality. The HCV liver disease is the most relevant comorbidity. The aim of the study is to determine the clinical characteristics of HIV/CHV co-infected patients in our cohort.

Material and method: 91 HIV/CHV coinfected patients where recluted during a period of 45 days. Exploratory data were collected at the time of the visit and other demographic data, laboratory and microbiology results, from the electronic medical record. The main was used to analyze quantitative variables and proportion for categorical variables. We use de statistical program SPSS, version 17 for data analysis.

Results: The prevalence of HIV/CHV coinfection was 60% in this sample. The mean age was 47.1 years, with 79.1% of males. 58% of patients had a CD4 levels > 350, 28.4% had a CD4 levels between 200 and 350 and only one patient had CD4 levels < 100. HIV viral load was undetectable in 85.6% of all patients. The route of transmission was primarily parenteral in 84.3% (associated with illicit drugs users), followed by heterosexual transmission in 9%. The 62.7% of patients were coinfected with an unfavorable HCV genotype (genotype 1 and 4 in 45.1% and 17.6% respectively); 14.3% of patients was genotype 3 and just one patient was infected by a genotype 2. Approximately 60% of patients had high HCV viral loads (> 800.000 copies). The duration of HCV infection was greater than 20 years in almost half of patients (47%) and less than 10 years in 4% of patients.

Conclusions: The prevalence of HIV/HCV coinfection in our cohort is 60%. The patient coinfected model in our area would be a middle-aged man, about 47 years old, with good immunological and virological monitoring of HIV infection. The main route of acquisition was parenteral (drug users) in 9 out of 10 patients, which could explain the higher prevalence of coinfection in our cohort than in others cited in the literature. Two out of three co-infected patients have an unfavorable genotype with a time evolution more than 15 years in almost 8 out of 10 patients.

A-237
DEGREE OF HEPATIC FIBROSIS IN HIV AND HCV COINFECTED PATIENTS MEASURED BY INDIRECT METHODS: APRI, FORNS AND FIBROSCAN

J. Martínez Carrilero, H. Aichner, L. Fernández de Orueta, G. Vicente Sánchez, M. Pérez Fernández, R. Regajo Gallego, G. Pérez Caballero, A. Monereo Alonso

Department of Internal Medicine. Hospital Universitario de Getafe. Getafe (Madrid), Spain.

Objectives: HIV infection changes the natural history of hepatitis C: increases the risk of descompensation and the risk of chronicity, accelerates the progression of liver fibrosis and decreased survival after the first decompensation. Extensive hepatic fibrosis is the best predictor of disease progression and, in addition, also has therapeutic implications: in case of significant fibrosis should be prioritized antiviral treatment, while in cases of minimal fibrosis, treatment would be contraindicated if there are predictors of poor response. The gold standard for assessing the degree of fibrosis in patients with chronic hepatitis C is liver biopsy, but it is an invasive procedure with complications. Furthermore, the fibrosis distribution is not homogeneous (cirrhosis diagnosis is lost in up to 10-30% of cases) and there are significant interobserver differences (errors of interpretation up to 33%). Therefore, other noninvasive methods have been developed such as APRI index, Forns index (IF) and FibroScan. The purpose of our study is to determine the degree of liver fibrosis in coinfected HIV/CVH patients and to investigate whether there are differences in certain aspects related to HIV infection (clinical CDC stage, CD4 count or HIV viral load) or HCV infection (genotype).

Material and method: we permorfed fibroscan to 91 coinfected HIV/CHV patients and APRI index (AST and platelets) and Forns index (age, platelets, GGT and cholesterol) were calculated in all of them. According to the Fibroscan value a fibrosis grade was assigned (METAVIR scale). For APRI and Forns index we established two breakpoints to classify the patients into low degree of fibrosis, high or indeterminate degree. The mean was used to analyze quantitative variables and proportion for categorical variables. For comparison between qualitative variables we used the chi-square test and for comparison of means, t-Student test or Mann-Whitney test. We use the statistical program SPSS, version 17.

Results: According to the APRI values, 23.9% of patients had an advanced degree of fibrosis (APRI > 1.5), 31.8% had low degree of fibrosis (APRI < 0.5) and 44.3% had undetermined grade of fibrosis (APRI between 0.5 and 1.5). According to the values obtained from the Forns index, 37.5% of patients had high degree of fibrosis (FI > 6.9), 11.4% low degree of fibrosis (FI < 4.2) and in 51.1% was indeterminate (between 4.2 and 6.9). The mean Fibroscan value was 12.82 kPa, which accord with a low grade of fibrosis in METAVIR scale (F0-F1), and was present in 40.2% of patients; 18.4% were F2, another 18.4% were F3 and 23% were F4 (high degree of fibrosis). The differences in the degree of fibrosis according to CDC stage, CD4 count, HIV viral load or the presence of favorable or unfavorable HCV genotype, were all no significant.

Conclusions: Only about half of patients could be classified by APRI and Forns index (55% and 49% respectively), being able to rule out significant fibrosis in 31% of patients with APRI and you 11.4% of patients by Forns index. Therefore, these methods were not applicable in a large percentage of patients. More than half of patients present with Fibroscan significant degree of fibrosis but not advanced fibrosis; these patients do not require immediate treatment or screening tests for complications of chronic liver disease. A quarter of patients have liver cirrhosis stage by Fibroscan (F4), being essential the screening and prevention of complications of portal hypertension and hepatocellular carcinoma in this group. There were no statistically significant differences in fibrosis degree as CDC stage, CD4 count, HIV viral load or favorable/unfavorable HCV genotype.

A-238
LABORATORY DATA OF LIVER DISEASE IN A COHORT OF COINFECTED HIV/HCV

H. Aichner, J. Martínez Carrilero, M. Pérez Fernández, G. Vicente Sánchez, R. Regajo Gallego, L. Fernández de Orueta, A. Monereo Alonso, G. Pérez Caballero

Department of Internal Medicine. Hospital Universitario de Getafe. Getafe (Madrid), Spain.

Objectives: HIV and HCV share similar transmission routes, with a coinfection prevalence of 25-33%. Antiretroviral treatment has caused a reduction in AIDS-related mortality, making liver disease by HCV in the most relevant comorbidity. HIV infection changes the natural history of hepatitis C virus, causing an increased risk of chronicity (up to 90%), accelerates the progression of liver fibrosis to cirrhosis (mean 26 years in coinfected versus 38 years in monoinfected), increased the risk of decompensation and, after the first episode, survival is reduced. The risk of developing hepatocellular carcinoma is, at least, similar to the general population. This study claims to determine the prevalence of this population and to record the degree of hepatic involvement in this population to determine the potential number of patients who are candidates for antiviral treatment and how many of them require screening for cirrhosis and hepatocellular carcinoma.

Material and method: a total of 91 HIV-CHV coinfected patients were recruited. Data were obtained from electronic medical records, with a minimum previous follow up of six months. The mean was used to analyze quantitative variables and proportion for categorical variables. This analysis was performed using statistical program SPSS version 17.

Results: The prevalence of coinfection was 60%. The mean value of AST was 54 and 78.9% had a normal or elevated value less than twice the upper limit of normal. The mean value of ALT was 58 means, and 80% had a normal or elevated less than twice the upper limit of normal. The mean of serum bilirubin level was 0.81; 88.9% of the patients had a normal value and only 6 patients had a bilirubin value greater than 2 mg/dL. Cholesterol levels were normal in 60.2% of patients, and were lower than desired in 20.5%. Severe thrombocytopenia (less than 50,000 platelets/L) was present in 6.7% of patients, 58% of patients had normal platelets levels (> 150,000 platelets), 19.3% a mild thrombocytopenia and 15.9% moderate. The leukocytes recount was normal in 86.7% of patients; any patient had leukopenia less than 1,500 cells/L. On examination, patients had hepatomegaly and splenomegaly in 19.3% and 10.3% respectively, 93.2% had no collateral circulation, and there were absence of spider veins in 89.8%. Around 23 patients had an upper endoscopy performed recently (past year).

Conclusions: the prevalence of coinfected HIV/HCV is 60%. Approximately 70% of patients will present whit AST and ALT levels normal or slightly elevated (no more than twice the upper limit of normal) and bilirubin value was normal in 9 of 10 patients. The finding of leukopenia and/or moderate or severe thrombocytopenia was uncommon. Cholesterol levels were lower than the normal value in 20% of patients.

A-239
COMPARISON OF NONINVASIVE METHODS FOR ASSESSING HEPATIC FIBROSIS: APRI, FORNS AND FIBROSCAN

H. Aichner, J. Martínez Carrilero, L. Fernández de Orueta, M. Pérez Fernández, G. Vicente Sánchez, R. Regajo Gallego, A. Monereo Alonso, G. Pérez Caballero

Department of Internal Medicine. Hospital Universitario de Getafe. Getafe (Madrid), Spain.

Objectives: Infection with the HIV virus alters the natural history of hepatitis C: increases the risk of chronicity, accelerates the progression of liver fibrosis with increased risk of decompensation and decreases survival after first decompensation. Extensive hepatic fibrosis is the best predictor of disease progression and it has also therapeutic implications. The gold standard for assessing the degree of fibrosis is liver biopsy, but it is an invasive procedure with complications, there is no homogeneous distribution of fibrosis (loss of diagnosis of cirrhosis in 10-30%) and there exists a significant interobserver variability (errors of interpretation about 33%). Therefore we have developed other noninvasive methods, among which include APRI index, Forns index and Fibroscan. The aim of our study is to assess the concordance of noninvasive biochemical methods to assess the degree of liver fibrosis compared to data obtained using FibroScan in isolation or in combination.

Material and method: We obtained de data of fibroscan (liver stiffness by ultrasound) from 91 HIV patients co-infected with hepatitis C from the Internal Medicine Department, and we also calculated values of APRI (AST and platelets) and Forns (age, platelets, GGT and cholesterol) for the same patients. Were taken as cutoff values to classify FibroScan liver fibrosis (METAVIR score): ≤ 7.0 kPa corresponds to F0-F1, from 7.1 kPa to 9.4 kPa corresponds to F2, from 9.5 to 14.5 kPa kPa corresponds to F3 and values > 14.5 kPa correspond to F4. The values of APRI and Forns < 0.5 and < 4.2 respectively excluding significant fibrosis, values > 1.5 and > 6.9 respectively, for diagnosis of significant fibrosis. The index used to assess agreement was kappa index, whose calculation was obtained with the statistical software SPSS 17.

Results: In our cohort, 23.4%, 37.5% and 41.2% of patients presented an advanced degree of fibrosis by APRI, Forns and Fibroscan respectively, and a low degree of fibrosis in 31.8% (APRI), 11.4% (Forns) and 41.4% (fibroscan). The degree of concordance of APRI index with Fibroscan showed a kappa index of 0.57 and 0.34 in case of Forns index. For advanced degrees of fibrosis concordance was 67% (21/31) for APRI index and 84% (27/34) for Forns index, being 100% (15/15) and 50% (5/10) for low degrees of fibrosis respectively. The concordance of both

biochemical methods simultaneously with Fibroscan was 0.58 in total, with 82% for the advanced degrees of fibrosis and 100% for low degrees of fibrosis.

Conclusions: Concordance of APRI with Fibroscan was moderate, however Forns index showed a poor concordance degree with Fibroscan. Both indexes used simultaneously shows fair agreement. Such methods could be useful in identifying the most extreme degrees of fibrosis, avoiding hepatic biopsy in a substantial proportion of coinfected patients whose degree of fibrosis measured by Fibroscan matches with at least one of the values estimated by biochemical indexes. A limitation of the study is not using liver biopsies to compare the results of biochemical methods or elastography.

A-240
INFECTIVE ENDOCARDITIS IN INTERNAL MEDICINE: A RETROSPECTIVE DESCRIPTIVE STUDY. SALAMANCA 2003-2012

M. Fraile Villarejo, I. González Fernández, S. Márquez Batalla, A. Plata Izquierdo, M. Borao Cengotita-Bengoa, P. Miramontes González, E. Puerto Pérez, M. Pérez García

Department of Internal Medicine I. Hospital Universitario de Salamanca. Hospital Virgen de la Vega. Salamanca, Spain.

Objectives: To analyze the epidemiological and clinical characteristics of patients with diagnosis of infective endocarditis in an Internal Medicine Service in Salamanca during the period from May 2002 to May 2012.

Material and method: Through review of the medical records of patients diagnosed of infective endocarditis, these data were analysed: year of diagnosis, age, gender, heart valve affected, risk factors, etiologic agent, clinical signs of sepsis, length of hospital stay and need of transfer to Cardiology Department.

Results: 14 of 12063 (0.12%) admissions in our Internal Medicine Department from May 2002 to May 2012 were diagnosed of infective endocarditis. Sex distribution was 57.15% men and 42.85% women. The average age was 69 years and the median 70 years (range 21-90). Valve involvement was: mitral (50%), tricuspid (28.6%), pulmonary (7.1%), pacemaker electrode (7.1%) and in one of the cases it was not identified the valve lesion. 71.4% of patients had a history of structural heart disease, the most frequent was valvular heart disease (57.14%). 42.9% of patients had prosthetic valve: 66.7% mitral and 33.3% aortic. One patient had ventricular-atrial derivation and another one a pacemaker. None were intravenous drug user. Staphylococcus aureus was the etiologic agent in 42.85% of cases, of which 83.3% were methicillin-resistant. 21.43% were coagulase-negative staphylococci, 14.28% Streptococcus sp., 7.14% Enterococcus faecalis, and in 14.28% of cases the responsible agent was not identified. The average hospital stay was 16 days and the median 15 days, with a range from 5 to 50 days. Related to clinical evolution, 57.8% had clinical criteria for sepsis, 21.4% died during the period of hospitalization, and 42.8% of patients were transferred to Cardiology Department.

Discussion: In our Internal Medicine Department, the diagnosis of infective endocarditis is a small number of cases a year (1-2). There is no major differences in gender distribution, and the mean age at diagnosis is 69 years. Patients most often affected are those with structural heart disease, especially prosthetic valve carriers. The valve most often affected is the mitral, followed by the tricuspid. The most common pathogenic microorganism is Staphylococcus aureus methicillin-resistant, followed by coagulase-negative staphylococci. During admission most patients present clinical signs of sepsis, and it is common the transfer to Cardiology at the poor clinical outcome and the possibility of needing surgical treatment.

Conclusions: Although very often suspected in patients admitted to Internal Medicine, infective endocarditis is a rare diagnosis. It is essential to exclude it in patients with signs of sepsis without a clear focus and with a history of structural heart disease, especially those carriers of prosthetic valves or other cardiac devices. Due to the high prevalence of infection with methicillin-resistant gram-positive cocci, it is necessary to identify the predisposing factors in order to start an appropriate empirical antibiotic treatment early. Infective endocarditis is a serious condition with a high rate of deaths and need of surgical management.

A-241
INFECTIOUS DISEASES IN PATIENTS WITH TYPE 2 DIABETES MELLITUS ADMITTED TO HOSPITALIZED INTO THE INTERNAL MEDICINE SERVICE

P. Mujica Addimandi, C. Rodríguez Martín, S. Calzada Simón, C. Jauset Alcalá, A. Serrano Morte, S. Miranda Riano, B. Monteagudo Nogueira

Department of Internal Medicine. Hospital Clínico Universitario de Valladolid. Valladolid, Spain.

Objectives: Determinate more susceptible infectious cause, host-factors and specific microorganism in patients with type 2 diabetes mellitus hospitalized in the Internal Medicine Service.

Material and method: A retrospective study was conducted between May 2011 and May 2012 at the Internal Medicine Service of The Clinical Hospital of Valladolid, among 113 type 2 diabetic patients hospitalized with clinical infection, identifying age, sex, glycosylated hemoglobin, morbidity process and microorganism isolated.

Results: From 113 type 2 diabetics hospitalized with clinical infection disease, 58% were males. There were 38.4% cases with confirmed etiology and 61.6% cases with clinically suspected etiology. 9.8% cases has an oncologic morbidity were admitted to hospitalized. The infectious diseases presented in type 2 diabetics hospitalized patients were 52.2% respiratory tract infections, 33.6% urinary tract infections, 6.2% skin infections, 4.4% intra-abdominal infections, 2.7% no focus infection and 0.9% bone infections. Total nosocomial infections were 6.3% went admitted to hospitalized. Escherichia coli was the most common agents isolated, being involved in 16 cases (13.3%), followed by Enterococcus faecalis (5.8%); Pseudomona aeruginosa (5%); Staphylococcus aureus (2.5%); Candida glabrata, Morganella morgani, Morganella catarrhalis, Staphylococcus epidermidis, Staphylococcus saprofiticus and Candida albicans, 2 cases reported each (1.7%). Methicillin-resistant Staphylococcus aureus, Corinebacterium, Acinetobacter, Streptococcus pneumoniae, Proteus vulgaris, Haemofilus influenzae, Klebsiella pneumoniae, Staphylococcus hominis, 1 case reported each (0.8%). The mean mortality rate during the hospitalization was 14.3%. Mortality in less than 80 years old patients were 7.4% and older than 80 years were 20.6% resulting statistic significative ($p < 0.05$). Glycosylated hemoglobin and mortality presented in controls with HbA1c less than 7% mortality were 14.7% and controls with HbA1c more than 7%, mortality were 13.6% not resulting statistic significative ($p > 0.05$).

Conclusions: Respiratory tract infections were the most common cause of infectious disease in patients with type 2 diabetes admitted to hospitalized in the Internal Medicine Service, followed by Urinary tract infections. More frequent isolated organisms were Escherichia coli, Enterococcus faecalis, Pseudomonas aeruginosa, Staphylococcus aureus. Mortality is higher in patients over 80 years. Not evidence statistic significant in mortality between patients depending on glycemic control.

Table 1 (A-241). Infectious diseases in type 2 diabetics hospitalized patients in the Internal Medicine Service

Infectious diseases	Frequency (cases)	Percentage (%)
Respiratory tract infections	59	52.2
Urinary tract infections	38	33.6
Skin infections	7	6.2
Intra-abdominal infections	5	4.4
No focus infection	3	2.7
Bone infections	1	0.9
Total	113	100

A-242
CLINICAL EXPERIENCE WITH RALTEGRAVIR IN HIV AND HCV COINFECTED PATIENTS IN A COHORT FROM THE SOUTHEAST OF SPAIN (PERIOD 2007-2011)

C. Smilg Nicolás, F. Vera Méndez, A. Moreno Hernández, L. Martínez Fernández, G. Tornel Sánchez, J. Vega Cervantes, M. Mozo Cuadrado

Department of Internal Medicine. Hospital General de Área Santa María del Rosell. Cartagena (Murcia), Spain.

Objectives: To determine the effectiveness, tolerability and safety profile of raltegravir (RAL) in HIV and HCV coinfected patients, as well as the main use indications of this antiretroviral agent in this population.

Material and method: Prospective cohort of 28 HIV and HCV coinfected patients in which we decided to start RAL as part of the antiretroviral regimen. In our study we evaluated the following variables: age, sex, CD4 lymphocytes cell count (cells/mcL) and viral load (VL; copies/ml), both at the baseline and the final of follow up, hepatic fibrosis grade determined by transitory elastography, use indications of RAL, clinical tolerability and hepatic toxicity grade in the clinical follow up.

Results: The cohort included 28 HIV-HCV coinfected patients, 3 of which were females (11%) and 25 males (89%), with a median age of 45 years. The median of CD4 lymphocyte cell count and VL at baseline was 407 cells/µl and 192 copies/ml (2.28 Log10) respectively. The study period covered from the 1st march 2007 to the 1st may 2011 with a median of clinical follow-up of 28 months. In 24 patients (86%) underwent transitory elastography to know the grade of hepatic fibrosis. Nine of them (37.5%) showed cirrhosis (> 14.5 Kpascal). Among the cirrhotic patients, the median of fibrosis grade by transient elastography was 15.9 Kpascal. The criteria for starting RAL in our cohort were: rescue therapy in 17 cases (60.71%), intensification therapy in 7 cases (25%), toxicity by other antiretroviral drugs in 2 cases (7.14%) [1 case by protease inhibitor (PI) and 1 case by Efavirenz, a non-nucleoside analog of reverse transcriptase] and in 2 cases (7.14%) as start therapy in naïve patients. During the follow-up no patient showed hepatic decompensated disease or 3-4 grade alteration in ALT-GPT and AST-GOT transaminases respectively. In 5 patients (17.85%) 3-4 grade transitory elevations of GGT were observed, which were caused by the abusive alcohol intake. No patient interrupted the RAL treatment during the follow-up. At the end of follow up, we observed an increase of the median CD4 lymphocytes cell count (80 cells/mcL) and all patients achieved completed suppression of viral load (VL < 25 copies/mL).

Discussion: The HIV-HCV coinfection increases the patogenity of both viral infections. The evolution of HCV to cirrhosis is faster among the coinfected subjects, being the hepatic morbi-mortality higher in this group than in patients only infected by HCV or HIV. RAL is the first integrase inhibitor approved for clinical use. It has the peculiarity of not being metabolized in the liver by the cytocrome p450 enzyme, as well as it happens with the IP, but metabolized by glucuronidation pathway. This confers additional advantages because there is not a significant increase in its plasmatic concentration (Cmax, Cmin, AUC) in patients with chronic hepatic disease and cirrhosis, even in case of moderated or severe hepatic insufficiency (B and C Child-Pugh class). This explains that RAL is a drug with low or nule liver toxicity. It also has few interactions, which makes it a first line drug in the HIV-HCV coinfected population and hepatic transplanted patients due to the absence of interactions with immunosuppressive therapy as cyclosporine or tacrolimus.

Conclusions: In our HIV-HCV coinfected patients cohort, RAL showed to be an effective, safe and well tolerated drug. A significant proportion of coinfected patients had cirrhosis criteria by transitory elastography, not being detected during the clinical follow-up significant hepatic toxicity or any hepatic decompensated disease.

A-243
LISTERIOSIS

M. García Gómez[1], E. Bereciartua[1], K. Aguirrebengoa[1], J. Goikoetxea[1], L. Guio[1], M. Montejo[1], L. López Soria[2], J. Hernández[2]

[1]Infectious Disease Unit, [2]Microbiology Department. Hospital de Cruces. Barakaldo (Vizcaya), Spain.

Objectives: 1. To describe the underlying conditions, clinical characteristics and received treatment of a cohort of patients with listeriosis in the last 4 years at our hospital. 2. To describe the predictor factors of mortality.

Material and method: Retrospective analysis of patients with isolation of Listeria monocytogenes in sterile body fluids admitted at our hospital between January 2008 and December 2011. Demographic, clinical, laboratory and therapeutic variables are collected. Neonatal cases are excluded. In this study we have used listeriosis-related mortality as the dependent variable. As independent variables, we used: age, L. monocytogenes serotype, immunosuppressive therapy, corticosteroids treatment, neurological symptoms, empiric treatment and definitive therapy. Univariate analysis was first performed. All variables with a p value < 0.1 were then introduced in a multivariate multiple linear regression model in order to identify independent predictors of mortality.

Results: At the 4 years studied period, we found 36 cases of adult listeriosis. 20 patients (56%) were men and 27 patients (75%) were < 65 years. The mean age at diagnosis was 57.81 + 15.64 years (median 61 years). The most frequent serotype was 4b, isolated in 16 patients (43%) followed by 1/2a in 14 (38%), 1/2b in 4 (11%) and 1/2c in 2 (5%). The most common underlying conditions were: malignancy in 18 patients (50%) -solid tumour in 11/18 and hematologic malignancy in 7/18-, immunosuppressive therapy in 17 (47%), corticosteroids treatment in 13 (36%), alcoholism in 13 (36%), hepatopathy in 9 (25%), pregnancy in 4 (11%) and diabetes mellitus in 5 patients (14%). There were 4 patients (11%) with no predisposing factors. The most common clinical presentations of listeriosis was: bacteremia in 29 patients (81%) - primary bacteremia in 23 cases (64%) and gastrointestinal bacteremia in 6 patients (17%) - and CNS infection in 7 patients (19%) - meningitis in 1 (3%) and meningoencephalitis in 5 (14%) -. Blood culture was positive in 30 patients (83%), CSF in 4 (11%), peritoneal fluid in 2 (5.6%) and one each (2.8%) in synovial fluid and in a vascular graft. The mean of C-reactive protein level was 11.04 + 8.48 (median 8.4). With

regard to the antibiotic treatment, 22 patients (61%) received inadequate initial empirical treatment. 24 patients were treated with ampicillin (67%) as definitive therapy, and 7 of them (20%) were also given aminoglycosides. In 8 cases, death occurred before any definitive treatment could be established (22%). There were 10 deaths related to listeriosis infection (28%). In the univariate analysis, listeriosis-related mortality was associated with CNS involvement from any origin (p = 0.001), corticosteroid therapy (p = 0.018) and a definitive treatment regimen without ampicillin (p = 0.002). The inadequate empirical treatment showed a borderline significance (p = 0.054). In the multiple regression model, only the CNS involvement from any origin (p = 0.022) and a definitive treatment regimen without ampicillin (p = 0.038) showed a significant independent association with listeriosis-related mortality.

Discussion: Listeria monocytogenes, a facultative intracellular gram-positive rod, is a recognized cause of bacteremia and meningoencephalitis in humans, especially in neonates, pregnant women, the elderly and immunosupressed hosts, associated with a high fatality rate.

Conclusions: The profile of studied population shows a clear predominance of malignancies as the most commonunderlying condition, representing the half of the cases of our cohort. Listeriosis-related mortality rate was high (28%) and it was associated with a definitive treatment regimen without ampicillin and with CNS involvement.

A-244
EPIDEMIOLOGICAL CHARACTERISTICS OF HIV-POSITIVE OVER THE LAST 5 YEARS OR IN A SIMILAR PERIOD 10 YEARS AGO

M. Pérez, J. Martínez, L. Fernández de Orueta, R. Regajo, G. Vicente, H. Aichner, J. Esteban

Department of Internal Medicine. Hospital Universitario de Getafe. Getafe (Madrid), Spain.

Objectives: see the differences between the characteristics of patients according to the date of HIV diagnosis, as it has occurred over the past 5 years or in a similar period 10 years ago.

Material and method: a retrospective descriptive review in which we chose 2 samples of patients according to the date of HIV diagnosis, as it has occurred over the past 5 years or in a similar period 10 years ago, to compare the different variables. In the first of these are patients whose HIV diagnosis occurred from January 1, 2007 to March 29, 2012 (n = 143) and the second are those who were diagnosed from 1 January 1999 to 31 December 2001 (n = 104).

Results: In relation to sex did not find significant difference (p = 0.9). With regard to infection we found that the most prevalent route of transmission was 10 years ago among UDVP (40) followed by sexual in heterosexual patients (36) and homosexual patients (16) while currently the most prevalent way is the sexual route in heterosexual patients (73) followed by homosexual (52) and UDVP (7) (p < 0.001). With respect to HCV coinfection in the first sample only 10% are coinfected (14) compared to 48.5% in the sample for 10 years (48) (p < 0.001). Regarding HBV coinfection no identifiable significant difference when comparing both periods (p = 0.19). Given the CDC classification at diagnosis in both periods we found no significant difference (p = 0.35). We have analyzed this variable taking just the clinical classification (A, B and C) and again we didn't find difference (p = 0.13) although there is currently a trend towards increasingly diagnosed in earlier stages (A: 67% vs C: 23.5%) compared with the sample of 10 years (A: 54.8% vs C: 33.7%). We found significant differences with regard to place of origin of the patients in both samples (p < 0.001) and for the past 10 years a 83.5% of Spanish (86) compared to 16.5% of immigrants (17) (53% African, 41.1% American and 5.9% in Europe (excluding Spain)) currently Spanish keep being the majority with 51.7% (74) and visualized a significant increase of immigrants to 48.3% (69) (33.3% African, 47.8% American, 17.4% from Europe (excluding Spain) and 1.4% Asia) almost reaching the Spanish match that attending outpatients.

Conclusions: we found statistical significance regarding the routes of transmission in which in the early years the most common route was by UDVP and currently the most common is the sexual route in heterosexual patients. There is also a smaller number of patients coinfected with HCV significant statistics. Also draws our attention at present, despite being the Spanish the most prevalent group increased immigrants has grown statistical significance to almost equal the Spanish group. On the other hand, we have found no statistical significance comparing the variable sex, HBV, and although each time the diagnosis is made at earlier stages, based on the CDC classification result was not significantly estatisitic.

A-245
INCIDENCE AND CHARACTERISTICS OF PALUDISM, AN EMERGING ILLNESS IN THE LAST FEW YEARS

R. Cabo, A. Blanco, C. Dueñas, V. Portillo, E. Salazar, M. Cuesta, S. Molinero, J. Lorenzo

Department of Internal Medicine. Complejo Asistencial de Burgos. Burgos, Spain.

Objectives: To analyze the epidemiology, clinical signs, complications and treatment of paludism in registered cases in a tertiary care hospital in the last five years.

Material and method: This is a retrospective cohort study in which 26 malaria cases were analyzed in the Complejo Asistencial Universitario de Burgos among 2007-2012. The diagnosis was executed using thick blood smear (in all the cases), serology and microscopy.

Results: In our series, 72% (18 patients) were men, 28% (7 patients) were women and the average age of the patients was 34 years old. 47.8% were Europeans, 34.8% were Africans, and the rest were from Asia (13%) and Central America (4.3%). 80% of the patients had travelled to malarious endemic areas but only 12% carried out the complete chemoprophylaxis. Plasmodium species was found in 60% of the cases, and the results are the following: P. falciparum 32%, P. vivax 20%, P. ovale 4%, mixed 8%. As regards the clinical manifestations, patients presented fever (100%), cephalalgia (58%), asthenia (66.7%), abdominal pain (29.2%), sickness (25%), diarrhoea (16.7%) and arthromyalgia (29.2%). Splenomegaly was observed in 47.8% of the cases, hepatomegaly was presented in 17.4%, anaemia in 45.8% and thrombocytopenia in 83.3%. As regards the complication data, it was detected hypoglycemia (8.3%), hypertransaminasemia (12.5%), hyperuricemia (6.3%), jaundice (29.2%), respiratory distress (4.2%) and a decrease in the awareness (8.3%). Three patients needed Intensive Care Unit (ICU) and two of them were dead (one P. Falciparum, the other one was not diagnosed). The response to treatment was good in most of the cases (48% quinine – quinidine + doxycycline, 20% atovaquone-proguanil and 20% chloroquina).

Discussion: Paludism is an illness caused by Plasmodium (P. falciparum, P. vivax, P. ovale, P. malariae, P. knowlesi). It is endemic in many parts of Africa, Asia and Central and South America. Moreover it is potentially lethal depending on the species that causes it, the age of the patient, the possible complications and the results of the treatment. The incidence in our country is

increasing due to the journeys and the immigration so we always have to bear it in mind when we find a patient with high fever who belongs to these groups mentioned before.

Conclusions: There is an increase in the diagnosis with malaria in our country. Despite the seriousness in some specific cases, when the diagnosis is made fast and the treatment is adequate, there are not complications. The execution of prophylaxis decreases the diagnosis but it does not exclude it.

A-246
PLASMA LEVELS OF PENTRAXIN 3 ARE ASSOCIATED WITH BACTEREMIA AND POOR OUTCOME IN FEBRILE PATIENTS WITH TYPE-2 DIABETES

J. Cedillo[1], N. Martín-Suñé[2], J. Rios[2], M. López-Rodríguez[2], E. López-Collazo[3], F. Barbado[2], C. Montiel[1], F. Arnalich[2]

[1]Department of Pharmacology and Therapeutics. Facultad de Medicina, UAM, IdiPAZ. Madrid, Spain. [2]Department of Internal Medicine; [3]Medical Research Unit. Hospital Universitario La Paz, IdiPAZ. Madrid, Spain.

Objectives: New markers are needed to predict bacteremia in febrile patients at high risk of poor outcome. We investigated the value of pentraxin 3 (PTX3) as a biomarker for disease severity in a cross-sectional non-interventional pilot study of type-2 diabetic patients presenting with fever at the emergency department.

Material and method: Plasma concentrations of PTX3 and C-reactive protein (CRP) were measured by an ELISA assay in 64 patients with fever (> 38.0 ºC) and signs of systemic infection for at least 2 days. Empirical antibiotics were initiated after blood cultures and adjusted according to clinical and radiological findings. At the 30-day follow-up visit blood samples were taken from 49 patients after full recovery. Nonparametric tests were used throughout the study. The Mann-Whitney U test was used for evaluating the difference between different groups, and Spearman's rank correlation coefficient for evaluating correlations. Statistical analysis was performed using SPSS 14.0.

Results: Bacteremia were detected in 17 patients (Gram-negative bacteria in 11 cases), 6 of whom developed septic shock (three deaths). Patient characteristics and laboratory data (median and range) are summarized below. The values of these biomarkers decreased to normal values at the follow-up visit and were: Plasma PTX: 3 4.7 µg/L (0.5-14 mg/L), and CRP levels: 2.1 mg/l (0-6.2.0 mg/L). High PTX 3 levels have better prognostic value for bacteremia (AUC = 0.72; 95%CI 0.60-0.83) than CRP (AUC = 0.67; 95%CI 0.59 -0.81).

Discussion: PTX 3 may be particularly useful to diagnose septic conditions because of its induction by proinflammatory cytokines and bacterial products (Pierrakos et al. Crit Care. 2010;14(1):R15). PTX 3 could be a better early marker of bacteremia than CRP due to its rapid release to blood-stream.

Conclusions: PTX 3 is an early predictor of bacteremia and septic shock in febrile patients with type 2 diabetes.

A-247
NUMBER OF CASES OF INFECTIOUS SPONDYLODISCITIS TWO YEARS DIAGNOSED IN INTERNAL MEDICINE SERVICE (IMS) OF A HOSPITAL OF SPECIALTIES OF THE SAS

V. Lechuga Flores, S. Romero Salado, A. García Egido, V. Manzano Roman, O. Mera Gallardo, G. García Dominguez, G. Ruiz Villena, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario Puerto Real. Puerto Real (Cádiz), Spain.

Objectives: Infectious spondylodiscitis (IS) condition which incidence has increased on last years. We study clinical and epidemiological characteristics EI diagnosed on SMI during two years.

Material and method: Descriptive observational study. Select patients admitted during two years, with EI diagnosis. Variables studied: age, sex, symptoms, clinic, evolution, additional tests, microbiological study (blood), time (guided spinal puncture, visceral abscess) and treatment (medical/surgical).

Results: Patients diagnose for IE: 7. male: 57%. Average age: 57 years old (35-81). Most common symptoms were low-back pain and fever, present on 100% cases; other symptoms were chills and shivering, asthenia and less frequently, root compression. Time between symptoms onset and diagnosis was 5 weeks. Patients presented a pathological X-ray on 100% cases. Other tests were conducted complementary: NMR on 100% cases and CT by 57%. Vertebral segment affected most frequent was lumbar (92.85%) followed by dorsal (8.2%). Patients percentage with isolated discitis was 16% and spondylodiscitis 84%. Location was vertebral unique on 71.5% and multiple on 28.5% of patients. Psoas abscess appeared on 42.85% and 28.57% epidural abscess. Patients presented severe Sepsis clinic on 42.85% of cases and data of Leukocytosis and high CRP on 71.4%. Septic focus was, in order of frequency: bacteremia of unknown origin, handling medical, urinary and previous spinal surgery. Microorganism isolated on blood cultures on 71.42% cases, spinal puncture guided 5.71%, cultivation of hepatic abscess 5.71, other 5.71%. No patient presented endocarditis associated. Most frequent microorganisms isolated were S. aureus and E. coli, on 42.85% each one, S. epidermidis was isolated on 14. 28%. For treatment, antibiotherapy was used on 100% of cases, most frequent were B-lactam and ciprofloxacin, on one case of B- lactam allergic patient vancomycin was used in addition vancomycin. psoas abscess needed drained on 14.28% patients and surgical intervention was required on 42.85% cases either by commitment neurological (28.57%) or by replacement of osteosynthesis materials (14.28%).

Discussion: Findings on our patients do not differ with characteristics described on bibliography, being location, differential delay, etiological agents and similar percentage of complications. If struck us by the frequency of enteric bacterium as etiology, although our series still small.

Conclusions: We must take IE into accounting differential diagnosis of patients with axial pain, fever and reactants increase, or history of infections or procedures susceptible of bacteremia. Lateral simple x-ray can make us suspect diagnosis must be confirmed with NMR and microbiological cultures. Diagnosis and home early treatment is essential to reduce number of complications and sequels.

Table 1 (A-246). Patients characteristics and laboratory data

	Bacteremia	Non-bacteremia	Septic shock	p value (bacteremia versus non-bacteremia)
Age, years	67 ± 11	68 ± 12	70 ± 9	
Pneumonia, n (%)	6 (35)	20 (43)	2 (33)	NS
Urinary tract infection	7 (41)	18 (38)	3 (50)	NS
Other or unkown focus	4 (24)	9 (19)	1(20)	NS
Charlson Index	4 (2-7)	4 (2-8)	5 (3-8)	NS
C-reactive protein (mg/L)	84 (31-175)*	79 (28-167)	91 (45-182)*	< 0.05
Pentraxin 3 (µg/L)	35 (10-217)**	16 (4-182)	58 (23-198)**	< 0.01

A-248
PATTERN OF DISEASES ASSOCIATED WITH MSSA OR MRSA

C. Amado[1], R. Portilla[1], L. Velasco[1], N. Calvo[1], A. Coduras[1], R. Teira[1], A. Campo[2], I. de Benito[2]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital Sierrallana. Torrelavega (Cantabria), Spain.

Objectives: Infections caused by Methicillin-resistant Staphylococcus aureus (MRSA) are cause of increasing concern worldwide, as its spread in the community seems to rise steadily. However, many aspects of its relative pathogenicity, invasiveness and clinical spectrum remain to be defined.

Material and method: We reviewed the medical records of all patients cared for at the Hospital de Sierrallana between January 2009 and December 2011 in any of whose biologic samples sent for bacteriologic culture Staphylococcus aureus had been isolated. Culture, identification and antibiotic resistance was performed throughout the period studied by means of the automated PHOENIX system (Becton-Dickinson, San Jose, USA) with panels PMIC/ID-73 according to the CLSI standards. Multiple isolates from single clinical episodes were counted as only one, as were multiple isolates from a single chronic source (most commonly, chronic vascular ulcers). Cases were classified into 2 groups according to the susceptibility of the isolates to oxacillin (MRSA, o methicillin-susceptible, MSSA), which were then compared regarding their clinical characteristics and in-hospital mortality. We used the Charlson index to evaluate co-morbidity, classifying patients as having no (index: 0), low (index: 1-2) or high co-morbidity (index > 2).

Results: 444 cases fulfilled the criteria specified above. Table 1 summarizes their most relevant clinic-epidemiologic characteristic broken down by study group (methicillin-resistance). Table 2 shows the clinical diagnoses. The distribution of the latter by study group revealed no significant differences (p = 0.120) Sixteen (13.9%) cases of MRSA and 93 (28.3%) of MSSA were complicated by bacteremia (p = 0.003). The in-hospital mortality was 12.2% and 7% for MRSA and MSSA groups respectively (p = 0.115).

Conclusions: MRSA represents a significant problem among both community acquired and nosocomial infections in our area. The pattern of diagnoses associated with S. aureus does not differ whether the isolate is MRSA or MSSA, although the frequency of bacteremia associated with each type of isolate does. However, this seems not to influence in-hospital mortality.

A-249
INCIDENCE OF ESBL GRAM-NEGATIVE BACILLI ISOLATED FROM URINARY TRACT INFECTIONS IN A SMALL COMMUNITY HOSPITAL IN NORTH SPAIN

M. Álvarez Pérez, M. Blasco, M. Platero, J. Costales Escudero, P. Bueno, M. Menéndez Calderón, A. Gómez, F. López

Department of Internal Medicine. Hospital Comarcal de Jarrio. Coaña (Asturias), Spain.

Objectives: The objective of the study is to describe the incidence of ESBL gram-negative bacilli isolated from urinary tract infections in a small community hospital in the north of Spain and compare our data with other sources.

Material and method: A retrospective study was designed. We collected data from the microbiology laboratory since April 2011 to April 2012. We analyzed Escherichia coli and Klebsiella psneumoniae strains isolated from urinary tract infections. We investigate the origin of the specimens: primary health care vs emergency department vs hospitalization.

Results: We analyzed 5,737 urinary cultives whom were positive 1583 (27.6%). The frequency of Klebsiella pneumoniae isolates were 95 specimens (6% of total) and the frequency of Escherichia coli isolates were 994 specimens (62.8% of total). The overall percentage (range) of ESBL production among Escherichia coli and Klebsiella pneumoniae was 6.3% and 5.2%, respectively. The total incidence of ESBL-type bacteria in urinary tract infections was 4.3% (68 from 1,583 cultives). The origin of the specimens were primary health care more than the hospital (60.3% of total); 41 vs 27 cases. These specimens from the hospital were obtained more frequently in the emergency department (70.3%) In our study, the principal risk factors related to the development of ESBL-producers bacteria in urinary tract infections were: reside in nursing homes, urinary catheterization and ambulatory antibiotic overuse.

Discussion: Extended-spectrum lactamase (ESBL)-producing Escherichia coli and Klebsiella pneumoniae are an increasing cause of community and nosocomial infections worldwide. In a Spanish study GEIH-BLEE 2006 published in 2009, the incidence was 4-5%, although some large hospital presented incidence between 10-20%. In this study the acquisition was considered community acquired in most cases. The positive urine cultive in the hospitalization, were cultives obtained in the emergency department.

Table 1 (A-248)

	Male sex	Age	Hospital acquired	Comorbidity (None/Low/High)	Risk factors for MRSA
MRSA (n = 115)	61.7%	73.8	18.3%	33%/33%/33.9%	60.9%
MSSA (n = 329)	63.1%	65.9	24.6%	52.3%/23.4%/24.3%	39.5%
p value	0.738	0.000	0.198	0.002	0.000

Table 2 (A-248)

	Primary bacteremia	Orthopedic surgery	General surgery	Other abscesses	Skin and soft tissue	Respiratory	Urinary
MRSA	11 9.6%	3 2.6%	7 6.1%	13 11.3%	58 50.4%	14 12.2%	9 7.8%
MSSA	49 14.9%	24 7.3%	26 7.9%	46 14.0%	140 42.6%	29 8.8%	15 4.6%
Total	60 13.5%	27 6.1%	33 7.4%	59 13.3%	198 44.6%	43 9.7%	24 5.4%

Table 1 (A-249). ESBL producers. Community-acquired vs hospital-acquired

Bacteria (N 68)	Community- acquired (N 41)	Hospital-acquired (N 27)
E. coli (N 63)	38 (60.3%)	25 (39.7%)
K. pneumonia (N 5)	3	2

Conclusions: The ESBL gram-negative bacilli mainly occurred in islolates from outpatiens more than hospitalization. The incidence of ESBL- type bacteria is relatively low (4-6%) in our hospital. We must prevent the mechanism of community-acquired of ESBL.

A-250
COMMUNITY ACQUIRED PNEUMONIA IN A SHORT STAY UNIT. CLINICAL-EPIDEMIOLOGICAL STUDY FOR 6 YEARS. UNIVERSITY HOSPITAL GUADALAJARA, SPAIN

M. Martínez Lasheras, L. Engonga, A. Costa Cerdá, E. Vilalta, E. Martín Echevarría, A. Pereira, M. Torralba, M. Rodríguez Zapata

Department of Internal Medicine. Hospital Universitario. Guadalajara, Spain.

Objectives: Pneumonia is a common cause of admission to the Short Stay Unit (SSU). Our goal is to make a descriptive study of clinical and epidemiological data of this entity in the province of Guadalajara, y and consider whether there are guiding factors of poor prognosis and long hospital stay.

Material and method: We reviewed the medical records of patients admitted to the SSU from June 2006 to May 2012. We collected clinical and epidemiological data of all patients diagnosed with pneumonia by chest radiographs pathological. Statistical analysis was performed using SPSS.

Results: There were 241 cases, with an incidence rate of 4%, the predominant sex was male 57.7%. The median age was 69 years (IIQ 47.25 to 79). The average stay was 4.4 days ± 4.2 days. We studied the frequency of smoking (18.7%), drinking (6.5%), COPD (22.8%), number of previous admissions for respiratory infections. 74% had no previous hospitalization. Clinically, in order of frequency cough (80.1%), fever (63.8%), malaise (61%), purulent sputum (58.9%) and pleuritic chest pain (42.3%). FINE 1 (25.6%) and 3 (25.2%) were the most frequent. FINE 4 (22.8%), FINE 2 (15%) and FINE 5 (11.4%). In CURB-65 scale score; 0 (30.1%), 1 (37%), 2 (26.4%) and 3 (4.5%). The presence of renal failure does not affect the average length of stay (p = 0.54) but it does respiratory failure (40.2%). Patients with respiratory failure have a stay over 3 days compared to those who do not (p = 0.006). FINE Patients with greater than 3 have an average stay of over three days compared to those with a FINE lower (p = 0.001). Patients who have a crub-65 greater than three have an average stay of over three days compared to those with a CURB-65 lower (p = 0.006). Blood cultures were taken at 30% yielding five isolates, two of pneumococcus. Sputum culture was requested in 16.6% with 5 isolates. Legionella antigen in urine was applied in 52% with two positive cases. Pneumococcal antigen in urine was applied in 51.6% to be positive at 6.1%. The BAAR was requested in 13% and detected two cases of tuberculous pneumonia. The median duration of treatment was 11 days IIQ (10-15). The median review in the clinic outpatients IIQ was 7 days (7 to 28.75). The most commonly used antibiotics were levofloxacin (48.4%), amoxicillin-clavulanate (15.4%), cephalosporins (12.6%) and 6.5% were associated with cephalosporin and macrolides. Only had to modify treatment in 18 patients, treatment failure (9) and gastrointestinal intolerance or allergy (5) mainly.

Discussion: The patients with pneumonia who are admitted in our unit do not have a significant critical condition, without previous admisions, no toxic habits and low CURB-65 and FINE, even without hospital admission criteria. However we have found that in these patients with FINE 1 and 2 with only 24-48 hours of admission decreased significantly the time of presence of symptoms, with less morbidity. We emphasize the low detection of bacteria in blood cultures (only 4 cases compared to 10-15% of the literature).

Conclusions: We obtained 241 cases of pneumonia where pneumococcus was the most frequently detected germ (two blood cultures and fifteen antigens in urine). They are men of 70 years on average, whithout toxic habits or bronchopaties. They present malaise, cough and expectoration with FINE 1 or 2, CURB-65 0 or 1. The hospital stay was 4.4 days and the treatment used was levofloxacin and amoxicillin-clavulanate with cephalosporins. We note the early defervescence of symptoms with hospital treatment for 24-48 hours. Patients with higher average hospital stay are those with respiratory failure, and CURB-65 and FINE greater than 3.

A-251
EVALUATION OF PATIENTS STUDIED BY PROLONGED FEVER IN INTERNAL MEDICINE CONSULTATIONS OF A REGIONAL HOSPITAL

A. Vergara Díaz[1], M. Gómez Hernández[1], C. González Becerra[1], A. Sanchis Osuna[2], C. Pereira Delgado[1], S. Vidal Serrano[1]

[1]Department of Internal Medicine, [2]Department of Family Medicine. Hospital San Juan de Dios de El Aljarafe. Sevilla, Spain.

Objectives: Assess the characteristics and final diagnoses of the patients studied in our consulting M. Internal by prolonged fever.

Material and method: A total of 51 patients referred to our consulting for evaluation of prolonged fever, was selected randomly, between January and December 2011. Patients with febrile episodes of short duration and resolved with the arrival to consulting were excluded. We conducted a descriptive study by reviewing the medical records analyzing variables such as sex, age, epidemiological history, source of derivation, previous antibiotic treatment, the application and results of acute phase reactants, tumor markers, ANAS, serology (hepatitis virus, mononucleosis, HIV, Rose Bengal, Rickettsia, Coxiella), mantoux, cultures and sample type, the existence of alterations in blood count (anemia, leukocytosis, lymphopenia, lymphocytosis, neutropenia and neutrophilia), application of imaging tests (primarily chest x-ray, abdominal CT, abdominal ultrasound), the existence of hepato-splenomegaly, if treatment with doxycycline was scheduled and the final diagnosis.

Results: The 54.90% were male with mean age of 46.43 years (age range 18-86) with no history of epidemiological interest (76.47%) only one patient with rickettsiosis referred tick bite. The 66.6% had received prior antibiotic therapy primarily: 23.5% amoxicillin-clavulanate, 11.76% 20.58% levofloxacin and doxycycline, several antibiotic regimens being used up by 23.5%. The 68.62% were referred from hospital emergency and the rest from A. Primary. The Mantoux only requested in 25.49%, tumor markers in 56.86%, acute phase reactants in 94.12%, ANAs in 56.86%, Hepatitis virus in 70.58%, the mononucleosis virus in 74.50%, cultures in 74.50% (68.42% blood cultures, 65.79% urine cultures, BK 13.16%, cultures of sputum 5.26%, stool cultures 18.42%, wound exudates and catheter culture in 2.63%, and more specimens in 55.26% especially HC and UC 42.85%). Only 2 urine cultures were positive, and remaining cultures were negative. In the blood count was obtained lymphopenia in 43.13%, neutropenia in 19.60%, neutrophilia 17.64%, and anemia in 19.60%. The mean value of ESR was 47.64 and of CRP was 58.8. HIV was positive only in one case, with HBV and HCV negative in all requested. EBV IgM was positive in 10.53%, CMV IgM in 15.79%, serology for Rickettsia in 16.67%, the Rose Bengal and IG M Toxoplasma negative in all cases. All patients were on a chest radiography, abdominal ultrasound in 70.59%, TAC in 45.09%, and in a case echocardiogram (patient with endocarditis). The 15.68% had hepatomegaly and 19.60% had splenomegaly. The 60.78% of the patients was treated with doxycycline. The final diagnosis was an infection in 74.51% (21.05% infectious mononucleosis and FOD inconclusive studies, 15.78% Q fever and 7.89% rickettsiosis), neoplasia in 9.80% (40% lymphoproliferative syndrome) and Systemic disease 15.68% (37.5% IBD).

Conclusions: Most of the patients in our center for prolonged fever are immunocompetent middle-aged without epidemiological history of interest, prior treatment with antibiotics, and they are derived after evaluation in our emergency department. In most

were request acute phase reactants, serology of hepatotropic virus including mononucleosis virus serology, Rickettsis serology and cultures (especially blood and urine cultures), and radiological tests, mainly chest film and abdominal ultrasound, and the treatment with Doxycycline was initiated before concluding the studies. The final diagnosis in most cases are infectious processes, especially infectious mononucleosis, Q fever and Mediterranean spotted fever followed by systemic diseases especially IBD, and finally neoplasia, mainly chronic lymphoproliferative syndrome, leaving a high percentage of fever of unknown origin with study despite inconclusive evidence.

A-252
PATIENTS WITH CHRONIC OBSTRUCTIVE LUNG DISEASE AND COMORBIDITIES

G. Chosnis, A. Rachioti, E. Zaronakis, E. Louka, P. Karamitrou, A. Loidoris, C. Karampampa, M. Rapti

Department of Internal Medicine. General Hospital of Livadeia. Livadeia, Greece.

Objectives: Chronic obstructive lung diseases commonly coexists with other severe chronic diseases such as heart failure, diabetes mellitus, arterial hypertension, etc. The target of the study is to find their correlation.

Material and method: Retrospective study of 250 patients with chronic obstructive lung diseases, hospitalised in the Department of Internal Medicine in the period 2009-2011. Patients' age distribution 50-85 years.

Results: Comorbidities found: diabetes mellitus 45%, heart failure 40%, arterial hypertension 35%, myocardial infarction 23%, obesity (BMI > 27) 47%, depression and organic functional psychosis 12%, lung cancer 3%, bowel cancer 5%, prostate cancer 0.8%, infections 60%, alcohol abuse 3%.

Discussion: A) Patients vaccinations compliance pneumonococcus 1%, Influenza 25%, B) Late stages of chronic obstructive diseases (Gold classification stages III and IV) are linked to increased incidence of steroid diabetes.

Conclusions: Chronic obstructive lung disease is a multifactorial disease with many comorbidities. The necessity of multilateral tackle is raised for early diagnosis through preventing complications and population awaking for vaccination.

A-253
THE ROLE OF CYTOLOGY AND HUMAN PAPILOMAVIRUS TESTING IN ANAL CANCER SCREENING IN HIV POSITIVE MEN WHO HAVE SEX WITH MEN

M. Rivero Rodríguez[1], C. Hidalgo Tenorio[1], A. Concha[2], M. López de Hierro[3], R. López Castro[2], P. Palma[4], C. Gil[1], J. Pasquau[1]

[1]Infectious Disease Unit, [2]Department of Pathology, [3]Department of Gastroenterology, [4]Department of General Surgery. Complejo Hospitalario Virgen de las Nieves. Granada, Spain.

Objectives: To evaluate in the screening of high-grade lesions (HGAIN) and C. in situ in anal mucosa, if together PCR of HR-HPV and citology of the anal mucosa are more sensitive than the citology alone in a cohort of MSM HIV.

Material and method: Prospective cohort study composed by HIV-positive MSM patients seen at an Infectious Diseases Unit. The collected data were epidemiological, clinical, analytical and were taken 2 samples from the anal mucosa: one for PCR of HPV, and one for cytology every 6 months, and rectoscopy was realized in case of HSIL, and/or HR-HPV or LSIL in two occasions in 6 months. The cytological classification used was Bethesda, and the histological was Richardt.

Results: 157 patients were included, 37.3 ± 9.7 years. At this moment, 79 rectoscopies were realized: 30.4% were normal and 69.3% pathological (61.8% AIN I, 36.7% HGAIN and/or C in situ and 1.8% indeterminate). The Sensitivity (S), Specificity (Sp), predictive positive (PPV) and negative Value (PNV) of the LSIL cytology to diagnosis HGAIN and/or C in situ, were 87.5%, 46.9%, 35%, 92%, p = 0.014; for HR-HPV alone were 76.7%, 33.3%, 31.7%, 77.8%. S, Sp, PPV and NPV of the cytology and HR-HPV were 100%, 17.5%, 31.8%, and 100%, respectively.

Conclusions: HR-HPV with cytology helps to better classify healthy subjects, so that when both tests are normal confirms that the patient does not have dysplasia. In patients with LSIL in the cytology, the rectoscopy should be done directly.

A-254
RISK FACTORS IN THE PROGRESSION OF LOW GRADE INTRAEPITHELIAL NEOPLASIA (LGAIN) IN A COHORT OF HIV MSM

C. Hidalgo Tenorio[1], M. Rivero Rodirguez[1], C. Gil[1], M. López de Hierro[2], I. Segura[3], R. López Castro[4], M. López Ruz[1], A. Concha[4]

[1]Infectious Disease Unit, [2]Department of Gastroenterology, [3]Department of General Surgery, [4]Department of Pathology. Complejo Hospitalario Virgen de las Nieves. Granada, Spain.

Objectives: To analyze in a cohort of HIV-MSM, the predictors of progression of LGAIN to HGAIN.

Material and method: We performed a prospective study (December 2008-April 2012) composed of VIH-HSH belonged to cohort of seropositive patients of an Infectious Diseases Unit from a hospital in southern of Spain. These patients were included in a program of anal dysplasic lesions screening. That program enclosed anal cytology, PCR of HPV and anuscopy. Patients diagnosed with AIN I were subjected to an annual checkup that included anal cytology, HPV PCR and anuscopy.

Results: 157 patients were included, with average age of 37.3 ± 9.7 years. In the basal visit 79 anuscopies were conducted: 30.4% normal and 69.3% pathological (61.8% AIN I, 36.7% HGAIN and/or carcinoma in situ and 1.8% indeterminate). 15.2% of patients with AIN I progressed to HGAIN in a median of 22 months; Density Incidence of progression was 9.6 new cases-1,000 person/year. Factors associated with progression of LGAIN to HGAIN were to be younger p = 0.036; number of sexual partners in 6 months prior, p = 0.03; diagnosis of HIV at a younger age p = 0.02, and higher levels of CD4 cells, p = 0.03. The rest of variables analyzed like education, employment, AIDS stage, ARV, smoking, alcohol, STD, genotypes or number of HPV, viral load were not related.

Conclusions: one in every six of patients with LGAIN progress to HGAIN in two years, and usually those who were diagnosed with HIV younger, early age and with more partners in the previous 6 months.

A-255
CLINICAL AND EPIDEMIOLOGICAL CHARACTERISTICS OF PNEUMONIA PNEUMOCOCCAL IN PATIENTS ADMITTED TO THE INTERNAL MEDICINE DEPARTMENT

S. Pérez Andrada, I. Muinelo Voces, E. Fernández Pérez, A. Moran Blanco, J. Guerra Laso, J. Mostaza Fernández

Department of Internal Medicine. Complejo Asistencial de León. León, Spain.

Objectives: To study the prevalence and clinical and epidemiological characteristics of pneumococcal pneumonia presented by patients who have been admitted to the Internal

Medicine Department of Leon University Hospital, Virgen Blanca Building in the period from November 2011 to February 2012.

Material and method: Retrospective descriptive study conducted by Internal Medicine Department in the period from November 2011 to February 2012. This study was carried out reviewing medical reports. Results were expressed as percentages and average.

Results: Out of total 1.388 patients admitted, 147 were diagnosed pneumonia, during this period. 13 of these persons (8.84%) were diagnosed with pneumococcal pneumonia. Means of acquiring pneumonia: 9 Community (70%), 3 healthcare associated (23%), 1 nosocomial (7.7%). Average age: 83 years. Gender: 46, 5% women, 53.8% men. Average Charlson Index: 4.8. Clinical signs: 73% cough, 73% dyspnea, 38.4% sputum production and 34.8%purulent sputum. Location of pneumonia: 61.5% LID, 30% LII, 15.4% LSI, 23% LSD. Affectation: 69.5% lobar and 30% bilobar. Sepsis associated: 77%. Average hospital stay: 13.15 days. Mortality rate: 15.4%. Empirical antibiotic treatment with beta-lactams 77.7%. Seasonal predominance: January: 38%; February: 54%; November: 7.7%. Diagnosis: 92.3% by urine antigens, 77.7% blood cultures and 4.4 % sputum culture. Due to sputum culture and blood cultures: 7.73%. Due toc ulture and urine antigen 7.73%.

Discussion: S. pneumoniae is the most common cause of community-acquired pneumonia. Nevertheless many studies show that the microorganism can only be identified between 5-8% of the cases. The sputum culture is negative in more than 50% of patients, even between patients with the bacteraemia. In the best situation, in the 17% of the cases, blood cultures are positive before antibiotic pre-treatment. However, we use a diagnostic test that it is not affected by treatment, and it presents a high sensitivity and specificity, as these are the determination of pneumococcal antigens in the urine. In our study the most frequent identified microorganism was S. pneumoniae. The most effective etiologic method of the diagnosis has been the pneumococcal antigen determination in the urine. Highlights in our study, the empirical antibiotic therapy had not been delayed by the adsense the etiologic diagnosis, as the most important clinical guidelines recommend. This actuation probably improved the good development of our patients with severe pneumococcal infections.

Discussion: S. pneumoniae. is the most common identified etiology as cause of pneumonia. In our study, the most useful diagnostic test, in the cause of classics signs and symptoms and radiological are present, it is the determination of pneumococcal antigens in the urine. The empirical treatment with beta-lactams has been effective, as it is possible to deduced from the high survival of our patients with severe pneumonia pneumococcal.

A-256
INFECTIOUS DISEASES CONSULTANCY IN SURGICAL DEPARTAMENTS IN A MEDIUM GENERAL HOSPITAL: EPIDEMIOLOGICAL DESCRIPTION AND VALUATION OF THE IMPACT OF ANTIMICROBIAL HOSPITABLE EXPENSE

S. Hernández[1], S. Ruiz[1], M. Tasias[1], O. Araujo[1], I. Martínez[2], R. Ramírez[1], A. Delegido[1], E. Pedrol[1]

[1]Department of Internal Medicine, [2]Department of Pharmacy. Hospital Sant Pau i Santa Tecla. Tarragona, Spain.

Objectives: There is evidence that interventions to improve antibiotic prescribing in hospitals are effective. The establishment of prospective audits with intervention and feedback ("audits") seems to be one of the strategies with most impact on the appropriate use of antimicrobials (level of evidence IA). Our purpose is to describe epidemiologically the attended patients with a infections consultancy in surgical services, and valuate its impact in the global pharmaceutical expense of antimicrobials.

Material and method: The program was developed in four surgical services for a period of 6 months. Every day we reviewed all positive cultures in the microbiology department, commenting each case with a microbiologist specialist. Then, we performed a non-tax specialist advice to the responsible physicians for each patient by one or more visits to patients. The consultant also receives direct interconsultations. We want to describe epidemiologically the patients attended and valuate the potential impact on pharmaceutical expense of antimicrobials measured by defined daily dose (DDD) and DDD/100 stays, comparing the period served against a similar period the previous year dates.

Results: We included a total of 94 patients during the studied period. The mean age was (DE) 64.93 (20.4) years, and the predominance of male sex 53 (56.4%). The type of infection was predominantly nosocomial (64.9%) compared to the community (35.1%). The most frequent comorbidities were diabetes mellitus (17.1%) and the existence of an active malignancy (17%). The most common location of infection was the urinary (46.8%) and infection of surgical wounds (30.9%). The most common bacteria was Escherichia coli producing extended-spectrum beta-lactamase (ESBL) (40.4%) followed by coagulase-negative Staphylococcus (9.6%) and Pseudomonas aeruginosa (9.6%). The predominant origin of patients was General Surgery (GS) (43%). Complications during follow-up were few (sepsis (3.2%) and septic shock (2.1%)). The number of visits during follow-up was (SD) 1.86 (1.72). Overall, we observed a decrease in expenses (40,677 vs 33,974 (-16.5%)), mainly due to service of GS (30,598 vs 22,499 (-26.4%)). The savings were primarily due to carbapenems and piperacillin tazobactam, although antibiotic consumption measured by DDD and stays DDD/100 was generally greater (4927 vs 6197 (+20.5%) and 210 vs 248 (+16.3%) respectively).

Conclusions: Efforts to optimize the use of antimicrobials may have a beneficial impact from the economic point of view. Efforts to optimize antimicrobial use have to meet the requirements of the optimization programs antimicrobial use in hospitals to measure and ensure its effectiveness.

A-258
PREVALENCE AND CHARACTERISTICS OF UROGENITAL TUBERCULOSIS IN PATIENTS PRESENTED WITH UROGENITAL INFECTION IN THE EMERGENCY DEPARTMENT OF A TERTIARY HOSPITAL

C. Voulgari[1], S. Siasiakou[1], R. Giannas[1], V. Kalogeri[1], N. Ptohis[2], S. Pagoni[1]

[1]3rd Department of Internal Medicine. Athens Regional Hospital G.Gennimatas, University Medical School. Athens, Greece. [2]Department of Nuclear Radiology. Athens Regional Hospital G. Gennimatas. Athens, Greece.

Objectives: Pulmonary tuberculosis (TBC) is more dangerous and obvious, but extrapulmonary TBC is also contagious and potentially lethal and it affects the quality of life much more than pulmonary tuberculosis. However, the total number of patients presented in tertiary hospitals with undetected, mostly complicated urogenital male TBC remains high among all patients with urogenital infection or newly diagnosed pulmonary TBC. Moreover, urogenital TBC is the second most common form of extrapulmonary TBC in countries with a low incidence of TBC.

Material and method: The rate and trend in extrapulmonary TBC incidence including urogenital TBC was estimated and recorded in 200 patients presented in the Emergency Department of our hospital for urogenital infection from January 2012 up to June 2012.

Results: In approximately 65% (n = 130) of the studied patients, involvement of the genitourinary system was due to a reactivation of an old dominant pulmonary disease. Abnormal urinalysis was

seen in up to 90% (n = 180) and sterile pyuria was detected in up to 75% (n = 150) of urogenital TBC patients. Hematuria was present in about 50% (n = 100) of patients. Non specific pyelonephritis was seen in 56% (n = 112) of patients. Mycobacterium tuberculosis was detected in urine in 64% (n = 128) of cases by urine acid fast bacteria cultures. In 34% (n = 68) of patients bacteriological verification was not possible due to the widespread previous use of quinolones for the treatment of concomitant urogenital infections. The Mantoux test was positive in more than 90% (n = 180) of patients. Ureter was involved in TBC process in 27% (n = 54) of urogenital tuberculosis cases, urinary bladder in 21% (n = 42), and in 43% (n = 86) of cases renal tuberculosis was combined with male genital tuberculosis.

Discussion: TBC is a common disease worldwide and has many implications for the clinician. In developed nations, TBC is relatively uncommon, but the risk of acquiring the disease is increased in older individuals presented with old pulmonary TBC. The signs and symptoms of renal TBC mimic those of other infections of the kidney, so diagnostic awareness may prevent unnecessary morbidity.

A-260
IMPORTED MALARIA IN A TERTIARY CARE HOSPITAL IN MADRID, SPAIN

A. Herrero Carrera[1], I. González Negredo[1], A. Salas Aparicio[1], D. Domínguez[2], J. Sanz[1]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital Universitario de la Princesa. Madrid, Spain

Objectives: To investigate the clinical and epidemiological features of patients with malaria infection in our department, as well as the rates of prophylaxis and the type of anti-malarial treatment used in these patients.

Material and method: We conducted a retrospective, descriptive study. We selected the confirmed malaria cases admitted to the Department of Infectious Diseases in our tertiary care hospital in Madrid during the period 1995 to 2011.

Results: Fifty one patients (32 males and 19 females with a mean age of 36.5 years) were included. Twenty seven cases (53%) were immigrants visiting friends and relatives (VFRs), twelve (26.5%) were tourist and the other twelve (26.5%) had traveled for work to malaria endemic areas. Malaria was acquired in Africa by 76.5% of patients and South America by 17.6%. The most common species was Plasmodium falciparum (70.5%), followed by P. vivax (17.6%) and P. ovale (4%). All of the patients were symptomatic (fever in 82%). Moderate anemia (cut off Hb level 9 mg/dL) was observed in 17.6% of the cases and thrombocytopaenia in 57%. Severe malaria was recorded in 9 patients (17.6%). Cerebral involvement was described in 5, respiratory distress in 5, acute renal failure in 4 and hyperparasitaemia (> 10%) in 4 patients. Six cases were admitted to the intensive care unit (one fatal case). All of the patients with severe malaria were infected with P. falciparum. Of the 51 cases, eighty percent (41) didn´t take any chemoprophylaxis, and only one followed a correct anti-malarial prophylaxis according to the WHO recommendations. Only 1 of 27 VFRs took prophylaxis. Quinine plus doxycycline was prescribed in 75%, while artesunate was given in three cases (6%).

Discussion: In the last few years, the number of immigrants from tropical countries where malaria is endemic and the number of travelers have increased significantly. Falciparum malaria, the most common species in travelers, can potentially cause severe clinical illness, causing renal impairment, coma, acute respiratory failure, disseminated intravascular coagulation or severe anemia. Lack of proper prophylaxis is associated with severe complications and death. However, the rates of use of chemoprophylaxis are still low, as in our series, particularly in immigrants visiting friends and relatives (VFRs), who constitute the most significant group of travelers for malaria importation in developed countries. Quinine and doxycycline are still the drugs of choice in our country for the treatment of P. falciparum malaria, although the artemisinin derivatives, such as artesunate, have been used for the treatment of severe malaria with clear benefits in recent years.

Conclusions: Malaria is a potentially severe and preventable disease in immigrants and travelers to endemic areas. We want to stand out the low rate of use of chemoprophylaxis and create awareness concerning this phenomenon. Quinine-based therapy remains the most widely used treatment for P. falciparum malaria, although the artemisinin derivates have became the treatment of choice worldwide.

A-261
ANTIMICROBIALS USED IN THREE CLINICAL DEPARTMENTS IN A THIRD LEVEL HOSPITAL

A. de la Vega Lanciego, J. Soto Delgado, M. Mateos Andrés, P. Sánchez Junquera, M. Chimeno Viñas, P. García Carbó, E. Martínez Velado, L. Mustapha Abadie

Department of Internal Medicine. Complejo Asistencial de Zamora. Zamora, Spain.

Objectives: To analize the most frequently used antimicrobials in the departments of Internal Medicine, Pneumology and Gastroenterology.

Material and method: Cross-sectional descriptive study about antimicrobials used in three clinical services (Internal Medicine, Pneumology and Gastrointestinal Department) randomly chosen in a specific day of May 2012. The antimicrobial used was reviewed as well as the administration route and the indication. The results were analized using the Excel database and the SPSS 19.0 software.

Results: Out of the 64 analized patients, 42 received an antimicrobial during their admittance (65.5%). The most common administration route was parenteral in 92.7% of cases and oral in only 7.3%. The indication of treatment was mainly due to a community infection (48.4%) and the most frequently used antimicrobial was ciprofloxacin (25.8%). The next ones most frequently used were piperacillin/tazobactam (22.6%) and amoxicillin/clavulanic acid (16.1%). In 7.8% of cases the indication was a hospital-acquired infection (nosocomial infection), when imipenem was by far the antibiotic most used. A 4.7% of cases were due to an infection acquired in a long stay center, like a hospice. In these situations piperacillin/tazobactam, ceftriaxone and levofloxacin were prescribed in 33.3% of the cases each. In 1.6% of cases the antibiotic indicated was unknown. Only one case was found where the antibiotic indication was prophylaxis and the one used was ciprofloxacin. By pathologies, the antimicrobials most used in intra-abdominal infections were imipenem and piperacillin/tazobactam, in the same proportion (50%). In acute gastroenteritis, metronidazole. In urinary tract infections without microbiological confirmation, cephalosporin (25%) and levofloxacin (25%). In pneumonias, piperacillin/tazobactam (33.3%) and levofloxacin (25%).

Discussion: More than half of the patients from the 3 hospital floors analized received on admittance an antibiotic and it was provided mainly intravenously. The infections because of which antibiotics were prescribed were very diverse. The majority of the antimicrobials used were given for the treatment of a community infection, choosing generally a quinolone. Conversely, when there was a nosocomial infection a broad spectrum antibiotic was preferred, similar to what is disclosed in the literature.

Conclusions: More than half of the patients admitted to the departments randomly chosen had an antibiotic prescribed the day of the study. The antibiotic was given mainly intravenously. The

results were similar to those reported in the literature, using quinolones for community infections and broad spectrum antibiotics for nosocomial infections.

A-262
MANAGEMENT OF EARLY ONSET PROSTHETIC JOINT INFECTION WITH DEBRIDEMENT AND IMPLANT RETENTION

A. Martínez Vidal, A. Nodar, A. Rodríguez Gómez, I. Villaverde, A. Sousa, A. Argibay, M. Pérez Rodríguez, C. Martínez Vázquez

Complejo Universitario de Vigo. Vigo (Pontevedra), Spain.

Objectives: The number of patients requiring a joint replacement is increasing worldwide. The most serious complication is infection, with an incidence of 1.5-2.5% for primary interventions. These infections can affect functional status and quality of life, and the economic cost is very important. Debridement with implant retention is an attractive option for the management of early onset prosthetic joint infection (EOPJI). Our objective is to describe the clinical characteristics and outcomes of patients with confirmed EOPJI in our institution.

Material and method: We retrospectively recorded the demographic characteristics, clinical manifestations, diagnostic tests, management and outcome of patients with prosthetic joint infection between June 2002 and June 2010 in our center.

Results: We included 78 cases of PJI, with 36 episodes of culture proved EOPJI, classified when symptoms presented less than 4 weeks after arthroplasty. The median age was 71 years (46-94) and 20 episodes occurred in women (55.6%). 83% of patients had a predisposing factor, cardiomyopathy was the most common comorbid condition (50%), diabetes mellitus (20%), liver disfunction (16%) and 4 four patients were receiving corticosteroids. The most frequent affected arthroplasty was the hip (52.8%), knee (44.4%) and shoulder (1 episode). Only 4 cases (11.1%) were not primary arthroplasties. The median time between the implant and the clinical presentation was 17 days, and the time between the first manifestation and the surgery was 10.3 days (0-32). Pain was the most habitual symptom (75%), followed by inflammatory signs (58%) and fever (25%). The erythrocyte sedimentation rate (ESR) and the C reactive protein were elevated in 94% and 97% (35/36) of the patients respectively. Arthrocentesis was performed in 7 cases, obtaining purulent joint fluid in 2 cases and positive cultures in 6 (all isolations were confirmed with surgical samples). Two patients had another concomitant infection (urinary tract infection (UTI) by Enterococcus faecium and UTI by Escherichia coli producing extended-spectrum beta-lactamases (ESBL). Blood cultures were obtained only in 3 episodes, and 2 were useful to identify the responsible microorganism (S. epidermidis and E. coli ESBL). Staphylococci were the most common pathogens: Coagulase negative S. in 16 patients (44.4%), S. aureus in 7 (2 with methicillin resistance), and one case either by E. faecium and E. faecalis), gram negative bacilli isolated included E. coli in 6 cases (2 ESBL), Enterobacter cloacae in 2, Proteus mirabilis (2), Pseusomonas aeruginosa, Klebsiella pneumoniae, Serratia marcenses and Acinetobacter baumanii. 7 infections (19.4%) were polymicrobial. Debridement with implant retention was the therapeutic option in 31 patients (86%), in 2 patients (5.5%) 1-stage and 2-staged reimplantation. All patients received parenteral antibiotic therapy, usually cloxacillin or vancomicin plus rifampicin for Staphylococcus methicillin sensitive or resistant respectively. The median duration of parenteral therapy was 4.7 weeks (3-13). Oral therapy was initiated in all except two cases (E. coli ESBL) during a median time of 20 weeks (2-52), discontinuing when ESR and CPR were normal and a sequential bone/gallium scintigraphy showed no sign of infection. The most used regimen was ciprofloxacin or levofloxacin plus rifampicin. The outcome was successful in 26 of the 31 patients treated with debridement, 2 patients died after completing antibiotics scheme, and the causes were not related to infection, and 1 patient was lost in the follow up. The success rate in the patients who were treated with this conservative option and who fulfilled the follow up was 93.5% (29/31). In two patients the treatment failed, one needed another debridement during suppressive oral treatment and the final outcome was favourable and other patient underwent an arthrodesis.

Conclusions: Our data suggest that debridement with implant retention combined with parenteral and oral antibiotic treatment until normalization of acute phase reactants and sequential bone/gallium scintigraphy is an effective and safe treatment option in EOPJI.

A-263
USE OF DAPTOMYCIN IN PATIENTS WITH ENDOCARDITIS OR INFECTION OF INTRAVASCULAR CARDIAC DEVICE DURING 2009-2012

D. García Rosado, C. Martín González, M. Alonso Socas, E. García Valdecasas, E. Martín Ponce, J. Gómez Sirvent, R. Alemán Valls, R. Pelazas González

Department of Internal Medicine. Hospital Universitario de Canarias. San Cristóbal de La Laguna (Santa Cruz de Tenerife), Spain.

Objectives: Infections caused by Gram-positive organisms are a therapeutic problem because of the spread of strains with multiple resistance to antibiotics used as first-line therapeutic options. Infective endocarditis is a serious form of infection with a high mortality. Medical management can be a challenge because of the sensibility of the microorganism to recommended antibiotics and safety profile. Daptomycin offers a good clinical efficacy profile because of its bactericidal activity and potential synergy with other antimicrobial agents. There are limited data on the use of daptomycin in cases of infectious endocarditis and infection of intravascular cardiac device. The aim of this study is to evaluate the baseline characteristics and mortality of a cohort of 21 patients admitted to our hospital with a diagnosis of infective endocarditis or cardiac implantable electronic device infection treated with daptomycin.

Material and method: We conducted a systematic record of all patients admitted to our hospital with a diagnosis of infectious endocarditis. We analyzed a subgroup of 21 patients treated with daptomycin, and evaluate the epidemiological characteristics, complications and mortality during hospitalization, three, six and twelve months after discharge.

Results: 90.5% of patients were men with a mean age of 64.2 years. As risk factors, 46.7% had underlying heart disease and 33% had heart valve prostheses. The clinical presentation is acute in 66.7% of patients with impaired left valves up by 56.7% and 9.5% of intravascular cardiac device infection. The common symptoms were fever and heart murmur at 43% and 23% debuted with heart failure. The diagnosis in the majority was complemented by transthoracic echocardiography with transesophageal echocardiography. 19% of patients had septic emboli, mainly spondylodiscitis. Up to 66% of patients had cardiac complications, particularly arrhythmias and heart failure. We found negative blood cultures up to 38% of cases, of which 38.1% had previous antibiotic treatment. The etiology was known in 16 cases: 7 cases were coagulase-negative staphylococci, 4 cases of viridans group streptococci, 3 cases of Enterococcus faecalis and 2 cases of Staphylococcus aureus, one of them was an MRSA. The mean treatment duration was 58 days. Required surgical treatment 47.6% of patients, mainly caused by poor control of sepsis with antibiotics and heart failure. During follow-up were three cases of recurrence, one of them was not the same microbiological etiology, and other two cases were of intravascular

cardiac device infection to which a first episode of the pacemaker wires were not removed. At twelve months follow-associated mortality was 24%.

Conclusions: No studies support the use of daptomycin in endocarditis, however is shown as a therapeutic option used increasingly in both endocarditis and in infection of cardiac intravascular device. Its low toxicity and ease of administration also makes an interesting use in patients with high comorbidity and impaired renal function.

A-265
INFECTIOUS DISEASES IN HOSPITALIZED PATIENTS IN CLINICAL AREAS

J. Soto Delgado, A. de la Vega Lanciego, M. Mateos Andrés, P. Sánchez Junquera, E. Martínez Velado, M. Chimeno Viñas, P. García Carbó, G. Hernández Pérez

Department of Internal Medicine. Complejo Asistencial de Zamora. Zamora, Spain.

Objectives: To learn about the characteristics of the patients admitted to clinical departments that had any kind of infectious disease.

Material and method: Observational descriptive study of patients admitted to the Internal Medicine, Gastrointestinal or Pneumology department of the Virgen de la Concha Hospital of Zamora that had any infectious process in a randomly chosen day of May 2012. The departments included in the study were also randomly selected. The following data were considered: age, sex, McCabe score and medical records of coma, kidney insufficiency, diabetes, neoplasia, COPD, immunosuppression (immunodeficiency, neutropenia, cirrhosis, hypoalbuminemia) or pressure ulcer. It was also analized if the patient was intubated, carried a central or peripheral catheter or a urinary catheter; location of the infection; type of infection; surgical procedure and isolated microorganism.

Results: Of a total of 64 patients, 29.7% were admitted to the Gastrointestinal department and the same percentage to the Pneumology one. Most of the patients were admitted to the Internal Medicine department (40.6%) and older than 65 (76.2%). A 65.5% of them were males and 34.4% females. In relation to the MacCabe score it was found that a 44.4% had a nonfatal disease and 20.6% had a rapidly fatal one. Only a 3.1% of cases were in coma when data were collected. A 20.3% of them had a kidney insufficiency. The same percentage had diabetes. A neoplastic disease had been diagnosed in 15.9% and COPD in 19%. The majority of patients didn't have immunosuppresion (98.4%), nor pressure ulcers. Cirrhosis was present in 6.3% and hypoalbuminemia in 17.2%. Only a 14.3% of patients carried a central catheter while a 93.8% carried a peripheral one. A urinary catheter was present in 17.2%. Only 1 patient was intubated (1.6%). The infection was located in a specific place in 48.4%. The highest percentage was seen in relation to pneumonia (18.8%) and the minimum to celullitis and gastroenteritis (1.6%). The majority of the infections were community-acquired (83%). Only a 3.1% had undergone surgery. Only in 15.3% of cases a microorganism was isolated, being Gram-negative bacteria the most frequent ones (11.5%). Staphylococcus aureus was present in 3.8%.

Discussion: In our study it can be ascertained that the majority of patients were males over 65, which might be related to the high prevalence of elders in the province of Zamora. The main pathological records were diabetes and kidney insufficiency. Most of the patients didn't have immunosuppresion that contributed to facilitate the infection. In more that 50% of the cases the location of the infectious process wasn't found. The majority of the infections were community-acquired. It was quite unexpected the limited isolation of microorganisms. Gram-negative bacteria were the most frequently isolated ones.

Conclusions: High percentage of admitted patients with an infectious process. Majority of patients carrying a peripheral catheter. Scarce isolation of the responsible microorganisms. Predominance of community-acquired infections.

A-268
PERITONEAL TUBERCULOSIS: REVIEW OF TEN CASES

L. Lourenço[1], P. Lopes[1], C, Portugal[2], L. Sancho[2], N. Bragança[1]

[1]Department of Internal Medicine, [2]Laboratory of Microbiology. Hospital Prof. Doutor Fernando Fonseca. Amadora, Portugal.

Objectives: Peritoneal tuberculosis (PT) is an uncommon site of extrapulmonary infection caused by Mycobacterium tuberculosis (TB). Symptoms mimic other abdominal diseases, which makes diagnosis difficult. Objective: retrospective review of all adults admitted to a secondary hospital located in an area of high incidence of tuberculosis and diagnosed with PT in the last 8 years.

Material and method: The authors reviewed clinical data from 10 patients admitted to our hospital and diagnosed with PT between April 2004 and April 2012. Past history, risk factors, presentation signs and symptoms, biochemistry and microbiology data, histopathological exams and diagnostic means used were analysed. Samples were stained with hematoxilin-eosin and Ziehl-Neelsen. The cultural growth means used were MGIT, Lowenstein-Jensen and BACTEC. Only the cases in which the diagnosis was confirmed by histology and/or microbiology were included.

Results: We included 10 patients in our study, 5 males and 5 females, with a median age of 36 years. We found history of other forms of tuberculosis (40%), AIDS (acquired immunodeficiency syndrome) (40%), alcoholism (30%) and cirrhosis (20%) as risk factors for PT. Clinical presentation included ascites (100%), fever (70%), abdominal pain (50%), weigh loss (30%) and diarrhea (20%). A paracentesis was performed and lymphocytic ascitis was found in all cases reviewed. The serum-ascites albumin gradient (SAAG) was less than 1.1 g/dL in 6 cases (among a total of 7 cases in which it was calculated) and adenosine deaminase (ADA) was elevated in the ascitic fluid of 7 patients, normal in 2 and not tested in one. Abdominal ultrasound (US) and/or computerized tomography (CT) were consistent with the diagnosis in 70% of cases. Peritoneal biopsy was performed by laparotomy and diagnostic in 2 cases. All patients started anti-bacillary treatment in the first week of admission and the use of therapeutic agents was then guided by the antimicrobial susceptibility test (AST). One patient died during admission in the onset of septic shock.

Discussion: History of tuberculosis and AIDS were the most important risk factors. In these patients, reactivation of latent tuberculosis may explain the clinical onset. Alcoholism was also relevant and its association with TB is also well known. Clinical presentation of PT cases in our series may resemble other conditions, which makes the diagnosis difficult. Cirrhosis as a simultaneous condition may obscure the diagnosis even more. The cultural exam for TB in ascitic fluid, opposite to direct stain, had a high rate of success (100%) and allowed to test the therapeutic agents. Peritoneal biopsy was performed only in two cases but also showed to be determinant for diagnosis. Other laboratorial parameters such as SAAG and ADA in ascitic fluid besides radiology exams (abdominal US and CT) showed to be useful in the majority of cases. Mortality was low, even in immunodeficient patients. This may support the relevance of starting anti-bacillary treatment in cases which PT is highly suspected.

Conclusions: The suspicion level for PT must be high in a patient with risk factors and lymphocytic ascitis. According to our experience, direct stain exam for TB in ascitic fluid is rarely useful. The cultural exam for TB in ascitic fluid may have a high rate of success and allows TSA. Nevertheless, treatment should be started

when there is a high suspicion and for that instance peritoneal biopsy, measurement of GASA and ADA in ascitic fluid and imaging studies should be considered to achieve the diagnosis.

A-269
DIFFERENCES BETWEEN PATIENTS DIAGNOSED HIV OVER THE PAST 5 YEARS REGARDING ORIGIN

R. Regajo Gallego, G. Vicente, L. Fernández, J. Martínez, M. Pérez, H. Aichner, J. Esteban, G. Gaspar

Department of Internal Medicine. Hospital Universitario de Getafe. Getafe (Madrid), Spain.

Objectives: Evaluating the clinical and epidemiological differences at present at the time of diagnosis of the HIV patients according to whether they are foreign or local.

Material and method: We selected a sample of patients whose HIV diagnosis occurred from January 1, 2007 to March 29, 2012, found in follow-up consultation of Internal Medicine, University Hospital of Getafe (n = 143) and compared their characteristics according to whether they were Spanish or foreign by using frequencies to describe the qualitative variables and the mean for quantitative variables. Using as statistics the p of Pearson Chi-square and the t-test with the statistical program SPSS 17.

Results: There were more men (78 vs 58/0.009) and older age in the Spanish group (41.9 vs 38/0.004). No differences were found about the mode of transmission (homo 46 vs 28, hetero 41 vs 62, IDU 6 vs 4 and unknown 7 vs 6). Clinically, there were no differences in the debut of infection (Acute 23 vs 12) nor in the CDC status: A (70 vs 64), B (7 vs 11) and C (22 vs 25)). The CD4 count (442 vs 374) and de viral load (147,256 vs 84,783) showed no significant differences. Finally the HBV or HCV status (1 vs 0 and 12 vs 7) were similar.

Discussion: The origin was not a determining factor in the clinical situation at diagnosis, with only epidemiological differences in age or gender, which could be explained by the integration in the universal health care system of this group.

Conclusions: Despite the asymmetry of the two groups regarding age or gender, we can conclude that currently being foreign or local is not a clinically important difference at the time of diagnosis of HIV in a community hospital of Madrid.

A-270
SPONTANEOUS BACTERIAL PERITONITIS: CHARACTERISTICS AND PATTERNS OF RESISTANCE TO ANTIBIOTICS

H. Enríquez Gómez, F. Fernández Fernández, R. Puerta Louro, S. Araujo Fernández, L. Novoa Lamazares, A. Arca Blanco, M. Rodríguez Arias, J. de la Fuente Aguado

Department of Internal Medicine. Povisa Hospital. Vigo (Pontevedra), Spain.

Objectives: Describe the clinical and microbiological characteristics of a population of cirrhotic patients with a diagnosis of spontaneous bacterial peritonitis (SBP).

Material and method: Retrospective study by reviewing medical records of cirrhotic patients with a diagnosis of SBP admitted to Povisa Hospital between 2005 and 2011.We collected the following variables: year of income, age, sex, underlying disease, cirrhosis etiology, clinical manifestations, evolution, classification of SBP, classification of Child-Pugh, MELD-Na, polymorphonuclear count in ascitic fluid, ascitic fluid culture, blood culture, sensitivity testing, antibiotic treatment and outcome.

Results: During the study period a total of 25 cirrhotic patients were diagnosed with SBP. Eighty percent of patients were male, with a mean age of 65 years. Eighty-four percent of patients had at least one associated underlying disease; the most common were liver cancer (36%), cancer (20%), renal failure (20%) and refractory ascites (16%). Etiology of cirrhosis was alcoholic in 60% and hepatitis C virus in 36%.PBE was community acquired in 32% of cases, related to health care in 28% and nosocomial in 40%. The most frequent symptom at diagnosis was abdominal distension (78%), followed by abdominal pain (32%) and fever (28%), with a mean time to onset of symptoms of 5 days. Stage B was the most frequent (52%) in the classification of Child-Pugh, and stage C in the remaining 48%. The mean value of Meld-Na was 20. Only 4 patients (16%) had received antibiotics in the previous 3 months, being the most used cefotaxime (50%). Ascitic fluid culture was positive in 36% and blood cultures in 37% of the cases that were performed. The most frequently isolated microorganism was E. coli (50%).Other microorganisms were Klebsiella pneumoniae, Klebsiella oxytoca, Proteus mirabilis and Streptococcus mitis. All of them were susceptible to amoxicillin, cefotaxime and ciprofloxacin. The most commonly used empirical antibiotics were third-generation cephalosporins, with a mean duration of treatment of 10 days. Fifty-two percent of patients received expansion with albumin. Renal failure developed in 48% of patients. At discharge, 31% of patients received prophylaxis with norfloxacin. Mean hospital stay was 19 days. During follow-up 39% of patients had a new episode of SBP and 88% of them died (36% during admission), being one third of deaths attributable to the SBP. The only independent predictor of death was renal failure. Mean time to death was 9 months during a follow-up period of 22 months.

Discussion: Spontaneous bacterial peritonitis (SBP) is a common infection in cirrhotic patients with ascites. The mortality is approximately 20%. Most cases are caused by the Enterobacteriaceae and Streptococcus sp., part of the intestinal bacterial flora. Third-generation cephalosporins are recommended as initial empiric therapy with a response rate of 80-90%. However, recent publications have raised the alarm about the increase in the incidence of cases of SBP caused by microorganisms resistant to third generation cephalosporins and increased mortality among patients with SBP associated with healthcare or nosocomial. In the study conducted in our area we do not find an increased incidence of organisms resistant to third generation cephalosporins, all of which are sensitive, even though two thirds of cases are nosocomial or related health care. The only independent predictor of death was renal failure. Both overall mortality as attributable to the SBP was similar to other published series. No statistically significant differences were found in regard to mortality related to the etiology of cirrhosis, the presence of cancer, the nature of PBE or received antibiotics in the previous 3 months.

Conclusions: In our environment we must not make changes standard empirical antimicrobial therapy. PBE is a marker of poor prognosis in cirrhosis. Renal failure is the only factor associated with increased mortality.

A-272
BACTEREMIA WITH STREPTOCOCCUS PNEUMONIAE. A HOSPITAL-BASED COHORT STUDY

R. Boixeda[2], E. Güell[1], J. Yébenes[1], G. Sauca[3], M. de la Torre[1], L. García[4]

[1]Intensive Care Unit, [2]Department of Internal Medicine, [3]Department of Microbiology, [4]Department of Pediatrics. Hospital de Mataró. Consorci Sanitari del Maresme. Mataró (Barcelona), Spain.

Objectives: To characterize a hospital-based cohort study among patients with Streptococcus pneumoniae bacteremia (SPB), to investigate the 30-day mortality, and factors associated.

Material and method: Design: A prospective observational cohort study was conducted over 18 months in a general hospital near

Barcelona. Study population: Patients were included if blood culture was positive for S. pneumoniae. Participants were identified by investigators on Clinical Microbiological Registry. Measurements: Clinical, analytic and sociodemographic variables were extracted from medical histories. Comorbodity was assessed using Charlson comorbodity Index. The focal diagnosis of the SPB was identified by a clinical judgment. We defined sepsis, sever sepsis and septic shock.

Results: Between 1st January 2011 and 31st May 2012 we identified 60 episodes of SPB. Of these patients, 13 were children, and 8 had a immunodepression (4 active malignancy, 3 HIV, and 1 LES with immunosupression treatment). The other 39 patients were identified and enrolled following informed consent. The median age was 64.6 (29-96) and 61.5% were men. The 30-day mortality for the cohort was 7.7%. The focal diagnostic of the SPB was pneumonia in 37 (99%). Of the 39 patients, 21 (54%) did not have sepsis, 13 (33%) had sepsis, and 3 (7%) had sever sepsis, and 2 (5%) had septic shock. The hospital stay was 6.8 days (0-21). As a comorbilities, 20% had diabetes, 26.3% COPD, 33% cardiopathy and 33% had anemia. Of the 39 S pneumoniae, all were found to be penicillin-susceptible. At arrival to emergency department, the analytical results showed leukocytosis like 15,862 (1,290-28,140) and PCR 34.8 mg/dl (0.8-78). Another analytical parameters and the serotype prevalence were reported.

Conclusions: We characterized a hospital-based cohort of adult patients with an episode of SPB, with a majority community-acquired pneumonia. The 30-day mortality was 7.7%. None of the S. pneumoniae isolated was penicillin-resistant.

A-273
MICROBIOLOGICAL DIAGNOSIS METHODS OF PNEUMONIA IN AN INTERNAL MEDICINE DEPARTMENT

I. Muinelo Voces, S. Pérez Andrada, E. Fernández Pérez, A. Morán Blanco, J. Guerra Laso, J. Mostaza Fernández

Department of Internal Medicine. Complejo Asistencial de León. León, Spain.

Objectives: To evaluate the microbiological diagnostic method of pneumonia in patients who have been admitted into the Internal Medicine Department of Leon University Hospital, Virgen Blanca Building, with the diagnosis of pneumonia, in the period from November 2011 to February 2012.

Material and method: Retrospective descriptive study was carried out reviewing medical reports of all patients admitted from 2011 November to 2012 February with the diagnosis of pneumonia. The following variables were assessed: prevalence, age, sex, type of pneumonia, the number of cultures: sputum, blood, bronchoalveolars lavages (BAL), antigens in urine, serological test. Also, we had evaluated the number of isolated microorganisms with each method and the identification of the microorganisms. The results were expressed by percentages and average.

Results: Out of total of 1,388 admitted patients, in the studied period, 147 presented the diagnosis of pneumonia (10.6%). The age average: 78.87 years old. Gender: women 44.2%, male 55.78%. Average of acquisition: 64% community, 28.6% healthcare associated and 7.5% nosocomial. Diagnostic methods: total the sputum cultures: 42.8% isolates 28.5%. The most common organisms: Pseudomonas spp 33.33%. Total the blood cultures: 53.06%. There were positive 18%. The most frequent identified organism: 50% coagulose negative staphylococcus. Total the urinary antigen in urine for the pneumococcal and the legionella 72.78%. There was positive 12.15%. All positive were of the pneumococcus. Total serologies tests: 12.24% There were positive 16.66%: Each of them: 33.33% (C. pneumoniae, M. pneumoniae and C. burnetti). Total samples from BAL 4.76%. There were positive 57.14%. Each of microorganisms identified were 14.28% (Aspergillus spp, P. jirovecci, 14.28% MARSA and E. coli). The etiologic diagnosis was achieved in 19% of the total cases. The most common organism is pneumococcal (46.42%), Pseudomonas spp (21.42%), 7.14% for Aspergillus, Haemophilus and Klebsiella and 3.57% for Pneumocystis, Coxiella and Chlamidya.

Discussion: The treatment of pneumonia is most effective when it is directed to the pathogen which has produced the pneumonia. There is not a wide consensus on the feasibility of achieving this goal due to differences in the value of diagnostic tests. In hospitalized patients this situation achieves more valuable. The problem is that the diagnostic test have a low effectiveness, so in the published studies about of the blood cultures the effectiveness was among 7-16%, in the sputum cultures was a among 10-86%, for pneumococcal antigens in urine was among 50-80% of sensitivity and 95% of specificity. Determining serologists tests and cultures of bronchoalveolar lavage should only been made in the serious and specific situations. Our findings are consistent with the published data. Few isolates in our culture samples: 11.1% sputum, 18% blood cultures, 12.15% urine antigen positive for pneumococcal, 57.14% BAL and 12.28% for serology. However we stress that the methods that it allow us to get a more effectiveness etiologic diagnostic are the antigens in urine, serology test and BAL and BAS culture. These actuations are the most recommended situations to get more wide etiologic diagnostic.

Conclusions: The diagnostic method available in our environment for etiologic diagnosis of pneumonia in hospitalized patients remains low. The determination of pneumococcal urinary antigen, serology tests and BAL culture are the methods which are brought us greater benefits.

A-275
BACTEREMIA S BOVIS IN THE HEALTH AREA OF LEÓN IN 8 YEARS (2004-2011) WHAT ABOUT AFTER DIAGNOSIS AND TREATMENT?

E. Castelar Delgado[1], F. Estrada Álvarez[1], A. Morán Blanco[1], I. Fernández Natal[2]

[1]Department of Internal Medicine, [2] Department of Clinical Microbiology. Complejo Asistencial de León. León, Spain.

Objectives: The Streptococcus bovis is a gram positive bacteria, Lancefield group D, has a large phenotypic and genotypic variation and this is the major cause of bacteremia and endocarditis. It is usually associated with neoplasms of the gastrointestinal tract and cirrhosis. In this research we describe the clinical, microbiology and treatment of patients with bacteremia due to S. bovis.

Material and method: We collected samples of patients in which Streptoccocus bovis was isolated by the CAULE Department of Microbiology during the years 2004-2011. Clinical Histories were reviewed.

Results: We reviewed the cases of bacteremia caused by S. bovis in the health area of León between 2004 and 2011. There were a total of 26 cases, with an average of 76 years old (range 0-95) and 58% of them were men. Most of the cases (18) were located between 2006 and 2008. About 61% of Streptococcus bovis infections admitted to Internal Medicine department and 12% in Oncology department. Fever was present in 73% of patients. Most of them were hospitalized for less than 15 days. 42% of patients were diagnosed with cancer and there were 8 new cases (5 colon, 1 hepatic, 1 pelvic and 1 breast). In addition 4 of them had chronic liver disease (alcoholic). 23% of the cases showed more than one microorganism. Typing was achieved for 50% of S. bovis: 31% (8 cases) are biotype I and 20% (5 cases) are biotype II. There were 38% of infectious endocarditis. Overall mortality was 20% (5 cases). 85% were treated with beta-lactams and 54% of those patients the

duration of the treatment was less than 14 days and 32% less than 9 days. There wasn't significant side effects. 61% of the patients were followed regularly in outpatient and 3 was associated neoplasia (two colon and one uterine) with a delay of two years.

Discussion: Streptococcus bovis infection produces a large number of bacteremia due to endocarditis. Subacute endocarditis is usually aggressive with significant mortality, classically associated with colon cancer and other cancers. In our series we found 60% of the bacteremia's cases. There were 8 new cases of malignant cancers, mostly colon cancer. It is involved in the pathogenesis of inflammatory mechanisms mediated by cytokines, alteration of tissues and induction of uncontrolled cellular proliferation. We reviewed the outpatient of the 61% of Streptococcus bovis infections by monitoring. An average of one or two reviews in less than a year. The new cancers detected were diagnosed by the appearance of new symptoms. This new cases of cancer were not followed. In our series, most of the cancers occur simultaneously with Streptococcus bovis infection. Two colon cancer and a gynecological were detected in 16 patients who were followed in the outpatient internal medicine, which is the main service that attends these processes. It is not defined in the medical literature worldwide for how long is necessary follow the Streptococcus bovis infections. But it seems obvious that we must control the outcome of patients with Streptococcus bovis infection with the likelihood of developing new tumors.

Conclusions: We emphasize the importance of monitored correctly of patients with Streptococcus bovis infections that can cause serious pathology.

A-276
EARLY DETECTION OF MRSA CARRIERS IN HIGH RISK PEOPLE

T. Ortega[1], M. Torres[1], M. Areses[2], T. Rubio[2], S. Pérez[2], J. Beloqui[3], J. García[4]

[1]Department of Preventive Medicine, [2]Department of Internal Medicine, [3]Department of Pharmacy, [4]Department of Microbiology. Hospital Reina Sofía. Tudela (Navarra), Spain.

Objectives: Description of the method for early detection of patients at high risk of being carriers of MRSA, as well as to descript the epidemiological characteristics of these patients in Tudela´s hospital (Navarra-Spain).

Material and method: In our hospital, the study of carrier MRSA is done to patients from nursing homes and other institutions which are considered of high risk. The service of Preventive Medicine reviews daily the patients in the hospital through medical records in order to detect early patients subject to screen and then they are communicated to the nurses of the different services of the hospital.

Results: During 2011 in our hospital 186 patients were hospitalized who required study of MRSA carrier because they have high risk of been carrier. They weren't collected to 27 (14.5%), 94 (50.5%) were negative and 65 positive (34.9%). By sex no differences (p = 0.814): 57 men (positive 24) and 102 women (41 positive). 165 patients (88.7%) were hospitalized in internal Medicine representing 6% of the admissions from this service in the year, the rest were hospitalized in general Surgery (8) and Traumatology (10). The average number of days to collect the nasal smear was 2.3 days (2.7 in general surgery, 1.9 in internal medicine and 1.1 in traumatology). Decolonization treatment was made to prevent transmission of the bacterium in 55 positive patients (84.6%). The mean age was 82.6 to positive and 85.2 to negative (p = 0.035). The average stay was 10.4 days in positive and 10.6 in negative (p = 0.470). 13 patients were moved to hospital at home (8 with positive nasal swabs) with an average stay of 12.9. There weren't aggregation of carriers according to the place of their nursing homes.

Conclusions: Early detection of patients colonized allows the timely implementation of interventions to prevent transmission and infection with this microorganism.

A-277
ENDOCARDITIS S. BOVIS IN THE HEALTH AREA OF LEÓN IN 8 YEARS (2004-2011)

E. Castelar Delgado[1], F. Estrada Álvarez[1], A. Morán Blanco[1], I. Fernández Natal[2]

[1]Department of Internal Medicine, [2]Department of Clinical Microbiology. Complejo Asistencial de León. León, Spain.

Objectives: Infective endocarditis is a disease characterized by involvement of the valvular endocardium but the infection usually can be located in a septal defect or any part of the mural endocardium. Streptococcus bovis endocarditis accounts for 10% of cases of bacterial endocarditis. To evaluate the clinical significance of S. bovis isolates from patients with endocarditis.

Material and method: During a 8 years period (2004-2011) all S. bovis isolated from blood cultures (BacT/AlertTM, bioMèrieux, France) were identified by using API Strep TM (bioMèrieux, France). Susceptibility to antimicrobial agents, by disc-plate method, was cathegorized using breakpoint established by CLSI criteria. The clinical records from all of the patients were retrospectively reviewed. We used SPSS v20.

Results: We found 26 bacteremia, of which 10 cases were infectious endocarditis (38.4%). The mean age of patients was 76.3 years (58-86) with 60% males. 90% of patients admitted for infectious endocarditis due to S. bovis did inthe Internal Medicine department. The average hospital stay for these patients was 35.5 days. Risk factors: smokers (20%), a drinker patients (10%) and diabetic (40%). Only in one case there was a history of colon cancer (10%), whereas 5 had a history of other neoplasies (1 thyroid, 1 cervix, 1 hepatocellular carcinoma and 2 hematologic). Fever was present in 70%. Only one case had coinfection with another organism (S. intermedius/milleri). S. bovis biotype I was identified in 70% of cases. Colonoscopy was performed at 80% of patients, there being in all cases colonic disease (4 adenomas and 4 adenocarcinomas). In two cases, 27 months and one year after admission and in the remaining 6 cases during hospitalization for bacterial endocarditis. Was affected equally on both valves, mitral (5) and aortic (7), in 2 cases together. Mortality was 30% for endocarditis compared to 12.5% of bacteremia (p 0.219). The presence of endocarditis was a clear risk to develop complications (p 0.001), two cases required valve replacement and deferred a pacemaker. About 80% were treated with beta-lactams. The mean treatment duration was 23.5 days. In neither case were no adverse reactions to treatment.

Discussion: S. bovis is a normal inhabitant of the gastrointestinal tract and production-related bacteremia, endocarditis, urinary tract infections and meningitis. Usually affects patients older than 60 years, whose most common complication is heart failure due to involvement of the aortic valve, with a mortality between 25 and 50%. These data are consistent with our cases in which the average age of our patients was 76.3 years with a mortality of 30%. In our series affected both aortic and mitral valve. The diagnosis of S. bovis endocarditis is performed in 95% of cases by blood cultures, dropping the 65% effectiveness when a patient has a history of antibiotic therapy, due to its high sensitivity to penicillin (MIC 0.25 to 2 ug/ml). In our patients blood cultures were positive in 100% of cases. Because of the association between colonic disease and bacteremia due to S. bovis, some authors have stressed the importance of endoscopy, and when this standard it should be included in monitoring patients by this method at least 2 to 4 years, as they have been detected in neoplastic colonic lesions is time after infection.

Conclusions: In our series, the association between S. bovis biotype I and colonic pathology was observed in 100% of patients with infectious endocarditis those who underwent colonoscopy (80%). Therefore, it is important to study the gastrointestinal tract to all patients with endocarditis by S. bovis and followed up for at least 2-4 years.

A-278
BACTEREMIA IN VERY OLD PATIENTS: EPIDEMIOLOGICAL FEATURES

B. García Martín[1], J. Hernández Pacheco[1], G. Candela Ganoza[1], P. Del Valle Loarte[1], M. Cervero Jiménez[1], J. Agud Aparicio[1], V. Fermín Ramírez[2], M. Flecha Curese[2]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital Severo Ochoa. Leganés (Madrid), Spain.

Objectives: To assess the characteristics of bacteremia in patients aged 85 years or older, diagnosed at the University Hospital Severo Ochoa between February 2011 and April 2012.

Material and method: In our center all episodes of bacteremia are stored in a database since January 2011. For the present study, we selected all patients aged ≥ 85 with bacteremia detected between February 2011 and April 2012. Data on demographic variables, comorbidity, source of infection, source of bacteremia, pathogen, antibiotic therapy and in-hospital mortality were extracted. Statistical analysis was performed using SPSS version 11.

Results: Total population: 61 patients. We analyzed 61 episodes of bacteremia; 54.1% (33 patients) were females. In 75.4% bacteremia was community-acquired, and only 24.6% were considered nosocomial (54.3% of the nosocomial bacteremias were acquired in nursing homes). The most frequent comorbidities were hypertension (39.3%), chronic obstructive pulmonary disease (COPD) (18%) and diabetes mellitus (DM) (14.8%). The most common isolated micro-organism was E. coli (49.2%), followed by Gram-positive cocci (staphylococci, 11.5%; streptococci 9.8%; and *Enterococcus*, 4.9%). Klebsiella ranked second among Gram-negatives (8.2%). The source of bacteremia was considered the urinary tract in 34.3%, the abdomen in 29.6% (biliary tract in 19.7% and non-biliary in 9.9%), respiratory tract in 21.3% and catheter related in 3.3%. After empirical and/or pathogen-directed antibiotic therapy, with or without drainage of the source of bacteremia and catheter withdrawal, clearing of the bacteremia was achieved in 83.6%, with an in-hospital mortality rate of 13.2% (half of the deaths, 6.6% of the total sample, occurred within 7 seven days of the diagnosis and were considered directly related to the bacteremia).

Discussion: Due to the scarcity of epidemiological data, knowing the characteristics and behavior of bacteremia in these very old patients seems interesting; according to our data, mortality seems lower than previously estimated. We observed that most bacteremias were community-acquired and that the most common bacterium was *E. coli*. As in other age groups, the urinary tract was the most common source. In our study, other common sources were the abdomen and respiratory tract, but catheter related bacteremia was less frequent than in previous publications. These old patients, in which hypertension, COPD and DM are the most frequent comorbidities, tend to show a favorable response, with a cure rate of 83.6% and a low mortality attributed to bacteremia. These results appear encouraging as compared with those of previous studies. A higher proportion of a UTI origin, which tends to an improved response, a better health status of present old patients, or a faster and broader antibiotic coverage, among other factors, could explain our favorable results.

Conclusions: 1. In patients aged 85 years or older, the most common pathogen was E. coli and the urinary tract the leading source of bacteremia. 2. Frequency of nosocomial bacteremia was low. 3. Cure rate was 83.6%.

A-279
DESCRIPTIVE STUDY OF MRSA

T. Ortega[1], M. Torres[1], S. Pérez[2], M. Areses[2], T. Rubio[2], J. García[3], J. Beloqui[4]

[1]Preventive Medicine Unit, [2]Department of Internal Medicine, [3]Department of Microbiology, [4] Department of Pharmacy. Hospital Reina Sofía. Tudela (Navarra), Spain.

Objectives: An objective of the World Alliance for Patient Safety of WHO is to decrease the infections by multiresistance microorganisms. It is especially important methicillin resistant Staphylococcus aureus (MRSA) for their characteristics (dissemination easy, resistance to drug, high mortality and the increase in hospital cost). Also, nowadays, in Spanish hospitals the prevalence of MRSA is increasing. We have an epidemiological study of MRSA cases who were detected during 2011 in Tudela's hospital (Navarra-Spain).

Material and method: Every day, the service of Preventive Medicine reviews all patients admitted in the hospital through computerized medical record. Also, clinical and microbiological doctors communicate if there are any MRSA cases, so the active search and collaboration between services allow the early detection of MRSA cases and so to avoid their transmission to other patients and health personal.

Results: During 2011 25 MRSA cases (10 men and 15 women), 7 are old cases, have been detected. 16 patients have been hospitalized in internal medicine service, 2 in general surgery, 3 in hemodialysis and 1 in emergency room. Carrier of MRSA was studied in all patients; it wasn't completed in 15 because they left the hospital before finishing the study. In any patient were the three smears positive. in 15 cases was repeated cultivation after the treatment. The mean age was 82.9 years, without significant differences by gender. 5 cases shared room for more than 48 hours, performing then the appropriate preventive measures. The most frequent localization of the microorganism was ulcers in 11 cases followed by sputum in 8 cases. In hemodialysis, all patients were placed with contact and drops isolation measures until they have the results of the first nasal swab.

Conclusions: Diagnosis and early preventive measures in MRSA cases prevents the spread of this microorganism and hospital outbreaks. Collaboration between Clinical Services and Preventive Service is necessary in order to prevent outbreaks too.

A-280
BACTERAEMIA DUE TO ESCHERICHIA COLI PRODUCING EXTENDED-SPECTRUM BETA-LACTAMASES (ESBL): HAVE THEY INCREASED IN OUR HOSPITAL?

M. Loring Caffarena[1], M. Martínez Delgado[1], V. Herrero García[1], C. Carranza Lees[1], S. Fernández Sepulveda[1], A. Guzmán González[2]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital Comarcal Axarquía. Velez-Málaga (Málaga), Spain.

Objectives: To analyze the epidemiological characteristics of patients admitted to Internal Medicine during 2008 and 2011, with Escherichia coli bacteraemia. Analysis of the antibiotics used pre and post-antibiogram as well as the prevalence of strains of extended-spectrum betalactamase-producing Escherichia coli (ESBL) and antibiotic resistance in the last four years.

Material and method: A retrospective descriptive study of medical records of all patients admitted to Internal Medicine in the years 2008, 2009, 2010 and 2011 with E. coli positive blood cultures. Analysis of antibiograms, antibiotic resistance in the last four years

and the clinical-epidemiological characteristics. Data were analyzed using SPSS software version 15.0.

Results: We included 96 episodes of bacteraemia due to E. coli admitted to Internal Medicine from 299 cases that were reported at the hospital during the four years. 56% were male and 43.8% women. The mean age was 74 years (range 18-100). 72.9% of the blood cultures were extracted at the emergency department and 27.1% in the wards. Among bacteraemia, 63.5% were community-acquired, 24% health- care related and 12.5% hospital-acquired. The origin of the blood stream infection were: urologic (56.3%), biliary (26%), intestinal (6.3%), respiratory (8.3%), catheter (1%), soft tissue infection (2%). Among the risk factors associated with bacteraemia there were: patients from nursing-homes (4%), urinary catheterization performed in emergencies or on the ward (12.5%), endoscopic or urological manipulation (7.3%), prior antibiotic therapy (11.5%), hospitalization or recent chemotherapy in 15.6% and 5.2% respectively, cutaneous ulcers (2.1%). Patient comorbidities: diabetes (40.6%), neoplasm (27.1%), immunosuppression (13.5%), hypertension (38.5%), dementia (17.7%), COPD (9.4%), renal insufficiency (22.9%). The de-escalation after antibiogram result was 40.6%. Death in 16.7% of patients and related to bacteremia in 13.5%.. Antibiotics used after outcomes of the antibiogram were: amoxycilin-clavulanic acid (26%), piperacillin-tazobactam (20.8%), 3rd generation cephalosporins (27%), quinolones (24%), imipenem (8.3%) and aminoglycosides (9, 4%). Comparing antibiotic resistance in two time periods (2008-2009 and 2010-2011), we observed that ampicillin has a resistance of 46.9% and 44.7% respectively, amoxyclavulanic acid goes from 30.6% to 8, 5% ($p < 0.05$). Cephalosporins of 3rd generation go from 14.3% to 8.5%, piperacillin-tazobactan from 8.2% to 10.6%. Quinolones from 24.5% to 29.8%. Aminoglycosides from 6.1% to 6.4%. There was no resistance to imipenem, vancomycin and tigecycline. As regards beta-lactamase producing E. coli, 12.2% appeared in the 1st period (2008-09) while in the 2nd period (2010-11) it decreased to 8.5%.

Discussion: Gram-negative bacteraemia continue to be one of the most important causes of morbidity and mortality in patients admitted in the ward, namely Escherichia coli is the most frequently microorganism found in blood cultures, both in community-acquired bacteremia as those associated with health care. The appearance of Extended-Spectrum Beta-Lactamase (ESBL) producing E. coli strains has aggravated the situation, being important to recognize in advance patients susceptible to these strains (nursing-homes, prior antibiotic therapy, permanent catheterization, recent hospitalization).

Conclusions: Our study reveals a slight decrease of Extended-Spectrum Beta-Lactamase (ESBL) producing E. coli strains in the last two years. Currently there are no carbapenemase-producing strains in our hospital. Regarding antibiotic resistance highlight the decreasing resistance to amoxycilin-clavulanic (from 30.6% to 8.5%, $p < 0.05$).

A-281
MALARIA PRESENTING TO A DISTRICT GENERAL HOSPITAL; ARE THERE LESSONS TO BE LEARNT

L. Ma[1], C. Lisk[2]

[1]*Department of Medicine. Royal London Hospital. London, UK.*
[2]*Department of Medicine. Barnet Hospital. London, UK.*

Objectives: Malaria is the most deadly vector borne disease in the world with 300-500 million cases worldwide annually. Plasmodium falciparum causes the most severe morbidity and mortality accounting for 95% of malaria diagnosis worldwide. In the UK, it is the most common imported tropical disease with an average of 1500 notifications yearly with 7 deaths. A 5 year (2004-2009) retrospective study analysing the epidemiology, clinical presentation and management of all patients with malaria presenting to a UK District General Hospital is conducted with a view to highlighting areas where improvements can be made in line with current UK malaria treatment guidelines published by the British Infection Society in 2007.

Material and method: The clinical files of all patients admitted to a District General Hospital with malaria over a 5 year period (2004-2009) were analysed. Demographic data, country of origin of patients, travel history, whether or not malaria prophylaxis was taken, symptoms on presentation including the recognition of the presence of severe symptoms of malaria, level of parasitemia, door to diagnosis time, door to treatment time and antimalarial treatment given were collated.

Results: 38 patients were identified with a male preponderance 25 (66%). Most patients were in the age range 40-49 years with the majority of patients 22(58%) originating from Sub-Saharan Africa and Asia. The majority of patients 27(71%) also had a recent history of travel to Sub-Saharan Africa. Most patients 26(68%) did not take any malarial prophylaxis prior to travelling. The commonest type of malaria was Plasmodium falciparum 30 (79%) followed by Plasmodium vivax 7 (18%) and plasmodium ovale 1 (3%). 18 (47%) patients presented within 7 days of symptoms with a further 10 (26%) patients presenting within 7-14 days. 2 patients presented a year after travel. The commonest symptom on presentation was fever followed by headache, vomiting, malaise, abdominal pain, arthralgia and altered level of consciousness. 8(21%) patients had severe malaria with having a parasitemic load of 2% or more. All of these patients had symptoms of severe malaria presenting with altered level of consciousness, renal impairment, respiratory distress and metabolic acidosis. The majority of patients had a door to diagnosis of time of less than 3 hours 30 (79%). Only half of patients had their treatment within 6 hours of presentation. The commonest treatment given was quinine 28 (74%). Blood glucose was checked initially in 23 (61%) patients but only monitored regularly in 8 (21%). The median length of stay was 3.5 days with a range of 0-7 days. 5 (12%) patients were treated in a critical care unit whilst 7 (18%) required tertiary referral to a tropical disease unit.

Discussion: Falciparum malaria is the commonest form of malaria presenting to a UK District General Hospital in London. The British Infection Society guidelines emphasizes early diagnosis, treatment and recognition of severe or complicated malaria. Our study shows that most patients come from and travel to Sub-Saharan Africa and the majority don't take antimalarial prophylaxis putting them at increased risk of malaria. There is a need shorten the door to diagnosis and door to treatment time and emphasize regular capillary glucose monitoring in patients with malaria.

Conclusions: Our findings suggest that it is necessary to continue to provide health education to the general public about the importance of taking antimalarial prophylaxis when travelling to a malarial endemic area as well as educating health care professionals regarding the latest guidelines in regards to diagnosis, management and chemoprophylaxis of falciparum malaria.

A-282
INFLUENCE OF ILB28 ON THE ACTIVITY OF VIRAL HEPATITIS C AND HCV-HIV COINFECTION

S. Miranda Riaño[1], M. Muñoz Moreno[2], E. González Sarmiento[4], C. Hinojosa Mena-Bernal[3], I. González Gilabert[3], A. Serrano Morte[1], C. Rodríguez Martín[1], S. Calzada Simón[1]

[1]*Department of Internal Medicine,* [2]*Support Unit at the Research,* [3]*Infectious Diseases Unit. Internal Medicine. Hospital Clínico Universitario de Valladolid. Valladolid, Spain.* [4]*Instituto de Endocrinología y Nutrición. Universidad de Valladolid. Valladolid, Spain.*

Objectives: To study the influence of genetic marker ILB28 with a better response to treatment (measured as RVR, EVR and SVR) and its relationship to the degree of fibrosis.

Material and method: We studied 51 outpatients with chronic hepatitis C from the Infectious Diseases Unit. Statistical study: the association of qualitative variables was analyzed by the Chi-square test of Pearson. If the number of cells with expected values under 5 are greater than 20%, has been used the Fisher's exact test or Likelihood Ratio test for more than two categories. Fibroscan and PCR values was compared with Mann-Whitney and Kruskal-Wallis test for independent samples when the number the group to compare was two or greater. Data were analyzed using SPSS version 19.0 for Windows, p-values < 0.05 are considered statistically significant.

Results: There were 37 (72.5%) men, 48 (94.1%) were from Spain, and 20 (39.2%) had HIV coinfection. 18 (35.3%) had hipertrigliceridemia and 9 (17.6%) insulinorresistance. 26 (51%) made hepatitis C treatment. The source of infection was in 34 (66.7%) the intravenous use or inhaled drugs, in 14 (27.5%) was unknown and the remaining sexual. 20 (39.2%) had HIV coinfection. 26 (51%) completed treatment of hepatitis. The 61.5% and 84.6% of patients with CC genotype had RVR and EVR respectively, compared to 30% of patients with CT or TT genotype. We obtained a higher SVR in patients with CC genotype (58.3%) compared to CT-TT genotypes (44.4%). 80% of null responders had a CT-TT genotype. The grade of fibrosis measured by Fibroscan was F3-F4 in 50% of patients with CC ILB28, compared to 27% of patients with CT and TT ILB28.

Discussion: Hepatitis C virus infection (HCV) is a serious health problem in the Western world, with chronic infection rates ranging from 1.5 to 3%. Treatment with pegylated interferon (peg-IFN) and ribavirin (RIB), manages to cure about 50% of cases of patients infected with genotype 1, which is the most common (75% of those infected). Several genome-wide association studies have demonstrated that single nucleotide polymorphisms located near the interleukin 28B gene strongly predict an SVR to peg-INF/RBV therapy, and also in HCV/HIV coinfected patients, as we can seen in our results. Other studies have observed less progression of liver fibrosis in patients with genotype CC, but we obtained no statistically significant results regarding the degree of fibrosis and genotype in our patients, and that´s probably because the small sample of patients.

Conclusions: Treatment patients with CC genotipe get more RVR, EVR and SVR than CT and TT genotype patients. However the number of null responders is higher in the CT and TT than in CC genotype patients. In our study, CC genotypes patients have a greater degree of fibrosis than CT and TT patients. We found no statistically significant differences between the degree of fibrosis (APRI, FIB-4 or Fibroscan), neither between HCV RNA and the different ILB28 genotypes. But CC genotype patients had more sever fibrosis degree than CT-TT genotype patients.

A-283
CONTROL OF URINARY CATHETERIZATION IN INTERNAL MEDICINE

M. Gómez Antúnez, F. de la Calle Prieto, M. San Julián Romero, O. López Berastegui, J. Santos Martínez, F. Cabrera Aguilar, B. Pinilla Llorente, A. Muiño Míguez

Department of Internal Medicine 2A. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: To evaluate the urinary catheterization in patients in an internal medicine unit, the indications for catheterization and the catheter-associated urinary tract infection (CAUTI).

Material and method: The authors studied prospectively consecutive patients with urinary catheter in an internal medicine unit. On register epidemiological data and comorbility, the place, indication, days of catheterization and urocultive before and after catheterization.

Results: A total of 72 patients were enrolled in this study. 50% of all patients were men, and the mean age was 79.21 years old (16-102) 99% of the patients had comorbidities. The patients presented antecedents of HTA in 68%, diabetes 31%, EPOC 25%, heart failure 31%, cognitive impairment 37%, renal failure 19% and 32% history of urinary tract infections. 8% of de patients had permanent catheterization The indication for catheterization was volume monitoring in 61% and obstruction in 15%. The catheterization was performed in emergency department in 71% of patients. The urine culture after catheterization was positive in 21 of 65 patients (32%) with a mean 4.7 days of catheterization. 8% of the patients had complications derived from urinary tract infection.

Discussion: Urinary tract infection is the most common nosocomial infection, and prolonged catheterization is the primary risk factor for CAUTI. From 15% to 25% of patients in general hospitals have a urethral catheter inserted at some time during their stay, and the rate of catheter use appears to be increasing. The indwelling urethral catheter introduces an inoculum of bacteria into the bladder at the time of insertion, facilitates ascension along the catheter-urethral mucosa interface, and allows for intraluminal spread of pathogens to the bladder. In hospitalized patients, catheter- associated bacteriuria accounts for many episodes of nosocomial bacteremia. Indwelling catheters should be placed only when they are indicated, but recommendations for urinary catheterization in newly hospitalized patients are inconsistent and unclear. Two thirds of our patients had urinary catheterization to volume monitoring, indication questionable if it can be controlled by other means. In hospitalized patients the benefits of catheterization should be balanced by potential complications.

Conclusions: The urinary catheterization is associated with a high percentage of catheter- associated urinary tract infection. The use of urinary catheterization must be restricted to patients who have clear indications and removing the catheter as soon it is no need.

A-284
EVALUATION OF THE RISK OF MORTALITY DUE TO TIGECYCLINE IN A REGIONAL HOSPITAL

J. Valdueza Benitez[1], B. Adalia Martín[2], M. González Pérez[1], B. López Virtanen[1], B. Nogal Fernández[1], M. Noguerol Cal[1]

[1]Department of Pharmacy, [2]Department of Internal Medicine. Hospital El Bierzo. Ponferrada (León), Spain.

Objectives: In view of the alert issued by the EMA ("European Medicines Agency"), FDA ("Food Drug Administration") and AEMPS (Sp. For "Spanish Agency of Drugs and Health Products") focusing on the bigger mortality in patients going through a treatment with tigecycline, a study is developed in order to assess the mortality rate in patients undergoing treatment with tigecycline.

Material and method: Descriptive study of patients to whom tigecycline was prescribed during their stay in El Bierzo Regional Hospital, in the period covered from January the 1st, 2009 and April the 30th, 2011. The studied aspects were: age, sex, culture and isolated microorganisms, main diagnosis, treatment's length, empirical or not empirical indication, previous and concomitant antibiotics, allergy to penicillin and exitus. Patients are selected by the control program of the use of restricted use antibiotics made by the hospital infection, prophylaxis and antibiotic policy committee. The statistical analysis was made with the SPSS program.

Results: 24 patients, of which 65% were women, were included. 8 patients passed away (33%). The average length of the treatment was 8 days. Microorganisms which are resistant or with medium feeling to tigecycline isolated in later cultures during or after the treatment with tigecycline were: Candida spp (5 patientts), M. morganii (2 patientts), P. mirabalis (2 patients), S. maltophilia resistant to tigecycline (1 patient), K. pneumoniae with intermediate feeling to tigecycline (1 patient). The diagnosis of the

patients that passed away was: intra-abdominal infection (12.5%), sepsis (12.5%), pneumonia (25%), urinal infection (25%), soft-tissue infection (25%). In all the patients that passed away the treatment was empiric and in three cases they were allergic to penicillin.

Discussion: The mortality rate was high, 33% compared to a 2.3% of the mortality issued by the EMA. This rate may be due to the fact that none of the patients that passed away received the correct antibiotic treatment for germs which are intrinsically resistant to tigecycline (3 out of 8 patients that passed away received treatment in monotherapy) even when they were serious infections or suspected of multiresistant germs. In five out of the eight patients that passed away tigecycline was used out of the authorized indications (pneumonia, sepsis and urinal infection), hence the importance of using the aforementioned antibiotic in the authorized indications.

Conclusions: The mortality rate is higher than the one issued by the EMA (probably due to an incorrect antibiotic supply). Tigecycline was used out of the authorized indications in more than a 50% of the patients that passed away. Since it's a descriptive study, it is difficult to establish a causality relation, and therefore, to claim less efficacy and security of the treatment in patients treated with tigecycline.

A-285
EXTRAPULMONARY TUBERCULOSIS PRESENTING AS LYMPHADENOPATHIES AT INTERNAL MEDICINE OFFICE: NEW DIAGNOSTIC APPROACH

J. Pilares[1], P. Guisado Vasco[1], G. Fraile[1], E. Navas[3], A. Benito[4], E. Mampaso[2]

[1]Department of Internal Medicine, [3]Department of Infectious diseases, [4]Department of Pathology, [2]Department of Microbiology. Hospital Universitario Ramón y Cajal. Madrid, Spain.

Objectives: Engrossed lymph nodes are the commonest form of extrapulmonary tuberculosis. This form of presentation is increasing in the last years, and requires a complex differential diagnosis. Although the bacterial culture is still the microbiological gold standard for detection of tubercle bacilli, the polymerase chain reaction (PCR) is a quick method, which requires small volumes of samples, and could help the physician to take a sooner and correct therapeutic decision. The purpose of our series is to report the clinical, microbiological and laboratory data, of consecutive patients diagnosed of lymph node tuberculosis.

Material and method: We performed an observational, descriptive and retrospective study in the internal medicine and infectious disease departments of the university hospital Ramon y Cajal, reviewing medical records of patients from 2007 to 2012. Eligible patients should have some of the next microbiological criteria: positivity Zielh-Neelsen or auramine-rhodamine stainings, grewing in solid or liquid cultures media and/or a positive amplification of genome (ARNr) of Mycobacterium tuberculosis (PCR). The patients should have peripheral lymphadenopathy of any location and a compatible cytology (necrotizing granulomas) by fine-needle aspiration (FNA). We excluded any other mycobacterium specimen's culture and those < 18 years old. HIV (+) cases were considered just for descriptive purpose. Contingency tables were conducted to assess the sensitive (Se), specificity (Sp), negative predictive value (NPV) and positive predictive value (PPV) of as diagnostic tests.

Results: We found 103 cases. The mean age was 52.89 years, and symptoms before diagnosis were reported with an average of 21.9 weeks. 44 cases (42.7%) were males and 71 cases (68.9%) came from local, non-immigrant population. The cervical area was the most frequent location of the peripheral lymph node (78.6%). 17 were HIV (+), whoe were finally excluded for diagnosis test analyses (16.5%). The Zielh-Neelsen staining was positive in 32 cases (37.2%) and auramine-rhodamine in 47 cases (54.7%); positivity for both staining methods reached 47 cases (54.7%). Cultures were positives in solid medium in 44 cases (51.2%) and liquid medium 57 cases (66.3%) - any positivity reached 57 cases (66.3%). Amplification of genome of M. tuberculosis (PCR) was obtained in 91 cases (88.3%). Tissue pathological analysis obtained by FNA described granulomas in 69 cases (71.9%) and necrosis in 55 cases (57.3%). The Se, Sp, PPV and NPV of the PCR against Zielh-Neelsen and auramine-rhodamine stainings were 0.95, 0.23, 0.6 and 0.81, respectively. When PCR were compared with any positive culture, Se, Sp, PPV and NPV results were 0.89, 0.17, 0.68 and 0.45, respectively. Then, it was compared the report of granulomas in FNA, obtaining the next results: 0.85 (Se), 0.11 (Sp), 0.76 (PPV) and 0.18 (NPV). Finally, the same approach was done for necrosis in cytology performance by FNA: 0.9 (Se), 0.2(Sp), 0.58 (PPV) and 0.63 (NPV).

Discussion: PCR have got a Se (over 80%) compared with classic tools of M. tuberculosis infection (Ziehl-Neelsen, cultures, FNA) and could be an excellent complementary technique of diagnosis. Our series have got some limitations: it is a retrospective; a low number of negative samples for any of the laboratories could influence the specificity results (so it could expected a higher values). So our results shows that positive PCR, together with FNA and/or alcohol-resistant bacilli stainings in the samples of the lymphatic nodes, could be a valuable tool to get a quick diagnose of tuberculous lymphadenitis and start aimed treatment in these patients.

Conclusions: In patients suspected of tuberculous lymphadenitis, positive PCR could be a sensitive method to start therapy against M. tuberculosis with safety.

A-286
ACUTE PYELONEPHRITIS (APN) IN ADULTS. REVIEW OF 128 CASES

M. Sanz Cerezo, L. Cabeza Osorio, E. Lozano Rincón, R. Serrano Heranz

Department of Internal Medicine. Hospital Universitario del Henares. Coslada (Madrid), Spain.

Objectives: Acute pyelonephritis (APN) is a relatively frequent disease among adults, but diagnostic approach, evolution, indication to hospitalization, and empiric antibiotic treatment are still open problems. We studied the risk factors, etiology and profile of antimicrobial resistance, the chest radiograph and initial antibiotic treatment and clinical outcome.

Material and method: We have made a retrospective analysis of adults patients hospitalized for APN, from the opening of our hospital in February 2008 to December 2011, with special attention to age, gender, predisposing factors, microbiological results (urine and blood cultures), the findings of the imaging (renal sonography, CT), antibiotic treatment (empirical, directed) and evolution.

Results: We identified 128 patients: 101 females (78.9%), with a mean age of 41.9 years (range 16-89 years), and 27 males (21.1%), with a mean age of 58.48 years (range 31-82) Predisposing risk factors for APN were detected in 73 cases (57.03%), highlighting the previous APN in 22 cases (30.1%), functional abnormalities of the excretory tract in 18 cases (14.06%), the presence of a double J stent in 10 cases (13.69%), predisposing conditions including diabetes, chronic renal failure, pregnancy, vesical catheter and represent a 31.5% (23 cases). In 55 cases there were no significant alterations (42.9%). Urine culture was positive in 60 patients (46.8%: Escherichia coli in 50 cases [83.3%] with 4 extended-spectrum beta-lactamase (ESBL) producing E. coli, Klelbsiella spp. in 5 cases [8.3%], Proteus spp. in 2 cases [3.3%], Pseudomonas spp. in 1 case [1.67%] and Enterobacter spp. in 1 case [1.67%]). Blood culture was requested from 77 patients and was positive in 18 cases. (23.37%: E. coli in 15 cases [83.3%], Klebsiella spp. in 2 cases [11.1%], Clostridium spp. in 1 case (5.55%). In 15 cases there was overlap

between the results of urine culture and blood culture, 14 of which correspond to E. coli. We found 43 negative blood cultures (55.8%) and 45 negative urine cultures (37.1%) Imaging tests were performed (renal ultrasound), in 105 cases (82%): in 50 cases (47.6%) had no significant radiological abnormalities; in 27 cases (25.7%) showed focal pyelonephritis; in 10 cases (10.5%) was visualized kidney stones; in 8 cases (7.6%) pelvicalyceal ectasia, and in 4 cases (3.8%) we found renal abscess. All patients started empirical antibiotic treatment intravenously with one if three regimens: beta-lactam monotherapy (56.2%) or in combination with an aminoglycoside (10.1%), or a fluoroquinolone (33.7%). It was only necessary to change the antibiotic regimen, after receiving the antimicrobial susceptibility, in 10 cases (7.8%): 4 patients with ESBL producing E. coli; fluroroquinolone resistant E. coli in 6 patients; ciprofloxacin resistant E. coli in 3 cases; ciprofloxacin resistant Klebsiella and intolerance to beta-lactams previously unknown in 1 case The outcome was favorable in all patients (100% survival). As complications, noted that nephrectomy was required in 1 patient with renal abscess and sepsis.

Conclusions: We can conclude that the demographics and the etiology of the APN were similiar to those reported in the literature. Emphasize the presence of double J, APN previous recurrent urinary tract infections and kidney stones as factors favoring APN in 36.7% of cases. Renal ultrasonography allowed detecting significant complications, such as focal pyelonephritis and renal abscess in a total of 31 cases. The low proportion of resistant organisms (ESBL producing E. coli and other gram-negative bacilli resistant to quinolone antibiotics), only forced to change the antimicrobial treatment in 7.8% of cases: in our health area, the administration of a beta-lactam antibiotic alone or in combination with an aminoglycoside remains the preferred empirical antibiotic treatment of APN in adults.

A-287
IMMUNE STATUS IN HIV CASES IN SANTA BÁRBARA SORIA HOSPITAL

M. Carrera, Ó. Terry, M. León, P. Sánchez, D. López, M. Del Valle, J. Gutiérrez, J. Barraza

Department of Internal Medicine. Hospital Santa Bárbara. Soria, Spain.

Objectives: Description of HIV cases assessed at Internal Medicine consultation including the type of infection, immune status, viral load and presence of co-infections during the period 2011-2012.

Material and method: A descriptive, retrospective and observational study of 33 cases of HIV infection in Santa Bárbara Soria Hospital 2011-2012. We collected the following data: age, place of origin, type of transmission, sexual practices, viral load, resistance, co-infection with other agents and their immune status.

Results: Of the 33 cases included the average age was 45 years, including 24 men and 9 women. Most of these cases are local and in the foreigners Latin Americans are the most predominant, in this group the majority are female. The most common means of infection is drug abuse (13 cases) followed by the heterosexual sexual transmission (8 cases), the route of infection of remaining cases is unknown and the details on their sexual habits are not provided. 14 cases are at stage AIDS at the time of diagnosis. In 20 patients the viral load is undetectable, 6 of them have less than 1,000 copies,2 of them between 1,000 and 10,000 copies and 5 of them have more than 10,000 copies. CD4 are > 500 in 18 patients, between 350-500 in 6 patients and below 350 in 9 cases. The average CD4 was 594 with a median of 531. In terms of resistances 28 of the patients do not have any resistance. HCV co-infection was observed in 16 cases and HBV co infection in 5 of them. The lues serology is positive in 4 cases.

Discussion: In our results the main route of infection is drug dependence although in 27% side route is unknown. Heterosexual transmission in female foreign population is more representative with a decrease in the homosexual transmission. The last cases diagnosed are 4 men and 3 women, 6 of them with heterosexual transmission. 78.78% of the patients have less than 1,000 copies at the time of diagnosis and 15.15% more than 10,000 copies. The patients with the highest viral load were those of African origin with a difficult treatment adherence. In general, immune status has been good with 72.72% of the patients with CD4 counts above 350 cells/L, and most of them with values higher than 500 cells/L. In our sample, we haven't found a lot of resistances, only 15.15% were documented. The HBV and HCV co-infections were 63.63% and lues co infection was 12.12% partly because in the group of patients held in prison prevails HCV co-infection, being these patients third of the total sample.

Conclusions: Of patients evaluated in HIV clinic at Soria we can conclude that most of those diagnosed are local men whose route of transmission were the drugs abuse, while foreigners diagnosed most of them were women of Latin American origin whose route of infection was sexual. Most of our patients have immunological stability in part because nearly a third of them are held in prison leading to an improved monitoring and more exhaustive adherence. But in turn this means that we have a higher rate of co-infections are mainly due to ex-drug abuse patients produces a greater number of HBV and HCV even prior to AIDS diagnosis.

Table 1 (A-287)

CD4 cells/µ	Number of patients (%)
< 350	9 (27%)
350-500	6 (18%)
> 500	18 (54%)

Table 2 (A-287)

Viral Load	Number of patients (%)
Undetectable	20 (60.60%)
< 1,000	6 (18.18%)
1,000-10,000	2 (6.06%)
> 10,000	5 (15.15%)

A-288
RETROSPECTIVE ANALYSIS OF THE PATIENTS WITH HIV INFECTION ADMITTED IN A THIRD LEVEL HOSPITAL

E. Sifuentes Díaz, F. García Colchero, P. Martín Peral, I. Ríos Holgado, A. Martín Aspas, F. Guerrero Sánchez, J. Girón González

Department of Internal Medicine. Hospital Universitario Puerta del Mar. Cádiz, Spain.

Objectives: To describe the features and to analyze the morbidity of the patients with HIV infection who needed to be admitted. To analyze the causes of admissions and mortality of patients with HIV infection in our hospital.

Material and method: It has been reviewed the clinical histories, of adults patients, aged more than 15 years old, with HIV infection admitted in our hospital, a third level hospital, in medical or surgical wards, during a period of five years, from 2007 to 2011. We excluded hospital admissions only for diagnosis tests. The statistic analysis was realized with the IBM SPSS statistic programme.

Results: We entered 392 episodes of admissions concerning to 203 patients. The distribution was irregular, in 2007 were admitted 62 patients, 31 in 2008, 18 in 2009, 62 in 2010 and 23 patients in

2011. 155 (76.4%) men, with a median age of 44.2 years. The average hospital stay was 13.4 days. The route of transmission was intravenous in 141 patients, 138 (68%) in previously parenteral drug users, and 3 cases only trough blood transfusion, followed by 47 (24.7%) of sexual transmission. 140 patients (69%) were co-infected by HCV, and 19 (9.4%) were co-infected by HBV. Most patients admitted were on HAART, 115, (56%); on the other hand 80 (39.4%) patients weren´t on HAART, normally not adherents patients. Almost half, 95 patients (46.8%) have a CD4 count > 200 cells/µl; and 124 (61.1%) have a CD4 count > 350 cells/µl. 63 (31%) patients had reached undetectable viral load. The causes of admission were due to non-HIV/AIDS-related conditions, in 231 (58.9%) of admissions. Firstly infectious diseases, 92 cases (24%), secondly advanced liver disease in 35 patients (12%), followed by neoplasms and cardiovascular events. 158 (40.4%) were as a result of HIV/AIDS-related events, usually opportunistic infections. The mortality was 37 patients (18.2%), 15 (40.5%) died in the first episode of admission. The distribution of deaths per year was also irregular, in 2007 died 9 patients (24.3%), in 2008 8 patients (21.6%), in 2009 9 deaths (24.3%), in 2010 8 deaths (21.6%), in 2011 5 deaths (13.5%). The most important cause of death were non-AIDS-related events, in 22 cases, (60%). 10 deaths (45.5%) due to liver disease, 7 (31.8%) due to infection and 5 (22.7%) due to malignant tumours. 15 patients (40%) died because of AIDS-related events, 12 (73.3%) because of infections, 2 (13.3%) because of neoplasms and 1 (6.6%) case due to an ischemic event.

Discussion: The progression and mortality due toHIV/AIDS infection has decreased dramatically since the introduction of the highly active antiretroviral therapy (HAART). In developed countries has changed consideration of HIV infection as a chronic manageable disease. The clinical benefits associated with HAART seems to be largely, primarily because of reductions in deaths attributable to AIDS-related conditions however, an increasing number of deaths are attributable to causes not conventionally considered to be HIV related. This study confirm these data, most of patients need to be admitted and die, because of non AIDS-related illnesses, moreover in our population, where HCV co-infection it's a great problem. Anyway, the immunological status seems to be also implicated in many of these not conventionally considered HIV-related conditions, so improving the treatments and the immunological status continue representing a specific target.

Conclusions: The most frequent transmission route in patients with HIV infection who needed admission, was the intravenous, in previously parenteral drug users. Most patients admitted were co-infected with CHV. Most of the patients were treated with antiretroviral therapy, nearly the half of them with CD4 cell count > 200 cells/ul and undetectable viral load. The most important cause of admission and mortality in patients with HIV infection was due to non-HIV/AIDS-related conditions.

EPIDEMIOLOGY OF HIDATIDIC CYST IN OUR SANITARY AREA

C. Fanciulli, M. Torrea, M. Artacho, C. Díez, P. Díez, M. Olmedo, J. Filgueira

Department of Internal Medicine. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: Human cystic echinococcosis (CE) cause by Echinococcus granulosus is a widely distributed zoonosis, known in the Greek antiquity, which may cause severe or even lethal disease in humans and considerable economic losses. Since the first case report in 1892, later studies reveal that the infection may be spreading from endemic (Austria, France, Germany, and Switzerland in Europe, Japan Islands and Northern Tundra Zone in North America) to non-endemic regions. Spreading risk factors identified are: increase of fox population sizes, increase of E. granulosus prevalence in foxes, invasion of cities by foxes, the establishment of urban cycles of the parasite, changes in land-use patterns and human behaviour. In Spain, endemics areas are "Castilla-León", "Aragón", "Navarra" and "La Rioja". It was an Obligatory Declaration Disease from 1981 to 1996 and its real incidence and prevalence is unknown in Spain. However persistence or re-emergence of this infection is well documented in some countries and is primarily caused by the lack or reduction of control measures. Based on the data of previous studies talking about an increase of this infection we have make an observational study to see the prevalence and clinical evolution of this disease in our sanitary area.

Material and method: We have made an observational descriptive study of all the cases from 1996 to 2011 in our sanitary area in Internal Medicine Services. We used the 9th Disease Classification for cystic echinococcosis (CIE-9), corresponding to codes from 120.0 to 122.9. We recollected epidemiological data such as the age of diagnosis, the diagnostic method, the treatment and the clinical evolution. We included all patients diagnosed by serological tests, after intervention or by radiological images. We used the SPSS statistical program to analyse the data.

Results: We identified 49 cases, 50.5% women. The mean age was 81 years old. The localizations of cyst were: 37 hepatic, 4 pulmonary, 1 renal, 2 pulmonary and hepatic and 5 diseminated. The diagnose technique used in 27 patients was abdominal CT, in 12 cases thoracic X-ray, in 7 cases abdominal ultrasonography and only three were diagnose by abdominal X-ray. Serology test were only used in 9 cases, being positive in 7 cases. Most therapy given was cyst resection (17 patients), using a combination with surgery and albendazol in 3 patients. Only one patient was treated with albendazol as unique therapy. 31 patients received no treatment. Patients without any treatment were incidental diagnoses.

Discussion: CE was thought to be an eradicated disease. However in our population of study, we have seen that there are still new cases diagnosed, and even in young people. These findings have been studied recently in Spanish population, with similar results. Analyse the potential risks factors of the disease was not possible due to the high percentage of incidental diagnose.

A-291
A 5-YEAR RESTROSPECTIVE REVIEW ABOUT CLOSTRIDIUM DIFFICILE-ASSOCIATED DIARRHEA IN AN INTERNAL MEDICINE DEPARTMENT

A. Silva[1], J. Silva[2], C. Cunha[3], T. Fonseca[1], G. Abreu[4], P. Caiano Gil[1], M. Barbedo[1], V. Paixão Dias[1]

[1]Department of Internal Medicine, [2]Department of Gastroenterology, [3]Department of Nephrology, [4]Department of Clinical Pathology. Centro Hospitalar Vila Nova de Gaia/Espinho. Vila Nova de Gaia, Portugal.

Objectives: Clostridium difficile infection (CDI) is the leading cause of health care-associated diarrhea and a significant cause of morbidity and mortality among elderly hospitalized patients. CDI is diagnosed when symptoms (usually diarrhea) are present and either a stool test is positive for Clostridium difficile toxins, colonoscopy or histopathology reveals pseudomembranous colitis. The aim of this study was to review CDI in patients hospitalized and to assess its symptoms, diagnosis, risk factors, treatment and complications.

Material and method: We conducted a descriptive and retrospective study including all inpatients admitted in an Internal Medicine Department between February 2007 and February 2012, who had symptoms of diarrhea and a stool test for C. difficile was requested. The laboratory test used was a toxin assays by enzyme immunoassay (EIA).

Results: A total of 392 patients were included in the study. Of these, 39 (9.9%) had a stool test positive for C. difficile. Of 353 patients with a negative stool test, 63 patients had colonoscopy and of these, 5 had pseudomembranous colitis. So, 44 (39+5) patients (11.5%) were diagnosed with CDI. In these 44 patients, the median age was 76.4 years, 63.6% were female and the average days of hospitalization was 39.9 days. In only 16 patients were documented other symptoms such as abdominal pain, bloating, fever and vomiting. 97.7% of these 44 patients had risk factors: 37 patients (86%) had ≥ 65 years old with 62.2% older than 75 years; 81.4% had antibiotic exposure, and the antibiotics most frequently associated were piperacillin/tazobactam, amoxicillin/clavulanic acid, ciprofloxacin and carbapenems; 58% had hospital-acquired CDI and the mean day of onset of symptoms was 15.2 days; 67.4% used proton-pump inhibitor (PPI); 27.9% had immunosuppression; 11.6% had feeding tubes and 4.6% had recent history of gastrointestinal surgery. Overall, 89% (39) of them were treated for CDI. Of those, 90% (35) of patients recovered with one course of antibiotics (30 with metronidazole, 4 with metronidazole + Vancomycin and 1 with vancomycin). 10% (4) patients required second course of therapy with vancomycin with resolution of symptoms. 8 patients with CDI died but CDI wasn´t the cause of death of any patient. Complications like toxic megacolon or bowel perforation were not documented.

Discussion: Our study is in concordance with what reported in the literature. The most commonly identified risk factors were advanced age, broad-spectrum antibiotic exposure, hospitalization and the use of PPI. Good clinical results were achieved with metronidazole and vancomycin which remain the mainstays of CDI treatment. The incidence of CDI in this study might be underdiagnosed because the laboratory diagnostic test for C. difficile used (EIA) has only moderate and variable sensitivity (65 to 95 percent) and colonoscopy was requested in a small proportion of patients with a negative Clostridium stool test.

Conclusions: C. difficile is an important cause of health care-associated infections. Watery diarrhea is the cardinal clinical symptom. The diagnosis should be based on results from a laboratory diagnostic test or an endoscopic evaluation that demonstrates pseudomembranes in the colon. Major risk factors for CDI include exposure to antimicrobial agents, hospitalization and advanced age. The cornerstones of CDI treatment are metronidazole and vancomycin.

A-292
BLOODSTREAM INFECTIONS CAUSED BY GRAM NEGATIVE BACTERIA IN AN INTERNAL MEDICINE WARD

J. Rojas Marcos, A. Domínguez, D. Benito, I. Barbolla, A. González, F. Hidalgo, S. Diz

Department of Internal Medicine. Hospital Universitario Ramón y Cajal. Madrid, Spain.

Objectives: To describe the clinical characteristics, epidemiology, treatment and complications in patients with bloodstream infection (BSI) caused by gram negative (GN) bacteria in an Internal Medicine ward.

Material and method: We carried out a descriptive study on bacteraemia caused by GN bacteria detected from December 1st, 2011 to May 15th 2012, in an Internal Medicine department with 114 beds. We analyse those patients who had positive blood cultures for GN bacteria. We describe the demographic, microbiological, clinical data and outcome of the patients affected. We consider appropriate treatment when the antibiotic used was effective in vitro according to the antibiogram susceptibility.

Results: From a total of 67 bacteraemia isolated from 63 patients, we collected 30 cases of bacteraemia caused by GN microorganisms (with a cumulative incidence of 2% of all admissions). The mean age was 84.6 years (range 76-97), being 7 males and 23 females. The mean Charlson score was 2.7 (DS: 1.6). For functionality evaluation our patients had a mean of 49.2 in Barthel index and 30% had a F-G Katz index. 9 (30%) had health care associated infections, while 9 (30%) were nosocomial. 8 (26.6%) had been hospitalized in the previous 3 months and 12 (40%) had been treated with antibiotics during the previous month. Blood cultures demonstrated isolation of Escherichia coli in 21 cases (70%), 3 Klebsiella pneumoniae, 2 Proteus vulgaris, 2 Pseudomonas aeruginosa. 6 bacteria had ESBL (extended spectrum beta-lactamase). The urinary tract was the most frequent source of infection with 21 cases (70%), followed by abdominal infection with 4 (13.3%). 17 patients (56.7%) had a clinical feature of sepsis, severe sepsis (7), septic shock (3) and multiorganic failure (2). 3 of these needed vasoactive drugs. Empiric treatment was started in 29 patients, it was considered adequate in 20 of them (66.6%), and afterwards sequenced to another antibiotic or oral equivalent in 20 patients (66.6%). 26 patients were treated successfully and 4 died (13.3%).

Discussion: We have a predominance of women (76.6%) and all our patients are over 75 years of age. We find a high dependency level and most patients have several comorbidities. The main pathogen found is E. coli and the most frequent source of infection is nephrourologic in accordance with other studies. ESBL was isolated in 20% of which 33.3% were health-care associated. All of them except one received an inappropriate empirical therapy, 2 (33.3%) died. This may be due to the fact that all of them where sequenced correctly after receiving the microbiological results. 2 (33.3%) of the ESBL isolated were community acquired, which is a higher rate than that found in other series. We have a death rate of 13.3%, which could be explained by the baseline characteristics of our patients. When referring to patients with health care associated infections mortality ascends to 33.3%, in the case of nosocomial infections it is of 11.1%. In the latter groups E. coli is still the main pathogen, but it is remarkable that there is a high rate of multiresistant strains. This may be one of the causes that explain why mortality is higher in both groups. 56.7% (17) patients presented with sepsis, 10% (3) of which had septic shock. All of the patients who died did so because of sepsis. 70.5% were community-acquired. As our data shows we have a high incidence of sepsis, which could be related to the characteristics of our patients.

Conclusions: GN bacteraemia is an important cause of morbidity and mortality in the adult population. E. coli is still the main pathogen related to the fact that urinary tract infections are the most frequent focus in this infections. Measures should be implemented to help prevent and reduce the incidence of health care associated and nosocomial infections. It is also important to identify risk factors for GN resistant microorganisms' BSI, which may help to optimize empiric treatment.

A-294
CANDIDA OSTEOARTICULAR INFECTIONS

L. Martín Fajardo, E. García Almodóvar, S. Urruela Urruela, M. Peñaranda Vera, M. Ribas del Blanco, M. Riera Jaume

Department of Infectious Diseases. Son Espases University Hospital. Palma de Mallorca (Illes Balears), Spain.

Objectives: To analyze the clinical features, risk factors, treatment and final outcome of patients with a diagnosis of *Candida* arthritis in a third level hospital.

Material and method: Retrospective analysis of patients with diagnosis of *Candida* arthritis admitted to Son Espases University Hospital (reference hospital for the Balearic Islands). They were evaluated by the Infectious Diseases Department, from 04/2009 to 05/2012. We analyzed medical history, risk factors, medical antifungal therapy, surgical treatment and final outcome.

Results: Six patients were identified: 2 men and 4 women. Average age was 56.3 years (SD: 13.6 y). Underlying conditions of

the patients included: Rheumatoid arthritis and Crohn´s disease (1), alcoholism and chronic liver disease (2), diabetes mellitus (1), heart failure (1). Four patients had prosthetic arthritis, all after reimplantation. One patient had postoperative arthritis after arthrodesis and one previously had had several surgical interventions due to ligament ruptures. The affected joint was the knee in five cases and the hip in one. According to the Tsukuyama et al. classification, we found two Type 1 infections, three Type 2 and one type 4. Two patients had had previous bacterial prosthesis infection due to Staphylococcus lugdunensis and Enterobacter cloacae, and they received antibiotic therapy for a prolonged period of time, between 2 and 4 months before *Candida* infection. The clinical presentation in all patients was mild pain, local sings and reduced mobility. None of the patients had fever. The erythrocyte sedimentation rate (average: 81mm/hr SD: 22.7 mm/h) and C-reactive protein (average: 7.67 mg/dl SD: 7.26 mg/dl) were elevated in all of them. The diagnosis was established by cultures; from intra-operative samples in 3 cases, from joint aspirations and intra-operative samples in 2 cases, and from wound exudates and intraoperative samples in 1 case. The species isolated were Candida albicans in three cases and Candida parapsilosis in three cases. Candida parapsilosis was resistant to fluconazole in one case and resistant to fluconazole and voriconazole in other case. Two patients had bacterial confection with Staphylococcus aureus and coagulase-negative Staphylococcus. Five patients received antifungal treatment for a prolonged time. Fluconazole was used in monotherapy in three cases. In other case the medical therapy consisted of amphotericin B followed by oral fluconazole. Of the two patients with antibiotic resistance, one was treated with amphotericin B followed by oral posaconazole and other with amputation. The surgical approach in the patients with prosthetic joint infection was debridement and prosthetic retention (2 cases) or arthrodesis and amputation (2 cases). Patients with no prosthetic arthritis were treated with debridement. The outcome in three cases was the resolution of the infection. Two cases continued on antifungal treatment with appropriate clinical course, and other case had an unfavorable outcome with femur supracondylar amputation.

Conclusions: We have observed a change in the pattern of Candida's osteoarticular involvement. Currently the main risk factors observed are prosthetic joint implantation with several surgical revisions, and several joint interventions. Previous bacterial prosthesis infection and previous antibiotic treatment for prolonged time can also be risk factors. The isolated species were Candida albicans and Candida parapsilosis. The outcome is not always favorable, and sometimes it is necessary to perform arthrodesis or even amputation.

A-295
OUTPATIENT PARENTERAL ANTIMICROBIAL THERAPY IN BACTEREMIAS

E. García-Almodóvar[1], L. Martín-Fajardo[1], L. Gil[2], J. Rascón[1], M. Riera[1], M. Del Río Vizoso[2]

[1]Department of Internal Medicine, [2]Hospital at Home. Complejo Asistencial Son Dureta. Palma de Mallorca (Illes Balears), Spain.

Objectives: Outpatient and home care can be an effective and safe alternative to conventional medical practice. One of their tools is the outpatient parenteral antimicrobial therapy (OPAT) in infectious diseases, including bacteremias, a common disease with high mortality. Analyse and evaluate a program of outpatient parenteral antimicrobial therapy in patients with bloodstream infections.

Material and method: Retrospective observational study of bacteremia treated in Hospital at Home in a tertiary care hospital between January 1, 2009 and December 31, 2011. We analyzed clinical manifestations, comobird conditions of patients, microbiological culture, parenteral antimicrobial, infusion devices, catheter changes, adverse reactions and safety profile of treatment.

Results: We included 27 patients: 22.2% in 2009, 29.6% in 2010, and 48.1% in 2011. 51.8% were women. Average age: 57.7 years. Average stay was 8 days. The departments involved were: Infectious (Internal Medicine) 33.3%, Oncology 29.6%, Short Stay Unit 11.1%, others 25.9%. 29.6% were immunocompromised patients, 25.9% were treated with chemotherapy or radiotherapy, and with prosthetic heart valve 11.1%. The gram-negative bacilli were responsible for 51. 8%. The community-acquired bacteremias for 59.2%, with 62.5% of gram-negative.(43.7% E. coli) Associated health care: 25.9% with 57.1% of gram-positive and 28.6% of E. coli ESBL, nosocomial 22.2%, 83.3% gram-positive (Staphylococcus aureus 66.7%) The most common organism isolates in blood cultures were E. coli in 37% (11.1% ESBL), S. aureus 22.2%, P. aeruginosa, S. epidermidis and Listeria 7.4%; E. faecalis, S. dysglactiae, S. hominis, Klebsiella pneumoniae, Enterococcus faecalis, Enterobacter cloacae 3.7%. A case polymicrobial urine culture was collected in 51.8%, with 42.8% cases negative. 28.6% positive for E. coli. A culture positive for Enterococcus fallinarum in abdominal fluid and joint fluid culture positive for S. aureus. On the ward, in 14.8% was performed TEE (transesophageal echocardiography) and 11.1% transthoracic echocardiography (TTE) with no findings of vegetations. Antibiotics used: ceftriaxone 25.9%, 22.2% cloxacillin, ertapenem 14.8%, 11.1% vancomycin and ampicillin, piperacillin-tazobactam 7.4%. There was no adverse drug reaction. In 29.6% a central catheter was introduced. For treatment the catheter average was 1.63. Average vancomycin was 3 catheters per treatment. Cause of parts: 50% phlebitis, extravasations 50%. The source of infection was: 29.6% of UTI (urinary tract infections) in all patients, and 42.1% of patients diagnosed with origin. Catheter infection 18.5%, 7.4% pneumonia, pyelonephritis, intraabdominal infection, infection prosthetic fistula and arthritis 3.7%, respectively. 44.4% of unknown origin. Destination on discharge: primary 92.6%, 7.4% readmissions, one for intervention, and another for poor outcome.

Conclusions: Hospital at Home is an effective and safe alternative to conventional hospitalization, and in our study clinical results were good with a low number of complications. To achieve optimum performance requires an adequate patient selection and home environment, a continuum of clinical and laboratory results, have a multidisciplinary team and a larger number of prospective trials. Hospital at Home can reduce health care costs, improve quality of life of patients and their families and reduce nosocomial infections. The intravenous care needs venous access and infusion rate of drugs. Antibiotics are the single ideal dose, infusion times short and stable. Vancomycin needs more of venous access for their osmolarity.

A-296
LISTERIOSIS IN THE ADULT IN A HEALTH AREA OF VIGO. PRESENTATION OF 11 CASES

L. Novoa, L. Valle, C. Casas, P. Sánchez, M. Páramo, L. González, R. Puerta, J. de la Fuente

Department of Internal Medicine. Povisa Hospital. Vigo (Pontevedra), Spain.

Objectives: Analyze comorbidity, clinical presentation, treatment given and medical evolution of episodes of infection with L. monocytogenes caused in the last 20 years in our hospital.

Material and method: We reviewed the medical reports of patients with the diagnosis of infection by L. monocytogenes in Povisa's Hospital of Vigo, from January 1992 to March 2012.

Results: Eleven patients were admitted with this diagnosis: 5 men and 6 women; mean age in males was 62 years old, and

72 in females. 9 patients (82%) had a disease or predisposing condition: 5 patients (55%) were diabetic, 3 (33%) were treated with corticosteroids, 2 cases (22%) had solid organ tumor and 1 case (11%) was diagnosed with a hematologic neoplasia. In 7 cases (63%) disease is manifested by involvement of central nervous system (5 cases as meningitis, one meningoencephalitis and one rhomboencephalitis), in 3 cases (27%) as bacteremia and one as septic arthritis. Five patients (45%) received treatment with ampicillin and five (45%) were treated with combined therapy ampicilin + gentamicin. The remaining patient received cotrimoxazole because he was allergic to penicillin.

Discussion: Listeria monocytogenes is an anaerobic gram-positive intracellular facultative coccobacillus, cause of infections acquired through ingestion of contaminated food. Listeriosis occurs mainly in neonates, pregnant women, elderly and in patients with affected cellular immunity, although occasionally can affect healthy individuals. 70% of infections outside the neonatal period are in context of hematologic malignancies, acquired immunodeficiency syndrome, organ transplantation and immunosuppressive therapy with corticosteroids, in which the infection is mainly manifested as bacteremia with or without accompanying meningoencephalitis.

Conclusions: Very often, patients with listeriosis have a predisposing disease associated. Empiric antibiotic therapy of meningitis or meningoencephalits in immunocompromised patients must take into account this possible etiology.

A-297
FUNGAL BLOODSTREAM INFECTIONS IN AN INTERNAL MEDICINE DEPARTMENT. EPIDEMIOLOGY AND MANAGEMENT

L. Martín Fernández, M. Pilares Barco, A. Pinto Martínez, M. Vierma Michelangeli, F. Hidalgo, I. Barbolla

Department of Internal Medicine. Hospital Ramón y Cajal. Madrid, Spain.

Objectives: Bacteremia is defined as the presence of bacteria in blood, evidenced by the isolation of these ones in blood cultures. Fungemia is the term used to describe the presence of fungi in bloodstream. Both of them are serious complications of bacterial and fungal infections, which yield high rates of severe sepsis and mortality. This paper tries to describe and analyse the clinical and microbiological features of the inpatients of an Internal Medicine Service who presented Candida spp. in blood cultures.

Material and method: We performed a retrospective and non-interventional study in an Internal Medicine Department of a Tertiary Care Hospital for six months (November 30th 2011-May 10th 2012). The inclusion criterion was fungal bloodstream infection proven by positive blood cultures described in patients studied in our department. We added baseline characteristics of our patients as age, gender, Charlson Score, Barthel and Katz scales, Candida Score and clinical (signs and symptoms during bacteremia, evolution of the infection) and microbiological (results of blood cultures, antibiotherapy) data.

Results: Among sixty-seven inpatients studied, four met inclusion criterion (5.9%). Mean age: eighty-two years; Gender: 100% male. In relation to risk factors to develop fungemia, we found that one of them had previously used antibiotics (25%) and one of them had previously received chemotherapy due to underlying disease (limphoma) and parenteral nutrition (25%). Among clinical manifestations, the four of them developed fever and leukocytosis and two of them presented elevated acute phase rectants. Related to the origin of the infection, we found that three patients came from an elderly care institution (75%). Community origin was seen in one patient (25%). Abdominal infection was the most frequent source (50%), followed by central venous access catheter (25%) and unknown source (25%). Three species of Candida were isolated in blood cultures: C. albicans (50%), C. parapsilosis (25%), C. glabrata (25%). The whole patients received broad-spectrum empirical antibiotherapy: Piperaciline/Tazobactam (50%), Piperaciline/Tazobactam and Vancomycin (25%), Cefotaxime (25%). Based on the sensitivity of the strain, treatments were changed to Fluconazole in 75% of patients. The course of the infection yielded death in two cases (one of them did not receive Fluconazole). One of them presented recovery of two episodes of fungemia and one of them developed severe sepsis.

Discussion: The rate of fungemia found in our study is similar to the rates found in Critical Care Departments (2-9%). Our results, shown among medical patients, are higher than rates previously studied among surgical patients (1%). Related to precedents of risk factors as central venous access catheter, our data are similar to previous studies as well (5-7%).In relation to risk factors to develop fungemia, in our patients we could prove the precedent of cancer (one patient), use of central venous access catheter (one patient), need of parenteral nutrition (one patient). Although the same antifungical treatment was finally used in all cases (Fluconazole), the course of fungemia yielded different outcomes, perhaps influenced by the different morbidity of our patients. Probably, outcomes would not have been different with other agents as Anfotericine B or Caspofungine whose effectiveness is similar.

Conclusions: In our study, we can conclude that most frequent clinical manifestations of fungal bloodstream infections are fever and leukocytosis. Most important risk factors are cancer, parenteral nutrition and central venous access catheter. The most frequent fungus isolated was Candida albicans. The most frequent treatment was Fluconazole. Fungal bloodstream infection yield high rates of severe sepsis (25%) and mortality (50%).

A-298
ENVIRONMENTAL MICROBIOLOGICAL STUDY IN A NEW HOSPITAL

A. Córdoba, S. Iftimie, A. López, I. Pujol, F. Ballester, A. Castro

Department of Internal Medicine. Hospital de Sant Joan de Reus. Tarragona, Spain.

Objectives: Establishing in the new facilities a working methodology based on preventive control, adopt an effective routine of controls that minimizes risk, establish warning system based on reliable indicators, define environmental quality standards and mechanisms for performance in the new hospital building (Level 2, of 326 beds, with a reference population of 250,000).

Material and method: This is a task-group that organizes the areas of the 90,000 m2 new building according to different kinds of air filtration and severity of hospitalized patients and agree on actions to detect early increases in levels of spores and mesolithic flora and take corrective action prior to the occurrence of nosocomial infections.

Results: A work table, that contains the type of area, its classification, when and how to collect microbiological controls, was created. Microbiological sampling of 327 samples during the first year of operation of the center revealed the proper functioning of the facilities and the efforts of different teams together with maintenance and housekeeping to preserve them (28 samples in

delivery rooms, 159 samples in operating rooms, 52 ICU samples, 20 samples in pharmaceuticals, 48 samples in filters, 20 samples in neonatal). Data analyze shows that: -Areas in which the installation has a triple filtration system with HEPA filter (10 general surgery operating rooms, 1 obstetric, 7 delivery rooms and 5 pharmaceutical wards) the results are kept within reference values according to regulations, except two pharmaceutical wards, that required an extraordinary intervention of cleaning and an organizational change. -Double infiltration areas without HEPA final filter (12 ICU-boxes, 5 neonatal boxes) the results are significant oscillations, that require thorough cleaning interventions, a filter change, 2 correction air-filter circuits, a change to ICU access. -Data analyse helped review frequency checks adjusting it according to microbiological results.

Discussion: The change to the new facilities means having to balance usual health care activity with the finalization or internal review of certain structures of the new building. Expectations for improvement are not always achieved immediately, starting an installation requires a lot of time and effort.

Conclusions: Developing this protocol avoids complications arising from indirect consequences that can have the social impact in terms of mistrust with the center to be news because of problems of nosocomial infections. And would give rise to significant cost increases for health care. In short, a protocol on environmental quality not only gains effectiveness but also efficiency.

A-299
FEBRILE NEUTROPENIA IN PATIENTS ADMITTED IN GENERAL HOSPITAL

A. Lazo Torres[1], M. Esteban Moreno[1], V. Castellon Rubio[2]

[1]Department of Internal Medicine, [2]Department of Oncology. Complejo Hospitalario de Especialidades Torrecárdenas. Almería, Spain.

Objectives: Febrile neutropenia in cancer patients is among the most serious complications related to chemotherapy when it is myelosuppressive (suppresses the bone marrow from producing blood cells). In patients with febrile neutropenia are treated with empirical antibiotics until the neutrophil count has recovered and the fever has abated. Our purpose was studied the epidemiological and clinical variables in patients with febrile neutropenia admitted in general hospital.

Material and method: Prospective study of 51 patients with febrile neutropenia of Torrecardenas Hospital from January until December 2011. We analyzed: age, sex, neutrophil count, daily living abilities of patients with ECOG performance status (Eastern Cooperative Oncology Group), type of neoplasic, chemotherapy and evolution. We also analyzed the microbiological variables. The data were analyzed by using SPSS 18.0 stadistical package.

Results: The following variables were studied: age 58 ± 13 years, sex 19 males (34%)/36 females (66%) and neutrophil count 327 ± 62/mm^3. ECOG performance status: 0 (24 patients: 43.6%), 1 (17 patients: 30.9%), 2 (8 patients: 14.5%), 3 (6 patients: 10.9%). 2 patients died (3.6%). We analyzed the neoplasia type: breast in 25 patients (45.5%), lung in 13 patients (23.6%), gastric in 6 patients (10.9%) and other (eg ovarian, prostate, CNS and pancreas cancer) in 9 patients (16%). We found metastases in 22 patients (40%). 69.1% (38 patients) received adjuvant chemotherapy. Blood cultures were performed in all patients in all patients. Only two blood cultures were positive (with methicillin-susceptible Staphylococcus aureus). The source of the fever was found in 8 patients: urinary in 2 patients, lung in 3 and abdominal in 3. 47.3% of patients received antibiotics at discharge. Analyzing therapeutic families antibiotics: fluoroquinolones (9 patients: 16.36%), amoxicillin clavulanate (8 patients: 14.5%) and a combinations with: fluoroquinolones + amoxicillin clavulanate (5 patients: 9.1%).

A-300
POTENTIAL RISK FACTORS RELATED TO RECURRENCE IN CLOSTRIDIUM DIFFICILE DISEASE

J. Cadiñanos Loidi[1], V. de la Cuesta Esteban[1], A. Gómez Berrocal[1], M. Hernández Olmedo[1], E. Díaz Guardiola[1], C. Sáez Béjar[1], A. Guiu[2]

[1]Department of Internal Medicine/Infectious Diseases, [2]Department of Microbiology. Hospital Universitario de La Princesa. Madrid, Spain.

Objectives: Clostridium difficile disease (CDD) is increasing in recent years as the population gets older and the use of broad-spectrum antibiotics becomes more frequent. Recurrence in CDD occurs in 10-15% in other series, but final risk factors for recurrence remain difficult to identify. The aim of our study is to analyze different features potentially linked with recurrence of CDD.

Material and method: We reviewed 111 computerized clinical histories of patients with positive Clostridium difficile toxin over a period of 2 years (between January 2010 and February 2012) from medical departments of the "Hospital Universitario de La Princesa", Madrid: Accident and Emergency department, Internal Medicine and Infectious Diseases wards. Epidemiologic, prognostic, laboratory and therapeutic features were analyzed with the SPSS 15.0 program.

Results: We identified 88 cases of CDD, mean age of 72 years (SD ± 18), with a recurrence rate of 13.6% (12) (we defined recurrence as new onset of symptoms with positive toxin detection) after 12 months of follow-up. 83% of recurrence in women (p = 0.07), 67% in immunosuppressed patients (p = 0.28), 41% (5) in patients older than 85 years (p = 0.18). 80% (70) from the whole group and 91% of those with recurrent disease were treated with metronidazole alone (p = 0.26). 50 patients had received proton-pump inhibitors (PPIs), 18% (9) of them had a recurrence (p = 0.17). The recurrence rate was higher among patients receiving glycopeptides (60%, 5 cases, p = 0.01) and penicillins (29%, p = 0.009). No relapse in the group of patients on clindamicin (7). We found 47 health-care associated cases, in that group 6 patients (12%) had a recurrence (p = 0.79). Relapse rate in the group of patients with leukocytosis on diagnosis was 26% (p = 0.019).

Discussion: CDD has a high recurrence rate as described in other series. We found no relation between advanced age or immunosupression and relapsing disease, nor between previous use of proton-pump inhibitors and recurrence. Recurrence rate was higher in the group of patients receiving glycopeptides and penicillins and was also higher in patients with leukocytosis on diagnosis.

Conclusions: In our study, advanced age, immunosuppression, prior use of PPIs and health-care associated cases were not linked with a higher recurrence rate of CDD.

A-301
GRAM-POSITIVE BACTERAEMIA IN AN INTERNAL MEDICINE SERVICE: CLINICAL, MICROBIOLOGICAL AND EPIDEMIOLOGICAL FEATURES

M. Vivancos, A. Pinto, M. Vierma, L. Martín, J. Pilares, F. Hidalgo, I. Barbolla, S. Diz

Department of Internal Medicine. Hospital Universitario Ramón y Cajal. Madrid, Spain.

Objectives: Gram-positive cocci are a common cause of bloodstream infections (BSI), these currently constitute a thera-

peutic problem caused by the emergence of strains with resistance to antibiotics used as the first-line therapeutic option. The aim of the study was to describe the clinical and epidemiological characteristics, and mortality associated with BSI in an Internal Medicine department.

Material and method: A retrospective, no interventional study was carried out in the Internal Medicine department of a tertiary level hospital over a 6 month period (December 1st 2011- May 15th 2012), including 30 patients who presented bacteraemia by Gram-Positive bacteria (GPB), confirmed in blood cultures.

Results: Overall, 32 episodes of bacteraemia were studied from 30 patients (2 patients presented 2 episodes of bactaeremia each: 2 new infections and 2 reinfections). Mean age of the patients included was 77.6 years, 53.12% were male. Community acquired and nosocomial bacteraemia was observed in 50% of the cases, respectively. Respiratory tract infections were the predominant cause of bacteraemia (21.8%), followed by unknown site of infection (18.7%); in only 3 cases (9.3%) bacteraemia was associated to a central catheter infection and 4 cases (12.5%) were secondary to a periphery vein access; in 2 cases (6.25%) was associated with osteoarticular infections, 2 (12.5%) cases with intraabdominal infections and 2 cases (6.25%) with skin infections. There was isolation of 4 different types of Gram-positive bacteria in cultures: 34.3% were Coagulase–negative staphylococci (CONS), 25% Staphylococci aureus, 28.1% Streptococcus, and 12.5% Enterococcus. In 2 cultures there was isolation of 2 Methicillin-resistent Staphylococci aureus (MRSA). There was an overall mortality rate of 37.5% associated to GPB bacteraemia: 41.6% by CONS, 25% by S. aureus (2 cases were caused by MRSA), 25% by Streptococcus (1 case was caused by S. pneumoniae), 8.3% by Enterococcus faecium. 50% of the deaths due to bacteraemia by GPB were nosocomial, 66.7% of the deceased patients had a Charlson score > 4 and were not receiving an adequate empiric antibiotic therapy, respectively.

Discussion: The population studied was characterized by elderly patients (> 77 years) with high comorbidity (represented with high Charlson, Kats and Barthel scores). Most of these patients reside in chronic care centers and/or nursing homes, which represent a predisposing factor for acquiring infections. Similar as previous series, the highest rate of bactaeremia was caused by CONS (34.3%), probably secondary to contaminants due to invasive techniques, such as placement of peripheral vein access. In second place, there was isolation of streptococci (28.1%), being streptococcus pneumoniae the main causal agent of respiratory tract infections; these infections were the main cause of bactaeremia (21.8%), followed by unknown site of infection (18.7%). Bacteraemia was secondary to nosocomial infections in 50% of cases, similar to previous studies, which can probably be related to the high comorbidity of our patients and their increasing need of frequent medical attention and hospitalizations. In our series, 40% of the patients had required antibiotic treatment during a prior hospitalization (within the previous 3 months). There was an overall mortality rate of 40%, which could be linked to the high incidence of nosocomial bacteraemia, inadequate empirical treatment (66.7%) and the epidemiological characteristics of the subjects studied.

Conclusions: Gram positive cocci bacteremia among the elderly is associated with high mortality, which can be related to high incidence of nosocomial bacteraemia, inadequate empirical treatment and high comorbidity. Due to high incidence of infections by contaminants isolated in cultures, it is possible that by intensifying strict hygiene measures during placement of vein accesses a reduction of nosocomial BSI can be achieved.

A-302
VARICELLA PNEUMONIA: SERIOUS COMPLICATION OF CHICKENPOX

M. Fernández, A. Castro, J. Hinojosa, I. Navas, B. Matía, C. Tojo, L. Horrillo, A. Zapatero

Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: Chickenpox pneumonia is the most severe complication when someone becomes affected by varicela-zoster's virus. This complication is mostly seen in adults (10-50% of adults). It's particularly severe in pregnant women and immunocompromised patients. Hypoxemia, thrombopenia, increased LDH, and elevated antitransferases are frequent, being the elevation of LDH and de hypoxemia at the admission to the hospital criteria associated with bad long-term prognosis. Diffuse interstitial infiltrates with basal nodules are frequent radiological findings. The objective is to describe the pattern of presentation of all diagnosed cases of varicela pneumonia since the opening of the Hospital Universitario de Fuenlabrada (HUFLR) between June 2004 and April 2012.

Material and method: Descriptive study of all cases of varicella pneumonia diagnosed in the period HUFLR June 2004 to April 2012. We analized the following items: age, sex, predominant months of onset, known source of infection, pneumonia predisposing factors (smokers, old age, immunosuppression and pregnancy). We also analyzed time until the diagnosis was preformed, the presence of respiratory symptoms, if the patient received previous treatment, thrombocytopenia, levels of LDH, AST, ALT, presence of coagulopathy, and hypoxemia.

Results: We diagnosed 13 cases of varicella pneumonia in the study period, mainly in the months of December (4 cases) and from February to April (6 cases). They were predominantly young patients (age: 32.38 years), women (69%) and smokers (85%). As risk population we found a immunosuppressed (splenectomized) patient. There were no pregnant women affected. 54% of the patients had no known source of infection. 77% (10) had received treatment previously. The symptoms were mainly respiratory in 77% and 4 cases (30.76%) presented severe respiratory distress. In 12 patients (92.31%) the rash was classified as severe. Only one was admitted to the ICU (48 hours) but didn't require mechanical ventilation. In all cases there was a nodular-interstitial pattern. Among the analytical data there is as constant elevation of AST/ALT/GGT (61.53%), thrombocytopenia (53.84%) and hypoxemia (46.15%). None presented data of coagulopathy. All patients received high-dose intravenous acyclovir at an early stage. There were no deaths.

Conclusions: We observed that varicella pneumonia is a serious complication that affects young patients and smokers (factor that favours pneumonia). We should suspect varicella pneumonia in the patients that start with acute respiratory failure who are diagnosed previously of varicella-zoster, in order to start the treatment as soon as possible, and always having in mind that they may require at some point ICU cares. The elevation of hepatic transaminases and thrombocytopenia is very common. Early treatment with intravenous acyclovir entails a better prognosis and early clinical improvement with rapid resolution of pneumonia.

A-303
VARIATION IN LIPID PROFILE IN HIV PATIENTS WHICH ANTIRETROVIRAL TREATMENT IS SIMPLIFIED GOING FROM STANDARD TRIPLE THERAPY TO MONOTHERAPY WITH PROTEASE INHIBITORS

B. Urdin, P. Pardo, J. Colom, M. Feliu, A. Córdoba, A. Castro

Department of Internal Medicine. Hospital de Sant Joan de Reus. Tarragona, Spain.

Objectives: The protective factor of some nucleoside analogues has been recently described, especially the tenofovir for lipid

abnormalities in HIV + patients with antiretroviral treatment. It also is widely described, how protease inhibitors can alter lipid profile with an increase in total cholesterol, LDL cholesterol and triglyceride of patients treated, and therefore increase risk of cardiovascular events. We want to observe how the lipid parameters behave in HIV patients treated with standard triple- therapy to which treatment has been simplified to mono-therapy with an IP.

Material and method: An observational, descriptive and retrospective study was done of samples of 24 HIV+ patients, controlled in our center, during the years 2010/2011. We observe, total cholesterol levels, LDL cholesterol, HDL cholesterol and triglyceride's, before the change to mono-therapy and at 3, 6 and 12 months of change.

Results: Of the 24 patients who started mono-therapy, 5 of them were excluded from the study (3 were transferred to other centers and two for not making the required controls). Of the remaining 19, six were women and 13 men, with an average age of 45 years. Of all patients included, 13 were treated with Tenofovir/Emtricitavina of which 9 began mono-therapy with darunavir and 4 with lopinavir. The other six patients were treated with abacavir/lamivudine, of which 3 initiated mono-therapy lopinavir and 3 darunavir (all patients, besides the pair of analogues, were treated with an IP, except for one patient who was in treatment with Efavirenz). Prior to the start of mono-therapy 6 patients were treated with lipid-lowering (1 with ezetimibe, 1 with omega3, 1 with fibrate and 3 with statin). In the following 12 months after the transition of triple-therapy to mono-therapy, at 4 patients lipid lowering therapy was initiated and 1 patient, who already had lipid lowering therapy, treatment was modified. It was decided to exclude patients who have initiated or changed lipid-lowering therapy during the follow-up treatment:.

Discussion: In the overall studied patients, independently of the previous analogous couple and IP in mono-therapy, there was a significant increase in the first three months of treatment with monotherapy in both, total CT as LDL cholesterol and TG's which then will decrease to stabilize between the 6th and 12th months after beginning mono-therapy. If we compare the lipid abnormalities according to previous analogous couple (TNF/FTC or ABC/3TC) the trend is similar in both groups: higher numbers are being seen in all parameters in the first 3 months, to go decreasing and stabilizing in the following months, but, patients on ABC/3TC start with higher starting levels. As for IP we can observe higher levels of total CTI, LDL and TG, in patients on Lopinavir as in patients on Darunavir.

Conclusions: The transition from triple-therapy to mono-therapy with IP, initially is accompanied by an elevation of lipid parameters in the first 3 months, to then decrease and stabilize, independently of the couple of analogues and the IP of mono-therapy at the start. Patients who initially had a couple of nucleoside analogues that included TNF started with lower levels of total cholesterol and triglyceride's, but at one year the numbers are equal regardless of the initial couple of analogues. Patients on monotherapy with darunavir have lower alteration of lipid parameters than those treated with lopinavir during the 12 month follow-up, something already described in literature. In patients observed at 12 months of initiation, IP monotherapy does not cause major alterations in lipid profile than standard triple-therapy, although further studies, designed for the purpose, with a greater numbers of patients included are needed for a more reliable conclusion.

A-304
WHIPPLE'S DISEASE. A RETROSPECTIVE STUDY FROM 1998 TO 2011

V. Pérez Carral, O. Pérez Carral, A. Pérez Iglesias, E. Seco Hernández, P. Rodríguez Álvarez, I. Fernández Regal, M. de Toro Santos, A. Chamorro Fernández

Department of Internal Medicine. Complejo Hospitalario Universitario Ourense. Ourense, Spain.

Objectives: Whipple's Disease (WD) is a chronic infection of multiorganic location, caused by the Tropheryma whipplei bacteria. Since 1907-2000, have been described approximately 1000 cases over the world. We studied epidemiological, clinical, diagnostic and therapeutic characteristics of WD cases in our hospital.

Material and method: Retrospective study from 1998 to 2011 in a hospital with 900 beds was made. Patients were selected with the diagnosis of classic WD. We selected those cases that fulfilled criteria in biopsy of protein chain reaction (PCR) from small intestine and positive histology. Cases were excluded if they had not sufficient clinical information.

Results: Six cases were selected. About the gender, 50% were male. The age range was between 65-79 years. There were no family cases. All individuals were Caucasian with Spanish nationality. Three cases were exposed to the ground and/or animals. The average time of delay between the beginning of the symptoms and the diagnosis was from 2 months to 12 years. In the cases that were diagnosed between 2005 to 2007, the average delay was 2 months, while in the 90s, the delay was 8-12 years. All the six cases (100%) had presented asthenia and loss of weight (83% < 10 kg). Three patients (50%) had fever before the diagnosis. Four (66%) had adenopathies. Six cases (100%) presented gastrointestinal involvement. 4 patient had arthralgias. 4 cases (66%) presented neurological involvement. On the other hand, 5 cases had anemia (83%), with iron deficiency in all of them, at the moment of the diagnosis. ESR and reactive C protein were raised in 100% and 33% respectively. In the 6 cases (100%), the reactants of acute phase were kept high in spite of the treatment. Regarding the diagnosis, the diagnoses were made by PCR in 3 cases (50%) and were PAS + in 5 (83%) patients. About the treatment, the cotrimoxazol was the most used. Three patients are followed at the moment. Actually, all the cases are still alive except a patient who died for other reasons without relationship to this disease.

Conclusions: The WD is highly infrequent and difficult to diagnose. In our series, we found a delay of at least two months, in the final diagnosis. The most frequent symptoms were the asthenia, the loss of weight and the diarrhea (in all the patients) followed by the neurological involvement (in four cases). Five cases had iron deficiency anemia and all of them had elevation of the ESR. The diagnosis was made by PCR and/or PAS in all cases and all of them received cotrimoxazol. The survival to the disease was 100%. All these findings were similar to other series.

A-305
PNEUMOCYSTIS PNEUMONIA FOLLOWING RITUXIMAB THERAPY

I. Martín-Garrido[1], A. Calzada Valle[1], M. Martínez-Risquez[1], M. Calero Bernal[1], R. Terán Redondo[1], E. Calderon Sandubete[1], E. Carmona[2], A. Limper[2]

[1]Department of Internal Medicine. Complejo Hospitalario Regional Virgen Del Rocío. Sevilla, Spain. [2]Pulmonary and Critical Care. Mayo Clinic. Rochester, MN. USA.

Objectives: Pneumocystis pneumonia (PcP) is an opportunistic fungal infection. Although Tcell immunity is classically related to Pneumocystis defense, recent data supports roles for B-lymphocytes in the development of PcP in animals, and we have observed several cases of PcP in patients receiving rituximab. These observations prompted a systematic review of our experience to define the spectrum of clinical presentations in which PcP has occurred in the setting of rituximab therapy.

Material and method: Using a computer-based search, we reviewed patients who received rituximab and developed PcP at Mayo Clinic Rochester over the years of 1998-2011 in order to establish the underlying conditions, clinical course, possible risk factors and potential association between this drug and the development of PcP.

Results: Over this period, 30 patients developed PcP during treatment with rituximab. The underlying diseases included

hematologic malignancies in 90% of cases. Glucocorticoids were used in 73% of these patients under different chemotherapeutic regimens. Three patients (10%) developed PcP in the setting of rituximab without concomitant chemotherapy or significant glucocorticoid exposure. Of these 30 patients, 88% developed acute hypoxemic respiratory failure and 53% required ICU admission. The clinical course was fatal in 30%.

Conclusions: PcP can occur in association with rituximab with the majority of cases having also received cytotoxic chemotherapy or significant doses of glucocorticoids. The clinical course of cases of rituximab associated PcP can be quite fulminant with significant mortality. Primary prophylaxis should be considered in patients at risk, and secondary prophylaxis provided unless immune reconstitution is well assured.

A-306
ORDERING BY DEFAULT. CONSIDERATIONS ABOUT SEROLOGICAL TESTS FOR RICKETTSIA CONORII REQUESTED BY CLINICIANS IN A THIRD LEVEL HOSPITAL

V. Hontañón Antoñana, R. Mayayo Alvira, C. García Cerrada, F. Montoya Lozano, M. Lizariturry, P. Romero, S. Caro Bragado, F. Arnalich

Department of Internal Medicine Service. Hospital Universitario La Paz. Madrid, Spain.

Objectives: Analyze the performance of *Rickettsia conorii* serologies requested in the last 2 years at the Hospital Universitario La Paz.

Material and method: Descriptive observational study of all positive serologies for Rickettsia conorii obtained using indirect immunofluorescence analysis (IFA) in our center. We sort out the results by way of dilution titer, analyzing only the positive results with a titer 1/160 or higher. This way we analise true positive results and avoid cross-reaction bias. The clinical records of patients are used to confirm the value and to interpret results obtained.

Results: In the period between 2010, 2011 and the first 2 months of 2012, serum samples of 155 patients were collected and used for detection of Rickettsia conorii. 30 samples (19.4%) had titers of 1/160 or higher and 5 of these (3.2%) were mentioned in the medical history of patients. Only 4 of the above samples (2.6%) were found to be true (as suspected clinically). The rest were rejected (Ricketrsia conorii was not the pathogen involved). 4 of the 5 patients with positive serology in the medical records were treated with doxycicline and one with levofloxacin.

Discussion: Despite the publication of series of cases in which infection is documented using positive 1/80, Rickettsia conorii titers to consider infection in our series even with higher titers of 1/160 has almost no value due to the lack of assessment by the physician of the results obtained. The estimated price per test, without the cost of staff and facilities, is 4 euros (€), which in our series involves a total expenditure of € 620 (approximately € 286/ year) .Being € 100 the estimated cost of tests not taken into account.

Conclusions: When we first evaluate a patient, we often encounter the uncertainty of the unspecific symptoms. The orientation of the diagnostic tests to apply are often conditioned by the rush to obtain a diagnose and the easy access to certain serological tests (like in our case). The similar form of clinical manifestation of many diseases often demands the use of tests, in this case of microbiological diagnosis, to ensure the correct diagnosis. Making a proper medical history sets the basis for a correct diagnostic approach and this, in turn, guides the request for additional diagnostic testing to reach a definitive diagnosis, although nonspecific symptoms and signs may make difficult to see a clear case. The indiscriminate application of diagnostic testing can lead not only to unnecessary healthcare costs, but also to confusion in diagnosis because of an incorrect interpretation.

A-307
THREE YEARS OF SEPSIS IN NA INTERNAL MEDICINE WARD

M. Antunes, G. Magalhães, Á. Chipepo, H. Gruner, A. Ferreira, A. Madeira Ventura, M. Vaz Riscado

Medicina 2. Hospital de Curry Cabral - Centro Hospital de Lisboa Central. Lisboa, Portugal.

Objectives: Sepsis is a systemic inflammatory response syndrome set by an infectious agent and usually associated with great mortality. The aim of this study is to characterize the patients with this diagnosis admitted to an Internal Medicine Ward, according to gender, age, etiology of the sepsis, infectious agent, antibiotic therapy used and mortality.

Material and method: A retrospective review of all admitted patients' files with the diagnosis of sepsis, between January 2009 and December 2011, was performed.

Results: Of 3,925 patients admitted during this time period, in 66 (1.68%) sepsis was the first or second diagnosis. It was a mainly male population (44 patients, 66.6%), with a mean age of 76.1 years, being that only 9 patients (13.6%) are under 65 years old and 14 (21.2%) over 85 years old. Most patients were dependent in the daily living activities and living at home. Urosepsis (37 patients, 56%) and sepsis from respiratory origin (14 patients, 21.2%) were the most common etiologies. The isolation of the infectious agent is difficult at times – that was possible in 63.3% of patients. The most frequent agents were E. coli (28.6%), MRSA (14.3%) and Klebsiella (14.3%). Almost all patients had underlying diseases such as type 2 diabetes (23 patients, 34.8%), chronic renal disease (22 patients, 33.3%) and cancer (7, 10.6%) that can predispose to an infection. A mortality rate of 39.4% (26 patients) was found, being that of the 5 patients that were transferred to ICU's, three died.

Discussion: Urosepsis (37 patients, 56%) and sepsis from respiratory origin (14 patients, 21.2%) were the most common etiologies. The isolation of the infectious agent is difficult at times – that was possible in 63.3% of patients. The most frequent agents were E. coli (28.6%), MRSA (14.3%) and Klebsiella (14.3%). Almost all patients had underlying diseases such as type 2 diabetes (23 patients, 34.8%), chronic renal disease (22 patients, 33.3%) and cancer (7, 10.6%) that can predispose to an infection.

Conclusions: Sepsis is not only present in ICU's but also in Internal Medicine Wards, although probably under-diagnosed but always associated with high costs due to antibiotic therapy. It's generally an elderly population, with multiple underlying diseases, high mortality which does not correlate to age, being that only 37.8% of patients was discharged.

A-308
ACUTE HEPATITIS OF INFECTIOUS ORIGIN IN HOSPITAL CLÍNICO SAN CARLOS IN MADRID: ADMISSION AND FOLLOW-UP BETWEEN 2007-2009

C. Granda París, J. Pedrajas Navas, P. Ruiz- Artacho

Department of Internal Medicine. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: To carry out a descriptive study of the number of patients admitted to a tertiary hospital in Madrid (Hospital Clínico San Carlos-HCSC) because of acute hepatitis with an infectious origin between 2007 and 2009.

Material and method: The data were collected through the Information System of the Hospital Admission and Clinical Documentation Service and were statistically processed with the

SSPS V 13.0 software. The corresponding statistic tests were used for each parameter.

Results: During the three-year period between 2007 and 2009, a total of 32 patients were admitted to the HCSC because of severe hepatitis with an infectious etiology: 62.5% of them were male. The predominant etiology was Hepatitis B Virus (HBV) (42%) followed by Hepatitis A Virus (HAV) (39%). The main consultation reasons were acholia, choluria and abdominal pain. Upon admission, 12.5% of patients was anemic, 9.4% had leucopenia, 3.1% leucocitosis, 12.5% thrombocytopenia, 6.2% renal failure and 35.5% had an INR equal or higher to 1.2. Among the study population, 100% showed elevated transaminase levels and only 12.5% showed a total level of bilirubin below 1. Upon arrival at the hospital, 71.8% of the patients (23) were in Child-Pugh class B while the rest were in class A. No class C case was detected. At admission, an echography was made to 62.5% of the patients. The most frequent results were hepatomegaly and an increase in the thickness of the gallbladder wall, both in 35% of the patients. 53% of the patients developed some kind of complication during admission, coagulopathy being the most frequent and requiring administration of vitamin K in 25% of the patients. No exitus was recorded during the study. Two patients started treatment with lamivudin and one with entecavir. Women had at admission statistically lower hemoglobin levels (without reaching anemia) and higher alkaline phosphatase levels (285.4 UI/L versus 191.3 UI/L). There were no statistically significant differences between genders in Child-Pugh score at admission. When compared by etiology, patients with a severe infection caused by HAV showed statistically significant higher hemoglobin, INR and ALT levels than HBV patients. There were no significant differences between these two etiologies regarding Child-Pugh score at admission. There is nevertheless a difference regarding the length of stay which is longer for patients who were admitted with severe hepatitis by HBV than for patients with HAV ($p = 0.064$). At discharge, 59.3% of the patients was followed. Among them 78.9% had no symptoms at the last medical visit, 5.3% had asthenia and 15.8% had asthenia combined with myalgia, abdominal pain or jaundice. The chronicalisation percentage was zero. When the analytical data collected at admission were compared with data from the last follow-up visit, there were statistically significant differences in the INR, transaminase, alkaline phosphatase, GGT, total bilirrubin, direct bilirrubin and albumin, showing normalized levels at the end of the follow-up. Regarding other analytical parameters, the differences were not statistically significant ($p = NS$).

Conclusions: 1) Admissions due to acute hepatitis with an infectious etiology are relatively infrequent. 2) The most frequent etiology for acute hepatitis is infection caused by HBV. 3) The length of stay is usually longer for patients with acute hepatitis caused by HBV who paradoxically show at admission lower INR and ALT levels 4) The clinical and analytical evolution is favorable with no chronicalisation phase and without exitus.

A-309
INFECTIVE ENDOCARDITIS IN A DISTRICT HOSPITAL, A POSSIBLE COEXISTENCE

L. Redondo[1], E. Reynaga[1], G. Sierra[1], A. Pedragosa[1], S. Montserrat[2], J. Brugués[1]

[1]Department of Internal Medicine. Hospital General de Vic. Barcelona, Spain. [2]Department of Cardiology. Centre Sociosanitari Hosp. Clínic i Provincial de Barcelona. Barcelona, Spain.

Objectives: To determine the epidemiological, clinical and microbiological characteristics of patients diagnosed with infectious endocarditis (IE) in the last 2 years in a district hospital. Descript the most common complications and reasons for referral to a tertiary hospital.

Material and method: A descriptive, prospective, observational study of patients with IE admitted between January 2010 and May 2012. Medical records with a primary discharge diagnosis coding of IE were reviewed. We used the modified Duke criteria for diagnosis (definite and probable). We included all patients over 15 years, fulfilling the final diagnosis.

Results: A total of 25 medical records were reviewed. 64% were men with a mean age of 72.4 years (39-93). The most frequent cardiovascular risk factor was hypertension (60%). Fever 64% and the murmur of recent onset 56% were the predominant symptoms and sign clinic, respectively. The 20% of the patients had pacemaker or ICD and 20% prosthetic valve. The microorganisms isolated were S. bovis 12%, Granulicatella adiacens 12%; S. aureus, S. epidermidis, S. viridians, Enterococcus faecalis, Pseudomonas aeruginosa (8% respectively); S. aureus MARSA, Aggregatibacter aphrophilus, S. hominis, Enterococcus sp, Candida albicans (4% respectively). 16% showed negative blood cultures. The findings echocardiographic were: vegetation 68% and 12% abscess. Other such as perforation, aneurysm or fistula were detected in 4% respectively. More frequent complications were heart failure 16%, cardiogenic shock and acute pulmonary edema (12% respectively). Transfer to tertiary hospital was 6 patients (24%) and of these 4 (66.6%) set out from surgical intervention. The main reason for referral were the complications and/or need for emergency surgery. The overall mortality was 16%, mortality in patients referred was 4% (25% overall mortality) and the non-referred was 12% (75% overall mortality).

Conclusions: The proper management of IE in a district hospital is probably, although is essential interdisciplinary work in coordination with a tertiary hospital, given the need for referred in a high percentage of cases. Frequent complications of IE require the immediate transfer a tertiary hospital, however more than 75% of endocarditis can be treated jointly, in a district hospital.

A-313
URINARY INFECTION WITH KLEBSIELLA AND E. COLI BACTERIA: CLINICAL AND ECONOMIC IMPLICATIONS OF BETA-LACTAMASE PRODUCTION

J. Paxiuta, I. Rossio, M. Faria, S. Alves, M. Lobão, J. Sequeira

Department of Medicine. HPP Hospital de Cascais. Cascais, Portugal.

Objectives: Infection due to extended-spectrum beta-lactamase (ESBL) Escherichia coli (EC) and Klebsiella (K) represents a major concern to healthcare providers implicating dangerous multidrug resistance, longer hospital length-of-stay (LOS) and heavier hospital spending. We analyzed the prevalence of these infections (ESBL positive and negative EC and K urinary tract infections) in patients admitted to an Internal Medicine ward and their impact on clinical outcomes and costs.

Material and method: We conducted a retrospective observational (transversal) study involving 207 patients with positive urinary cultures for EC and K ESBL and non ESBL, for the whole year of 2011. Excluding criteria involved evidence of colonization and harboring of two different specimens in the same sample and in the same hospitalization. Variables related to hospital LOS, antibiotics used and costs involved were assessed.

Results: 158 of all 268 urinary cultures positive to EC or K were included in the study. Forty-one isolates (11 EC and 30 K) were ESBL positive (30% of all 158 isolates). In the group of K infection, ESBL positive isolates had identical hospital LOS (35.5 days) to the ESBL negative group (35.7 days). In the group of EC, the hospital stay was longer in EC ESBL positive (36.0 vs 25.8 days in EC non ESBL – $p < 0.05$). This value is 24 days longer than the all-patient average LOS (11 days) of our department, involving an extra cost of 4.800 € per patient. Around 88% of all ESBL cultures were empirically treated with antibiotics before bacteria isolation and in 28% of all

cases the choice was piperacillin-tazobactam. Susceptibility to carbapenem was universal, and this antibiotic was used in 68% of all isolates. Imipenem contributed with 1.870 € of all hospital expenses per patient.

Conclusions: This study confirmed that EC and K urinary infection were associated with significantly longer hospital LOS and greater hospital costs. These findings have serious implications for antibiotic prescription and economic planning; strategies to control and prevent nosocomial spread are essential and must be implemented.

A-314
THE PARAOXONASAS AS AGENTS INVOLVED IN ACUTE INFECTION AND POTENTIAL MARKERS OF MALIGNANCY

S. Iftimie[1], A. Cordoba[1], A. López[1], F. Ballester[3], I. Pujol[3], J. Camps[2], A. Castro[1]

[1]Department of Internal Medicine, [3]Department of Microbiology. Hospital de Sant Joan de Reus. Tarragona. [2]Laboratory. Centre de Reserca Biomedica Reus. Tarragona, Spain.

Objectives: Alterations in circulating levels of enzyme PON1 and lactonase were described in several infectious and inflammatory diseases involving oxidative stress. The purpose is to investigate differences between activity, concentration of PON1 and lactonase activity in patients with or without infection associated with catheter, to analyze the relationship between these findings and pathological background, the severity of the infection/colonization.

Material and method: We performed a prospective study. Were recruited patients with central vascular catheters or bladder catheters during admission in our center, which they had to remove one or more of these devices, debit to the presence of a related infection or catheter- or because it did not require its use. On the day of catheter removal was performed on all participants with a blood analysis, was performed microbiological culture of vascular catheter and sediment and urine culture in patients with urinary catheters which we draw. Anthropometric data were collected, medical history, presence of infection or catheter-related colonization, presence of other acute or chronic infection, treatment at the time of the study, clinical laboratory variables.

Results: We studied 23 patients with central venous catheter, 15 men, 8 women; 7 with gastrointestinal malignancies, 2 with urologic tract cancers; 6 of 23 had a positive tip culture, other cultures were negative. Trend is observed when comparing the statistical significance of the lactonase activity, the average being higher in the group with positive culture. We examined 124 people who we get urinary catheters, 96 men, 28 women; 55 with urinary tract neoplasms, 4 with gastrointestinal malignancies; 19 urine cultures were positive, negative 105. It is trend to statistical significance in terms of data lactonase paraoxonase activity and the values being higher in the group with positive urine culture. Significant differences were observed between patients diagnosed with urinary tract neoplasia and without cancer, with higher PON activity and reduced its concentration in the first subgroup ($p < 0.02$ and $p < 0.05$). Statistical analysis was performed using SPSS version 18.0 (SPSS Inc, Chicago, IL, USA).

Discussion: Infectious diseases are the leading cause of morbidity and mortality worldwide, so the appropriate and timely treatment of them will have a major impact on health indicators. The small number of patients studied and the technical barrier could explain the limited statistic results.

Conclusions: The relationship between catheter infection/colonization with germens and the functions of PON1 and lactonase could have clinical implications, could be a potential therapeutic target. The activity and PON1 concentration could be used as a predictive marker of malignancy of the urinary tract. These determinations could find a curative intent.

A-315
IMPLEMENTATION OF A CLINICAL PATHWAY FOR THE MULTIDISCIPLINARY APPROACH OF PROSTHETIC JOINT INFECTIONS. RESULTS AFTER FIVE YEARS

A. Fernández Rodríguez[1], F. Brun Romero[2], L. Vela Manzano[1], F. García Colchero[1], P. Romero Cores[1], A. de los Santos Moreno[1], F. Guerrero Sánchez[1]

[1]Department of Internal Medicine, [2]Department of Orthopedic Surgery. Hospital Universitario Puerta del Mar. Cádiz, Spain.

Objectives: To analyze the optimization of the multidisciplinary approach to prosthetic joint infections (PJI) of knee and hip in our Centre, after application of a clinical pathway arrived at by consensus between Orthopedic Surgery and Internal Medicine services.

Material and method: Prospective observational cohort of adult patients with PJI diagnosed from January 1, 2007 to December 31, 2011 in our hospital, after implementation of cooperation protocol between Internal Medicine and Orthopedic Surgery. The first objective of the clinical pathway was prophylaxis of infections measure: it was started strict hygiene and antibiotic prophylaxis at the three levels (preoperative, intraoperative and postoperative). Compliance with the diagnostic protocol was considered adequate if were taken at least 4 intraoperative samples prior to starting antibiotic therapy. The suitability of the treatment performed (antibiotics plus type of surgery realized) was adjusted to the indications proposed by the protocol (retention of the prosthesis in the early and hematogenous infections, two-stage replacement in the chronicles, or otherwise assessing more or less aggressive treatment). The PJI were classified according to the classification of Tsukayama et al modified into 4 types: 1) early postsurgical infection or type I (< 1 month after the intervention); 2) late postsurgical infection or type II (> 1 month and < 1 year); 3) hematogenous infection or type III (> 1 year after surgery without symptoms); and 4) positive culture without previous suspicion of infection or type IV. The diagnosis was made by different samples: intraoperative cultures, pus macroscopic with negative cultures or presence of one or more sinus tract communicating with the joint. Analysis peformed using SPSS versión 19.0.

Results: Sixty one patients were included, with a median age of 69 (IQR 39-91) years. Seventy two percent were women. Thirty-three cases (54.1%) were knee prosthetic, with an infection rate of 4.35%; 28 cases (45.9%) were due to infectious complications of hip replacement, with an infection rate of 2. 78%, 77.7% of wich were total and 22.2% partial prosthetic. Adherence to diagnosis protocol was adequate in 61% of cases. When such adherence was analyzed in relationship at the time of implementation of the protocol, we observed a progressive increasing compliance: 47.4% in the first year, and 85% in the fifth year. All cases were treated with antibiotics according to antibiogram. The surgical treatment was adequate according to the protocol in the 79.1%. It also aimed to a gradual adjustment, with a 60% at the beginning and 80% at the last period. Infection rate decreased from 4.8% to 1.7% in PJI of knee and from 6.8% to 1.0% in the PJI of hip, five years later.

Conclusions: After a period of five years was possible to obtain a progressive increase in the number of samples taken prior to the choice of the antibiotic, measured pattern that contributes the success of the management. The surgical procedure was considered adequate at a high percentage since the beginning of the analysis. The application of the clinical pathway resulted in a reduction of infection rate in our cohort of patients. The value of our studio is

the optimization of multidisciplinary management of PJI after the implementation of a clinical pathway, with a common protocol of action inter-services.

A-316
PREVALENCE AND EPIDEMIOLOGICAL CHARACTERISTICS OF EXTENDED SPECTRUM B-LACTAMASE PRODUCING ENTEROBACTERIACEAE URINARY TRACT INFECTIONS

A. Arca[1], J. Lamas[1], L. Novoa[1], C. Casas[1], M. Fernández[2], M. Rodríguez[2], J. Bermudez[1], J. de la Fuente[1]

[1]Department of Internal Medicine, [2]Department of Microbiology. POVISA. Vigo (Pontevedra), Spain.

Objectives: Extended spectrum B-lactamase (ESBL) producing Enterobacteriaceae urinary tract infections (UTI) are associated with long hospital stays, increased costs and limited therapeutic options by conditioning the use of more antibiotics. The objective of the present study is to determine the prevalence of ESBL in our hospital and analyze the epidemiological characteristics of these patients.

Material and method: We performed a descriptive study of all ESBL-producing Enterobacteriaceae urinary tract infections in 2011. Both inpatients and outpatients of all hospital services were included. We excluded pediatric patients. Available patient data from hospital databases was reviewed.

Results: Among 6.162 urine cultures 1600 were positive with 98 ESBL-producing bacteria isolated in 78 patients. The ESBL-producing bacteria prevalence was 6.12%. The proportion of females was higher (64.3%). The mean age was 68.46 ± 17.29 years (range 18-96). The majority of ESBL-producing bacteria were community-acquired (72.4%). The 55.1% were patients admitted to hospital. The microorganisms isolated in order of frequency were: E. coli (84.8%) followed by K. pneumoniae (9.09%), K. oxytoca (3.03%) and E. cloacae, P. mirabilis, P. vulgaris with 1.01% each. Risk factors for ESBL-producing bacteria present in our study group include: urinary catheter (30.4%), neoplasm (25.5%), diabetes mellitus (21.4%) and institutionalized (15.3%). A proportion of 7.1% of these patients were admitted to the intensive care unit. The most common clinical presentation was lower urinary tract infection (61.2%), followed by asymptomatic bacteriuria (16.3%), pyelonephritis and sepsis with 4.1% each. There was a 90 days previous use of antibiotics in 46.9% of cases, being the most common family of antibiotics, penicillin (19.4%), quinolones (15.3%) and cephalosporins (14.3%). Empiric antibiotic therapy was adequate in 22.4% of cases, 28.6% inappropriate and 51% no data available. In 75.5% of cases the infection was resolved, in 13.3% there was a relapse and in 11.2% no available data. The overall 30-day all-cause mortality from the date of culture positivity was 8.2% with a mean age of 71.

Discussion: UTIs by ESBL-producing enterobacteriaceae are a growing problem. These pathogens are resistant to a wide range of beta-lactams, including third generation cephalosporins, which complicates the treatment and limited therapeutic options. A higher prevalence of these pathogens has been reported in community-acquired infections in recent years. In our study, the majority of ESBL-producing bacteria were community-acquired, supporting that there are important reservoirs of these pathogens outside of hospitals. These findings may increase the rate of antibiotic resistance and determine empirical treatment failure.

Conclusions: ESBL producing enterobacteriaceae constitute a significant proportion of microorganisms producing UTI. Moreover, there is an increasing incidence of community-acquired UTIs by ESBL-producing enterobacteria, which is a growing problem. It is necessary to consider this situation for appropriate empirical antibiotic treatment.

A-317
RISK FACTORS FOR MORTALITY IN PATIENTS WITH CLOSTRIDIUM DIFFICILE DISEASE

A. Gómez Berrocal[1], M. Hernández Olmedo[1], J. Cadiñanos Loidi[1], V. de la Cuesta Esteban[1], E. Díaz Guardiola[1], C. Sáez Béjar[1], A. Guiu[2]

[1]Department of Internal Medicine/Infectious Diseases, [2]Department of Microbiology. Hospital Universitario de la Princesa. Madrid, Spain.

Objectives: Clostridium difficile disease (CDD) is increasing in recent years as the population gets older and the use of broad-spectrum antibiotics becomes more frequent. Several risk factors have been thought to be associated with a poor prognosis of this entity. The aim of our study is to analyze different features potentially linked with mortality of CDD.

Material and method: We reviewed 111 computerized clinical histories of patients with positive Clostridium difficile toxin over a period of 2 years (between January 2010 and February 2012) from medical departments of the "Hospital Universitario de La Princesa", Madrid: Accident and Emergency department, Internal Medicine and Infectious Diseases wards. Epidemiologic, prognostic, laboratory and therapeutic features were analyzed with the SPSS 15.0 program.

Results: We identified 88 cases of C. difficile-associated diarrhea, mean age of 72 years (SD ± 18) with a mortality rate at 30 days of 12.5% (11). All-cause mortality in patients who presented with symptoms related to CDD was 7% (p = 0.069). Among patients who died, 9 (81%) had health-care associated disease (p = 0.043), 4 (36%) had active cancer, 5 (45%) had diabetes mellitus (p = 0.04) and 5 (45%) had chronic kidney disease. 63% (7) had received proton-pump inhibitors (p = 0.69) and 63% (7) prior antibiotic therapy (p = 0.20). We identified 46 patients with immunosuppression criteria whose mortality at 30 days was 21% (p = 0.006). All patients treated wih fosfomycin (2) died (p = 0.03). Mortality among patients who had received prior fluoroquinolone treatment (10) was 10% (3) (p = 0.72). There were no deaths among patients on clindamycin (7), glycopeptides (5) or aminoglycosides (5).

Discussion: Mortality in patients with CDD in our sample was higher in the group of immunosuppressed patients, especially in patients with chronic kidney disease, diabetes or active cancer. Health-care associated infection also showed a higher mortality. These data are consistent with results of previous studies. Although CD ribotype more aggressive have been described with certain prior antibiotic treatment, our study did not suggest a relation between prior antibiotic and poor outcome.

Conclusions: We identified health-care associated disease and immunosuppression as factors potentially linked with mortality.

A-318
ANTIRETROVIRAL TREATMENT OPTIMIZATION. IS THERE ROOM FOR IMPROVING EFFICIENCY?

M. Torralba González de Suso[1], A. Espinosa Gimeno[1], S. Laínez[1], L. Sánchez[1], C. Betancort Plata[1], E. Martín-Echevarría[1], A. Lázaro[2], M. Rodríguez Zapata[1]

[1]Department of Internal Medicine, [2]Department of Hospital Pharmacy. Hospital Universitario. Guadalajara, Spain.

Objectives: HAART is one of the most cost effective pharmacotherapeutic interventions. Nonetheless, within HAART, there exist numerous combinations with advantages in efficiency. Given the considerable cost of antiretroviral treatment, it is necessary to optimize HAART so that, by maintaining efficacy, costs are minimized. Our objective was to assess whether the implementation of predefined antiretroviral combination strategies

is capable of reducing the bill of the antiretroviral drugs with comparable efficacy (theoretical model).

Material and method: All the antiretroviral drug combinations for each and every one of the patients were analyzed together as well as their costs. Three strategies were proposed. 1) Change from 2 ANRTI +1 PI to PI/r (mono-therapy); 2) Change from TDF + FTC + ATV/r to ABC+3TC+ATV and 3) Change from TDF + FTC + NEV or RTG to ABC + 3TC + NEV or RTG. These strategies are firmly based on clinical trials or on ample experience. It was assumed that efficacy would be the same with the change. Costs were applied following the GESIDA guideline.

Results: 289 patients who had been undergoing treatment in the previous 6 months were analyzed. 53.6% of whom were using NN, whilst 45% were on PI. 77.2% were using TDF and 9.3%, ABC. 87.6% of the patients with NN were being treated with EFV whilst 12.3% with NEV. Out of the patients treated with PI, 45.8% were using DRV/r, 29% ATV/r, and 21.4% LPV/r whilst 3.1% FPV/r. 1.4% of the patients were being treated with Etravirin, 4.1 with Raltegravir and 1.4% with Maraviroc. The actual cost of the antiretroviral treatment was 206.586€ per month. After implementing the above-mentioned strategies, the guidelines were altered in the following manner: No change was effected on 64% (184/289) of patients. 17% (49/289) would shift to monotherapy (strategy 1), 11.8% (34/289) would change from TDF + FTC + ATV/r to ABC + 3TC + ATV (strategy 2) whilst 7.6% (22/289) would shift from TDF + FTC + 1 NN or RTG to ABC + 3TC + NN or RTG (strategy 3). After optimization the cost would be 182.917€. This would mean a monthly saving of 23,669€ or 284,028€ per annum. Being conservative and accepting 25% of the proposed monotherapies and 25% of strategies 2 and 3, the monthly costs would be: 201,325€ whilst the monthly saving would come to 5,261 € or to 63,132 € per annum. The cost of HLA B 5701 at our hospital would be around 1,000 €.

Discussion: In the heat of the current economic crunch it is imperative that optimization of therapeutic intervention strategies, given the same efficacy, be less costly. Strategy 1 has been validated in clinical trials (Monet, Monark), as has been strategy 2 (ARIES). Strategy 3 is often used in clinical practice especially on patients with VL below 100,000 copies, (HEAT). We believe that it is urgent to optimize antiretroviral treatment as we consider these optimization strategies as safe.

Conclusions: Optimizing antiretroviral treatment with boosted PI mono-therapy, by substituting either TDF + FTC + ATV/r for ABC + 3TC + ATV (400 mg) or TDF + FTC for ABC + 3TC, when administered together with either NN or RTG, seems to be an efficient strategy that should be implemented in clinical practice.

A-319
THE PROMETHEUS INDEX AS AN INDICATOR OF HEPATIC FIBROSIS PROGRESSION IN HCV-HIV PATIENTS

T. Megino Moreno, M. Torralba González de Suso, A. Espinosa Gimeno, P. Chacón Testor, L. Abejón López, S. Laínez Justo, A. Costa Cerdá, M. Rodríguez Zapata

Department of Internal Medicine. Hospital Universitario. Guadalajara, Spain.

Objectives: HCV infection progressively causes hepatic fibrosis that can, if untreated, lead to cirrhosis or end stage liver disease. Our objective was to characterize hepatic fibrosis in HCV and/or HIV patients by means of elastography at our hospital and also to analyze the variables that are associated with greater fibrosis progression.

Material and method: Design: single cohort prospective study. Hepatic fibrosis was determined by fibroscan at baseline value (t0) and after one year (t1). Other variables such as sex, age, the HCV VL, genotype, polymorphism of the IL28b gen and Prometheus index (PI) were studied. Univariate lineal or logistic regression was used. The change in the fibrosis (t1.t0) served as the dependent variable.

Results: 88 patients, whose elastoraphy were available, were studied. 75 had HCV (83% PCR HCV+) and 15 control group (VIH+HCV-). 62% were genotype 1, 18% genotype 2-3 and 20% genotype 4. 6% had HBsAg. 37% had been treated with PEGIFN + RIB. 90.8% were co-infected by HIV. 47.7% presented F0-F1; 15.9% F2 and 36.3% F3-F4. 34.5% presented IL28b gen CC polymorphism, 60% CT and 5.5% TT. Median PI was 60% (IQR: 30-85%). HCV patients showed greater fibrosis than the control group ($p < 0.0001$). In the HCV subgroup (75 patients) the only variable associated with a greater fibrosis was the Prometheus Index ($p = 0.018$; R^2 quadratic: 0.27; R2 lineal: 0.10) No statistically significant association was found with: VL HCV ($p = 0.36$), Genotype 1-4 versus 2-3 ($p = 0.76$), HBsAg ($p = 0.51$), IL28b gen CC polymorphism ($p = 0.58$).Neither the presence of HIV co-infection ($p = 0.82$), nor previous IFN+RIB treatment($p = 0.29$) was associated with fibrosis progression. After a year, the median increase in fibrosis was -0.1 Kpasc (IQR: -2.9 to +1.5). The only variable linked to the Fibrosis progression was PI: (beta: -0.15; 95%CI: -0.15 a -0.029; $p = 0.006$; R^2: 0.36). For every 10% increase in the PI (baseline), the annual fibrosis progression diminishes by 1.5 Kpas.

Discussion: Given that PI includes HCV VL, HCV genotype, hepatic stiffness and IL28b gen polymorphism, in our study, this index tells us in advance those patients whose fibrosis will worsen within a year. The worse the PI is, the greater the fibrosis progression. This becomes useful when planning more aggressive therapeutic strategies.

Conclusions: HCV presence and a lower Prometheus Index are associated with greater hepatic fibrosis. Moreover, an increase in the Prometheus Index is associated with a lower fibrosis progression in the short term.

A-321
POSTINFECTIOUS GLOMERULONEPHRITIS IN DEVELOPED COUNTRIES AND STAPHYLOCOCCUS

A. Rial-Villavecchia[1], J. Mora Luján[1], J. Gómez Junyent[1], X. Solanich[1], M. Gomá[2], R. Pujol Farriols[1]

[1]Department of Internal Medicine, [2]Department of Pathology. Hospital Universitari de Bellvitge. L'Hospitalet de Llobregat (Barcelona), Spain.

Objectives: To describe the epidemiological, pathological, microbiological, immunological and clinical data of patients with PIGN (postinfectious glomerulonephritis) in a developed country with free universal access to health care.

Material and method: A retrospective study of biopsies with PIGN performed at our center during the years 2007-2011 with compatible microbiological, clinical and immunological features. We have collected only streptococcal and staphylococcal infectious related PIGN. The diagnosis of infection was performed by infection site cultures or serology on Streptococcus patients.

Results: 4 biopsies were collected supporting PIGN related to Staphylococcus (PIGNSA) with skin infection in 2 patients and joint infection in 2 patients. 2 Streptococcal related PIGN (PIGNSt) were identified, with symptoms of upper respiratory tract in one of them and cellulitis in another. The four PIGNSA patients were male, aged between 42 and 76 years old. The PIGNSt patients were women, 38 and 73 years old. PINGSA showed higher comorbidity with arterial hypertension (3 of 4) and DM (2 of 4). In 3 of 4 PIGNSA immune study could be made in the biopsy, highlighting IgA and C3 deposition, not present in PIGNSt. The infection could not be resolved completely in 3 of 4 patients PIGNSA. The 6 patients had worsening of kidney function, with acute kidney failure in 2 of each group. 2 PIGNSA case presented with anasarca or nephrotic syndrome, acquiring nephrotic range proteinuria in 3 of 4. All six

patients had hematuria. 3 of 4 patients PIGNSA remained with chronic kidney disease and the other one requires hemodialysis, while the 2 PIGNSt recovered kidney function. Kidney impairment was significantly worse in PIGNSA, as creatinine and glomerular filtration showed. Serum albumina was lowered in all four patients PIGNSA, only in one PIGNSt. In the immunological study, 2 of 4 PIGNSA patients had normal complement. Cryoglobulins were positive in 2 PIGNSA and 1 PIGNSt. Serum IgA and IgG were elevated in both PIGNst, while in PIGNSA IgG was positive in 1 and IgA in another. 5 of the 6 patients had active infection.

Discussion: In developing countries PIGN is caused most often by prior infection with nephritogenic strains of group A beta-hemolytic streptococcus. In Europe, as well as in other developed countries, this PIGNSt has become less frequent, as some authors have shown in the last years. PIGNSA incidence have increased, with different underlying pathological mechanisms, risk factors, clinical and serum expression, as well as poor prognosis Our series, dominated by cases of PIGN secondary to chronic infections by staphylococci, show some of the literature reviews results. This subgroup of patients has more risk factors, worse prognosis and different pathological features at biopsy, as well as active infectious disease.

Conclusions: In developed countries the etiology, epidemiology and clinical manifestations of PIGN are changing. In our hospital patients with clinical and pathological features compatible with PIGN were PIGNSA predominant and had more comorbidities, worse kidney function, proteinuria and serum albumina. It should be noted this condition in patients with acute worsening of renal function, hematuria and proteinuria and carry out active treatment causal infection.

A-322
CLINICAL FEATURES IN PATIENTS WITH CENTRAL NERVOUS SYSTEM INFECTION

I. González Negredo, A. Herrero Carrera, J. Sanz

Department of Infectious Diseases. Hospital Universitario de la Princesa. Madrid, Spain

Objectives: To investigate the clinical and epidemiological features of patients with central nervous system infections in our department, as well as the need for intensive care and survival rates.

Material and method: We conducted a retrospective, descriptive study. We selected the cases with central nervous system infections admitted to the Department of Infectious Diseases in our tertiary care hospital in Madrid during the period 2008 to 2011. Brain abscess and cerebrospinal fluid shunt infections were excluded. The diagnosis was made based on cerebrospinal fluid findings, along with imaging tests and clinical symptoms.

Results: Fifty five patients (29 males and 26 females with a mean age of 52 years) were included. They were divided in 3 subgroups: a) Twenty four cases (43%) were diagnosed with bacterial meningitis. HIV infection was present in 3 patients, whereas 6 cases had immunosuppressive conditions other than HIV. The cerebrospinal fluid cultures were positive in 70%: 7 cases (29%) of S. pneumoniae were reported. No cases of meningococcal infection were observed. Fever was present in 17 cases (70%) of bacterial meningitis and altered mental status in 14 (58%). The combination of fever, neck stiffness, and headache was observed in 6 (25%). Only 2 patients had seizures. Imaging tests supported the diagnosis in 13 cases (54%). Despite appropriated treatment, 9 patients (37.5%) required admission to an intensive care unit. Three patients died and other 9 had severe sequelae. b) Aseptic meningitis was reported in 19 cases (34%). Four were infected with HIV and 1 patient was receiving immunosuppressive therapy. Only 3 cerebrospinal fluid cultures were positive. Aseptic meningitis of unknown etiology was diagnosed in 16 patients. Headache was the most common symptom and was present in 17 cases (89.4%) of aseptic meningitis, while fever was in 73.6%. The combination of fever, neck stiffness and headache was present in 21%. Three patients debuted with motor deficits and one of them with seizures. Only in 3 cases (15%) the imaging test supported the diagnosis. One patient required admission to an intensive care unit and another one died. c) Twelve cases of encephalitis were reported. 1 case was infected with HIV and another one had underlying immunosuppression. Polymerase chain reaction was positive for herpes simplex virus in 4 cases and cytomegalovirus was reported in 1 patient. All cerebrospinal fluid cultures were negative. The most common clinical manifestations were altered mental status (83%) and fever (58%). Seven patients debuted with motor deficit; no seizures were observed. In 6 cases (50%) the imaging test supported the diagnosis. During the follow-up period, 2 patients (16%) required admission to intensive care, one died and 3 had moderate sequelae.

Discussion: Central nervous system infections may be associated with significant morbidity and mortality, often necessitating emergent interventions. Aseptic meningitis of viral etiology is the most common form of meningitis. Despite improvements in primary prevention level with the widespread use of vaccines and chemoprophylaxis, central nervous system infections remain a common disease world-wide and involve high mortality rates with significant neurological sequelae, especially in acute bacterial meningitis, as in our series. In recent years, the increase in immunosuppressive therapy and HIV infections has changed the epidemiology and clinical manifestations concerning central nervous system infections.

Conclusions: Based on our data, acute bacterial meningitis is the most common and severe CNS infection, with high rate of ICU admissions and neurological long-term effects. Early empiric therapy is crucial to improve the prognosis in these patients.

A-323
A RETROSPECTIVE SURVEY OF ACUTE Q FEVER IN GRAN CANARIA (2005-2011)

A. Gil Díaz, S. Santana Báez, R. Castillo Rueda, S. Alonso Rodríguez, M. Moreno Santana, M. Serrano Fuentes, S. Suárez Ortega, P. Betancor León

Department of Internal Medicine. Hospital Universitario de Gran Canaria Dr. Negrín. Las Palmas de Gran Canaria (Las Palmas), Spain.

Objectives: To describe the clinic and epidemiological characteristics of Q fever in the north of Gran Canaria, and to study the relationship between these characteristics and the different forms of presentation.

Material and method: All diagnosed cases of acute Q fever during the last seven years were analyzed. Epidemiological data, clinical characteristics, biochemical, serological and radiological results, duration of symptoms before diagnosis, need for hospital admission, clinical presentation, antibiotic treatment received and evolution were collected. Q fever diagnosis was established by seroconversion or increase of at least four times the anti-phase II IgG antibodies titers against Coxiella burnetii by indirect immunofluorescence (> 1/200) or by complement fixation with cutoff values of > 1/32, with clinically compatible symptoms. The major presentation forms were classified as pneumonia, hepatitis, self-limited-flu-like syndrome and other manifestations. A Chi square test and a relative risk analysis were performed to study the relationships between the different forms of presentation and epidemiological characteristics of the sample.

Results: Q fever was diagnosed in 124 patients, being 76.6% men. The mean age was 48.3 years (SD 14.5), with a range from 17 to 86 years old. 49.2% of the patients were from rural areas, and at least

32 patients (25.8%) referred contact with animals. The most frequent comorbidities were heart disease (19.4%), diabetes (15.3%), active smoking (37.9%) and alcohol intake (21.8%). The annual incidence rate of Q fever was 17.7, taking place 44.4% of the cases in spring. The most common symptoms were averaged 15.7 days of fever (84.7%), headache (30.6%), respiratory symptoms (28.2) and myalgias (21.8%). Biochemical characteristic findings were prolonged aPTT (> 37 seconds) in 65.7%, increase in transaminase levels (AST > 38 or ALT > 41 U/l) in 71.9%, lactate dehydrogenated levels > 250 U/L in 84.6% and erythrocyte sedimentation rate > 12 mm/h in 79.4% of the patients. Self-limited-flu-like syndrome with light liver enzyme elevation was the most frequent form of presentation (51.6%), followed by hepatitis (26.6%) and pneumonia (15.3%). Antibiotics were prescribed in 63.7% of the patients during a mean of 13.5 days, receiving doxycycline 59.5% of them. 36.3% of the patients required admission and three of them died secondary to Q fever infection. Significant associations between patients with 38-48 years old and hepatitis (p = 0.024; RR = 1.95), and more than 57 year-old patients and pneumonia (p = 0.007; RR = 2.95) were found. Pneumonia was also associated with diagnosis in November-February period (p = 0.003; RR = 1.35), bad prognosis (p = 0.012; RR = 11.05) and need for admission (p = 0.001; RR = 2.50). Self-limited-flu-like syndrome was negatively associated with need for admission (p = 0.048; RR = 0.58).

Discussion: We agree with other surveys that the typical Q fever infected patient is a middle-aged man with fever of intermediate duration and light hepatic enzyme elevation, in spring, with favorable evolution. Therefore it often goes unnoticed since the patient doesn't visit the doctor because clinical signs of Q fever are often subclinical or extremely mild.

Conclusions: We highlight the high prevalence of Q fever observed in our series, usually in the clinical form of self-limited-flu-like syndrome. It should be noticed that the pneumonic form of presentation is associated with hospital admission, advanced age patients, earliest month's appearance and worse outcome.

A-325
EXPERIENCE IN THERAPEUTIC DRUG MONITORING OF ATAZANAVIR IN HIV INFECTED INDIVIDUALS

J. Soto Delgado, M. Cordero Sánchez, P. Sánchez Junquera, A. de la Vega Lanciego, M. Mateos Andrés, E. Martínez Velado, M. Chimeno Viñas

Department of Internal Medicine. Complejo Asistencial de Zamora. Zamora, Spain.

Objectives: To evaluate the effect of the therapeutic drug monitoring (TDM) of atazanavir (ATV) in the virological suppression of the replication of the HIV, in the immune response of the CD4 count and in the presence of adverse reactions related to ATV in patients infected by the HIV.

Material and method: An observational retrospective study was conducted in the department of Infectious Diseases of the University Hospital of Salamanca. Patients considered were those: older than 18 years, infected by HIV, under antiretroviral therapy with ATV boosted or not with ritonavir (RTV) and with TDM of ATV. The Data were collected from 2005 to July 2011. The informs of the TDM and of the clinical records were reviewed. According to the plasma concentrations of ATV the following groups were considered: infratherapeutic, if they were under 0.15 mg/L, and toxic, if they were over 0.85 mg/L. It was defined as virological failure the detection of VC in plasma after 24 weeks of antiretroviral treatment or the detection of VC in two consecutive measurements after being undetectable (< 50 copies/mL).

Results: Our series included 55 cases whose epidemiological characteristics are in Men 43 (78.2), Age (years) 47.3 (8.5). The median of the plasma triglycerides concentrations in the groups of infratherapeutic, therapeutic and toxic levels of ATV were 141.5 mg/dL (P25-75: 89,6-256), 187.5 mg/dL (P25-75: 138-288) and 173 mg/dL (P25-75: 126.5-215), respectively. When ATV was boosted with RTV, the levels of triglycerides were higher than in the cases where ATV was not boosted. Patients with therapeutic and toxic levels of ATV showed an increase in the values of bilirubin of 2.3 mg/dL and 2.8 mg/dL, respectively; after dosing adjustment they decreased to 2.2 mg/dL and 2.5 mg/dL. In the group of infratherapeutic levels of ATV, the average of the CD4 count increased from 362 cells/mL (+77) to 480 cells/mL (+99) after dosing adjustment. The number of patients with undetectable VC increased in the infratherapeutic and toxic groups after dosing adjustment in 3 (37.5%) and 1 (50%) patients, respectively. This meant avoiding a possible virological failure in 4 cases.

Discussion: The debate about the clinical usefulness of the TDM of the antiretroviral therapy is reflected in the contradictory recommendations in the treatment guidelines for the HIV used all over the world. The British HIV Association support the usage of TDM in specific situations. Guidelines in the United States support TDM without providing any specific recommendation. WHO guideline do not recommend its use in environments with limited resources. In this context our study back up the current evidence about the clinical utility of the TDM of the ATV in the prevention of possible virological failures. Current literature show that ATV is not associated to a significant increase in triglyceride levels. However, in our series hypertriglyceridemia was one of the adverse effects present in the groups of toxic and therapeutic levels of ATV. This could be related to the concurrent use of other antiretroviral drugs that produce disturbances in the lipid metabolism such as nucleosid analogues.

Conclusions: The TDM of the ATV proved to be a useful tool to guarantee that ATV plasma concentrations are in a therapeutic range, eluding any possible virological failure. In our series it was effective in properly avoiding a 7.2% (4/55) of the virological failures, belonging mostly of them to the infratherapeutic group 5.4% (3/55). The main adverse effects of TDM of ATV were hyperbilirubinemia and hypertriglyceridemia. They were more important when the treatment with ATV was boostered with RTV and when plasma levels of ATV were in toxic range.

A-326
PROSPECTIVE AND DESCRIPTIVE STUDY OF FUNGAL ENDOCARDITIS IN THE UNIVERSITY HOSPITAL MARQUES DE VALDECILLA (CANTABRIA-SPAIN)

A. Arnaiz García[1], M. Pajarón Guerrero[2], S. Bellisco Roncal[1], M. Cobo Belaustegui[3], B. Negueruela García[2], E. Arnaiz García[4], F. Gutiérrez Díez[4]

[1]Unit of Infectious Diseases, [2]Unit of In-Home Health Care, [3]Department of Cardiology, [4]Department of Cardiovascular Surgery. Hospital Valdecilla. Santander (Cantabria), Spain.

Objectives: Endocardial involvement in fungal disease is uncommon. However, it is one of the most serious manifestations of fungal systemic infections, remaining with high rates of morbility and mortality even though performing cardiac surgery. The aim of this study is to describe the clinical and epidemiological characteristics of this cohort of patients diagnosed with fungal endocarditis (FE).

Material and method: Prospective cohort study of all patients diagnosed with FE from 1st of January of 2008 to 30st of April of 2012 in the University Hospital Marqués de Valdecilla (Cantabria-Spain). Data about epidemiological characteristics of patients, surgery and complications in the postoperative period were collected.

Results: From the total of 205 cases of infective endocarditis, 8 (3.9%) were diagnosed with FE: 5 (62.5%) males, with a mean age of

62.7 (SD 19.5) years. Six patients (75%) had a Charlson index = 4. ASA index was > 4 in all cases. Five (62.5%) were receiving immunosuppressive therapies: 2 (25%) were recipients of bilateral lung transplantations, 2 (25%) had metastatic cancers (lung and colon) and 1(12.5%) had rheumatoid arthritis under treatment. One (12.5%) had previous infective endocarditis due to S. bovis. Two (25%) cases were on prosthetic valve and one (12.5%) over pacemaker. Four (50%) of the patients had FE over mitral, three (37.5%) over aortic and 1(12.5%) over tricuspid valve. Embolic symptoms were found in 6 (75%) patients, existing fever in 5(62.5%) patients. Etiology was: C. albicans in 62.5% cases, and C. parapsilosis, S. prolificans and A. fumigatus in 12.5% respectively. The recipients of lung transplantation develop non-Candida FE. Surgery was underwent in 62.5% patients. The average hospital stay was 35.4 (32.3) days. Mortality in the group of surgical patients (5 patients) was 50%, and 66.6% in the group of suppressive therapy (3 patients), and this occurred at 28 (21) days and 64 (12) days respectively.

Discussion: Fungal endocarditis (FE) is an uncommon occurrence. Previously published series reported fungi as causes of infective endocarditis in 1.3 to 6% of the cases. Advances in medical and surgical therapies, including reconstructive cardiovascular surgery, implantation of intracardiac devices, prolonged use of intravenous catheters, exposure to multiple broad-spectrum antibiotics, and immunosupression have been implicated as causes of the perceived increase in the number of cases of fungemia and FE seen during last decades. FE has been characterized by excessive mortality (> 50%) and morbidity, regardless of treatment. A combined medical-surgical approach seems to offer an improved outcome. However, there are no clinical trials to support or refuse this opinion, largely because the rarity of the syndrome.

Conclusions: Fungal endocarditis is a rare cause of infective endocarditis (3.9% in our series), mainly due to Candida albicans (62.5%). All patients are in a high-risk group (Charlson = 4 in 75% of the patients). Immunosuppression was present in 62.5% patients. No-Candida FE was only found in receptors of lung transplantation. Mortality remains high regardless of treatment (50% in surgical patients and 66% in medical suppressive treatment).

A-327
MALARIA IN HIV-INFECTED PATIENTS IN THE HOSPITAL OF FUENLABRADA

A. Castro, M. Fernández, N. Cabello, J. Ruiz, R. Calderón, B. Matía, I. Navas, J. Canora

Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: HIV/AIDS and malaria have a major impact on the socio-economic development of Africa. It is currently considered a re-emerging disease, with great social and health impact. In our hospital, we declare around the 12% of all malaria cases reported annually in the Community of Madrid. Malaria plays a crucial physiopathogenic roll in HIV-infected patients by decreasing the number of CD4 and transiently increasing viral load, especially in patients with fever. It also represents an increased risk of both sexual and vertical transmission. HIV destroys CD4 cells, the same immune cells, critical to the development of immunity to malaria. Our objective is to describe the epidemiological, clinical and laboratory data of HIV-infected patients with malaria.

Material and method: A prospective descriptive study of cases of malaria diagnosed in HIV-infected patients since the opening of the Hospital Universitario de Fuenlabrada (HUFLR) until August 2011. We analyzed the epidemiological, clinical, and laboratory outcomes.

Results: There were 129 cases of malaria diagnosed during the 8 years that were analyzed in the Universitary Hospital of Fuenlabrada, there is an average of 16.12 cases/year. Among the cases analyzed there were 7 cases detected of patients with HIV infection (5.4%) of the 129. Only three of the seven cases were HIV positive, were known previously, the rest were diagnosed during the study of malaria. The most severe case occurred in a previously known HIV with a very immunosuppressed stage (C-3) with high parasitemia, it coursed with cerebral malaria and multiorgan failure. In our series, we found a high percentage of HIV pregnant women, a particularly vulnerable group. HIV screening has not been performed systematically in all patients (HIV test was performed in 89/129 cases of malaria, 68.9%). In most cases there wasn't a correct follow-up.

Conclusions: When malaria is diagnosed, it is essential the active screening for HIV infection and other transmissible diseases (hepatitis, TB) during hospitalization. We have found that even patients with a strong indication for malaria prophylaxis don't do it correctly when making visits to their countries of origin. Our series showed an excellent outcome after treatment with HAART and antimalarials.

A-328
HOSPITAL ADMISSIONS OF HIV-INFECTED PATIENTS TO AN INFECTIOUS DISEASE UNIT. A SEVEN-YEAR STUDY

D. Andres García, E. Martínez Pagán, C. Martín Durán, E. Artajona Rodrigo, M. Rubio Rubio, E. Lambán Ibor, P. Hernández Machin, P. Arazo

Department of Internal Medicine. Infectious Diseases Unit. Hospital Universitario Miguel Servet. Zaragoza, Spain.

Objectives: To assess the evolution of the admission of HIV-infected patients during the past 7 years in an infectious disease unit (IDU) of a reference hospital.

Material and method: We analyzed data on hospital activity in the Infectious Disease Unit based on Diagnostic Related Groups (DRGs) during the period 2005-2011. We analyzed the evolution of the admission proportion of patients diagnosed with HIV with respect to the total number of admissions, taking into account gender, average age, average length of stay, proportion of hospital stays compared to the total ones in IDUs, and total mortality.

Results: In these 7 years there have been a total of 967 admissions. The number of such admissions has progressive and proportionally decreased from 2005 to 2011 (43.3% and 25.0% respectively). Both sex (3:1 male/female ratio) and mean age (40.30 years) have remained stable. The proportion of the total of consumed stays has declined as well: 49.68% in 2005 and 28.33% in 2011. Mortality has fallen from 5.95% in 2005 to 3.48% in 2011 but has been oscillating throughout these seven years.

Conclusions: There has been a clear decline in admissions and hospital stays of patients infected with HIV. This constitutes an opportunity for IDUs to address patients with infectious diseases other than those related to HIV.

A-329
EPIDEMIOLOGIC, CLINICAL CHARACTERISTICS, COMPLICATIONS AND TREATMENT ASSOCIATED WITH CLOSTRIDIUM DIFFICILE INFECTION AMONG HOSPITALISED PATIENTS

J. Soto Delgado, A. de la Vega Lanciego, M. Mateos Andrés, P. Sánchez Junquera, P. García Carbó, M. Chimeno Viñas, E. Martínez Velado, L. Mustapha Abadie

Department of Internal Medicine. Complejo Asistencial de Zamora. Zamora, Spain.

Objectives: To describe the epidemiologic and clinical characteristics, complications and treatment of patients with Clostridium difficile infection (CDI) among hospitalised patients.

Material and method: A descriptive observational historic study was conducted in Virgen Concha Hospital among patients with CDI. Cases were detected by enzyme-linked immunoassay for A and B toxins of Clostridium difficile in stool of inpatients for a period of two years (2010-2011). Variables obtained were age, gender, inpatients days until diagnostic suspicion, relevant clinical signs and symptoms, complications, microbiological, endoscopic, histological and laboratory findings, as well as antimicrobials, chemoterapic drugs and proton pump inhibitors exposure before infection onset, and the treatment used for CDI. Community-associated infection was considered in patients without hospitalization within 12 weeks of onset or who were identified with CDI within 48 hour of admission. Healthcare-associated infection was considered in patients who had hospitalization within 12 weeks of onset or infection detected after 48 hours of admission. Long-term facility associated infection was considered in patients who lived in residential care homes for the elderly. In cases where some antibiotics were used before CDI only those with the most long-term use and related in time with CDI.

Results: From 44 cases with CDI, 27(61.4%) were male and 17 (38.4%) female, with a mean age of 75 ± 16.9 years. Regarding the origin of infection 27 (61.4%) cases were community-associated and 12 (27.3%) healthcare-associated and 5 (11.4%) long-term facility associated. The prevalent clinical profile was diarrhea with 40 cases (90%) abdominal pain 21 (47%) and fever 12 (27%). From 9 (20.5%) cases who had a colonoscopy only two of them were consistent with pseudomembranous colitis. Regarding to laboratory test in 43 cases were done blood count and in 38 cases albumin, 23 (53.5%) of them had leukocytosis (15,160 ± 2,891/ mm^3) or leukopenia (3,662 ± 212.8/mm^3) and 22 (57.9%) hypoalbuminemia (3.2 ± 0.65 mg/dl) respectively. The first complication was hypotension with 6 cases (13.6%) and the second ileus-abdominal distension 3 (6.8%). There were 2 exitus associated to abdominal distension, renal failure at hospital admission and hypoalbuminemia. In 29 patients (65.9%) administration of antibiotics was established before the CDI, most frequently used antibiotics were amoxicillin-clavulanate 7 (24.1%), ceftriaxone 7 (24.1%) and imipenem 6 (20.7%). The usage of proton pump inhibitors was present in 37 cases (84%) with a median of 7 days (P25-75-2 and 16) with 7 habitual users. The most frequent initial treatment for CDI was metronidazole with 41 (83.3%) cases, and the most frequent administration route was oral 33 (78.6%) and the mean of duration 10.1 ± 4 days (there were two cases with no treatment registrated).

Discussion: A high prevalence of CDI community-associated was found 61.4% (27), although nowadays this prevalence is not well characterized, community incidence seems to be increasing in Spain. This high prevalence may be related to most existing elderly population, greater use of antibiotics and dissemination of carriers from the hospital. Our series originally consisted of 74 cases. The number of stool cultures for common bacteria were negative. Pathological studies were carried out 5 of which none was compatible with ICD, although the clinical and the presence of toxins in feces were compatible.

Conclusions: The most prevalent epidemiologic characteristics: male with a mean age of 75 years being the main origin of the infection the community. Previous use of antibiotics: the most prevalent amoxicillin-clavulanate, ceftriaxone and imipenem. Proton pump inhibitors were used in more than 80%. The antibiotic therapy for CDI most used was oral metronidazole followed by oral vancomycin.

A-330
MORTALITY PREDICTORS IN THE EXTENDED-SPECTRUM BETA-LACTAMASES K. PNEUMONIAE BACTERAEMIA

C. Villamor[1], O. Martín[1], L. Téllez[1], L. Moreno[1], A. Delgado-Iribarren[2], F. Valverde[2], J. Losa[1], M. Velasco[1]

[1]Department of Infectious Diseases and Internal Medicine. [2]Microbiology Unit. Hospital Universitario Fundación Alcorcón. Alcorcón (Madrid).

Objectives: Isolation of extended-spectrum beta-lactamases (ESBL) Klebsiella pneumoniae (EKP) is a new and growing problem in Spain. Little is known about factors associated with mortality. To evaluate predictors of mortality in (ESBL) Klebsiella pneumoniae (EKP) bacteraemia we designed this study.

Material and method: We evaluated all patients attended in our hospital during 2011 with bacteraemic Klebsiella pneumoniae infection. Mortality was assessed at the first month. We evaluated clinical and epidemiological variables associated with mortality, including ESBL status. Results are expressed as average (SD) or percentage. Independent predictors of mortality of EKP bacteraemia were evaluated by multivariate logistic regression.

Results: A total of 46 patients were included; mean age 75.5 (2.1) years and 39.1% females. EKP was isolated in 15 patients (32.6%). Mortality was 26.7% in both groups (presence or absence of ESBL). Patients who died were older (83.4 [11.0] vs 73.2 [14.4] years, p = 0.031), more frequently male (37.0% vs 11.1% p = 0.08), dependent (62.5% vs 11.1%, p = 0.009), living in nursing home (50.0% vs 16.1%, p = 0.029) suffered dementia (53.3% vs 13.3%, p = 0.01) presented fever more days (0.9 [0.7] vs 1.6 [0.9]; p = 0.032) and received antibiotic treatment less time, (4.2 [4.8] vs 15.3 [4.7]; p < 0.001; but received adequate empirical antibiotic treatment less frequently 16.2% vs 66.7% p = 0.02. Time from bacterial isolation to death was 20.7 [20.7] vs 6.7 [7.5] days; p > 0.05.

Conclusions: Mortality in Klebsiella pneumoniae bacteraemia with or without ESBL was the same and it was very high. Inadequate empirical treatment, to live in a nursing home or to be dependent were factors associated with mortality.

Patients with multimorbility and elderly patients

EA-1
EVALUATION OF THE NUTRITIONAL CONDITION USING THE MNA TEST (MINI NUTRITIONAL ASSESSMENT) IN A COHORT OF 127 PATIENTS IN A MEDIUM - LARGE STAY UNIT OF A GERIATRIC HOSPITAL - MLSUGH

R. Qanneta[1], O. Díaz Crombie[1], R. Martínez Ripoll[2], P. Amigó Correig[3], A. Gotor Olabarría[4], A. Cebada Ferrer[4], M. Olona Cabases[5], E. Moltó Llarena[1]

[1]Department of Internal Medicine, [2]Department of Family and Community Medicine, [3]Department of Nutrition, [4]Nursing. Hospital Sociosanitari Francolí. Tarragona, Spain. [5]Department of Epidemiology and Preventive Medicine. Hospital Universitari Joan XXIII. Tarragona, Spain.

Objectives: The MNA is a method validated and relatively simple to use, that help to evaluate the nutritional condition in the hospitalized patients, by means of 18 questions divided in four blocks. The punctuation obtained allows to classify the patients in

normal nutritional condition (> 23.5 points), risk of malnutrition (17 to 23.5 points) and malnutrition (< 17 points). The objective is to determine the prevalence of malnutrition in patients attended in a MLSUGH at the moment of admission using the MNA test, valuing the correlation of the test with parameters anthropometric and analytical (albumin and prealbumin) as well as with the presence of pressure ulcers.

Material and method: A transversal descriptive study including a total of 127 older adults patients (> 65 years) admitted in a MLSUGH from January until March of 2011. In all patients a MNA test, an anthropometric and biochemical evaluation has been done. It has been realized the statistical descriptive and comparative analysis by means of the chi-squared test and t-student test with the program SPSSPC v 15 for Windows.

Results: Of the total of 127 patients: 74 (58.3%) were women and the mean age was 77.1 ± 10.4 years. 112 patients (87.5%) came from acute care hospital (31.3% were patients subsequent to major surgery) and 15 (12.5%) from primary care center. 12 patients (9.4%) had pressure ulcers. The average stay was 47 ± 26.4 days. The destination was to home in 87 (68%) patients while 15 (11.7%) were death and 20 (15.6%) are continue hospitalized. However 3 (2.3%) patients have returned to a social residence and other 3 (2.3%) to acute care hospital. According to the MNA test 37 (28.9%) patients presented malnutrition (62.2% being male/p = 0.009) and 79 (61.7%) were at risk. When correlating the three categories of MNA test with the presence of pressure ulcers, anthropometric and laboratory parameters, we observed that 18.9% of the malnutrition group have pressure ulcers, body mass index in the same group is 22.9 ± 5.9 kg/m^2 and the difference between habitual weight and current weight is 8.7 ± 8.1 kg (significant results between groups: p = 0.04, p = 0.005 and p = 0.01 respectively). Statistical trend was seen in albumin between groups (p = 0.08). It has shown a statistically significant relationship between the presence of pressure ulcers with low albumin concentration (p = 0.01) and the weight difference (p = 0.03), while statistical trend was seen in age (p = 0.06). Of the 15 patients who died 60% (9 patients) had malnutrition while the other 40% (6 patients) were at risk of malnutrition.

Discussion: O. Izaola et al in their study of 145 patients (An Med Intern, 2005) had found that the malnutrition prevalence was 68.2% and risk of malnutrition 29.6% (in our study we found a predominance of risk of malnutrition 61.7% vs 28.9% with predominance of males 62.2%). Vellas et al (Nutr Health Aging J, 2006) showed that with MNA scoring sensitivity was found to be 96% and predictive value 97% as well as the MNA scale was also found to be predictive of death (11.7% in our series vs 5.7% observed in the analysis of 106 patients conducted by Sanchez M et al (Rev Clin Esp, 2010). We found a relationship between malnutrition and pressure soars (p = 0.01) result similar to that found by Pardo C et al (Nutr Hosp, 2011).

Conclusions: It is possible to identify older adults at risk for malnutrition (condition detected frequently in our hospital) by MNA score and can be easily corrected by nutritional intervention that can prevent complications.

EA-2
ELDERLY PATIENTS OVER 90 YEARS OLD ADMITTED TO THE DEPARTMENTS OF INTERNAL MEDICINE (IM)

C. Granda, V. Isernia, S. Elgheadi, R. Sanz, G. Sotres, E. Ruano, J. Marco

Department of Internal Medicine. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: The population aged over 90 years of age constitutes 0.6% of the total of people living in our country but generates 6% of admittances to IM Departments. Our hypothesis is that this "very elderly" population (over 90 years of age) is responsible for some of the overall results of health-care activities in Internal Medicine (IM), as well as mortality and the consumption of resources. The aim of this study is to analysed some of these parameters.

Material and method: Patients admitted to the departments of IM in Spain between the years 2005 to 2007 were analysed from the data obtained from the MBDS (Minimum Basic Data Set), in which administrative and clinical data were collected from all patients admitted to the public and private hospitals in Spain. Patients over 90 years old were considered "very elderly". Urine infection, the appearance of decubitus ulcers, side effects related with the medication, thromboembolic disease during admission, acute confusional syndrome and hip fracture of admitted patients were defined as intrahospital complications. Clinical and demographic data, as well as the complications rate, were compared among elderly individuals (65-90) and very elderly (> 90).

Results: During the analysed period, 1,567,659 individuals were admitted to IM, of which 90.079 (5.7%) were over 90 years old, 67% of these were women. The "very elderly" patients had a greater complications rate (OR 1.35 95%CI 1.32-1.37), and twice the risk of death (OR 2.28 95%CI 2.24-2.32), than the rest of the elderly people. The risk of having a decubitus ulcer (OR1.73 95%CI 1.68-1.79), a urine infection (OR 1.38 95%CI 1.35-1.41), acute confusional syndrome (OR 1.58 95%CI 1.52-1.65) or a hip fracture (OR 2.05 95%CI1.70-2.49) was clearly greater in the very elderly people.

Discussion: To sum up, in this study we have demonstrated that a very high percentage of the "very elderly" patients admitted to Spanish hospitals are attended to in the departments of IM. Our population consisted of patients with high mortality and high risk of complications during admission, some of which were preventable. Given the magnitude of the study, we think that the photography of the patients is quite reliable, despite of the weakness that the information is based on a clinical-administrative database. The increase that this group of patients has experienced in recent years, that will no doubt continue increasing given the current demographic tendency, obliges us to keep investigating this study and the specific measures aimed at improving the management of these patients in close collaboration with geriatricians and other professionals in the health industry.

Conclusions: One in every 20 patients admitted in IM are very elderly. These patients have more intrahospital complications, a much higher death rate and a greater consumption of resources.

EA-3
ADMISSIONS OF CENTENARIAN PATIENTS: OUR CURRENT SITUATION

M. Chimeno Viñas, E. Martínez Velado, P. Sánchez Junquera, A. de la Vega Lanciego, J. Soto Delgado, M. Mateos Andrés, P. García Carbó, G. Hernández Pérez

Department of Internal Medicine. Complejo Asistencial de Zamora. Zamora, Spain.

Objectives: The "oldest old", those aged 85 years or more, are an important segment of present society. A special subgroup of the oldest old are the centenarian, patients more than 100 years. The objective of our study is to know the current situation of the centenarian patients admitted to Complejo Asistencial de Zamora (CAZA) during 2011.

Material and method: Observational, descriptive, retrospective study. We ask for the Admission Service the information about patients aged over 100 years that were admitted to CAZA (Complejo Asistencial de Zamora) in 2011. We reviewed the records and we analysed the next data: age, sex, number of admissions within the study period. type of admission (elective or urgency), admitting service, length of stay, main diagnoses and survival.

Results: There were 25 centenarian patients admitted a total of 29 times during the study period. All of them were admitted from

Emergency Service (none in an elective form). There were 9 men (36%) and 16 women (64%). Most patients were admitted only once during the study period, two patients were admitted twice and one patient was admitted three times. The mean age was 101. 4 years. 11 patients were 100 years (7 women and 4 men); 7 were 101 years (5 women), 4 were 102 years (2 men), 1 woman were 103, 1 man were 105 years, 1 woman were 106 years and 1 woman were 107 years. The mean length of stay was 8.7 days. There were 5 deaths (20%). The admitting service was medical for 20 patients (80%); orthopaedic for 2 patients (8%) and general surgical for 3 patients (12%). The main diagnoses were: respiratory infection in 7 patients, stroke in 3 patients, heart failure in 3, urinary infection in 2, hip fracture in 2, heart attack in 2, sepsis in 2. Each of the following diagnoses occurred in 1 patient: gastrointestinal bleeding, gangrene, incarcerated hernia, diverticulitis, acute renal failure, head trauma, heart block, dehydration.

Discussion: Centenarian admitted to our Health-care Complex in 2011 were predominantly women, had a favorable prognosis without high hospital mortality rates and with a variety of diagnoses. The type of admission was never elective. The majority of patients were admitted to medical services. Only two centenarians had suffered a hip fracture. The results of our study are similar to the data of previous studies except for the fact that hip fracture wasn´t the most common reason for hospitalization in our patients.

Conclusions: 1. Nowadays, admissions of centenarian patients isn't unusual. 2. There are more women than men. 3. They are admitting mainly in medical services. 4. Most of them are discharged.

EA-4
FRAILTY IN THE OLDEST OLD: PREVALENCE AND ASSOCIATED FACTORS

A. Ferrer[1], F. Formiga[2], H. Sanz[3], D. Mestres[1], D. Chivite[2], R. Pujol[2], G. Octabaix[1]

[1]Department of Family Medicine. Cap El Pla. Sant Feliu de Llobregat (Barcelona), Spain. [2]Department of Internal Medicine. Hospital Universitari de Bellvitge. Barcelona, Spain. [3]Unitat Suport a Recerca Costa Ponent. USR Costa Ponent. Cornellà (Barcelona), Spain.

Objectives: To describe frailty prevalence and to study the factors associated with frailty syndrome in the oldest old.

Material and method: Design: cross-sectional study, nested within a randomized clinic trial. Participants: two hundred and seventy-three 86-year-olds registered at seven primary healthcare centres. Measurements: Data on functional status, comorbidities, social risk and participation in the intervention to prevent falls and malnutrition and blood tests were compiled. Subjects were assessed using the phenotypic definition of frailty and a comparative analysis was performed between patients with and without frailty (defined as non-frail, pre-frail and frail).

Results: Fifty-six subjects were defined as frail (20.5%), 148 were pre-frail (54.2%) and 69 non-frail (25.3%). The model with the best fit according to the Akaike information criterion (AIC) indicated that factors significantly associated with frailty were functional status (OR: 4.92; 95%CI 2.54-9.53), nutritional risk (OR: 2.33; 95%CI 1.26-4.32), drugs taken (OR: 1.17; 95%CI 1.09-1.26), Gijon test (OR: 1.13; 95%CI 1.01-1.26), CD4-lymphocytes (OR: 1.03; 95%CI 1.01-1.06). Participation in the intervention emerged as a protective factor associated to frailty (OR: 0.48; 95%CI 0.29-0.80).

Conclusions: The present study found a high prevalence of frailty in the oldest old, and the main morbidities associated with frailty were decline in functional status and nutritional risk. Individual target intervention was a protective factor. These findings may encourage clinicians to initiate measures for preventing and treating frailty at an earlier date.

EA-5
PREVALENCE OF E. COLI INFECTIONS IN A CHRONIC PATIENTS HOSPITAL

M. Ulla Anes[1], B. Escolano[1], F.P Rojas[2], T. Bellver[1], C. Barrasa[1], G.G. Melcón[1], J. Casado[1], J. Forero[3]

[1]Department of Internal Medicine, [2]Department of Geriatrics, [3]Department of Admission. Hospital Virgen de la Torre. Madrid, Spain.

Objectives: Escherichia coli (EC) is a common etiologic agent of urinary tract infections, bloodstream infections and acute diarrhea, and is frequently involved in nosocomial and community bacteremia. Moreover, the existence of beta-lactamase producing strains (ESBL) is a major problem because of its high morbidity and mortality. The objective is to determine the prevalence of infection by EC in our hospital with special emphasis on the antibiotic resistance profile.

Material and method: We have reviewed the medical records of patients with positive cultures for EC in the period January to December 2011. The Hospital Virgen de la Torre is a 100-bed hospital for chronic patients with acute exacerbation. We have reviewed epidemiological, clinical, microbiological and treatment items.

Results: Patients admitted 2473, cultures (+) for EC 49c (1.98%), 38 females (75.51%) 11 males (24.49%). Mean age 85.06 (R: 61-99). Previous pathology: 1. Hypertension 36c (73.4%) 30 f (83.3%) 6 m (16.7%). 2. Diabetes 23c (46.9%) 19f (82.6) 4m (17.4%). 3. Dyslipidemia 20c (40.8%) 17f (85%) 3m (15%). 4. Heart disease 18c (36.7%) 13f (72.2%) 5m (27.8%). 5. COPD 5c (10.20%) 5m (100%). Admission diagnosis: 1. Urinary tract infection 34c (69.3%). 2. Respiratory Infection 8c (16.3%). 3. Febrile Syndrome 3c (6.1%). 4. Acute Gastroenteritis 2c (4.1%). 5. Infected pressure ulcers 2c (4.1%). 6. Pancreatitis 1c (2%). Cultures (+) for EC: 1. Urine 44c (89.8%) 36f (81.8%) 8m (18.2%). 2. Blood culture 4c (8.2%) 4f (100%). 3. Sputum 4c (8.2%) 3m (75%) 1f (25%). 4. Pressure ulcer 2c (4.1%) 1f (50%) 1m (50%). Acute phase reactants: 1. Hyperfibrinogenemia 41c (83.7%) 33f (80.5%) 8m (19.5%). 2. > C-reactive protein 40c (81.6%) 29f (72.5%) 11m (27.5%). 3. - leukocytosis 23c (47%) 19f (82.6%) 4m (17.4%). 4. Thrombocytosis 7c (14.3%) 5f (71.4%) 2m (28.6%). Antibiotic resistance: 1. Ampicillin 37c (75.5%). 2. Quinolones 23c (46.9%). 3. Cotrimoxazole 18c (36.7%). 4. Aminoglycosides 12c (24.5%). 5. Cephalosporins 10c (20.4%). 6. Aztreonam 9c (18.4%). 7. Amoxi/clavulanic 6c (12.2%). 8. Fosfomycin 3c (6.1%). 9. Nitrofurantoin 1c (2.%). 10. Ureidopenicillin 1c (2.%). None were resistant to carbapenems and tetracyclines. EC ESBL infection 9c (18.3%). Treatment given: 1. Monotherapy 23c (46.9%). 2. Combined therapy 26c (53.1%). Quinolones 18c (36.7%), fosfomycin 12c (24.5%), amoxi/clavu 12c (24.5%), cephalosporins 11c (22.4%), carbapenems 10c (20.4%), cotrimoxazole 4c (8.2%), aminoglycosides 3c (6.1%). The EC ESBL infection received combination therapy with carbapenems and a second antibiotic. Average stay 11.043 days. There wasn't mortality related to EC.

Discussion: EC infection is more prevalent in females in relationship with urinary tract infection. It is accompanied by significant elevation of acute phase reactants, especially C-reactive protein and fibrinogen. We have observed a high rate of resistance to ampicillin, quinolones and cotrimoxazole. However, carbapenems, tetracyclines, ureidopenicillins, nitrofurantoin, fosfomycin and amoxi/clavulanate has a good sensitivity profile. Highlights 9 cases of EC ESBL infection (18.36%), higher than that reported in most of Europe (1-5%) and Spain (5-10%), and similar to Ireland, Italy and Portugal (10-25%). This high prevalence is probably related to the type of patients (chronic and institutionalized patients with multiple hospital admissions and antibiotic treatments).

Conclusions: 1. The urinary tract is the most prevalent location of infection with EC. 2. EC infection is associated with significant elevation of acute phase reactants in 75% of cases. 3. EC has a high

rate of resistance to ampicillin and quinolones, it should be avoided in empirical treatment of urinary tract infections with a high suspicion of EC implication. Fosfomycin/nitrofurantoin for uncomplicated infections and amoxi-clavul/ureidopen/carbapenen for infections with sepsis have a good profile of sensitivity. 4. EC ESBL infection is highly prevalent in our series. However, we have had good response to combination therapy with carbapenems and a second antibiotic chosen by antibiogram. We had no mortality associated with EC infection.

EA-6
ASSISTANCE AT THE END OF LIFE: AN INESCAPABLE PURPOSE OF MEDICINE

T. Saez Vaquero, T. Fluxá Egea, L. Lucas Fernández, G. García Melcón, M. Candel Rodríguez, R. Pacheco Cuadros, S. de Juan García, C. Pantoja Zarza

Department of Internal Medicine. Hospital Virgen de la Torre. Madrid, Spain.

Objectives: To study the activity of a palliative care unit of average complexity, integrated over the internal medicine service.

Material and method: A descriptive study. Registration of the main demographic and clinical variables of patients admitted during 2011. Comorbidity criteria according to Gª Morillo et al. Assessment of caregiver burden by reduced Zarit scale. Basic statistics of centralization and dispersion for quantitative variables, distribution of frequencies for qualitative variables. Comparison of means: t student, proportions: χ^2 Pearson. Level of significance: $p < 0.05$.

Results: 298 patients were admitted. A 58.4% male, mean age 76 years (SD 11). Average stay 9.4 days (SD 9.2, range 1-60). Media PPS 32%, 23 Barthel, Pfeiffer 4. Enter from primary care (ESAD) 43%, from the emergency 18%, 25.4% from acute Hospital. Patients with comorbidities were 47%. 90% were cancer patients. 68% admitted for symptom control, 24% agony. Main symptoms: dyspnea (49%), cachexia-anorexia (33%), pain (28%), delirium (24%). The primary caregiver was the spouse in 54%, other relatives, 32%, 11% lived alone and 3% in residence. Caregiver burden was detected in 67.5% of cases. Patient knowledge about the diagnosis/prognosis was: they know 67%/40%; do not know 13%/27%; don´t want to know 6%/11%; 21% had cognitive impairment. There were two cases with previous instructions. The family knew the diagnosis/prognosis 100%/97.5%. Contact with psychologist/social work: 74%/40%. They explained 21% sedation. Mortality rate 78%. It was found a significant association between no cancer patient, dependency, caregiver burden, and admission to agony.

Discussion: Advances in medicine to prolong life often at the expense of more suffering, more diseases and more spending. The goals of medicine should consider the comfort of pain and suffering caused by disease, care and healing the sick and care for the incurable, and avoidance of premature death and the search for a peaceful death.

Conclusions: Patients without cancer have less access to palliative care, the estimated long-term survival should not be justified: it is necessary to develop predictive models and mitigation needs assessment, permitting its early attention, multidimensional and multidisciplinary. The limited diagnostic and prognostic knowledge hinders Advance Care Planning, according to patient preferences. Effective care and quality, must include strategies for care and support to families. The philosophy of palliative care should extend to all health care settings, including specific knowledge of symptom control, adequacy of therapeutic effort, communication, and attention to the death.

EA-7
QUALITY IMPROVEMENT CYCLE IN HIP FRACTURE CARE

A. Peláez[1], M. Miluy[1], J. Simón[1], J. Mulero[1], E. Mené[1], A. Gil Martínez[2]

[1]Department of Internal Medicine, [2]Codification Unit. Hospital Rafael Méndez. Lorca (Murcia), Spain.

Objectives: Internists are more and more present in orthopedic hospitalisation departments. The aims of this study are to improve hip fracture care; their morbimortality registry, the minimum data set; and to prove that surgery delay goes against patients and physicians.

Material and method: We reviewed electronic and paper medical history of patients with code discharge 820 of ICD-9, hip fracture, between February and August 2010. In February 2012 we started a quality improvement cycle: a Resident assess comorbidities stability at admission of all the patients with hip fracture and if decompensated a staff internist must see the patient daily until improvement. We discuss in meetings with traumatologists, anesthetists, rehabilitators and nurses, the key points in medical care, and constructed five quality criterions to observe: 1. Surgical delay. 2. Comorbidity revision by internist. 3. Nurses alerts. 4. To be seated for 48 hours (post- operative). 5. Urinary catheter use for incontinence. We recodify the CMBD (Conjunto Mínimo Básico de Datos or Minimum Data Set, MDS), to be sure of the quality of history records. We compare morbidmortality rates with the same period in 2012 using a similar database variables: age, sex, number of compensated and compensated co morbidities, Principal and Secondary diagnoses, anticoagulants or antiplatelet drugs use, number of drugs consumed and actualised treatment, days of internist consultation, complications, surgery delay, stay, inhospital mortality, ambulatory mortality and walking ability, biochemical and hematological parameters, transfusions, and the five quality criterions. In the 2012 patients, we compared five clinical prognostic scores: ASA, Barthel, Pfeiffer, PROFUND and the ALBERTA hip fracture in hospital mortality risk. Statistical analysis is made using the SPSS.

Results: Until fifteenth of May we have reviewed 133 patients; 89 patients from 2010 and 44 from 2012, and we finished on August 2012 presenting the final results. Baseline Characteristics of patients are similar in both years: in hospital, mortality is 5.6% and 4.5% respectively, the number of complications by patient 0.76 and 0.70; number of comorbidities compensated at admission are 2.42 and 2.86; comorbidities decompensated are 0.12 and 0.06; all without statistical difference between 2010 and 2012. Grouping the 133 patients, decompensated comorbidity at admission in deceased patients is 0.8571, and in patients surviving 0.0598; the compensate co morbidity is 3.14 and 2.54 in deceased and alive respectively, not reaching statistical significance. In a preliminary analysis the rate of at least one complication between patients taking oral anticoagulants is 80%, with 33% mortality and surgery delay of 4.3 days; patients taking clopidogrel have 57% complication and 5.57 delay days, patients taking 100 mg of aspirin 14.2% complication and 3.7 delay days; and patients not taking anti haemostatic drugs 17% complication and 1.95 delay days. When we recodified the 2010 clinical ICD-9 diagnostics we found in 10% of cases an increase from 2.3116 to 4.2130 in GRDs weight. The best prognostic score in 44 patients predicting exitus is the PROFUND INDEX followed by the ALBERTA ($p < 0.05$). Barthel index has a p of 0.08 and the others are far from significant. Concerning the quality cycle there is a significant improvement in compliance of nurse's alerts; there is no significant improvement in the others.

Discussion: A rapid resolution of hip fracture permits better rehabilitation and less morbimortality. It is said that patients who suffer a fall with hip fracture were previously ill. In our study only 6 to 12% have a decompensated comorbidity, and we saw how often patients at high risk had complications. Surgery delay must be

essentially to avoid surgical and anaesthetic risks and no more; not for threatening complications or comorbid decompensations that probably will worsen when confined to bed. Antihaemostatic drugs are of great interest for discussion.

Conclusions: It's essential at admission to detect medical decompensation, and in polypathological patients to assess the risk of complications appearing, in order to reduce surgical delay in high risk patients. The PROFUND INDEX may be a good tool for prediction.

EA-8
DIFFERENCES IN PALLIATIVE SEDATION PRACTICE IN A PALLIATIVE CARE UNIT RESPECT TO INTERNAL MEDICINE AND ONCOLOGY SERVICES

L. Díez Porres[1], J. García Puig[2], A. Alonso Babarro[1], M. Lacasta[1], Y. Vilches[1], J. Díez[3]

[1]Acute Palliative Care Unit, [2]Department of Internal Medicine, [3]Department of Biostatistics. Hospital Universitario La Paz. Madrid, Spain.

Objectives: Patients in the last days of life may present refractory symptoms that require palliative sedation. Objective: to compare palliative sedation practice at the end of life in a Palliative Care Unit respect to Internal Medicine and Oncology.

Material and method: Observational, retrospective, cohort study. Subjects: patients died in Palliative Care Unit (PCU), or in Internal Medicine or Oncology (Non-PCU); consecutively included. Protocol: a) Retrospective review of medical record. b) Family perceived quality study by telephone interview after death. Selection of those sedated cases.

Results: 166 patients died between 01/10/09 and 27/02/10, bellowing 66 to PCU cohort and 100 to Non-PCU. Palliative sedation was prescribed in 13 patients (19.7%) of PCU, vs 9 (9.3%) of Non-PCU (p = 0.065). Seventeen (77%) were male and mean age (SD) was 65 (10.7) years, without differences between both cohorts. All PCU patients suffered a terminal oncologic illness, vs 7 (78%) Non-PCU (NS). The 2 no oncologic cases in Non-PCU were terminal dementia and COPD. Indications: cause of sedation was recorded in MR in 100% of PCU vs 3 Non-PCU patients (33%) (p = 0.001). Most frequent recorded indication was dyspnea: 6 PCU patients (46%) and the 3 recorded Non-PCU patients (100%). Decision making: decision was discuss with 6 PCU patients (46%), vs 2 Non-PCU (22%) (p = 0.046). It was discuss with family in 100% of PCU vs 3 Non-PCU cases (33%) (p = 0.001). The most common drug used was midazolam, in 11 PCU patients (85%) and 100% in Non-PCU (NS). In 4 Non-PCU patients (44%) it was used combined with morphine with sedation intention. No PCU case received morphine with sedation intention (p = 0.008). Levomepromazine was the second most used drug in PCU (5 patients, 38%). Drugs were administered subcutaneously, except in 1 Non-PCU patient, where intravenous via was used (NS). Midazolam mean (SD) dose used was 49 (16,6) mg/24 h in PCU vs 26 (10.1) mg/24 h in Non-PCU (p = 0.001). Symptoms were recorded systematically in 92% PCU patients vs 25% Non-PCU (p = 0.002). The sedation time range was between 3 h to 7 days in PCU cohort, with median (SD) 34 (52.1) h and between 1,5 to 40.5 h in Non-PCU, with median (SD) 10 (13.8) h (p = 0.01). In a 0 to 10 scale, global satisfaction mean with care received was 9 in PCU and 8 in Non-PCU (NS); there were no differences with satisfaction family in no sedated.

Conclusions: Systematic guarantees (sedation indication-refractory symptom and decision making) were followed in a significant greater percentage in PCU cohort of sedated patients. Systematic symptom register and sedation time were greater in PCU group. Global family satisfaction was high.

EA-9
CREATION OF AN ACUTE GERIATRIC UNIT AS A SHORT STAY UNIT IN A REGIONAL HOSPITAL

E. Bustamante[1], F. Ramos[1], E. Esteve[1], J. Aligué[1], O. Boutrouki[1], J. Herms[1], A. Baraldés[2], R. Pérez[1]

[1]Department of Internal Medicine, [2]Hospital at Home Unit. Althaia - Xarxa Assistencial de Manresa. Manresa. Barcelona, Spain.

Objectives: Acute Geriatric Units (AGU) were created with the objective of providing better assistance to elderly people, and of preventing the loss of functional capacity and dependence often associated with institutionalization. Here we describe AGU, which maintains all the characteristics of a geriatric unit.

Material and method: We designed an AGU with 12 beds. The interdisciplinary team comprised two doctors (internal medicine doctors with specific knowledge of geriatrics), three nurses and three auxiliaries (one per shift), a physiotherapist, a nutritionist and a social worker. The unit depends on the Internal Medicine department. In almost all cases, patients were admitted from teh Emergency department; some were admitted from the Day Hospital, and a very small from outpatient visits. The admission criteria were: age over 80 years; good functional capacity (defined as a score of over 60 on Barthel's index; good mental status (defined as few than five mistakes Pfeiffer's questionnaire); fewer than seven days in care remaining; availability of social support.

Results: We analysed the first six months of operation of our AGU (September 2011 to March 2012). Three hundred and six patients were discharged from the unit (55% men). Mean age was 83 years, and mean length of stay was 6.3 days (0-40 days). Readmissions (1-30 days) occurred in 7.8% of cases. In the geriatric assessment of functional status, the mean Barthel's score was 84.7 points; as regard mental status, the mean number of mistakes on the Pfeiffer questionnaire was1.7. As for comorbidity, the mean score on the Charlson Index was 2.8. The main diagnoses at discharge were: heart failure (31.3%), pneumonia (20.2%), and COPD (18.5%). At the time of discharge 86% of patients returned home, one per cent was transferred to a convalescence unit for functional rehabilitation, and one per cent to a tertiary hospital for complex attention not available at our hospital. Ten per cent remained hospitalized in the Hospital at Home Unit (UHaD). Mortality was 2%.

Discussion: Strict criteria were established for admission to the AGU. Patients had to be aged 80 or more, frail but with good functional and mental status. We reached our objective of a length of stay of less than seven days (mean stay 6.3 days) with the help of the UHaD and the Day hospital. Patients were conventionally hospitalized while in need of medical care that can only be provided in hospital; after stabilization, they could be discharged to the UHaD to finalize their hospitalization, and then discharged to home with visits scheduled at the Day hospital in the next few days for clinical control or blood tests, X-ray, and so on. The readmission rate was 7.8%, similar to that recorded in other areas in the department. The geriatric assessment reflected good functional capacity (Barthel's score 84.7) and good mental status (Pfeiffer 1.7). Some authors say that the best candidates for admission to the AGU are frail patients with good functional status. The mean length of stay was 6.3 days (0-40 d). The principal diagnoses were heart failure, pneumonia and COPD, mostly decompensated chronic diseases. Our patients were pluripathological, with a medium-high mean Charlson's index of 2.8 points. At time of discharge 86% of patients were at home, and only 1% was transferred to a convalescence centre for functional rehabilitation. The mortality rate was low (2%).

Conclusions: We created an AGU as a short stay unit with two key features: 1. Strict inclusion criteria before admission. 2. The aid of the Hospital at Home Unit and Day hospital to allow early discharge, without any increase in readmissions.

EA-10
IDENTIFYING THE CHARACTERISTICS OF STROKE PATIENTS: ELDERLY VS ADULTS

V. Binay Safer[1], O. Oken[1], F. Koseoglu[1], U. Safer[2]

[1]Department of Physical Medicine and Rehabilitation. Ankara Physical Medicine and Rehabilitation Education and Research Hospital. Ankara, Turkey. [2]Department of Geriatrics. Gulhane Medical Faculty Training Hospital. Ankara, Turkey.

Objectives: The aim of this study was to define the demographic and clinical characteristics of stroke patients who referred to physical medicine and rehabilitation clinic and to detect the differences between these characteristics in regard to age.

Material and method: Stroke inpatient case notes, recorded between 2009-2012 in national rehabilitation center were evaluated in a retrospective study. Demographic data, etiology of stroke, duration of stroke, effected side in stroke and comorbid diseases of the patients were recorded. Differences regard to age were evaluated.

Results: One hundred thirty six stroke inpatient case notes (77 men, 55 women; mean age, 64.8 ± 1.1 years) were evaluated. Elderly stroke patients had more ischaemic etiology (88.4% vs 74.6%), more hypertension (76.1% vs 61.5%), more diabetes (33.8% vs 23.1%) and more atrial fibrillation (28.2 vs10.8%); adult stroke patients had more hemorrhagic etiology (25.4% vs11.6), more ischaemic heart disease (33.8%, 26.8%), more dyslipidemia (21.5% vs 16.9%) and more dyspeptic complaints (36,5%vs 28.2%). Other age related variation in clinical characteristics of stroke patient were as in table.

Discussion: Age seems to be an important factor on clinical characteristics of stroke patients.

Conclusions: It may be important to address such differences when developing stroke preventative strategies in stroke survivors of Turkish population.

EA-11
PULMONARY HYPERTENSION (PH) IN INTERNAL MEDICINE: ECHOCARDIOGRAPHIC DIAGNOSIS

N. Aldezábal, E. Bello, L. Acevedo, M. Barrientos, B. Mora, A. Torres, O. López, L. Álvarez-Sala

Department of Internal Medicine 2. Hospital General Universitario Gregorio Marañón. Madrid, Spain.

Objectives: 1) To define the prevalence of PH among patients admitted to an internal medicine ward. 2) To describe the characteristics of these patients and the prevalence of the different causes of PH in this population.

Material and method: Retrospective study of patients with PH admitted to an internal medicine ward of a third level general hospital in a 1 year period: Jan 01 to Dec 31, 2010. Analyzed variables: age, sex, cardiovascular risk factors (CVRF), chronic renal failure (CRF), left heart disease, lung disease and others etiologies of PH (1, 1´, 2 and 5 groups of the 2009 European PH guidelines), the diagnostic method of the PH, the potential relationship of PH as the cause of admission and PH hospital mortality. PH diagnosis was done according to echocardiographic criteria. Statistical analysis: quantitative variables are shown as mean ± SD, qualitative variables as percentages and compared using the chi squared test. Differences were considered significant at $p < 0.05$. All statistical analyses were performed using SPSS version 17.0.

Results: Prevalence of PH was 16% of total admissions: 77 patients, 66,2% women, with a mean age of 81 years. The most frequent findings in their medical records were arterial hypertension (84.6%) and atrial fibrillation (70.1%) and smoking among men (77%). The most prevalent cause of PH was linked to lung diseases (36.4%), with statistically significant differences between men and women (69% and 45% respectively, $p = 0.0003$), followed by the left heart disease (32.5%), sharing both diagnosis 9.1% of the cases. Among the lung diseases, chronic obstructive pulmonary disease (COPD) (61%) was the most prevalent disorder, followed by obstructive sleep apnea-hypopnea syndrome (OSAHS-OHS) (17%) and interstitial diseases (5%). The PAH and chronic thromboembolic pulmonary hypertension were uncommon features (1.3% and 2.6% respectively). Prevalence of other PH etiologies was null. In 13% of the patients PH mechanisms remained unclear. In most patients the reason for consultation on admission was associated with PH (67'9%) being the main causes dyspnea and right heart failure. The mortality rate of PH patients during hospitalization was a 6.4%.

Discussion: Up to date no comparative epidemiological data are available about the prevalence of different causes of PH in patients admitted to internal medicine wards. According to data of our study, it is predominantly secondary to 2 common disorders found in general clinical practice: left heart disease and lung disease. Prevention and treatment of PH in these patients include appropriate management of these underlying conditions. There is a percentage of patients (13%) in whom HP has an unknown origin, and could be an undiagnosed IPAH, thus they would benefit from a right heart catheterization.

Conclusions: 1) Prevalence of PH in our study was 16% of patients admitted to an internal medicine ward of a 3rd level general hospital. 2) The diagnosis of PH was done in all patients by echocardiography. 3) The most frequent causes of PH in this series are lung diseases (36,4%), mainly COPD, and left heart disease (32.5%). A mixed cause of PH were found in 9.1% of patients. 4) PH due to thromboembolic disease (1.3%) and PAH (2.6%) are rare in this series. 5) In 13% of the patients PH mechanisms remained unclear.

EA-12
HOSPITAL ADMISSIONS IN CENTENARIANS: HAVE THERE BEEN CHANGES IN THE LAST FOUR YEARS?

M. Chimeno Viñas[1], P. García Carbó[1], A. de la Vega Lanciego[1], P. Sánchez Junquera[1], E. Martínez Velado[1], J. Soto Delgado[1], M. Mateos Andrés[1], T. Garrote Sastre[2]

[1]Department of Internal Medicine, [2]Department of Admission. Complejo Asistencial de Zamora. Zamora, Spain.

Objectives: Centenarians surpass the current human life expectancy with about 20-25 years. Nowadays, they are an growing

Table 1 (EA-10). Demographic and clinical characteristic of the study population

	Age < 65 years 8 (n = 65)	Age > 65 years (n = 69)
Mean SD age, year	54.6 ± 1.1	74.2 ± 0.8
Mean SD stroke time, month	5.8 ± 1.4	5.4 ± 2.2
Etiology of Hemiplegia	Ischaemic = 47 (74.6%) hemorrhagic = 16 (25.4%)	Ischaemic = 61 (88.4%) hemorrhagic = 8 (11.6%)
Hemiplegic side	Right = 28 (44.4%) Left = 33 (52.4%) Bilateral = 2 (3.2%)	Right = 28 (44.4%) Left = 33 (52.4%) Bilateral = 2 (3.2%)
Gender	Male = 42 (66.7%) female = 21 (33.3%)	Male = 28 (64%) female = 15 (36%)

segment of society and clinicians will increasingly encounter this group. We sought to determinate characteristics of centenarians admitted to CAZA (Complejo Asistencial de Zamora) over a 4-years period.

Material and method: To describe the characteristics of the centenarians, we conducted a retrospective case series analysis of all patients 100 years of ages an above admitted to CAZA. We reviewed the medical records of these centenarian patients who were admitted in the last four years (2008-2011). We analyzed the next data: number of admissions, sex, age, type of admission (elective or urgency), admission service, length of stay, main diagnosis and survival.

Results: There were 81 admissions with a mean age of 101.1 years (range 100 to 107 years). The main diagnoses were: respiratory infection (25%), Heart failure (8%), hip fracture (7%), stroke (6%), and gangrene (6%). The admitted service was medical for the majority patients (86%); only one centenarian was admitted to the intensive care unit. The mean length of stay was 8.86 days. There were 27 deaths (33%). None of admissions was elective. See Table 1.

Discussion: Little information exists on the hospitalization in the centenarians. We tried to know some data about them and to analyze the possible changes happened in the last four years. There weren´t important differences in the data obtained in our study. The admissions have increased in the last years. Most of the patients were admitted to medical services. The mean length of stay was similar to the rest of patients who was admitted in those services. The mortality rate in the 2011 is lower than in other years.

Conclusions: The centenarians admitted to CAZA have increased in the two last years. They are admitted mainly in medical services. The mean length of stay in centenarians are similar than the rest of the patients. The hospital mortality rates aren't high (about 33%).

EA-14
VALIDATION OF THE CHANGE VERSION OF THE TREATMENT SATISFACTION QUESTIONNAIRE FOR CARERS OF DEPENDENT PATIENTS WITH TYPE 2 DIABETES (STCD2-C)

J. Herrero Herrero, J. García Aparicio

Department of Internal Medicine Los Montalvos. University Hospital. Salamanca, Spain.

Objectives: Our group has recently developed the STCD2 questionnaire: an instrument directed to assess the satisfaction with blood glucose-lowering treatment in carers of dependent patients with type 2 diabetes. The purpose of this study was to develop and validate a version of this questionnaire intended to assess satisfaction after introducing changes in the blood glucose-lowering therapy.

Material and method: Observational study conducted in the 'Los Montalvos' Internal Medicine Department of the University Hospital of Salamanca (Spain). The change version of the STCD2 questionnaire (STCD2-c) was developed and administered by researchers of the medical team of this Department. It was validated in carers of consecutive, dependent patients with type 2 diabetes receiving anti-diabetic medication, admitted at the hospital for any reason, in which anti-diabetic therapy had been changed in some way during hospital admission (following routine clinical criteria). Validation was performed using the data obtained in telephone interviews carried out eight weeks after discharge from hospital and further telephone interviews four weeks later in which the questionnaire was repeated. The minimum number of participants necessary to validate the test was determined using the Streiner and Norman methodology. A scoring system was established ranging from 5 points to 1 point for each of the questionnaire items. An overall satisfaction index was defined as the sum of the scores for the seven items. The internal consistency of the survey was calculated using Cronbach's alpha coefficient. The test-retest reliability was analysed by calculating the intra-class correlation coefficient between the two administration times of the questionnaire. The construct validity was investigated by estimating the Spearman correlation between the individual and overall scores for the questionnaire and levels of satisfaction with the patient's blood glucose levels.

Results: The change version of the STCD2 questionnaire was created. It consist of 7 questions with a 5-response scale, from "very satisfied" to "very dissatisfied" in the first six items and from "I would definitely recommend it" to "I wouldn't recommend it at all" in the last item. The first item refers to overall treatment satisfaction, the next 5 assess satisfaction in specific areas and the final item concerns whether or not they would recommend the patient's current treatment. The validation of the survey was carried out in 127 cases. Cronbach's alpha coefficient was 0.92. Correlation was demonstrated between all the items ($r = 0.33$–0.79, $p < 0.001$). In the test-retest reliability analysis, the intra-class correlation coefficient was 0.96 (95%CI, 0.95–0.97, $p < 0.001$). The construct validity was demonstrated in the correlation matrix. The scores for all the questionnaire items and the overall satisfaction score were correlated with the satisfaction scores for the blood glucose levels ($r = 0.44$–0.78, $p < 0.001$). In 8 cases (6.2%) and 0 cases (0%) respectively, extreme scores were achieved (floor/ceiling effect).

Discussion: Satisfaction with treatment, knowledge about the disease and assessment of the impact on the patient's quality of life are all considered as measurements for assessing results in clinical practice. When assessing satisfaction in dependent patients, the opinion of their carers becomes more important, since they are the ones administering the medication and it is they who will detect any side effects. Specific therapeutic strategies aimed at managing dependent patients with type 2 diabetes can be designed knowing the effects of changing treatment on satisfaction of their carers.

Conclusions: The STCD2-c questionnaire is a consistent and valid instrument for measuring satisfaction with the blood glucose-lowering treatment after changing the anti-diabetic therapy in carers of dependent patients with type 2 diabetes.

Table 1 (EA-12). Results in every year

	2008	2009	2010	2011
Numbers of admissions	17	16	19	29
Sex	12 F/5 M	12 F/4 M	9 F/10 M	19 F/10 M
Mean age (years)	101,1	100.5	101,6	101,4
Mean of length of stay (days)	10.6%	9.06	7.1	8.7
Admitted to medical services	87%	81%	94%	83%
Deaths	6 (35%)	7 (43%	9 (47%)	5 (19%)

EA-15
APPLICATION OF THE STCD2-C QUESTIONNAIRE IN CARERS OF DIABETIC PATIENTS IN A SPANISH INTERNAL MEDICINE SERVICE

J. García Aparicio, J. Herrero Herrero

Department of Internal Medicine Los Montalvos. University Hospital. Salamanca, Spain.

Objectives: The objective of this study was to administer the recently validated STCD2-c questionnaire in carers of dependent patients with type 2 diabetes, to determine their satisfaction after introducing changes in the blood glucose-lowering treatment, in a Spanish internal medicine service.

Material and method: The STCD2-c questionnaire was applied to the carers of consecutive, dependent, type 2 diabetic patients receiving anti-diabetic medication, admitted (for any reason) to the 'Los Montalvos' Internal Medicine Department of the University Hospital of Salamanca (Spain). Carers were invited to take part in the study when the patients they were caring for were on drug treatment to control their blood glucose levels and had changed treatment during hospitalization. When hospitalized, patients were treated in line with the routine clinical criteria of the medical team whose attention they were under. A change in therapy was considered to be any modification to the type of drug or the number of times the blood glucose-lowering medication was administered. An overall satisfaction index was defined as the sum of the scores for the seven items (minimum = 7 points, maximum = 35 points) of the questionnaire. The survey was administered over the telephone eight weeks after discharge from hospital by members of the investigating medical team.

Results: The STCD2-c questionnaire was given to 127 carers of patients. The changes made to treatment in these cases were described. The median number of daily administrations for the antidiabetic medication (insulin and/or oral antidiabetic) was 1 (0–4). The degree of satisfaction with the change (the sum of scores for each of the items in the change questionnaire) was 27.3 (95%CI, 26.4–28.2). Statistically significant differences in the questionnaire score were found based on the change in treatment between those with a change in the dosage and those with no dosage change (25.1; 95%CI, 23.8–26.4 vs 28.3; 95%CI, 27.1–29.5, $p < 0.01$) and between those in whom all blood glucose-lowering medication was discontinued and all other changes (30.8; 95%CI, 27.8–33.8 vs 26.6; 95%CI, 25.7–27.5, $p < 0.01$). The cases in which a long-acting insulin analogue was included in the new treatment had higher scores for the item referring to greater satisfaction with the patient's blood glucose levels (4.6; 95%CI, 4.3–4.9 vs 3.9; 95%CI, 3.7–4.1, $p < 0.001$) and for the item asking about greater satisfaction in terms of continuing with the treatment after the change (4.5; 95%CI, 4.2–4.9 vs 4.0; 95%CI, 3.8–4.2, $p < 0.01$). Carers of patients receiving more frequent administration of their anti-diabetic medication prior to the change were more satisfied with the change ($r = 0.24$, $p < 0.001$). Similarly, correlation was found between the number of daily administrations for blood glucose-lowering medication after the change and the degree of satisfaction ($r = -0.43$, $p < 0.001$).

Discussion: In this study, the degree of carers satisfaction increased after changing treatment, being the most appreciated change discontinuation of all blood glucose-lowering medication. Significant differences were also observed in the increase in overall satisfaction as the number of medication administration times reduced after the change. This highlights the fact that simplifying the treatment is one of the most influential factors on satisfaction. Carers of patients receiving only a long-acting insulin analogue showed an overall satisfaction index higher than those of the patients of the remaining therapeutic groups. Also, when introduced in the treatment change, once-a-day administration of long-acting insulin or analogue made the carers more likely to feel satisfied with the blood glucose levels and to recommend the treatment to others.

Conclusions: Simplifying the treatment is one of the most influential factors on satisfaction of carers of dependent patients with type 2 diabetes.

EA-16
POLYPHARMACY AND COMPLIANCE WITH START CRITERIA IN PATIENTS ADMITTED AT A MEDIUM-LONG-TERM CARE HOSPITAL

A. Pardo Cabello[1], S. Bermudo Conde[1], V. Manzano Gamero[2], I. Ródenas Iruela[1], J. García Monlleó[1]

[1]Department of Internal Medicine. Hospital Universitario San Rafael. Granada, Spain. [2]Department of Internal Medicine. Complejo Hospitalario Virgen de las Nieves. Granada, Spain.

Objectives: The START criteria (Rev Esp Geriatr Gerontol. 2009;44:273–9) aim to ensure the prescription of drugs that have shown to be beneficial in certain diseases, in people over 65 years of age. Our objective was to analyse if these criteria were met in patients of a medium- long-term care hospital.

Material and method: A cross-sectional study was carried out that included a sample of 81 patients over 65 years of age who were hospitalized at the Department of Internal Medicine of the Hospital Universitario San Rafael of Granada, on April 10, 2012. The variables elicited by the physician in charge of each patient were age, gender, number and type of drugs prescribed (excluding serum therapy and topical treatments), and diagnoses to analyse the drug prescription according to the patient's disease, following the START criteria.

Results: The mean age of the patients was 78.2 ± 7.2 years, and 54.3% of the patients were male. Each patient received 10.7 ± 3.4 drugs. 25.9% of the patients received the drugs indicated according to the START criteria; in 37% of the patients 1 START criterion was unmet; in 25.9%, 2 criteria were unmet; in 7.4%, 3 were unmet and in 3.8% of the patients, 4 or 5 criteria were unmet. The table shows the START criteria that were met the least.

Discussion: In our sample, and in spite of the polypharmacy detected, the drugs that were prescribed the least, in spite of their

Table 1 (EA-16). START criteria most frequently unmet in the patient sample (n = 81)

Description of the START criterion	Percentage of patients in which the START criterion is unmet
Statins in diabetes mellitus associated to one or more vascular risk factors	29.6%
Statins with a history of arteriosclerotic disease, independence for everyday life activities and a life expectancy greater than 5 years	24.7%
Platelet antiaggregants in diabetes mellitus associated to one or more vascular risk factors	13.6%
ASA or clopidogrel with a history of arteriosclerotic disease in patients with sinus rhythm	12.3%
Metformin in type-2 diabetes mellitus in the absence of kidney failure	11.1%
Calcium and vitamin D supplements in patients with known osteoporosis	8.6%

indication, were statins and antiaggregants (in primary and secondary prevention), possibly due to the perception of futility of said treatments in elderly patients. We highlight the scarce prescription of calcium and vitamin D in patients with osteoporosis, probably for the aforementioned reason.

Conclusions: Statins and antiaggregants, followed by calcium supplements and vitamin D, were the indicated drugs, according to START criteria, that were prescribed the least among patients of over 65 years of age.

EA-17
INADEQUATE PRESCRIPTION ACCORDING TO STOPP CRITERIA IN INPATIENTS OF A MEDIUM-LONG-TERM CARE HOSPITAL

A. Pardo Cabello[1], S. Bermudo Conde[1], V. Manzano Gamero[2], C. Romero Morell[1], J. Carrillo Santos[1]

[1]Department of Internal Medicine. Hospital Universitario San Rafael. Granada, Spain. [2]Department of Internal Medicine. Complejo Hospitalario Virgen de las Nieves. Granada, Spain.

Objectives: The inadequate prescription of drugs in elderly patients is a frequent problem that increases the risk of adverse reactions to drugs. The STOPP criteria (Rev Esp Geriatr Gerontol. 2009;44:273–9) aim to prevent the prescription of potentially inappropriate drugs in people of over 65 years of age. Our objective was to analyse the inadequate prescription in patients of a medium-long-term care hospital.

Material and method: A cross-sectional study was carried out that included a sample of 81 patients over 65 years of age who were hospitalized at the Department of Internal Medicine of the Hospital Universitario San Rafael of Granada, on April 10, 2012. The variables elicited by the physician in charge of each patient were age, gender, number and type of drugs prescribed (excluding serum therapy and topical treatments), and diagnoses to analyse the potentially inappropriate prescription following the STOPP criteria.

Results: The mean age of the patients was 78.2 ± 7.2 years, and 54.3% of the patients were male. Each patient received 10.7 ± 3.4 drugs. Thirteen point six percent (13.6%) of the patients received an adequate prescription without meeting any STOPP criteria; 37% of the patients met 1 STOPP criterion in their treatment; 18.5% met 2 criteria; 14.8% fulfilled 3 criteria, 8.6% met 4 criteria and 7.4% met 5 or 6. The table shows the most frequent STOPP criteria of the sample.

Discussion: In our sample, we detected that 86.4% of the patients had at least one inadequate prescription in their hospital treatment according to STOPP criteria. This figure is clearly greater than the one reported recently (45.8%) when using the STOPP criteria to review the home treatments of patients who were admitted to an Internal Medicine Department (Rev Clin Esp. 2012;212:268-70) although the number of drugs per patient was lower (7.6 ± 0.4) than in our study. In our sample, the drugs that motivated the most inadequate prescription were sustained PPIs at high doses (34.6% of the patients), which could be justified by the percentage of antiaggregated or anticoagulated patients of our sample (49.4%), due to their elevated polypharmacy and their advanced age. The extended use of benzodiazepines and neuroleptics stands out in elderly patients due to their high prevalence and their association to a greater risk of iatrogenesis (confusion, nocturnal sedation, falls, extrapyramidal symptoms, etc.).

Conclusions: A high percentage of Internal Medicine inpatients receive an inadequate prescription. Benzodiazepines and neuroleptics are the drugs involved in most cases of inadequate prescription, which is why caution must be exercised when they are prescribed, and their indication must be reassessed periodically.

EA-18
FUNCTIONAL STATUS IN PATIENTS HOSPITALISED IN A GENERAL INTERNAL MEDICINE SERVICE: DIFFERENCES IN BARTHEL INDEX PRIOR TO ADMISSION AND AT DISCHARGE

J. Trullas[1], S. Iglesia[1], D. Sadurní[1], M. Mayola[1], E. Puigdemont[1], E. Martínez[2]

[1]Department of Internal Medicine. Hospital de Sant Jaume. Olot. Girona, Spain. [2]Universitat de Girona. Girona, Spain.

Objectives: To analyze the clinical characteristics and the changes in the functional status of patients admitted to an Internal Medicine Service.

Material and method: We prospectively studied all patients hospitalised in an Internal Medicine Service between 1st of July and 31st of October, 2011. The functional status was determined by Barthel Index: prior to admission, at admission and at discharge.

Results: 234 patients were included. 56% were males and median age (IQR) was 79 (15) years old. Only 16 (6.8%) were living in nursing home facilities. Respiratory (24%), cardiovascular (20%), infectious (15%) and neurologic (14%) diseases were the main reasons for admission. 18 (7.7%) patients died during admission. At discharge 20% of patients were referred to a nursing home facility. The median (IQR) punctuations of Barthel index were: 95 (40) prior to admission, 55 (65) at admission and 85 (50) at discharge. When comparing Barthel index at discharge with Barthel index before admission we found similar values in 34%, lower values at discharge (functional impairment) in 39% and higher values at discharge (functional improvement) only in 15%. The following variables were significantly related with functional impairment during hospitalisation: age, neurologic disease, length of hospitalisation, referral to a nursing home facility at discharge and lower values in all Barthel index measurements.

Conclusions: Hospitalisation implies a great functional impairment in the patients admitted to an Internal Medicine Service. Patients with advanced age, neurological disease and lower Barthel index values at admission experience functional impairment more frequently. Functional impairment implies a longer hospitalisation and a more frequent requirement of a nursing home facility at discharge.

Table 1 (EA-17). Main causes of inappropriate prescription according to the STOPP criteria applied to the sample (n = 81)

Description of the STOPP criterion	Percentage of patients with STOPP criteria
PPIs for peptic ulcerative disease at full therapeutic doses (esomeprazole 40 mg/d) for more than 8 weeks	34.6%
Benzodiazepines in patients with previous falls	24.7%
Prolonged use of benzodiazepines with long half life	22.0%
Neuroleptics in patients with previous falls	21.0%
Prolonged use of neuroleptics as hypnotics	19.8%

Table 1 (EA-18). Changes in functional status in patients admitted to an Internal Medicine Service

	No changes in functional status	Functional improvement	Functional impairment	p value
Male gender	43 (54%)	23 (66%)	48 (53%)	0.40
Age (years)	70.5 (18)	79 (9)	82 (10)	< 0.001
Nursing home facility prior to admission	2 (3%)	4 (11%)	5 (6%)	0.17
Main diagnosis at admission	Respiratory (31%). Infectious (21%). Cardiovascular (19%)	Respiratory (23%). Cardiovascular (23%). Other (23%)	Neurologic (25%). Respiratory (19%). Cardiovascular (19%)	0.001
Hospitalisation (days)	4 (4)	5 (4)	7 (7)	< 0.001
Nursing home facility at discharge	3 (4%)	4 (11%)	29 (37%)	0.001
Barthel bef admission	100 (0)	80 (35)	90 (35)	< 0.001
Barthel at admission	100 (35)	55 (45)	45 (45)	< 0.001
Barthel at discharge	100 (0)	95 (25)	50 (65)	< 0.001

EA-19
PREVALENCE AND IMPACT OF MALNUTRITION IN CHRONIC AND PLURIPATHOLOGIC HOSPITALIZED PATIENTS

I. Moreno[1], P. Moral[1], Y. Torres[1], K. García-Malpartida[2], M. Argente[2], F. Merino[2]

[1]Department of Medium to Long Stay, [2]Department of Endocrinology and Nutrition. Universitary and Politechnic La Fe Hospital. Valencia, Spain.

Objectives: Malnutrition is a serious disorder that is frequently undervalued in hospitalized patients for other conditions, becoming more relevant with long stays at hospital. Our aim is to assess the prevalence of malnutrition in elderly patients hospitalized in the Medium to Long Stay Unit in a Universitary Hospital. We also want to determine the possible association between this condition and patient´s clinical characteristics in terms of comorbidity, functional status, cognitive impairment and dysphagia.

Material and method: We performed a descriptive, observational and cross-sectional study including 122 patients admitted to our unit over 4 months. They were evaluated by an interdisciplinary team of nurses and internists. Administrative and general data (age, sex, stay length...) were recorded along with the cause of hospitalization, comorbidity (Charlson), cognitive impairment (Pfeiffer) and functional status (Barthel) assessment by physicians. The diagnosis of the nutritional status was made by the validated test Mini-Nutritional-Assessment (MNA). Symptoms and signs that could be the cause or effect of malnutrition were recorded along with analytic parameters of interest (albumin, total protein, lymphocyte count and cholesterol). Trained nurses assessed the presence of pressure ulcers and did a thorough anthropometric evaluation. The presence of dysphagia was evaluated by the Volume/Viscosity test. Results are expressed in mean, standard deviation and percentages.

Results: The age of our group was 76.8 years (12.6), with a slight prevalence of men (53.3%). The two main reasons for hospital admission were chronic obstructive pulmonary disease (22.2%) and stroke (17.3%). The stay length was 24.6 days (20.5). The Charlson index showed that 59% of them had comorbidity. The Barthel index was 34.7 (30.9), where 64.4% of patients had severe or total dependence, and 28.7% had mild to severe cognitive impairment (Pfeiffer). The BMI was 22.9 kg/m^2 (5.8). According to the MNA score 55.7% of the elderly were malnourished, and 39.3% at risk of malnutrition. The prevalence of dysphagia was 35%. We found an association between malnutrition and weight/BMI (p 0.000 for both), Age (p = 0.013), Pfeiffer (p = 0.003), Barthel (p = 0.000), dysphagia (p = 0.001), total protein (p = 0.015), lymphocyte count (p = 0.008) and presence of pressure ulcers (p = 0.002).

Discussion: The age and prevalence of comorbidity, cognitive impairment and functional decline clearly reflects the complexity and frailty of our population. There is an elevated prevalence of malnutrition and risk of becoming malnourished in our group, similar to those reported in the literature. The use of the MNA score has shown to be useful in the malnutrition diagnosis; the weight and BMI could help to identify highly vulnerable patients. Malnutrition has been related with some clinical conditions (age, mental decline, comorbidity, functional status and dysphagia), probably they act as important etiological factors. It is also related with the presence of pressure ulcers and low lymphocyte count, showing the impact of this condition in the immunitary system and the healing process.

Conclusions: Malnutrition is a problem of elevated prevalence and impact in our population. It is of paramount importance to correctly evaluate the presence of risk factors and diagnose this condition in order to prevent/treat it accurately. It is necessary to conduct larger and prospective studies to provide a better understanding of both its prognosis and its therapeutic approaches.

EA-20
COMPARATIVE STUDY OF INADEQUATE PRESCRIPTION BETWEEN INTERNISTS AND GERIATRICIANS OF A MEDIUM-LONG-STAY HOSPITAL

A. Pardo Cabello[1], S. Bermudo Conde[1], V. Manzano Gamero[2], I. Ródenas Iruela[1], J. García Monlleó[1]

[1]Department of Internal Medicine. Hospital Universitario San Rafael. Granada, Spain. [2]Department of Internal Medicine. Complejo Hospitalario Virgen de las Nieves. Granada, Spain.

Objectives: The inadequate prescription of drugs in elderly patients is a frequent problem that increases the risk of adverse reactions to drugs, which is why the STOPP criteria, which aim to prevent this situation, was published recently (Rev Esp Geriatr Gerontol. 2009;44:273–9). Our objective was to compare the characteristics of the inadequate prescription in elderly patients by internists and geriatricians of a medium-long-term care hospital.

Material and method: A cross-sectional study was carried out that included a sample of 81 patients over 65 years of age, admitted to the Department of Internal Medicine of the Hospital Universitario San Rafael of Granada, on April 10, 2012. The variables elicited by the physician in charge (internist or geriatrician) of each patient were age, gender, number and type of drugs prescribed, and diagnoses to analyse the inadequate prescription of drugs, following the STOPP criteria. The data collected were compared according to the specialty of the prescribing physician.

Results: The group of patients attended by geriatricians (n = 47) was matched for age with the group attended by internists (n = 34) (77.6 ± 6.8 years vs 79.1 ± 7.7 years, respectively; p = 0.359).

Patients of internists received more drugs than those of geriatricians (12.4 ± 3.3 vs 9.5 ± 2.9, respectively; p = 0.0001). No statistically significant differences were found when comparing the mean of STOPP criteria in patients treated by internists and patients treated by geriatricians (2.24 ± 1.6 vs 1.7 ± 1.4, respectively; p = 0.117). When comparing both groups (see table), the only STOPP criterion that showed any differences was the use of neuroleptics as hypnotics.

Discussion: We detected that the patients attended by internists received a greater number of drugs than those attended by geriatricians, although without an increased inadequate prescription. The use of PPIs at full doses was the most frequent STOPP criterion in both groups. A high use of benzodiazepines and neuroleptics was also detected in both groups, entailing risks in elderly patients.

Conclusions: A predominance of the use of neuroleptics as hypnotics was detected in internists compared to geriatricians. Generally speaking, the use of benzodiazepines and neuroleptics was high in both groups.

EA-21
CAN WE PREVENT MORTALITY OF HIP FRACTURE PATIENTS? RESULTS OF INTEGRATED CARE IN A PRIMARY HOSPITAL

M. Salas Alcántara[1], M. Ruiz Mariscal[1], E. Aguilar Cortés[1], A. Aller Blanco[2], P. Aguelo Asensio[1], C. Piqueras Serrano[1]

[1]Department of Internal Medicine. Hospital General de Alcañiz. Alcañiz. Teruel, Spain. [2]Department of Preventive Medicine. Hospital General San Jorge. Huesca, Spain.

Objectives: The number of hip fractures occurring in Europe and postsurgical outcome are a major public health concern. As a result, Internal Medicine care has been integrated in Traumatology Department of our primary hospital since five years ago.Our primary objective was to define the profile of patient who dies of hip fracture and our secondary objective was to assess the extrinsic factors that contribute to mortality.

Material and method: Patients who died during the early postoperative of hip fracture over the past three years were included in this retrospectively study. Results were evaluated with the SPSS 15.0 statistic programme.

Results: The study sample consisted of 30 cases (20 women and 10 men) with a mean age of 87 years where the 63.3% had cognitive impairment. Preoperative ASA risk score was III-IV in the 71.4% of cases and waiting time until the surgery was 4 days. The main cause of death was congestive heart failure. Table 1 shows annual death rates.

Discussion: Despite the elevated mean age of our patients the prevalence of other diseases was low, which can be explained by the familiar support, only 13.3% were living in nursing homes and/or intermediate-care facilities. In Spain the mean waiting time until surgery is 3 days, it is essential to know that in our patients it was one day more. Although the mean hemoglobin at time of admission was 12.5 mg/dl the main postsurgical complication was anemia, which is a well-known risk factor of developing heart failure, that is our primary cause of death.

Conclusions: 1. Since heart failure was the main cause of death and cardiovascular disease was the most often comorbidity in our study, an intensive treatment should be administered during hospital phase. 2. More studies are needed to determine predictive risk factors of mortality.

EA-22
COMPARATIVE STUDY OF COMPLIANCE WITH START CRITERIA BETWEEN INTERNISTS AND GERIATRICIANS OF A MEDIUM-LONG-STAY HOSPITAL

A. Pardo Cabello[1], S. Bermudo Conde[1], V. Manzano Gamero[2], J. Carrillo Santos[1], C. Romero Morell[1]

[1]Department of Internal Medicine. Hospital Universitario San Rafael. Granada, Spain. [2]Department of Internal Medicine. Complejo Hospitalario Virgen de las Nieves. Granada, Spain.

Objectives: The START criteria (Rev Esp Geriatr Gerontol. 2009;44:273–9) aim to ensure prescription of drugs that have shown to be beneficial in certain diseases, in people over 65 years of age. Our objective was to compare the compliance with these criteria in patients treated by internists and geriatricians of a medium-long-stay hospital.

Material and method: A cross-sectional study was carried out that included a sample of 81 patients over 65 years of age, admitted to the Department of Internal Medicine of the San Rafael University Hospital of Granada, on April 10, 2012. The variables elicited by the physician in charge (internist or geriatrician) of each patient were age, gender, number and type of drugs prescribed, and diagnoses to analyse the drug prescription according to the patient's disease, following the START criteria. The prescription by internists was compared to the prescription by geriatricians.

Table 1 (EA-20). Comparison of the most frequent STOPP criteria, depending on the specialty of the prescribing physician

Most frequent STOPP criteria in internists (% of patients who present it)	Most frequent STOPP criteria in geriatricians (% of patients who present it)	p
PPIs at full therapeutic doses (esomeprazole 40 mg/day) for more than 8 weeks (38.2%)	PPIs at full therapeutic doses (esomeprazole 40 mg/day) for more than 8 weeks (31.9%)	0.555
Benzodiazepines in patients who are prone to falling (32.4%)	Benzodiazepines in patients who are prone to falling (19.1%)	0.174
Prolonged use of neuroleptics as hypnotics (32.4%)	Prolonged use of neuroleptics as hypnotics (10.6%)	0.015
Prolonged use of benzodiazepines with a long half life (26.5%)	Prolonged use of benzodiazepines with a long half life (19.1%)	0.434
Neuroleptics in patients who are prone to falling (20.6%)	Neuroleptics in patients who are prone to falling (21.3%)	0.940

Table 1 (EA-21). Annual Death Rates

	Total hip fractures	Total exitus	Crude mortality rate	Surgery mortality rate
2009	125	8	5.93%	2.22%
2010	137	14	10.21%	8.19%
2011	125	9	7.20%	3.52%

Table 1 (EA-22). Comparison of the START criteria that are infringed upon more frequently, depending on the physician's specialty

START criteria that were most infringed upon among internists (% of patients where said criterion was not met)	START criteria that were most infringed upon among geriatricians (% of patients where said criterion was not met)
Statins in diabetes mellitus if one or more vascular risk factors coexist (29.4%)	Statins with a history of arteriosclerotic disease (34%)
Statins with a history of arteriosclerotic disease (11.8%)	Statins in diabetes mellitus if one or more vascular risk factors coexist (29.8%)
Metformin in type-2 diabetes mellitus in the absence of kidney failure (8.8%)	Platelet antiaggregants in diabetes mellitus if one or more vascular risk factors coexist (19.1%)
Bisphosphonates in patients with maintenance oral corticoids (8.8%)	ASA or clopidogrel with a history of arteriosclerotic disease (14.9%)

Results: The group of patients attended by geriatricians (n = 47) was matched for age with the group attended by internists (n = 34) (77.6 ± 6.8 years vs 79.1 ± 7.7 years, respectively; p = 0.359). Internists prescribed more drugs than geriatricians (12.4 ± 3.3 vs 9.5 ± 2.9, respectively; p = 0.0001). Although the number of unmet START criteria was low in both groups, significant differences were found when comparing the mean of unmet START criteria in patients treated by internists and by geriatricians (0.97 ± 1.0 vs 1.49 ± 1.1, respectively; p = 0.033). When comparing both groups (see table), the only START criterion that showed any differences (p = 0.015) was the indication of statins in patients with arteriosclerotic disease.

Discussion: We detected that internists prescribe more drugs than geriatricians, although the latter infringe more START criteria than the former. The START criteria that were more infringed upon were the use of statins in primary and secondary prevention, probably due to the type of patients who are admitted to the hospital, usually the elderly, having multiple diseases and a life expectancy of less than 5 years. However, we believe that emphasis must be placed on the importance of these treatments in the management of vascular disease, even in elderly.

Conclusions: Statins were the drugs that were less prescribed in spite of their indication. The diseases in which more START criteria were unmet were diabetes and atherosclerotic disease. It is necessary to raise awareness on the benefit of prescribing these drugs, even in elderly patients for whom this is an indication.

EA-23
ARTERIAL HYPERTENSION AND COMORBIDITY IN ELDERLY PATIENTS

E. Martínez Velado[1], L. Seisdedos Cortés[1], M. Chimeno Viñas[1], P. Sánchez Junquera[1], A. de la Vega Lanciego[1], J. Soto Delgado[1], M. Mateos Andrés[1], V. López Mouriño[2]

[1]Department of Internal Medicine. Complejo Asistencial de Zamora. Zamora, Spain. [2]Department of Internal Medicine. Hospital Comarcal de Monforte. Monforte de Lemos (Lugo), Spain.

Objectives: Arterial hypertension (AH) represents the most prevalent factor of cardiovascular (CV) risk, and it presents with important economical repercussion on pharmaceutical expenses, morbidity and mortality which it associates. Other cardiovascular risk factors often coexist, making a joint approach of several different conditions to be necessary. All that should focus on a society where the prevalence of those diseases rise with aging, and because of this, it results of paramount importance since their increase is foreseen for our population during next decades due to a longer life expectancy linked to improvement of CV-related therapies and prolonged survival of those patients who suffer from them. Present recommendations from protocols and guidelines on hypertension include systolic blood pressures not higher than 140 mmHg and diastolic figures less than 90 mmHg for adults, while few articles assessing elder patients are available.

Material and method: Descriptive, observational and retrospective assessment was performed based on 100 randomized patients more than 80-year-old, admitted at Internal Medicine department of Zamora´s Hospital Virgen de la Concha through year 2011. Age, gender, rural or urban origin, presence of diagnosed AH or other CV risk factors (diabetes mellitus - DM -, heart, cerebrovascular and/or renal condition) and electrocardiogram changes, together with main cause of admission were assessed.

Results: 48 out of 100 patients analized were male gender, with a mean age of 88 years and higher number of patients from rural origin (64%). AH was present at diagnosis in 71% of them; two new patients added at discharge. DM prevalence of patients assessed was 30% and presence of heart or brain conditions was 32% and 19% respectively, rising up to 49% and 23% at discharge. Chronic kidney disease was verified in 29 patients according to serum creatinine levels and in 54 by means of MDRD formula. Two or more CV risk factors coexisting in 81% of patients assessed, AH together with heart and renal condition as most frequent association seen (17% of total amount). Atrial fibrillation (AF) was present in 33% of patients from our series, and another 17% showed other electrocardiogram changes. The higher percentage of admissions was due to heart failure (27%).

Discussion: In recent years a significant rise of incidence in CV risk factors has been seen for Spanish population, leading to its prevalence increase due to higher life expectancy as well as coexistence of several linked conditions for one only patient. A great percentage of individuals with chronic kidney disease would not be diagnosed if only serum creatinine levels were used. AF constitutes the main arrhythmia seen in developed countries, with general prevalence of 1%, rising up to 9% for patients more than 80-year-old, and progressively for elder age ranges.

Conclusions: There is a high prevalence of CV risk factors at this population here assessed, possibly linked to an elder age. The elderly often associate two or more CV conditions. The kidney constitutes the most frequently AH-related organ affected. Higher prevalence of AF patients within our series.

EA-24
EPIDEMIOLOGICAL STUDY OF CENTENARIAN PATIENTS ADMITTED IN THE DEPARTMENT OF INTERNAL MEDICINE I FOR A PERIOD OF 7 YEARS

L. Mateos Polo, M. García García, A. Crisolino Pozas, S. Argenta Fernández, N. Cubino Bóveda, A. Sánchez Rodríguez

Department of Internal Medicine. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca, Spain.

Objectives: To establish the clinical and biological characteristics, previous associated conditions, main diagnosis, comorbidities (decubitus ulcers, percutaneous feeding tubes), type of dementia, stage of dependency according to Barthel's index, death and cause of death in all the centenarian patients admitted in the Department of Internal Medicine I for a period of 7 years.

Material and method: We reviewed the clinical records of all centenarian patients admitted in the Department of Internal Medicine during a period of 7 years who met the following requirements: complete anamnesis and physical exploration, assessment of the degree of dementia and dependency, complete analysis, thoracic X-ray, brain CT scan and thoraco-abdominal CT scan. The statistics were made with SPSS.18 for the analysis of the descriptive frequencies, Student's t-test for independent variables and chi-squared test for dependent variables.

Results: In a period of 7 years, the Department of Internal Medicine I has registered 8603 arrivals. 77 cases were selected, 22 of which were ruled out because they did not meet the requirements presented in the Material and Methods section. The remaining 55 cases represent 0.8% of all the arrivals in the Department. In this group, 76.40% were women and 23.60% were men. 99% of the patients had a personal record of ictus (which was ischemic in 85% of the cases), anemia of chronic disease in 87.3% of the cases, hypertension in 58.2% of the cases, chronic kidney failure in 38.2% of the cases and diabetes mellitus in 20% of the cases. There was cognitive deterioration in 75.9% of the patients (slight in 42.6% of the cases and moderate in 22.2% of the cases). The type of dementia was vascular in 49% of the cases and Alzheimer's disease in 16.4% of the cases. The diagnosis at arrival was sepsis and/or shock in 58.7% (pneumonia in 38.2% of the cases, urinary tract infection in 14.6% of the cases), 14.5% of the cases presented brain thrombosis, 11% showed heart failure and 9.1% presented digestive bleeding. De novo acute renal failure was detected in 32% of the cases, and this finding showed a statistically significant association with the death of the patients ($p < 0.02$).15% of the patients were institutionalized and 3.6% of the patients had a feeding tube. The death rate was 21.8%, with no significant association with sex (p 0.52; OR 0.58). The cause of death was sepsis in 75.1%, and this factor had a statistically significant relation with the creatinine levels ($p < 0.05$; OR 0.5).

Conclusions: Our series reveals a high proportion of women of more than 100 years old, with vascular dementia, who survived a previous ictus, hypertense and diabetic, with a slight cognitive deterioration, who are not institutionalized and do not use a feeding tube, compared with other series that show a higher proportion of centenarian patients who are institutionalized, with gastrostomy feeding tubes and moderate or severe cognitive deterioration. Our centenarian patients, both men and women, die because of sepsis secondary to community-acquired pneumonia, and kidney failure is the only factor significantly associated with their deaths.

EA-25
DEVELOPMENT AND VALIDATION OF AN INDEX TO PREDICT MORTALITY OR READMISSION AFTER DISCHARGE FROM AN ACUTE GERIATRIC UNIT (AGU)

M. Cabré Roure[1], J. Fernández Fernández[1], L. Vilar Elias[1], R. Monteis Cahis[2], E. Palomera Fanegas[3], M. Serra-Prat[3]

[1]Department of Internal Medicine, [2]Day Hospital of Complex Frail Patients. Hospital de Mataró. Mataró (Barcelona), Spain. [3]Department of Research. Consorci Sanitari del Maresme. Mataró (Barcelona), Spain.

Objectives: Acute hospital readmissions are frequent and costly and often preventable. The objective is to develop an index of risk of readmission or death within three months after discharge to help physicians identify patients who could benefit from a more intensive and coordinated intervention to avoid readmissions in acute hospitals.

Material and method: A prospective observational study of a cohort of patients over 70 years hospitalized for a medical condition in an AGU. A random selection of 70% of all patients discharged during the period January 2001 to December 2010 for the study of factors associated with mortality and readmission at three months and the development index. The remaining 30% of patients were selected for the validation study. We excluded patients who died during hospitalization and patients with metastases. Study factors: sociodemographic variables, comorbidities, geriatric syndromes, cognitive status, functional status (Barthel Index), nutritional status (Mini Nutritional Assessment), dysphagia, previous admissions in the last year, and hospital length of stay and laboratory. We recorded the mortality and readmission after discharge of three months. The variables associated with mortality and readmission at three months were included in multivariate analysis. The index included those variables with significant independent effect.

Results: We studied 2029 patients (61.0% women), mean age 84.8 (6.2) years. Mortality or readmission at three months was 36.6%. The validation cohort was 860 patients (mortality or readmissions at three months of 36.5%). The Index was constructed with a maximum of 9 points with the following 9 items: cancer, oropharyngeal dysphagia, ischemic heart disease, heart failure, chronic lung disease, anemia (Hb < 10), lymphopenia (< 800), number of previous admissions in the last year and hospital length of stay (more than 10 days). In the validation cohort, there was an area under the ROC curve of 0.647. In patients with an index of 0 points, mortality and readmissions within three months was 13.6%, those with an index between 0.5 and 1.5, 23.3%, those with an index between 2 and 3.5 points, 40.1%, those with an index between 4 and 5.5 points, 50.4% and in those who scored 6 or more points 75.0%.

Conclusions: The proposed prognostic index uses 9 easily identifiable risk factors at discharge, allows a stratification of patients over 70 discharged from AGU with low, medium or high risk of mortality or readmission to the three months. This index could be a useful tool to help clinicians identify patients who require a more intensive and coordinated intervention of care in the different settings.

EA-26
PREDICTING FUNCTIONAL RECOVERY IN ELDERLY HOSPITALIZED FOR AN ACUTE ILLNESS

M. Cabré Roure[1], J. Fernández Fernández[1], L. Vilar Elias[1], R. Monteis Cahis[2], E. Palomera Fanegas[3], M. Serra-Prat[3]

[1]Department of Internal Medicine, [2]Day Hospital of Complex Frail Patients. Hospital de Mataró. Mataró (Barcelona), Spain. [3]Department of Research. Consorci Sanitari del Maresme. Mataró (Barcelona), Spain.

Objectives: The incidence of functional decline after hospitalization is a common complication, increases with age and is an indicator of poor prognosis. This decline can probably be prevented by adapting hospital units to the health needs of the elderly population. The objective is to identify those risk factors associated with functional recovery during hospitalization to help select and plan care during hospitalization and discharge.

Material and method: Prospective observational study of a cohort of patients over 70 years hospitalized for a medical problem in acute geriatric unit (AGU) for the period January 2001 to December 2010. We excluded patients with Barthel Index (BI) levels < 5 and those who died during hospitalization. Study factors: age, sex, origin, comorbidities, Charlson comorbidity index, discharge diagnosis, geriatric syndromes, cognitive status, nutritional status (Mini Nutritional Assessment) (MNA), handgrip, dysphagia, laboratory data (hemoglobin, serum albumin, cholesterol, and lymphocytes), and functional status: BI pre-admission, admission and discharge, and length of hospital stay. Functional loss was

defined as a decline of 5 points in BI at admission respect to pre-admission. Partial functional improvement was defines as an improvement of 5 points or more from admission to discharge and complete functional improvement as an improvement in BI at discharge that reach the BI score pre-admission (± 5 points). The variables associated with functional recovery were included in a multivariate analysis.

Results: We studied 2224 patients (61.9% women) with a mean age of 85.1 (2.8) years. 49.5% were over 85 years. The pre-admission, admission and discharge BI were 72.0 (24.8), 42.2 (26.0) and 57.0 (28.5) respectively. The length of hospital stay was 10.9 days (7.7). The functional recovery was: No recovery 572 cases (26.1%), partial recovery 1130 cases (51.6%) and complete recovery 489 cases (22.3%). The independent variables associated with complete recovery were: age (< 85 years) (OR: 0.71; 95%CI: 0.51-0.98), chronic lung disease (OR: 1.46; 1.05-2.01), loss of BI at admission (respect to pre-admission) under 40% (OR: 2.08; 1.46-2.96), handgrip (> 18 kg in men and > 9 kg in women) (OR: 0.59; 0.42-0.83), and hospital days (OR: 0.94; 0.91-0.97).

Conclusions: We identified some factors associated with functional recovery of elderly patients during hospitalization in an AGU, such as age, chronic lung disease, pre-admission functional capacity, hand grip or days of hospital stay. Attention to these factors can help to improve functional capacity at discharge.

EA-27
HOSPITAL DEATHS IN CENTENARIAN PATIENTS

M. Chimeno Viñas, E. Martínez Velado, A. de la Vega Lanciego, P. Sánchez Junquera, J. Soto Delgado, M. Mateos Andrés, P. García Carbó, L. Mustapha Abadie

Department of Internal Medicine. Complejo Asistencial de Zamora. Zamora, Spain.

Objectives: Life expectancy at all ages has continued to increase in other countries. Nowadays, the centenarian patients are a particular and little-known group. There is not much information about hospital mortality in these patients. We propose to know the survival after hospitalization in the centenarians in CAZA (Complejo Asistencial de Zamora).

Material and method: Retrospective, observational study of patients ages 100 years and older who died in CAZA (Complejo Asistencial de Zamora) during the last four years. We reviewed the medical records of these patients and analyzed the next data: age, sex, length of stay, admission service and diagnosis.

Results: 27 centenarians died in the study period: 6 (4 female/2 male) in 2008, 7 (6 female/1 male) in 2009, 9 (6 female/3 male) in 2010 and 5 (female) in 2011. The mean age was 101.4 years (range 100 to 107 years). There were 21 women (78%) and 6 men (12%). The mean length of stay was 9.1 days. The admitting services were: Internal Medicine 24 patients (88%), Neurology 1 centenarian (4%), Traumatology 1 patient (4%) and Intensive Care Unit another patient (4%). See Table 1.

Discussion: There is not much information about centenarian patients in the papers. The results of our study show: a high mean age (101.4 years) and women die more. Respiratory infection is the first cause of death in our study. Although hip fracture is important cause of admission in other publications, it´s no relevant in our paper. We have also found a great variety of diagnoses.

Conclusions: 1. Centenarian women die more than men in the hospital during the last four years. 2. High mean age (101.4 years). 3. Respiratory infection is the first cause of death in our centenarians.

EA-28
CHRONIC OBSTRUCTIVE PULMONARY DISEASE AND LUNG CANCER: A COMMON ASSOCIATION

S. Ragozzino, R. Díez Bandera, R. Macías Casanova, N. Castro Iglesias, A. Barbosa Ventura, G. Spalter Glicberg, J. Torres Triana, F. Domínguez Moronta

Department of Internal Medicine. Hospital Clínico Universitario de Salamanca. Salamanca, Spain.

Objectives: Chronic obstructive pulmonary disease (COPD) and lung cancer have a strong relationship. The aim of this study is to describe epidemiological and clinical characteristics of the patients with both diagnosis of COPD and lung cancer.

Material and method: We performed a retrospective analysis of COPD patients diagnosed with lung cancer between 2009 and 2010 in a tertiary hospital. We described: epidemiological characteristics such as age, sex, comorbidities, number of smoking pack-years, occupational exposure; COPD features such as phenotype, forced expiratory volume in 1 second (FEV1%), carbon monoxide diffusing capacity (DLCO) and Global Initiative for Chronic Obstructive Lung Disease (GOLD) stage; lung cancer characteristics such as histology, stage and follow up.

Results: We recollected data about 61 patients. Fifty nine of them were male (96.7%), with a mean age (standard deviation) of 67.2 (9.8) years. Regarding underlying diseases, the patients had a mean Charlson Index of 2.6 (2.5). Seventeen patients (27.9%) presented history of another malignancy. Among them, 7 tumours (38.9%) were tobacco-related: tongue, larynx, esophagus, urinary bladder, lung and kidney (2). All the patients had history of tobacco smoking: 41 (67.2%) were ex-smokers. The mean number of pack-years smoked was 62.3 (28.9). In 13 cases (26.5%) there was also history of occupational exposure. COPD phenotypes were: chronic bronchitis/frequent exacerbator 29 (47.5%), emphysema 21 (34.4), asthma-COPD 7 (11.5%), others 4 (6.6%). FEV1% and DLCO mean values were 67.3% (21.1) and 70.8% (17.0), respectively. About GOLD stage, 20 patients (32.8%) were in GOLD I, 27 (44.3%) GOLD II, 7 (11.5%) GOLD III, 7 (11.5%) GOLD IV. Regarding lung cancer histology, it was available in 58 cases and all were non small cell lung cancer: squamous cell carcinoma 32 (55.2%), adenocarcinoma 14 (24.1%), large cell carcinoma 4 (6.9%), other types 8 (13.8%). We registered a higher proportion of squamous cell carcinoma (72.7%) among patients with GOLD stage III and IV. Thirty eight patients (64.4%) were diagnosed in early stage (I and II), 11 (18.6%) in locally advanced stage, 10

Table 1 (EA-27). Main diagnosis

	Number of patients
Respiratory infection	10
Sepsis	4
Heart failure	3
Stroke	3
Gangrene	2
Hip fracture	1
Dehydration, neoplasia, renal failure, myocardial infarction	1, 1, 1, 1.

(16.9%) in metastatic stage. About treatment, 34 patients (55.8%) received surgery, in 9 cases with adjuvant chemotherapy, 8 (13.1%) combined radiotherapy and chemotherapy, 5 (8.2%) radiotherapy alone, 5 (8.2%) chemotherapy alone, 9 (14.8%) palliative care. Follow up was available in 36 cases: at the moment of the study (mean follow-up time of 16 months) 17 patients (47.2%) died and 4 (11.1%) were in progression disease, whilst 11 (30.6%) were disease-free and 4 (11.1%) in partial response or in stable disease. Stratifying by GOLD stages, we didn't find significant differences in cancer stages, but we did find in clinical outcomes: GOLD stage III and IV were associated with higher rate of progression disease and mortality (90.9%).

Discussion: Our study is characterized by a low proportion of women, probably related to the smoking trends in Spain, with women massively exposed after 1950s. Of special interest is the high prevalence of other malignancies among our patients, confirming the increased cancer risk among COPD patients recently reported by other authors. In agree with previous observations, most of the patients (77.1%) were in milder GOLD stages. The most frequent tumour type was squamous cell carcinoma. Its prevalence was greater among patients with more severe GOLD stages. No case of small cell lung cancer was registered in our study population. A great proportion of patients was diagnosed in early stages and received surgical treatment. COPD patients with more severe GOLD stages had worse outcomes despite presenting no differences in cancer stages with those with milder GOLD stages.

Conclusions: COPD and lung cancer are frequently associated. Lung cancer occurs more frequently in patients with milder airflow obstructions and the most prevalent histological type is squamous cell carcinoma.

EA-29
NUTRITIONAL ASSESSMENT OF PATIENTS IN A WARD OF INTERNAL MEDICINE

R. Serras Jorge[1], R. Gomes[2], F. Santos[3], R. M Santos[1]

[1]Department of Internal Medicine, [2]Department of Immunoallergology, [3]Department of General Surgery. Centro Hospitalar e Universitário de Coimbra HUC. Coimbra, Portugal.

Objectives: Assess the nutritional profile of inpatients in a ward of internal medicine. Check the consistency between the various methods used. Assess the weight variation during hospital stay.

Material and method: All inpatients were evaluated by two examiners. Measured the weight, height, tricipital (TSF) and subscapular (SSF) skinfolds, brachial circumference (BC) and calf circumference (CC). Each parameter was rated 2 times, taking into account the tolerance values for the discrepancy between measurements of skin folds and calculated the mean. The weight and the height were estimated by Chumlea formulas when it was not possible to evaluate them. The ideal weight was calculated by the Lorentz formula when the patient didn't mentioned his initial weight. Patients unable to undergo the anthropometric methods were excluded. The results are presented with mean and standard deviation, maximum and minimum. Patients were classified according to WHO's Body Mass Index (BMI) criteria. Material used: tape measure, scale, Harpender skinfold caliper, properly calibrated.

Results: Assessed 28 patients with an mean age of 76 (± 13.73, Max 97, Min 39). The BMI was 20.8 Kg/m^2 (± 4.13, Max 29.1, Min 11), with 16 patients in the normal weight category, 3 overweight and 8 underweight. The mean weight variation was 18.2% (± 9.8, Max 37.8%, Min 1.6%), 4 patients showing weight increase and the remaining weight loss. The mean weight loss was 13.7 Kg (± 5.08, Max 25.2, Min 4.9). Individuals with normal BMI or underweight, had all TSFs and BC under reference values, with the exception of 3 patients (1 with normal, another with TSF above average and another with normal BC).

Discussion: Although most patients have a normal BMI, almost all patients had weight loss. Most patients with normal BMI presented TSF and BC below the average of reference values, which may be related to the fact that 12 had pathologies with predisposition to the formation of edema.

Conclusions: We found that BMI may not adequately reflect the nutritional status, particularly if used alone. The prevalence of weight loss is high among inpatients. Further studies are needed in order to identify the right methods to assess nutritional status and to identify the reasons and consequences of weight loss.

EA-30
EPIDEMIOLOGICAL STUDY OF LOWER GASTROINTESTINAL BLEEDING IN THE PATIENTS ADMITTED IN THE INTERNAL MEDICINE I UNIT OF THE CLINICAL HOSPITAL OF SALAMANCA IN A PERIOD OF 3 YEARS

L. Mateos Polo, R. Fernández Santalla, M. García García, S. Argenta Fernández, J. Herraez García

Department of Internal Medicine. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca, Spain.

Objectives: Retrospective study of patients with a diagnosis at arrival was lower gastrointestinal bleeding (LGIB), who were admitted in the Internal Medicine I Unit in a period of 3 years, in order to establish their clinical and biological characteristics, age, sex, associated diseases, gastroerosive drug use, impact of the bleeding and death rate.

Material and method: We gathered the clinical records of all patients with LGIB diagnosis from January 2009 to December 2011 which included complete anamnesis, complete blood count, use of erosive medication, symptoms, duration and impact of bleeding, gastroscopy and/or colonoscopy, indication of CT scan and/or arteriography, diagnosis and death. The duration of the bleeding was classified as acute (less than 3 days) and chronic and/or continuous (days or weeks). The impact of the bleeding was classified as: slight: < 15% or between 500-750 ml; moderate: 15-25% or 750-1,250 ml; severe: 25-35% or 1,250-1,750 ml; and massive: > 35% or > 1,750 ml. The statistics were made with SPSS.18 for the analysis of the descriptive frequencies, Student's t-test for independent variables and chi-squared test for dependent variables.

Results: 101 patients were analyzed, and 27 were ruled out because they did not meet the requirements. Out of the remaining 74 patients, 51.4% were women with an average age of 86 years and 48.6% were men with an average age of 79 years. In 43% of the cases, no associated disease was found. 45.9% of the patients did not receive iatrogenic medication, while 37% received antiaggregants (58% of the women) and 13.5% received anticoagulants. A decrease in the hemoglobin levels revealed a significant relation with age (higher in women $p < 0.019$), with the use of iatrogenic medication ($9 < 0.24$) and with the associated diseases ($p < 0.013$). The main symptom at presentation was rectorrhagia in 79.7% of the cases (85% of the women), and the bleeding was acute in 90% of the cases. The colonoscopy was diagnostic in 86.5% of the cases: diverticulosis in 23.5% of the cases (87% of the women), hemorrhoidal varices in 20.3% of the cases (67% of the women), colon neoplasia in 9.5% of the cases, and ischemic colitis in 5.4% of the cases. The CT scan was not performed in 77% of the patients. The bleeding had no impact in 54% of the cases.

Conclusions: Patients with LGIB admitted in the Internal Medicine I Unit are elderly women who receive platelet antiaggregants and/

or anticoagulants as iatrogenic factors, with acute rectorrhage secondary to diverticulum and/or hemorrhoidal varices as the main symptom, without significant hemodynamic impact. We can highlight the profitability of colonoscopy in the diagnosis of lesions that cause LGIB, probably due to the presence of an endoscopist in our internal Unit and our hospital, which makes it possible to obtain an early diagnosis. There is a remarkably low number of colon neoplasias in our series.

EA-31
EPIDEMIOLOGICAL STUDY OF THE PATIENTS WITH ACUTE CEREBROVASCULAR ACCIDENT (ACV) ADMITTED IN THE UNIT OF INTERNAL MEDICINE I IN THE CLINICAL HOSPITAL OF SALAMANCA IN A PERIOD OF 3 YEARS

L. Mateos Polo, A. Crisolino Pozas, C. Martín Hernández, S. Argenta Fernández, M. Pérez García

Department of Internal Medicine. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca, Spain.

Objectives: Retrospective study of patients with a diagnosis at arrival of acute cerebrovascular accident who were admitted in the Unit of Internal Medicine I in a period of 3 years (from January 2009 to January 2012) in order to determine the kind of ACV (hemorrhagic, thrombotic), the clinical and biological characteristics, age, sex, associated diseases, degree of dementia according to Barthel's Index, complications and death rate.

Material and method: We reviewed the clinical records of all the patients with a diagnosis at arrival of ACV from January 2010 to April 2012 which included complete anamnesis, associated diseases, EKG, thorax X-ray, CT scan and/or brain NMR, diagnosis, treatment at discharge and death. The statistics were made with SPSS.18 for the analysis of the descriptive frequencies, Student's t-test for independent variables and chi-squared test for dependent variables.

Results: 201 patients were analyzed, and 19 of them were ruled out because they did not meet the requirements in the "Material and method" section. Out of the 182 remaining patients, 57.1% were women with an average age of 85 years and 42.9% were men with an average age of 83 years. No associated diseases were found in 43% of the patients. 62% of the patients presented normal sinus rhythm, with no statistically significant differences regarding sex, but significant with ACV emboli and alteration of rhythm ($p < 0.001$) In 34% of the cases there was some alteration in the rhythm (31% presented auricular fibrillation and 2.4% presented flutter). Some degree of dementia was observed in 18.7% of the patients. 46% of them had a personal record of arterial hypertension, 24% were diabetics, 23% had suffered a previous ACV, ischemic cardiopathy was found in 15.2%, and in 34% of the patients there were more than 2 different diseases in their personal records. The diagnosis at arrival was ischemic ictus in 93% of the cases and hemorrhagic ictus in 6.6% of the cases. 18% of the patients were anticoagulated, with INR > 2.1, with no statistically significant relation with the presence of hemorrhagic ictus. 40% of the patients received antiaggregants (58% of the women). In 57% of the women there was some complication (20% were respiratory complications), and 19.2% of the patients died, with no statistically significant relation with sex.

Conclusions: Patients admitted in the Unit of Internal Medicine I with ACV are generally women of a very advanced age with a personal record of previous ACV, hypertense and diabetic, with non-cardioembolic stroke, who receive platelet antiaggregants. Exists on relation of 34 times more of cerebral embolism on the person with atrial fibrillation. The ACV is mainly complicated due to respiratory infections, and it presents a high death rate.

EA-32
THE JOINT CHRONIC DISEASE PATIENT PROGRAM (CP) OF THE HEALTH DEPARTMENTS OF ELCHE-CREVILLENTE AND TORREVIEJA

M. Antolinos García[1], M. Medina Martínez[2], V. Canovas García[3], C. Catalán Oliver[2], J. Blázquez Encinar[4], J. Zafrilla Martínez[4], H. Caro Moreno[5]

[1]Family Doctor, [2]Department of Management Assistance, [3]Department of Internal Medicine. Hospital del Vinalopó. Elche-Crevillente. Alicante, Spain. [4]Department of Internal Medicine. Hospital de Vinalopó y Hospital de Torrevieja. Alicante, Spain. [5]Department of Primary Care. Hospital Torrevieja Salud Ute. Torrevieja. Alicante, Spain.

Objectives: Due to progressive ageing of the population, the number of chronic disease has increased. Such patients require complex care and use a high percentage of socio-health resources. Thus, a different management model is required to ensure continuity with a multidisciplinary approach to improve quality of healthcare. Consequently, the Health Departments of Torrevieja and Elche-Crevillente have conceived a comprehensive chronic disease patient management pathway between Primary Care (PC) and Hospital Care (HC).

Material and method: The Chronic Program has been conceived to monitor chronic disease patients, both globally and at all levels of the Kaiser pyramid in order to avoid patients moving up to another level. "+Health" (in Spanish, +Salud) is a preventive healthcare program to be carried out at Primary Care by the Nursing team that will focus on women, teenagers and adults' healthcare prevention and vaccination. Workshops will also move towards the same direction: to train caregivers, promote self-care and prepare informed patients. Multidisciplinary working groups composed of PCP (Primary Care Physicians), Hospital Specialists and Nurses are generating action protocols, based on Clinical Practice Guidelines, of most common diseases (heart failure, cirrhosis, chronic bronchitis, chronic liver disease, HIV, cardiovascular risk, chronic kidney failure, arthrosis, cancer or degenerative pathology) for the monitoring of patients at levels I and II of the Kaiser pyramid. The CP has developed a pathway to ensure care continuum for those complex patients at the pyramid's apex or level III. Such patients have to meet at least one major inclusion criteria (a diagnostic category in the multiple-condition criteria in Andalusia) and two minor ones (age: > 75, multi-medication: > 12 drugs, Barthel index: < 60 and frequent hospital user: > 6 admissions and/or 10 ED visits in 2011). Management groups have been formed in each Health Centre composed of a Liaison Internist (LI), half the PCPs, a Case Managing Nurse (CMN), a Social Worker (SW) and a Community Nurse (CN). The management groups meet once a week to revise each PCP's complex patients and to devise an individual treatment pathway in order to ensure care continuum via on-line PC-HC referrals on their own Florence EMR system (shared Electronic Medical Record system for PC and HC) and telephone follow-up. In both Health Depts. admissions take place in Internal Medicine, a feature that allows for a proactive and fast identification of patients likely to enter the program. Thus, the Liaison Hospital Nurse (LHN) can notify the SW and the LI as well as include the patient in the CP on "Chronic Patient", the specific Florence episode, and, prior to discharge, may schedule appointments with the PCP and the CMN. In the future, an alert will be issued addressed to the PCP or the LI in case of hospital readmission. A Call Center has also been envisioned in order to follow up with patients via standardized calls and provide information support to patients. Soon begin a pilot program for telemonitoring.

Results: Using the Florence program we have stratified the population and obtained 500 Level-III patients in each Dept. The CP started with the continuous assessment of home visits, ED visits, hospital admissions, phone calls, avoided costs as well as patient,

caregiver and professional satisfaction. Our process indicator is the pharma-therapeutical revision (REFAR). Indicators at the beginning show 1017 readmissions and 2007 ED visits.

Conclusions: The program is an efficient tool for the correct diagnosis, treatment and follow-up of chronic disease patients from a multidisciplinary point of view. Our aim is to improve quality of healthcare and reduce resource consumption.

EA-33
EMERGENCY DEPARTMENT USE BY EXTREMELY ELDERLY PATIENTS (NONAGENARIANS)

J. Benítez Macías[1], V. Reina Lora[1], F. Brun Romero[2], D. García Gil[1], M. Moreno Gómez[1]

[1]Department of Emergency, [2]Department of Traumatology. Hospital Universitario Puerta del Mar. Cádiz, Spain.

Objectives: To document presentation characteristics, use of resources, diagnosis, outcomes and length of stay of very elderly patients in an emergency department (ED) metropolitan hospital.

Material and method: A review of medical records was carried out for all patients aged more than 89 years presenting to ED (medical and traumatology wards) over two randomly 30-day periods: period A in summer (July 1st-30th 2011) and period B in winter (January 1st-30th 2012). It was conducted to identify demographic features, main admission symptom, medical history, physical dependency (defined as Barthel score less than 100), request for laboratory tests or X-ray examination (thoracic, abdominal or skeletal), diagnosis, consequences, length of time spent in ED (minutes) and re-visit in a 30-day period. Descriptive and analytical research methods were used. Qualitative variables were expressed as frequencies (percentages) and quantitative variables as medians (25th and 75th percentiles). Statistical analysis was performed using non-parametric tests and a two-tailed p value less than or equal to 0.05 was considered statistically significant.

Results: One hundred and seventy one subjects were included in the study, this means 1.25% of the total who were attended in those periods of time; 112 (66) females and 59 (34) males. The median age of patients was 92 (90-94) years and the period A to period B ratio was 1:1.7. The most common admission symptoms were: cardiorespiratory 47 (38), musculoskeletal 35 (21) and abdominal 24 (14). Hypertension was the most frequent cardiovascular risk factor: 120 (71), more often than diabetes: 44 (26). Ninety eight (58) patients used any antiaggregant drug, from which 89 (91) was acetylsalicylic acid. One fifth of patients had atrial fibrillation, nevertheless only 10 (6) of them were anticoagulated (8 (80) used acenocumarol). The number of patients receiving drugs to protect against acute gastric mucosal lesions was 116 (69), mostly proton pump inhibitors 110 (95). Ninety five (59) patients suffered from any level of physical dependence, as well as 64 (38.6) were already diagnosed as having dementia. Laboratory blood tests were ordered in 121 (71) subjects and X-ray examinations in 139 (81.3); 97 (57.1) patients were taken a chest radiography. The diagnosis made by ED physicians were respiratory infection in 38 (22) patients, wound or contusion in 18 (10.5) and urinary tract infection in 15 (8.8) of them. Fifty (29) patients were hospitalized: period A 15 (24) and period B 35 (32); no statistically significant difference. The median of time spent in ED by a patient was 240 (130-379) minutes: male 279 (148-490) vs female 213 (117-354); p = 0.02. Length of time spent by patients when a laboratory blood test was required was 310 (197-439) and when the subject was submitted to a chest radiography was 314 (186-439). There was no significant difference in the duration of the stay when it was compared among patients who suffered from physical dependence (272 (130-391)) or dementia (275 (144-409)) and those who did not. Forty (23) subjects re-visited the ED in a 30-day period, 35 (68) of them consulted for the same symptoms.

Discussion: Within the proper limits of study design (retrospective, deficiency in contents of the medical records), summer and winter random series of very elderly patients visiting our ED were described. This improves knowledge and therefore care of these patients.

Conclusions: We found in this survey that very elderly patients attended are mostly female and hypertensive. More than a half are receiving antiplatelet therapy, with cardiorespiratory and musculoskeletal as predominant disorders and a high incidence of subjects who suffered from physical dependency were assisted. Complementary exams were required in most of cases, the time spent in the ED by male was significant longer than female and nearly a quarter of patients consulted again in a 30-day period.

EA-34
ASSESSMENT OF THE INTEGRATED CARE PLAN FOR POLYPATHOLOGICAL PATIENTS IN BAJO DEBA AREA

E. Montero Aparicio[1], A. Maíz Egaña[1], A. Moreno Rodrigo[1], N. Gurruchaga Arrillaga[1], P. Bernardo Galán[1], F. Egido Arroyo[2], M. García González[1], J. Taboada Gómez[3]

[1]Department of Internal Medicine, [2]Department of Primary Care, [3]Department of Preventive Medicine and Epidemiology. OSI Debabarrena. Mendaro. Guipúzcoa, Spain.

Objectives: 1. The global objective is to modify the natural course of disease, delaying its progression and improving healthstatus in patients with multimorbidity of the region of Bajo Deba. 2. To describe de program, the activities established and initial results.

Material and method: Investigation-action project. To achieve the objective of establishing an Integrated Care Plan (ICP) of polypathological patient, different levels of care (Primary Care and Specialty Care) are covered such as different professional groups (medical and nursing) involved. This process rests on the circuit of communication and the relationship established between levels and coordination between states. The main principles of the model are: 1. Identification and risk stratification of the polypathological patients. 2. Polyphathology criteria. 3. Integral evaluation and individualized care program. 4. Reference internist sectorization. 5. High resolution outpatient setting. The five Primary Care Centres belonging to our Speciality Care Hospital have been progressively included during one year. We present the analysis of patients included from March 2011 to May 2012 of one of the centres. The main health outcome variables studied are mortality, days of hospital admission, Barthel, Tinetti, Lawton and Brody and social-familiar Gijon Index and well as anthropometric and analytical variables.

Results: A total of 183 patients have been included in the 14 months of plan developing with 127 hospitalizations (in the first 8 months patients were recruited, if fulfilled polypathology criteria, from hospital, adding patients from Primary Care later on). 44.3% are females and the mean of age is 79.8 years. The median polypathology criteria is of 2 and 6.5% of patients fulfil 5 criteria. The main three chronic diseases are COPD, chronic heart failure and chronic renal failure. 28% present a moderate rate of dependence (Barthel) with high risk of fallings in 69% of patients (Tinetti). Social risk (Gijon) is determined low in 48% and 58% have instrumental management capacity (Lawton Brody) reduced. 77% require carers, husband or wife in 38% of them. The mean of hospital stay is 8 days. 86 consulting phone calls have been registered with a satisfactory communication and relationship between both levels (Primary and Speciality Care). 36 patients have been followed by outpatient setting (Day Hospital, High resolution outpatient), and 16 evaluated in the Emergency Room avoiding in all of them the hospitalization. One clinical meeting is hold monthly with an average attendance of 10 doctors and 5 nurses.

Discussion: Preliminary results are positive. However, more study time is necessary to draw general conclusions. The results will help

us with risk dependent intervention stratifications and integral evaluation and individualized care program offer, establishing global strategic objectives in the polypathological patient assistance.

Conclusions: The increased prevalence of chronic diseases and the consequent increase in the number of patients with multiple chronic conditions makes it necessary to establish a new model of shared care intervention among primary care and specialty care. The establishment of a model of this type should have a significant beneficial impact on morbidity and quality of life related to health in this patient population.

EA-35
LENALIDOMIDE IN COMBINATION WITH DEXAMETASONE IS ACTIVE AND SAFE IN ELDERLY PATIENTS WITH MULTIPLE MYELOMA IN RELAPSE OR REFRACTORY

A. Cánovas, J. Barreiro, J. Alonso

Department of Internal Medicine. Hospital Universitario de Cruces. Barakaldo. Bizkaia, Spain.

Objectives: Lenalidomide is an oral immunomodulatory drug that with proved efficacy on increasing response rates and survival in relapsed or refractory multiple myeloma (MM), used in combination with dexametasone (L/D). In unselected patients, the results in terms of efficacy and toxicity may be different from those obtained in controlled studies. Our objective was to evaluate the efficacy and toxicity of L/D as rescue therapy in a unselected population of relapsed or refractory MM patients.

Material and method: All the patients with MM followed in our department from January the 1st 2007 to January the 31st 2012 were reviewed. We analyzed the patients with relapsed or refractory disease after one or more therapeutic regimens who received treatment with L/D. Informed consent was obtained in every patient, and anti-thrombotic prophylaxis with low molecular weight heparin routinely prescribed. Treatment was continued until the occurrence of disease progression or unacceptable adverse events. Efficacy variables were response rate and time to progression (TTP). Complete response (CR) was defined as the disappearance of both monoclonal serum protein (tested by IF) and urinary component. Partial response (PR) was defined as a 50-99% monoclonal serum protein reduction and 90% reduction in urinary component, whereas non response (NR) was defined by an inferior reduction or progression. Response was assessed after at least one L/D treatment course. Toxicity WHO scale was used as a safety measure. Statistical methods: descriptive, chi^2, Fisher exact test, Kaplan-Meier tables, log-rank test and Cox binary logistic regression.

Results: Twenty-two patients were included, with a median age of 76 years (47-86) and 68% of them were 70 or more years old. The median time from diagnosis was 4.1 years (0.3-20), and median number of prior therapies 4 (1-13). Forty-five per cent had previously undergone an autologous stem cell transplantation (ASCT), 91% had been treated with bortezomib and 23% with thalidomide. The reason for therapy with L/D was relapse in 12 cases and refractoriness to prior therapy in 10. The median duration of treatment with L/D was 3.8 months (0.13-51). Twenty-one patients were assessable for response: 4 obtained CR, 13 PR (CR + PR: 81%) and 4 NR. Eighteen patients relapsed in the follow-up. The median TTP from the beginning of L/D was 18.6 months and the median survival 27.5 months. We analyzed the association of age, functional status, reason for therapy, previous ASCT, number of previous therapies, and time to treatment with L/D with response to treatment and TTF, but none of them was significantly associated. Overall survival, functional status and reason for therapy were near to statistical significance (p: 0.06). Most common toxicity was hematological (neutropenia or thrombocytopenia grade 3 or 4) in 13 patients, and it was significantly associated with a higher number of prior lines of therapy (p: 0.078) or previous ASCT (p: 0.015). With of the Cox binary logistic regression only previous ASCT remained significant. Four patients had non-hematological toxicity grade 3, and this was related to previous ASCT previous (p: 0.0082).

Discussion: : L/D as salvage therapy in refractory/relapsed MM showed, in this series of heavily pre-treated and elderly patients, similar efficacy to that reported in pivotal clinical trials in this setting with acceptable tolerance. The response and the TTP was not related with age therefore this therapy seems a good option for aged MM patients relapsed or refractory.

Conclusions: In our experience, the combination L/D has a remarkable efficacy in response rate and TTP in relapsed and refractory MM patients, even in elderly and previously multi-treated patients. Adverse events were mostly hematological and controllable. The only significant variable related with the toxicity was prior ASCT.

EA-36
IMPACT OF POVERTY ON HEALTHCARE DEMAND FOR A HOSPITAL-AT-HOME UNIT OF A SOUTHERN EUROPEAN IN A 25-YEAR PERIOD

J. Galindo Ocaña, C. Aguilera González, R. Parra Alcaraz, S. Gutiérrez Rivero, J. Romero Mena-Bernal, J. Garrido Nieto, S. Sobra Calderón, A. Fernández López

Department of Internal Medicine. Hospital Virgen del Rocío. Sevilla, Spain.

Objectives: It is well known that social disadvantage associates to poorer healthcare outcomes. Objectives: To determine the areas with higher impact of social exclusion on healthcare demand for a hospital-at-home unit during a 25-year period.

Material and method: Since 1984 to 2010, all consecutive patients admitted to a hospital at home unit affiliated to a southern European university hospital were included. Patients were classified for place of living (city districts). The total amount of patients and their percentages, and the population of the respective districts are exposed below.

Results: 11,342 patients were attended in the study period. The population of the Hospital Universitario Virgen del Rocío accounts for 550,000 inhabitants among the population of Seville: District 1 (Centre) 47,524 inhabitants (8.64%), Districts 4 and 5 (Nervión) 86,564 inhabitants (15.74%), District 6 (Amate, Candelaria, La Plata, Palmete) 82,871 inhabitants (15.07%), District 10 (Triana) 43,361 inhabitants (7.88%), District 12 and 14 (Bermejales y Bellavista) 33,692 inhabitants (6.13%) and District 13 (Polígono Sur) 29,235 inhabitants (5.32%). The healthcare demand per district was as follows: District 1 (Centre) 782 patients (6.90%), Districts 4 and 5 (Nervión) 1,305 patients (11.51%), District 6 (Amate, Candelaria, La Plata, Palmete) 2,476 patients (21.83%), District 10 (Triana) 1,426 patients (12.57%), Districts 12 and 14 (Bermejales y Bellavista) 458 patients (4.04%) and District 13 (Polígono Sur) 1,642 patients (14.48%).

Discussion: Thus, Districts 6 and 13 almost doubled the expected demand (expected/actual = 21/39%), those with the worst economic incomes and poorer infrastructures in Seville, while richer Districts, 1, 4 and 5, had an inverse relationship (expected < actual demand). This evident asymmetry is clearest for the district Polígono Sur (district 13, population/demand 5.32/14.48%), which exceeds by almost three times the expected percentage of demand. Socioeconomic status has been well addressed in Polígono Sur (source: Plan Integral del Polígono Sur, Delegación del Gobierno en Andalucía y Ayuntamiento de Sevilla. 2004). This area is the poorest of the city, having extensive social exclusion, illiteracy rates, school abandon percentages, unemployment (40%) and scarce economic resources, drug abuse and delinquency, weak social networking and even scarce public services. Many flats often have architecture

barriers (no lift, no ramps, small rooms). Of these people, about 65% live with limited social benefits, accounting for the 34.4% of the economic resources. Commonly these homes receive only one salary (retirement 26%, invalidility pension 21%, widow's pension 16%, unemployment benefit 12%). The life expectancy is the lowest in Seville, 70.1 years among men and 81 years among women, higher in comparison with the other districts: 74.6 and 82.3 years, respectively. The incidence of chronic conditions doubles the incidence in other Seville districts (COPD, gastric or lung cancer, infectious diseases) or even more (AIDS). Mortality rate exceeds 1.4 times those from other Seville areas. Some of these features are shared by districts 6 and 10, although in a lower degree. Richer districts (areas 1, 12 and 14) showed lower healthcare demands than expected by population rates.

Conclusions: An excessive healthcare demand is related to social exclusion and poverty, present in several areas of Seville.

EA-37
USE OF OXYGEN THERAPY IN NON COPD PATIENTS

J. Miramontes González, A. Bello Conesa, D. Pescador Hernández, J. Martín Oterino, I. Corbacho Cambero

Department of Internal Medicine. Hospital Universitario de Salamanca Virgen de la Vega. Salamanca, Spain.

Objectives: Usually the domiciliary oxygen is used in COPD apcientes when exist respiratory failure. The objective of this study was to determine the diseases that need domiciliary oxygen in non COPD patients, that we treated in a unit of Internal Medicine.

Material and method: We conducted a retrospective study, period of 3 years, with the patients admitted in a unit of M. Internal. We used a database which extracted coded patients that in the discharged needs the treatment with oxygen domiciliary. Of these patients medical history is reviewed and discarded patients with COPD. Patients who are selected for the study we collect demographic data, previous diseases, the cause of hospital admission and discharge diagnoses.

Results: We have studied a total of 1358 patients of which 159 have oxygen at home. We discarded patients with COPD as underlying disease to administer oxygen, the result was 41 patients with different diseases. The advanced tumor disease was 34% of cases, 27% cor pulmonale, pulmonary hypertension (primary and secondary): 20%. Interstitial lung disease: 19% of all.

Conclusions: 1. The main cause of indication of domiciliary oxygen is COPD. 2. Other diseases, are also, less common, cause of home oxygen therapy indication. In our experience highlights a large number of patients presenting tumoral processes and needs oxygen on the treatment. Emphasizes in an important way patients with chronic cor pulmonale. Usually we associate parallel the domiciliary oxygen in COPD. It 's necessary to know other conditions requiring domiciliary oxygen and is necessary the control their respiratory failure. The appropriate use of chronic oxygen therapy on an outpatient basis affects the quality of life and survival of these patients.

EA-38
RELEVANCE OF AN INTERNIST ASSIGNED TO A TRAUMATOLOGY WARD

C. Gómez del Valle, A. Flamarique Pascual, M. Callejo Plazas, M. Navarro Aguilar, J. Navarro Calzada, M. Iguzquiza Pellejero, I. Torres Courchoud

Department of Internal Medicine. Hospital Clinico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: To assess if the provided care for an internist assigned to a traumatology ward reflects an improvement in the quality of care of patients hospitalized for hip fracture, trying to reduce the morbidity and mortality.

Material and method: Quasi-experimental study of patients over 65 years with osteoporotic hip fracture who are tracked for 1 year (2009) from the date of admission. The control group is a historical cohort of patients admitted for the same reason in the previous year.

Results: We collected 633 patients being 273 (43.1%) belonging to the prospective group. In gender distribution of cases were 509 women. The average age was 84.21 (SD ± 6.77). There were no statistical differences in both groups on these variables. The average stay was higher in the prospective group (18.48 vs 16.95) ($p = 0.77$) Comparing deaths during hospitalization, it was a lower percentage in the monitoring group 6.2% versus 10.3% in the control group ($p = 0.08$). If we refer to the mortality just one month discharged from the hospital, it was 2.5% in the prospective versus 5.4% ($p = 0.12$). In relation to mortality at 3 months after leaving the hospital it was 1.4% versus 3.1% ($p = 0.23$). In the evaluation of early readmissions (which are those readmitted after the first month out) in the prospective group were readmitted less by 6.4% compared to 9.4% of the retrospective ($p = 0.16$).

Discussion: Hip fracture is the most important reason for the admission in the traumatology ward. They are elderly patients and they have significant comorbidity and a high risk of developing complications during hospitalization stay, by what will often require an assessment by an internist physician. There are various studies that support the benefit of the assessment and follow-up during the hospitalization stay of these patients by the internal medicine staff, mainly to reduce the mortality and average length of stay (Montero Ruiz et al.). Our study shows a trend to reduction in mortality (similar to the one described in the other studies), especially during hospitalization and the mortality just one month discharged from the hospital. The average stay shows no difference between the two groups. This could be related with the delay in the operation room.

Conclusions: The role of the internist assigned to a traumatology ward shows a clear tendency to decrease mortality and early readmissions in patients with hip fracture. Apparently it does not influence significantly in a decrease in the length of stay.

EA-39
CAREGIVER PERCEIVED QUALITY OF PATIENTS WHO DIED IN A UNIVERSITY HOSPITAL. ROLE OF A PALLIATIVE CARE UNIT

L. Díez Porres[1], M. Lacasta[1], J. García Puig[2], A. Alonso Babarro[1], Y. Vilches[1], J. Díez[3]

[1]Acute Palliative Care Unit, [2]Department of Internal Medicine, [3]Department of Biostatistics. Hospital Universitario La Paz. Madrid, Spain.

Objectives: Most western world deaths occur in acute hospitals and are predictable generally. Studies have shown that patients who die and their families have an inadequate satisfaction of their needs. Objective general: to evaluate the effectiveness of a Palliative Care Unit in the quality of care in the last days of life of patients and families, comparing those who died in the Unit with Internal Medicine and Oncology. Specific: To compare the primary caregiver perceived quality.

Material and method: Design: observational, retrospective, cohort study. Subjects: patients died in Palliative Care Unit (PCU), or in Internal Medicine or Oncology (Non-PCU); consecutively included. Protocol: a) Retrospective review of medical record. b) Caregiver perceived quality study by telephone interview between 7th and 15th day after death.

Results: We included 166 patients who died between 01/10/09 and 27/02/10, bellowing 66 to PCU cohort and 100 to Non-PCU (51 from Internal Medicine and 49 from Oncology). The mean age (SD) was 68 (13.6) and 72 (14.7) years, respectively, without differences between both cohorts. 53% were male in the whole sample. The primary caregiver mean age (SD) was 57 (13.9) years and 69% were female; there were no significant differences between both groups. On a scale of 0 to 10, the average overall satisfaction with the care provided was 9 in PCU and 8 in Non-PCU ($p < 0.01$).

Conclusions: Primary caregivers of dying patients cared in a Palliative Care Unit have a higher overall satisfaction regarding the perceived quality of care received in the last days of life.

EA-40
DIFFERENTIAL FEATURES OF THE POLYPATHOLOGICAL PATIENTS ADMITTED TO INTERNAL MEDICINE OR ACUTE CARE GERIATRICS UNITS: PLUPAR STUDY

F. Gomes Martín[1], P. Revillo Pinilla[2], B. de Escalante Yangüela[3], E. Munilla López[1], A. Jimeno Sáinz[4], E. Ubis Díez[5], J. Díez Manglano[1] and the PLUPAR STUDY Investigators[6]

[1]Department of Internal Medicine. Hospital Royo Villanova. Zaragoza, Spain. [2]Department of Internal Medicine. Hospital Universitario Miguel Servet. Zaragoza. Zaragoza, Spain. [3]Department of Internal Medicine. Hospital Clínico Universitario. Zaragoza, Spain. [4]Department of Internal Medicine. Hospital Ernest Lluch Martín. Calatayud (Zaragoza), Spain. [5]Department of Geriatrics. Hospital Sagrado Corazón de Jesús. Huesca, Spain. [6]Other Hospitals. Servicio Aragonés de Salud. Zaragoza, Spain.

Objectives: To determine the differences between PP admitted to Internal Medicine wards (IM) and acute Geriatrics (G) units.

Material and method: PLUPAR (Paciente PLUriPatológico en ARagon) study is an observational, prospective, multicenter study participated in by 13 hospital centers throughout Aragon (Spain). PP admitted to an IM or G department and attended by investigators consecutively between March 1 and June 30, 2011 we included. Readmissions and patients who died during the hospìtalization were excluded. Data registered included age, gender, living in nursing residence or at home, disease category diagnosis, number of chronic drugs on admission, Charlson index, Barthel index, Lawton-Brody index, Pfeiffer questionnaire, socio-familial risk Gijón scale, number of admissions in the previous year, delirium in the previous admission, need for a caregiver, having a caregiver and PROFUND index. The need of a caregiver was defined when the Barthel index was < 60 or Pfeiffer questionnaire ≥ 5 errors.

Results: There were 1,870 hospital admissions, 1,466 to IM and 404 to G units. 30.8% in IM and 44.0% in G were PP. Finally we included 471 PP. Patients in G were older and more frequently women. Heart (62.9% and 49.2%; $p = 0.006$), digestive (8.0% and 3.0%; $p = 0.047$) and oncohematological diseases (30.0% and 18.7%; $p = 0.01$) were more frequent in patients of IM units and neurological (41.2% and 65.7%; $p < 0.0001$) and degenerative osteoarticular diseases (20.8% and 37.3%; $p = 0.0002$) in patients of G units. There was no difference in number of disease categories but Charlson index was higher in patients of IM (4.0 ± 2.1 vs 3.5 ± 2.1; $p = 0.04$). Heart failure, myocardial infarction, diabetes with target organ damage and severe liver diseases were more frequent in patients of IM and dementia, hemiplegia and peptic ulcers were more frequent in patients of G units. Patients of G have more cognitive impairment (Pfeiffer questionnaire 5.5 ± 3.7 vs 3.8 ± 3.3; $p = 0.0008$), more dependence on basic (Barthel index 38.8 ± 32.5 vs 60.6 ± 34.7; $p = 0.0009$) and instrumental activities for daily living (Lawton-Brody index 0 9 ± 1.6 vs 3.0 ± 2.9; $p = 0.0007$), and more frequently needed a caregiver (87.8% vs 53.6%; $p < 0.0001$) and had it.. Also more frequently they had a caregiver. Delirium was more frequent in G patients (30.1% vs 170%; $p = 0.002$). Although patients of IM units were hospitalized more frequently in the previous 12 months (2.1 ± 1.4 vs 1.8 ± 1.1; $p = 0.03$), there was no difference in the number of chronic prescribed drugs (8.3 ± 3.4 vs 8.1 ± 3.6; $p = 0.41$). The PROFUND index score is higher in patients of G units (10.0 ± 4.3 vs 7.9 ± 4.8; p0. 0001).

Conclusions: There were differences among the diseases of PP admitted to IM and G units. The functional dependence and cognitive impairment were also different. PP admitted in G units had worse prognosis according to the PROFUND index.

EA-41
KNOWLEDGE AND UTILIZATION OF TOOLS FOR MULTIDIMENSIONAL ASSESSING OF POLYPATHOLOGICAL PATIENTS BY INTERNISTS OF ARAGON

J. Gomes Martín, S. Isasi de Isasmendi Pérez, P. Al-Cheikh Felices, E. Del Corral Beamonte, J. Ferrando Vela, J. Díez Manglano

Department of Internal Medicine. Hospital Royo Villanova. Zaragoza, Spain.

Objectives: To determine the knowledge and utilization of the tools for multidimensional assessment of polypathological patients (PP) patients in internal medicine departments.

Material and method: In June 2011 we sent by mail a survey to all the internists and internal medicine training physicians (residents) of Aragon (Spain). Twenty-eight of them participated in a study about care of PP. We report the description of data obtained from responses to the survey.

Results: We sent 132 surveys, 43 to residents, and we obtained 37 (28%) responses. The response rate of residents was lower than of staff physicians (9.3% and 33.7% respectively). All responders knew the concept of polypathology and 32 (86.5%) the criteria used to label patients as PP. They reported that in their daily work 73.8% patients had multimorbidity and 41.1% were PP. Only 7 (19.4%) thought that to establish a prognosis for PP is easy and 32 (88.9%) knew a prognostic tool. Thirty-seven (100%) responders reported to know Barthel index, 21 (56.8%) Lawton-Brody index, 31 (83.8%) Pfeiffer questionnaire and 21 (56.8%) sociofamilial risk Gijón scale. Charlson index was known by 26 (70.3%) and PROFUND index by 23 (62.2%) responders. In their daily work 32 (86.5%) physicians utilized the Barthel index, 7 (18.9%) the Lawton-Brody index, 18 (48.6%) the Pfeiffer questionnaire, 5 (13.5%) the Gijón scale, 7 (18.9%) the Charlson index and 6 (16.2%) the PROFUND index. Eighteen (48.6%) of responders were participating in a study about care of PP and knew more frequently the PP criteria (100% and 73.7%; $p = 0.02$), and Lawton-Brody index (94.4% and 21.0%; $p < 0.0001$), sociofamilial risk Gijón scale (94.4% and 21.0%; $p < 0.0001$), Charlson index (94.4% and 47.4%; $p = 0.002$) and PROFUND index (100% and 26.3%; $p < 0.0001$). However they reported that they cared less often PP (25.6% and 33.7% respectively; $p = 0.002$).

Discussion: PP have become a challenge for the health care system of European countries in the 21st century and a progressive increase of polypathology is expected. Patients of internal medicine departments are frequently PP. They are vulnerable, have poor related quality of life and frequently have mental and functional impairment. To care PP a multidimensional assessment is advisable. In Aragon the internists know the tools to assess the PP, but however they utilize them less of desirable.

Conclusions: Although 41.1% of patients cared by internists are PP, the use of multidimensional assessment tools is low. Participation in studies of caring PP can help to know these tools.

EA-42
CORRELATION BETWEEN BODY MASS INDEX AND SEVERE OSTEOARTHRITIS OF THE KNEE IN A GROUP OF ELDERLY LIVING IN THEIR HOME IN TUNISIA

S. Hammami[1], N. Hammami[2], S. Baccar[2], S Mahjoub[1], S. Hajem[2]

[1]Department of Internal Medicine. EPS F Bourguiba, University of Monastir. Monastir, Tunisia. [2]Department of Geriatric. National Institute of Public Health. Tunisia.

Objectives: Worldwide, osteoarthritis (OA) is estimated to be the fourth leading cause of disability. OA is strongly associated with ageing and Tunisia is ageing rapidly. OA of the knee has been linked to obesity. Clinical observations suggested that there is a direct relationship between the degree of obesity and the severity of knee OA. Obesity is a modifiable risk factor associated with progression of arthritis, activity limitation, disability, reduced quality-of-life, total joint replacement and poor clinical outcomes after joint replacement. Objectives: this present study aimed to determine the prevalence of severe osteoarthritis of the knee (SOA) on a subset of elderly living in their home in Tunisia, we also examined the impact of obesity.

Material and method: This study based on data from the investigations of medico-social on the health and the lifestyle of elderly (aged more than 65 years living in their homes. This study approved by ethics committee and supported by OMS and FNUAP. It's a cross sectional study of randomly selected homes in randomly selected geographical islets. Study concern 598 elderly aged more than 65 years (mean age 72.3 ± 7.4 years, 66% women). The questionnaire includes identification, socio-demographic data and health behaviors. Obesity was defined using Body Mass Index (BMI) ≥ 30 kg/m2. Central obesity was considered at a waist circumference of > 102 cm in men and > 88 cm in women.

Results: In total, we included 598 subjects, The prevalence of severe osteoarthritis (SOA) of the knee with doctor diagnosed was 7.3%, mean age: 78.3 ± 7.4 vs 71.7 ± 7.3 years for subjects without SOA, $p < 0.001$. The mean of systolic blood pressure value was higher in SOA group (136 ± 17 vs 126 ± 17, $p < 0.001$). The weighted prevalence of obesity was considerably higher in SOA group (61.5% vs 47.7%, $p < 0.05$). However, a large waist circumference was more frequent but not significantly in SOA group, the mean WC was (106.8 ± 15 vs 103.3 ± 12 cm, $p = 0.07$). In addition the weighted prevalence of disability according Katz score was estimated at 16.3% and was more frequent in SOA group (44.2% vs 14.3%, $p < 0.001$). Multivariate logistic regression was performed to evaluate associations between the risk factors of SOA. Behind age, systolic blood pressure and disability, obesity was found to be the strongest predictor for SOA (OR [95%CI], 3.4 [1.2–9.1]; $p < 0.0001$).

Conclusions: Obesity is a risk factor for many conditions, including knee OA. The benefit of modifying this risk factor may cause significant risk reduction of knee OA in the general population, especially in Eldely Tunisian's people where obesity is prevalent.

EA-43
ADEQUACY USE OF ANALGESIC OPIOIDS IN HOSPITALIZED PATIENTS

A. Perona Mediavilla, A. Martínez Baltanás, J. Morcillo Huertas, L. Navarro Peiró, R. Pascual Peréz, M. Pesce

Department of Internal Medicine. Hospital Virgen de la Salud. Elda. Alicante, Spain.

Objectives: Analyze the characteristics of patients treated with opioids and their relevance, optimization and the presence of adverse effects.

Material and method: Data were collected from clinical histories of patients treated with opioids, hospitalized in oncology and internal medicine in Elda's General Hospital. We analyzed the following variables: age, sex, multimorbidity disease, dependency, family aid, analgesic drugs, dosages, pain control and adverse effects.

Results: We analyzed 41 patients (56.1% women) with a mean age of 69.63 years. 48.8% admitted to internal medicine, 43.9% in oncology. 68.4% were independent for basic activities of daily life. 63.4% had no toxic habits. 95.1% had social and family support. 85.4% were oncological patients. 43.9% had no multimorbidity, a 9.8% suffered depression/anxiety, heart disease 7.3%, and 4.9% associations (chronic lung disease, heart disease). The main causes for treatment with opioids were: 14.6% musculoskeletal pain, 9.8% lung carcinoma, 9.8% kidney carcinoma, 7.3% breast carcinoma, pancreatic and colon adenocarcinoma, respectively. The 61% of patients hospitalized, had metastases. The main route of opioid administration was the transdermal (61%) followed by the oral route (31.7%), subcutaneous (2.4%) and intravenous (2.4%). The first drug used was fentanyl (61%), followed by oxycodone/naloxone and hydromorphone (9.8%). 65.9% of patients did not require further assistance, however 12.2% used intravenous morphine. The mean equivalent dose of oral morphine was 86.92 mg/day. Other variables included in the study were the use of other analgesics, 41.5% required a treatment with first-line analgesics, 12.2% other adjuvants, and 34.1% didn´t need any treatment. Prophylactic antiemetics were used in 48.8% and laxatives in 53.6%. 24.4% of patients presented vomits and constipation in 36.6%, with opioids. 14.5% showed a decreased level of consciousness secondary to morphine. Pain was controlled in 63.4%. Progressive dose adjustment was made in 95.1%, with a mean value of 4.31 reading in the visual analogic pain scale.

Discussion: Opioids are drugs widely used in the treatment of oncological pain; there are multiple, safe and efficient methods of administration. Treatment with opioids is used for two main aspects: neoplasic and musculoskeletal pain, most of them are oncologic patients (especially women) who require this type of treatment. The main route of administration was transdermal, because it´s easy to use in hospitals. Laxatives and antiemetics were associated in approximately 50% prophylactically, but patients did not present this pathology in large percentages. In most cases a good management of pain was achieved. Dose adjustment was made without neurological damage. Opioids are a good alternative to help those patients who don´t get good pain control with first-line drugs.

Conclusions: Despite the importance of controlling pain in oncological patients, this objective is achieved in only 2/3 of patients. That is why hospital guidelines are needed for a good reduction of the pain and its secondary effects in those patients who need it. Constipation (36.6%) was the most common secondary effect, followed by nausea and vomiting (24.4%) and decreased level of consciousness (12.2%). Fentanyl was the main drug used (61%).

EA-44
PREVALENCE AND IMPACT STUDY OF ORAL HEALTH STATUS IN A MID- TO LONG-TERM STAY UNIT

Y. Tung[1], I. Moreno[2], P. Moral[2], M. Antolin[2], R. Ros[2], F. Merino[3]

[1]Department of Internal Medicine, [2]Department of Mid- to Long-term Stay, [3]Department of Endocrinology and Nutrition. La Fe Universitary and Polytechnic Hospital. Valencia, Spain.

Objectives: Oral diseases are a major public health problem, frequently neglected in hospitalized older adults, with potential deleterious effects (malnutrition, dysphagia, etc.). Despite high burden and risk of adverse outcomes, oral diseases have been little studied in our ambit. The aim of this study was to investigate the oral health status of an elderly patients population admitted in the Medium to Long Stay Unit (MLSU) of a universitary hospital. We also evaluated the possible impact in terms of quality of life and the possible relationship with complications such as oropharyngeal dysphagia (OPD) or malnutrition.

Material and method: A descriptive, observational and cross-sectional study was performed; we included 81 patients admitted to the MLSU during 3 months. The assessment was performed by a multidisciplinary team approach. Physicians registered epidemiologic variables (age and gender), clinical items (reason for admission; comorbidity [Charlson]; cognitive status [Pfeiffer]; functional capacity [Barthel]) and the presence of malnutrition with the validated test Mini-Nutrition Assessment (MNA). Trained nurses performed a complete oral examination to establish the presence of oral lesions and mucosal disorders (aphtas, periodontitis, xerostomia), the total teeth number and the use of well-adjusted removable dentures. To assess OPD, a volume-viscosity swallow test (V-VST) was administered. We estimated the oral health quality of life using the Geriatric Oral Health Assessment Index (GOHAI), a compact questionnaire with 12 items, validated with high sensitivity and specificity in geriatric population to determine the need for dental care.

Results: The mean age of the group was 78.51 (SD 12), of whom 51.9% were males. Chronic obstructive pulmonary disease was the most common reason for hospital admission (22.2%), followed by stroke (17.3%) and sepsis (12.3%). The average length of hospital stay was 18.54 days (SD 11.99). The Charlson index showed that 60.5% of them had comorbidity. The Barthel index media was 32.5 (25), where 67.5% of patients had severe/total dependence, and 33.3% had mild to severe cognitive impairment (Pfeiffer). According to MNA score, 55.6% of the elderly were malnourished. V-VST detected swallowing disorders in 46.8% of the patients. The presence of mucosal disorders was detected in 46.2% of the patients. Our patients had a median of 5 teeth (rate of edentulism: 35.8%). Despite 55.6% used dental prosthesis, only 43.1% had it well adjusted. All patients obtained values below the established GOHAI cutoff point, needing bucodental care. No significant relation was observed between the number of teeth or GOHAI and the other recorded variables.

Discussion: The prevalence of oral and mucosal disorders, as well as badly adjusted removable dentures was extremely high. It should be stressed that no statistically significant relation was observed in our study between the number of teeth, GOHAI or any of the oral pathologies considered and the presence of malnutrition, epidemiologic, functional or clinical items. This could be owed to the small sample size we analyzed, and therefore underpowered to detect possible correlations.

Conclusions: To date, very few studies have been conducted on oral health status in hospitalized adults in Spain. The results of the present study show that oral disorders, edentulous and badly adjusted dental prosthesis are highly prevalent disorders in our population. In consequence, GOHAI appears to be less valuable, due to the low specificity for identifying highly vulnerable patients who need dental care in our unit. A multidisciplinary team may offer early diagnosis and assessment, allowing individualized treatment. Due to the limited study size and underpowered results, further larger studies are suggested to confirm our findings and prove our hypothesis.

EA-45
DERIVATION OF PATIENTS TO A POST-ACUTE CARE HOSPITAL

S. Olivera González[1], G. Vila Castillo[1], C. Baydal Cardona[2], S. Escrivá Durá[4], F. Cholbi Llobell[3], R. Guillem Pérez[5], P. Olcina Lloret[1], P. Martín Rico[1]

[1]Department of Internal Medicine, [2]Department of Medicine at Home, [4]Social Work, [3]Department of Rehabilitation, [5]Nursering. Hospital de Denia. Denia (Alicante), Spain.

Objectives: evaluate the referral of patients from an acute-care hospital, to a long-stay hospital.

Material and method: A cross-sectional study was performed with 52 patients, between April 2010-April 2011. We studied the following variables: days of stay, age, gender, main diagnosis, reason for transfer, associated social problems, and service of origin. Statistical analysis was performed using SPSS 18.0.

Results: 52 patients were derived, with a mean age of 70.9 years (SD 12.4, range 41-90). 56.6% of patients were women (mean age 72.5, SD 13.2) and 43.4% men (mean age 68.9, SD 11.3). The diagnosis most frequently motivated the request for transfer was stroke (30.8%), followed by multiple trauma/fracture of the hip (9.6%), and skin ulcers/skin sepsis (7.6%). 55.7% were transferred for rehabilitation, 28.8% for convalescence, and 15.4% as palliative patients. 51.92% of patients had associated social problems. The service of origin was in this order: Internal Medicine (83%), Traumatology (5.7%), Surgery (5.7%), ENT (3.8%), and Hospital at home Unit (1.9%). The average stay in hospital for acute patients was 24.3 days (SD 20.2, range 0-123). By correlating the age of the patient days of hospital stay, there was no relationship (rho Spearman -0166). There is a relationship between age and area of movement ($p < 0.05$), but there was no relationship between age and diagnosis, or with associated social problems. There was no association between social problems and the area of patient transfer. There was no relationship between the number of days of income and associated social problems.

Discussion: In our study we found no predictors of a need for long stay, although there is a clear relationship to the existence of social problems (half of our patients had). The main causes of needing for referral of patients to long-stay hospital were stroke and hip fractures, pathologies due to increased life expectancy in our country, that presumably will continue increasing in frequency along time. Prolonged stays occur prior to transfer to a long hospital stay, and it would be important a right patient selection, through proper geriatric assessment, and after the initial evaluation, a quick tap of the patient. The main problem with any referral program, and we also have found in our study, is the lack of resources available at the time of referral of patients evaluated, since many of them are not likely to be taken to a hospital for long stay, but would benefit from living in residences or their own homes, if we could have services or support measures, which we don't have. All this is exacerbated by the current economic crisis that we are suffering.

Conclusions: We need a proper selection of patients once the acute hospitalization period has ended to achieve the optimization of available resources. There is a significant resource gap, which is becoming more evident as the increase in life expectancy, which is an increase in demand for these resources. A good option for long-stay hospitals would be new residences, day-care centers and home physiotherapy and rehabilitation units.

EA-46
INTERNAL MEDICINE EXPERIENCE OF INTERCONSULTATIONS BY SURGICAL DEPARTMENTS

I. Marañón Zabalza, M. Martínez Lopéz, M. Tejero Delgado, J. Morís de la Tassa, A. García Vallina, J. González Vallés

Department of Internal Medicine. Hospital de Cabueñes. Gijón (Asturias), Spain.

Objectives: Describe the characteristics of the consultations demanded by surgical departments -General & Digestive Surgery (GDS), Urology, Otolaryngology (H&N) and Vascular- to Internal Medicine, determine the factors that have prognostic influence on these patients and assess the associated workload.

Material and method: Prospective study of the consultations carried out by the surgical services during 2011.

Results: One hundred and nine interconsultations were request, 60.6% were men. Median age was 71.5 years (range 16-93). General

Surgery was responsible of 43.4%, Head&Neck 17.4%, 28.4% Vascular surgery and 11% Urology. The request was urgent or in the same day in 75 occasions (68.8%). The patients were followed during 3.69 days. The average of interconsultations was 1.22 (DT 0.51) for each patient. When analyzing the comorbidities, we founded a Charlson Comorbidity Index (CCI) of 2.27, without different among the services. The main reasons for consultations were dispnea (33%), analytical alterations (11.9%), treatment adjustment and conciliation (8.25%) and fever (5.5%). Cardiac failure (17%), sepsis (10.1%) and respiratory infection (8.38%) were the main diseases found. Twenty two patients died (19.3%), 13 (59%) of them patients of in GDS. This mortality rate is higher than the global mortality for these services during the study period (3.26%) and that found in GDS (4.33%). The mortality was higher in that patients admitted through emergency unit (14 of 21) than those with programmed care. Sepsis was the main cause of death (6 patients). The average length of hospital stay in the study group was 19.6 days, while was 6,9 days for the cohort of patients admitted to surgical services during the same period; in GDS the medium length of stay was 10.51 days in General Surgery. Internists adjusted or modified the treatment in 84 patients (71.1%), but this change was registered only in 22% of the surgical discharge report.

Discussion: Most of the interconsultations were for elderly men with multiples comorbidities that required urgent medical assistance. When comparing our data with other studies previously published, we didn't found differences in sex, age, mortality, number of visits, CCI, the principal cause for consultations and most frequent diagnosis. Nonetheless, the patients of this study have a smaller average hospital length of stay, perhaps because traumatological patients were not included in this study. However, the average length of stay is higher than that of the same Service, perhaps, because most of the patients with interconsultations have a more severe diseases and CCI. The principal causes of death were related with the disease responsible with the admission to the hospital or with its complications. Although consultation physicians make a great number of medical interventions, few of discharge reports showed these changes when patient is discharged.

Conclusions: Surgical interconsultations account an important workload for internist due to the severity and complexity of their conditions. Thorough evaluation of these patients with chronic conditions and high risk must be done at admission, or in the emergency department, and before surgical procedure. An additional discharge report complimented by internists with adjustment of treatment and tailored for their chronic conditions contribute to assure the continuity and improvement of care.

EA-47
ADRENAL INSUFFICIENCY IN ELDERY PEOPLE: A DELAYED AND LIFE-THREATENING DIAGNOSIS

E. Oviedo[1], P. Villacé[2], C. Feijoo[1], R. Comet[2], M. Villarino[2], I. Torrente[2]

[1]Department of Internal Medicine, [2]Acute Geriatric Unit. Hospital de Sabadell. Barcelona, Spain.

Objectives: Adrenal insufficiency (AI) has a non-specific clinical presentation, especially in elderly patients. Moreover, laboratory findings may easily be attributed to other entities. A high suspicion index is necessary for detection and treatment. Our goal is to describe the clinical presentation, physical examination, laboratory findings and chronic corticosteroid use in all patients 75 years or older diagnosed with AI. We also reviewed their comorbidities and prognosis upon one year follow-up.

Material and method: Retrospective study reviewing the clinical chart of all the patients diagnosed of AI in a 5 year period (2007-12). Inclusion criteria: discharge diagnosis and/or laboratory criteria (basal cortisol levels < 3 µg/dL or response to low dose ACTH stimulation < 20 (µg/dL) .We excluded patients with a clinical diagnosis without biochemical confirmation. The study was performed in the Corporació Sanitària Parc Taulí (420,000 reference population (21,942 > 75 years), 765 teaching beds. Data collection in database and descriptive analysis with statistics package SPSS v19, using student t-test or U Mann-Whitney for quantitative variables and Chi-square for qualitative.

Results: N = 26 (11 women, 15 men). Mean age at diagnosis is 79.50 years old (range 75-89). 96.2% of patients were diagnosed with AI secondary to exogenous glucocorticoid (GC) treatment. The most common complaint was weakness 80.9%, gastrointestinal symptoms (anorexia, nausea and vomiting) 69.2% and weight loss 26.7%. Physical examination highlighted sustained hypotension in 69.2% as well as dehydration in 30.7%. 53.8% of our patients had history of chronic obstructive pulmonary disease (COPD), 15.4% with asthma and 26.9% with autoimmune disease. 96.15% of patients were taking some form of GC therapy at diagnosis (inhaled 19.2%, systemic 30.8%, both 42.3%). Fluticasone propionate (FP) was the most common inhaled GC (46.2%) followed by budesonide (7.7%). Mean doses of FP were 1,346 mg/day (400-2000). At diagnosis, 80.7% were taking some antihypertensive treatment (angiotensin-converting enzyme 38.5%, angiotensin II receptor-antagonist 19.2%, aldosterone antagonists 19.2%, diuretic 65.4%, others 46.2%). Laboratory findings were: Mean Na was 133 mEq/L (range 112-144), mean K was 4.5mEq/L (range 3.1-6.7). Mean baseline serum cortisol level was 5.25 µg/dL (range 1.3-17.80). Mean stimulated peak cortisol level was 13.93 µg/dL (range 5-28.28). The relationship between FP dose and serum cortisol levels or peak cortisol level after stimulation showed a marked adrenal suppression with doses above 1,500 µg/day, unlike the systemic treatment (6.39 µg/dL versus 19.63 µg/dL serum cortisol level, p = 0.323; and 13.49 µg/dl versus 16.39 mcg/dl for stimulated peak, p = 0.57). Additional tests performed were: endoscopy study 42.3%, cranial RMB or CT scan 26.9% and thoracic-abdominal CT scan 57.8%. The most common comorbidities were infections (pneumonia 41.4%, urinary tract infection 15.3%, septicaemia 15.3%) and complications of underlying disease (respiratory insufficiency 38.5%, Congestive heart failure 30.7%). 50% of elderly patients were treated in wards of internal medicine (acute internal medicine 26.9%, acute geriatric unit 23.1%), followed by pulmonary disease unit 19.2%. 50% of patients died in the year after the diagnosis. Patients with a lower cortisol level had a higher probability of death (p = NS).

Conclusions: Exogenous GC treatment was the most common cause of AI in the elderly. All patients had multiple comorbidities and more than 90% were treated with GC therapy. Inhaled GC can be harmful in these patients. High doses of inhaled GC tend to be related to lower basal serum cortisol level or lower stimulated peak cortisol level. Frequent use of antihypertensives can mask the clinical presentation and delay diagnosis. The low specificity of the clinical signs and symptoms may lead to unnecessary testing. Screening is recommended to identify patients at risk.

EA-48
A PROSPECTIVE PNEUMONIA STUDY: MICROBIOLOGY AND INITIAL EMPIRIC ANTIBIOTIC THERAPY

G. Llerena[1], A. Dragoi[1], N. Gago[1], A. Pellicer[1], J. Ramos[2], F. Pedro[1], I. Díaz[1], M. Quiles[1]

[1]Department of Internal Medicine, [2]Department of Microbiology. Hospital General Universitario de Valencia. Valencia, Spain.

Objectives: Analyze epidemiological, clinical, microbiological findings, resistance patterns and antibiotic treatment in patients admitted with diagnosis of pneumonia.

Material and method: Prospective study of 111 patients consecutive admitted with a pneumonia diagnosis to the Internal Medicine ward of the Valencia General University Hospital from November 2011 to April 2012.

Results: We studied a total population of 111 patients, 56.8% were women, mean age 83.56 years, Barthel Index 10. Most of them would come from their home (58.6%) and 36% from a nursing home. The 54.1% was diagnosed of healthcare-associated pneumonia (HCAP). We evidenced some type of malnutrition in 82.8% of patients. One antibiotic was given as initial empiric antibiotic therapy in 64% of patients; meanwhile 2 antibiotics were given in 35% of them. The most used antibiotic was levofloxacin (55 patients), followed by piperacillin/tazobactam (33), cephalosporins (28, amoxicillin/clavulanate (28). The mostly used empiric antibiotic association was piperacillin/tazobactam with levofloxacin (15) and ceftriaxone with levofloxacin (14). Of all the 60 patients diagnosed of HCAP, only 11 received initial empiric antibiotic therapy currently indicated in the pneumonia guidelines covering common hospital pathogens with piperacillin/tazobactam and levofloxacin and only 8 with piperacillin/tazobactam. We observed a lower mortality in patients who received antibiotics earlier (mean time 3.63h in 16 patients vs 5.60h in 20 patients) with no statistical significance. 81 samples were sent for microbiological analysis, reaching an etiological diagnosis in 24 of them. We performed the following tests: blood culture 44 (yield 18.2%), sputum culture 23 (yield 52.2%), pneumococcus antigen 56 (yield 21.4%), Legionella antigen 54 (all negative). We obtained 3 pleural effusion cultures and two serological studies, but all were negative. From the 24 etiological diagnosis, we found: S. pneumoniae (11), A. baumannii (3), H. influenzae (2), MRSA (2), S. aureus (2), P. aeruginosa (2), M. morgagni (1), E. cloacae (1), E. coli ESBL (1). The average length of stay (ALOS) was 13.98 days with a total mortality rate of 27%. The subgroups ALOS and mortality rate was respectively: HCAP 15.1 days and 28%, community-acquired pneumonia (CAP) 12.13 days and 27%, hospital-acquired pneumonia (HAP) 13.92 and 42.86%.

Conclusions: Nowadays, with the continuous dynamic social environment having frequent contact with hospitals and the new forms of health-care facilities, the classical paradigm of pneumonia approach needs continuous changes based on evidence from clinical trials. Therefore, our interest on conducting this prospective study where we have objectified a high incidence of HCAP and total mortality of 27% related to the common features of our population and the lack of an adequate initial empiric antibiotic therapy according to current guidelines, but the almost equal mortality of HCAP and CAP induce to think that the treatment administered was correct because of no excess of mortality. A low percentage of etiology was demonstrated, but of all the etiological findings, we evidenced a high incidence of common hospital pathogens (A. baumannii, MRSA, P. aeruginosa and E. coli ESBL). Gram stain of reliable tracheobronchial aspirates has proven a minor incidence of inappropriate treatment when used to guide the initial empiric antibiotic therapy. In our study, we noticed that sputum culture and gram stain have a yield superior to 50%, despite the low performance of this test in our patients. Although the high HCAP criteria at admission, the association piperacillin/tazobactam and levofloxacin (which follows treatment guidelines) keep being underused empirically, which might be because of the low incidence of atypical pathogens in our population of study. Piperacillin/tazobactam alone is also a good option in our patients, but it is also not used empirically on every patient diagnose of HCAP. Even though we had a low incidence of HAP, its prognosis and mortality keeps being the highest.

EA-49
CAUSES OF ANEMIA IN AN INTERNAL MEDICINE WARD

S. Mendes[1], A. Pinheiro Sá[2], M. Neves[1], J. Espírito Santo[2], P. Cantiga Duarte[2]

[1]Department of Hematology, [2]Department of Internal Medicine. Hospital Santa Maria. Lisboa, Portugal.

Objectives: This database studies a population of inpatients of an Internal Medicine ward for short periods of time with a purpose of identifying the most prevalent types of anemia and its association with comorbidities and duration of institutionalisation.

Material and method: This is a prospective study developed over a period of 6 months (April-September 2011) in a Internal Medicine ward. The purpose was to identify the most frequent types of anemia, his association with comorbidity and length of hospitalisation. Male patients with a haemoglobine (Hb) level inferior to 13 g/dL and female patients with an Hb inferior to 12 g/dL were eligible for the study. Patients who had a transfusion in the previous six months were excluded. Information was collected about physiologic condition (sex, age and weight) and health status (associated comorbidities). Blood tests were performed for anemia study. Classification of anemia was based on laboratorial and clinical criteria allowing a division in four groups: ferropenic anemia (serum ferritine < 12 ng/mL, transferrin saturation < 15% and serum iron > 60 µg/dL), chronic disease anemia/inflammation (serum iron > 60 µg/dL and serum ferritine > 60 ng/mL), chronical renal insufficiency anemia (creatinine clearance < 30 ml/min) and multifactorial cause anemia.

Results: Of the group of 101 patients, 50.4% (51) were male and 49.5% (50) were female. The subjects had a mean age of 73 years old. The patients with a diagnosis of anemia had an average length of stay of 10.4 days. Ferropenic anemia comprised 5.94% of cases, the most prevalent was chronic disease/inflammation anemia (74.25%) and chronic renal insufficiency anemia was present in 21.8% of patients. Multifactorial anemia was verified in 57.4% of patients and the longest length of hospitalisation was attributed to this type of anemia.

Discussion: Anemia in elder individuals (over 65 years) presents etiologies much different to those present in young adults. That being said it becomes an important prognostic marker associated with increased number of hospitalisations, longer stays and morbi-mortality. The results should be adjusted to the values of markers of acute inflammation and re-evaluated when the patient is stable as we believe that inflammation is responsible for many of the reported cases. For further studies, acute inflammation markers should be included and it would also be interesting to verify the survival over a one year period.

Conclusions: Chronic disease/inflammation anemia was the most prevalent in a Medicine ward in patients with ages above 65 years old over the 6 months of study. Nevertheless, the multifactorial anemia is responsible for an enlargement of the hospital stay, confirming the idea that a patient with more associated comorbidities will have more complications. Individuals with a known story of chronic renal insufficiency and anemia will also have a prolonged hospital stay.

EA-50
CHRONIC COMPLEX PATIENTS AND ACCURATE DRUG PRESCRIPTIONS: DEGREE OF OBSERVANCE OF STOPP/START CRITERIA IN OUR EXPERIENCE

J. Galván-Román, Á. Gutiérrez, M. García, S. Yago, M. Martínez, C. Suárez

Department of Internal Medicine, Unidad del Paciente Pluripatológico. Hospital Univeristario de La Princesa. Madrid, Spain.

Objectives: In order to improve drug prescriptions, many recommendations and scales have been developed. The STOPP/START criteria are valid for elderly patients, and their fulfilment correlates with less drug adverse effects. Whereas STOPP criteria penalize inaccurate drug prescriptions according to several clinical characteristics, scoring bad prescriptions, START criteria penalize those drugs that should ideally be prescribed. In conclusion, the higher number of STOPP/START criteria, the worse the prescription is. The main objective of this study was studying the level of

optimization of chronic treatments during an admission at the PPU, according to the STOPP/START criteria. Other aims of the study were describing the characteristics of the population sample and detecting which were the least observed criteria, when patients were admitted and discharged; assessing the drug adverse reactions during the admission period, as well as analyzing the factors that may determine the observance of these criteria.

Material and method: Observational retrospective study. Sample constituted by patients monitored by the PPU admitted in the HUP between June 2011 and April 2012. Exclusion criteria were age under 65 and death during admission. Data were collected from the computerized clinic history (social and demographic data, regular treatment at admission and at discharge, and their STOPP/START criteria). To the statistical analysis we used the R 2.12.2 program, considering statistical significance for the parameters analyzed $p < 0.05$.

Results: It was analyzed a 37-patient sample (24 women and 13 men), whose average age was 85 years old (range 68-97). From these, 65% (24) had comorbidity criteria, and also 65% satisfied polypharmacy criteria. A relevant proportion of the patients (15, 40.5%) had some degree of cognitive impairment according to the GDS scale. Two patients were institutionalized and 21 had a caregiver. At admission our patients consumed an average of 6.76 drugs (range 1-15), of which 0.81 (range 0-5) were psychoactive drugs. After admission, therapy was reduced to 6.49 drugs (2-13); 0.78 (range 0-3) for psychoactive drugs. Once the STOPP/START criteria (chart 1) were collected, there was a decrease in STOPP and in START criteria. Analyzing the factors that may influence the quality of the prescription, we found correlation between dementia of any degree and the presence of at least one STOPP criterion ($p = 0.0008$). There was also found a statistically significant relation between the number of psychoactive drugs and the number of STOPP criteria, at admission ($p = 0.005$) as well as at discharge ($p = 0.004$). Four drug adverse reactions (DAR) were recorded as leading to admission, 2 of them were benzodiazepine intoxication.

Discussion: There is a high degree of potential inappropriate medications in elderly patients. Some clinical conditions, such as cognitive dysfunction or regular psychoactive drugs, could be related with a worse observance of STOPP criteria. This could be attributable to the fact that these were not specifically designed to these type of patients.

Conclusions: Patients admitted to the PPU are very elderly, with high rates of comorbidities and dementia. The DAR number was low, and lower than in other series. The long and the short of it, modifications of the patient's treatment during admission in our PPU can optimize drug prescription, following the STOPP/START criteria.

EA-51
PLURIPATHOLOGIC PATIENTS: MARKERS PREDICTIVE OF MORTALITY INTRA ICU AND AFTER 6 MONTHS OF ADMISSION

C. Jiménez Guardiola[1], J. Murcia Zaragoza[1], F. Laghzaoui[2], E. Pérez Rubio[2], J. Cepeda Rodrigo[1], C. Giménez-Esparza Vich[2], V. Martínez Sampere[1]

[1]Department of Internal Medicine, [2]Department of Intensive Care. Hospital Vega Baja de Orihuela. Orihuela (Alicante), Spain.

Objectives: Patients with multiple comorbidities (pluripathological patients) is an emerging population in intensive care units (ICUs), not without high morbidity and mortality. It is important to identify markers predictive of mortality for this population. Our objective is to identify markers predictive of mortality in PP patients admitted to the ICU from January to June 2011 during his stay in the ICU and at 6 months follow up.

Material and method: Retrospective study. Inclusion criteria: all patients who met the definition of PP and admitted to the ICU during the study period. Exclusion criteria: PP patients from surgery scheduled and PP patients admitted on a scheduled basis for placement of intravascular devices. Primary endpoint: mortality and ICU mortality at 6 months after admission to the ICU. Explanatory variables: We analyzed the clinical characteristics, care, functional status of chronic disease, number of categories of chronic disease, prognostic indices (functional: Barthel Index, Comorbidity: Charlson and Profund indices. Severity: Apache II). They conducted a descriptive and comparative analysis between PP patients who died in ICU and in the next 6 months with the rest of PP patients of different explanatory variables with SPSS 17.0.

Results: During the study period we included a total of 46 patients who met the definition of PP. The mean age was 71.3 ± 11 years. The most prevalent chronic diseases were: chronic heart failure (56.5%), chronic renal failure (54.3%) and chronic respiratory disease (37%). During admission, 19 patients died in ICU (41.3%). The clinical categories that were associated with ICU mortality were presence of neurological disease that causes permanent motor deficit and constraint to the basic activities of daily life (26.3% vs 3.7%, $p = 0.002$) and the presence of a solid tumor active subsidiary not treated with curative intent (36.8% vs 0%, $p < 0.001$). Among patients who died had significantly higher scores on the Profund index to the rest (6.7 ± 2.2 vs 2.2 ± 1.2, $p = 0.001$), no significant differences in baseline Barthel score, Charlson index and APACHE II. At 6 months of ICU admission 32 patients had died (69.9%), the variables associated with mortality at 6 months were: PP patients from hospital wards (62.5% vs 14.3%, $p = 0.003$), presence of hypoalbuminemia (2.8 ± 0.6 vs 3.4 ± 0.6, $p < 0.001$), low Barthel index score at baseline (82.8 ± 17.2 versus 97.7 ± 7.6, $p < 0.001$) and higher scores on the Profund Index (6.5 ± 4.3 vs 1.1 ± 0.9, $p < 0.01$).

Conclusions: There is a high ICU mortality and medium term on PP population admitted to the ICU. Variables that were associated with increased risk of mortality were: to present a solid neoplasic disease subsidiary not cure, submit a neurological disease that causes motor deficits, lower scores on the Barthel index and higher baseline Profund index score.

EA-52
ANALYSIS OF THE DISCREPANCIES FOUND BETWEEN PATIENT'S PHARMACOLOGICAL HISTORY AND THEIR ACTUAL DRUG PRESCRIPTIONS IN POLYPATHOLOGICAL PATIENTS, AS WELL AS THE MAIN DRUGS INVOLVED AND THEIR SEVERITY

M. Nieto Martín[1], E. Alfaro Lara[2], A. González Molina[1], M. Galván Banqueri[2], J. Galindo Ocaña[1], M. Martín Sanz[1], J. Santos Morano[3], B. Santos Ramos[2]

[1]UCAMI, [2]Department of Pharmacy. Complejo Hospitalario Regional Virgen del Rocío. Sevilla, Spain. [3]Department of Internal Medicine. Hospital de la Serranía de Ronda. Ronda. Málaga, Spain.

Objectives: To analyze the discrepancies found between the home treatment of polypathological patients and their active

Table 1 (EA-50). STOPP/START criteria in our study

STOPP criteria at admission/at discharge//variation	41/28 criteria//- 13 criteria (-31.7%, p = 0.046)
START criteria at admission/at discharge//variation	27/22 criteria//- 5 criteria (-18.5%, p = 0.044)
STOPP group more frequent on admission/at discharge	H, falls risk after drugs: 11/7
START group more frequent on admission/at discharge	F, primary prevention in diabetes mellitus: 13/10

prescriptions, defining the most frequent kind of error in this group of patients, as well as the acceptance percentage of the intervention. To identify the major drug groups affected by the discrepancies, both in frequency and severity. Assess the severity of these errors, according to the categorization of The National Coordinating Council for Medication Error Reporting and Prevention's (NCC MERP).

Material and method: Prospective observational study. Carried out by performing a reconciliation at admission of 100 polypathological patients, as defined under the Andalusia's integrated care process, in a tertiary hospital. The main information source used was the digital medical history, both from the hospital and from the primary care, using clinical interviews if necessary. To assess the error incidence, we estimate the main quality indicators of the reconciliation process recommended by the Reconciliation Group of the Spanish Society of Hospital Pharmacy. The following variables were collected: number of prescribed drugs, number of discrepancies requiring clarification with the prescriber, number of reconciliation errors (RE), type of error (omission, commission, differences in dose, route or timing, incomplete prescription), and acceptance rate and pharmacological groups involved. We evaluated the severity of each reconciliation error according to the classification of NCC MERP.

Results: Among the 100 patients, 76 of them showed at least 1 CE, ergo there were 76% patients with CE. The patients had 1,153 drugs prescribed, of which 196 showed discrepancies requiring clarification with the prescriber. Among these 196 not justified discrepancies, the doctor changed the prescription in 162 of them, considered reconciliation errors. These data give a figure of reconciliation errors in 82.65% of the discrepancies and 14.05% of prescribed drugs with CE. The error types were: omission of drugs (83.33%), being remarkable antidepressants and iron supplements, commission (4.32%), different dose or timing (6.79%) and incomplete prescription (5.55%). Among the different pharmacological groups involved antidepressants and iron supplements could be highlighted as the most frequent errors, and anticoagulants and antiplatelet agents as the most serious. In terms of severity, 4.32% were potential errors, 16,05% of the errors produced did not reach the patient, 67.9% reached the patient but caused no damage, and the 11.73% caused no harm, but would have required monitoring patient.

Discussion: Although the severity is low, the activity of reconciling the medication should be seen as an opportunity to improve patient safety and is essential to develop and implement standardized procedures in vulnerable patients, as is the case of polypathological patients.

Conclusions: 1. There is a high incidence of reconciliation errors in these patients. The most frequent error is the omission of the drug, possibly due to the large number of drugs prescribed in patients with multiple comorbidities. 2. Antidepressants, iron supplements, anticoagulants and antiplatelet agents are the major pharmacological groups affected. 3. The severity of these errors is low.

EA-53
FIVE YEARS OF NONAGENARIAN AND CENTENARIAN ADMISSION IN THE UNIVERSITY GENERAL HOSPITAL OF ALICANTE (SPAIN): IMPLICATION OF THE INTERNAL MEDICINE SERVICE

J. Mateo González[1], A. Zurita Estarrona[1], D. Galvis Cárdenas[1], H. Pinargote Celorio[1], R. Sánchez Martínez[1], J. Sastre Barceló[2], A. Tello Valero[1], J. Ramos Rincón[1]

[1]Department of Internal Medicine, [2]Department of Admission. Hospital General Universitario de Alicante. Alicante, Spain.

Objectives: Older adults constitute the largest subgroup in the internal medicine practice, and providing optimal care to this population can be challenging. Patients over 90 years are increasing in proportion among the general population. The aim of this study was to investigate in which units they were admitted in hospital, which diagnoses they were given, and the outcomes of hospitalization in these nonagenarian and centenarian patients for five years in the city of Alicante (Spain).

Material and method: Cross-sectional study of the 2,461 episodes of admission by patients ≥ 90 years old that were attended for five years (from 2007 to 2011) in a public teaching hospital without a geriatric service. Demographic data, diagnoses at hospital discharge, and mortality were obtained.

Results: Throughout the period of study there were 165,870 episodes of hospital admission, 2,461 (1.5%) were patients ≥ 90 years. The number of annual admission ranged from 475 to 507. Five hundred and sixty one episodes (26%) were re-admitted to hospital during the period of study: two times in 58.6% (329/561), three times in 24.2%, four times in 8.2% and other ≥ 5 times (8%). Average age of admission was 92 years old (range: 90-108 years). Only 38 (0.9%) admissions were in centenarian patients. The gender of admission was female in 64.8% and male in 35.2% episodes. Most of admissions came from Emergency Room (95.5%). The main service for admissions was the internal medicine service (IMS) (761 episodes; 30.9%) and short stay unit (SSU) (655 episodes; 26.6%). The other medical services were: gastroenterology & hepatology (6.8%), neurology (NS) (4.4%), and cardiology (2.9%). The main surgical services were orthopedics and traumatology (OTS) (7.3%), general surgery (2.8%), and vascular surgery (2.6%). From the overall number of discharge from IMS, nonagenarian represented 10.2%, from SSU represented 6.1%, from OTS represented 2.8%, from gastroenterology service was 2.0%, and from neurology was 1.9%. The average length stay hospitalization was 5 days (range: 0-79 days). The main cause of admission was lower respiratory tract infection and pneumonia (19.5%), followed by heart failure (10.9%) and hip fracture (8.1%), septicemia (3.9%), urinary tract infection (3.8%), and stroke (3.5%). The mortality rate of admission was 17.0%, however in IMS was 49.1%, in SSU was 13.3%, in NS was 7.3% and in OTS was 4.1%. The main destination at discharge was home (64.9%), followed by home hospitalization (9.1%); 5.7% of discharged patients were referred to a long stay hospital.

Discussion: Nonagenarian and centenarian admissions have been constant for five years of study, most of which were female, one out of four was re-admitted to hospital and mortality was high. IMS represents the main service of admission with a higher mortality rate than others.

Conclusions: The attention to nonagenarian and centenarian patients should be adequate to the main diagnosis of these patients.

EA-54
ARTERIAL HYPERTENSION IN PATIENTS WITH DIABETES MELLITUS OF 1 TYPE WITH ORTHOSTATIC DISORDERS AND POSSIBILITIES OF CORRECTION

V. Schekotov

Department of Internal Medicine. Perm State Medical Academy. Perm, Russia.

Objectives: To characterize peculiarities of diabetic nephropathy (DN) and cognitive functions in patients with arterial hypertension (AH) suffering from diabetes mellitus (DM) of I type, complicated with orthostatic hypotension (OH) and to estimate use of venoprotector for correction of dyscirculatory encephalopathy (DE) and DN.

Material and method: Sixty patients with DM of I type in combination with AH and OH took part in the investigation. Schellongs' orthostatic probe, microalbuminuria (MAU) screening with "Micral-Test-11", MMSE-test, 10 words memo probe, Spielberg

test, Beck questionnaire were used. Hypotensive therapy with enalapril and insulintherapy were carried out in patients of group 1. Venoprotective therapy - with Diosmin was carried out in addition to hypotensive and insulin therapy in patients of group 2. Duration of treatment was 1 month.

Results: In the selection of the individual daily dose of enalapril in all patients achieved target BP levels in both groups. However, in group 1 were observed side effects of antihypertensive therapy in the form of strengthening the subjective symptoms of postural hypotension (pre-treatment complaints were present in 59.3% of patients on therapy - 95% of patients, $p < 0.05$). In the second group noted a significant decrease in subjective symptoms of postural hypotension (pre-treatment complaints were present in 53.3% of patients, on therapy - 14% of patients, $p < 0.05$) and objectively in the form of reduced incidence of systolic (SBP) and diastolic blood pressure (DBP) from baseline. In both groups before treatment there was a significant increase in the level of microalbuminuria during the AOP ($p > 0.05$). After treatment with the ACE inhibitor in group 1 there were significant increases in MAU after 1 month of starting treatment with 219.3 ± 62.6 to 437.8 ± 84.3 mg/l ($p < 0.001$). In the second group there was a significant reduction in MAU with 346,5 ± 88 to 169.8 ± 48 mg/l ($p < 0.001$). In neuropsychological testing, MMSE score and parameters mnestic areas were below the normal limit. After treatment in the group with combined therapy, short-term rates, long-term verbal and visual memory increased. In addition, change and qualitative indicators: reduced memory zigzag curves, indicating a decrease in the lability of the process of memorization and reproduction of words, had achieved a plateau of the curve memory. In the group without indicators detraleks mnestic function remained without positive trend. Combined therapy of short-term rates, long-term verbal and visual memory increased, the average number of plays by more than 7, which correspond to become the norm ($p < 0.05$).

Discussion: Orthostatic insufficiency in patients with type 1 diabetes should be regarded as an important pathogenetic factor in end-organ damage. When orthostatic decrease in blood pressure increases the level of microalbuminuria, which indicates the potential damage of nephron in orthostatic hypotension. These results suggest the presence of severe cognitive dysfunction and emotional disturbances in patients with hypertension against the background of type 1 diabetes complicated by orthostatic hypotension. Based on these data suggest that the elimination of repetitive episodes of systemic hypotension with venoprotectors leads to stabilization of hemodynamics and significant decrease in cognitive disorders, also allows the use of venoprotectors significantly reduce MAU in these patients.

Conclusions: Postural hypotension in patients with DM in combination with AH leads to aggravation of MAU and cognitive dysfunction. Use of venotonic permits to level signs of postural hypotension, decrease the level of MAU and symptoms of cognitive dysfunction.

EA-56
SYNDROME OF INAPPROPRIATE SECRETION OF ANTIDIURETIC HORMONE IN HEMORRHAGIC BRAIN INJURY: REAL LIFE EXPERIENCE FROM A TERTIARY HOSPITAL

C. Voulgari, S. Siasiakou, I. Vasili, L. Mantzaris, S. Paximadas, S. Pagoni

3rd Department of Internal Medicine. Athens Regional Hospital G. Gennimatas, University Medical School. Athens, Greece.

Objectives: Hyponatremia has been described in patients with hemorrhagic brain injury (HBI). This study aims at ascertaining the incidence of hyponatremia in HBI with its etiologic diagnosis, biochemical confirmation, and severity correlation with initial Glasgow Coma Scale (GCS) score and computed tomography (CT) abnormality.

Material and method: All patients more than 70 years old with severe and moderate HBI with CT confirmed abnormality were included. Daily sodium level was monitored for 15 days. Central venous pressure (CVP) was measured for assessment of volume status. Fractional excretion of uric acid was measured in all patients with hyponatremia, both before and after its correction.

Results: Of 10 consecutive patients, 8 remained for analysis. Hyponatremia was seen in 2 (25.0%) patients, of whom 1 developed it within the first week. Mean duration of hyponatremia was 10 days. We found that 5 patients had an elevated CVP consistent with the syndrome of inappropriate antidiuretic hormone (SIADH), whereas 3 had low CVP consistent with cerebral salt wasting syndrome (CSWS). Uric acid levels did not show consistent pattern to suggest a biochemical distinction. There were 33.3% of moderate, and 16.6% of severe HBI among hyponatremic patients. Hyponatremia was seen in Rotterdam CT scores I to IV in increasing incidence ($r = 0.86$, $p = 0.03$), and had significant correlation with initial GCS ($r = 0.75$, $p = 0.05$).

Discussion: Hyponatremia due to SIADH is more common in HBI. Fractional excretion of uric acid measurement could not make a distinction between SIADH and CSWS. CT scoring of severity and initial GCS are equally predictive of hyponatremia.

EA-57
KNOWLEDGE AND UTILIZATION OF TOOLS FOR MULTIDIMENSIONAL ASSESSING OF POLYPATHOLOGICAL PATIENTS BY PRIMARY CARE PHYSICIANS OF ZARAGOZA (SPAIN)

J. Gomes Martín, S. Isasi de Isasmendi Pérez, P. Al-Cheikh Felices, E. Bejarano Tello, J. Díez Manglano

Department of Internal Medicine. Hospital Royo Villanova. Zaragoza, Spain.

Objectives: To determine the knowledge and utilization of the tools for multidimensional assessment of polypathological patients (PP) in primary care.

Material and method: In June 2011 we sent by mail a survey to all the primary care physicians of health sector Zaragoza I. We report the description of data obtained from responses to the survey.

Results: We sent 117 surveys, and we obtained 37 (31.6%) responses. Twenty-nine (78.4%) of responders knew the concept of polypathology and 20 (54.0%) the criteria used to label patients as PP. They reported that in their daily work 36.2% (95%CI 31.3-41.1) patients had multimorbidity and 29.4% (95%CI 25.4-33.4) were PP. Twenty-nine (78.4%) primary care physicians thought that to establish a prognosis for PP is easy but only 14 (37.8%) knew a prognostic tool to do it. All responders reported to know Barthel index, 17 (45.9%) Lawton-Brody index, 37 (100%) Pfeiffer questionnaire and 4 (10.8%) sociofamilial risk Gijón scale. Charlson index was known by 4 (10.8%) and PROFUND index by 4 (10.8%) responders.

Discussion: Caring PP has become a challenge for the health care system of European countries in the 21st century and a progressive increase of polypathology is expected. They are vulnerable, have poor related quality of life and frequently have mental and functional impairment. To care PP a multidimensional assessment is advisable. In Zaragoza nearly one third of patients of primary care are PP. but primary care physicians reported knowledge gaps about sociofamilial risk, comorbidity and prognosis assessment.

Conclusions: There are important knowledge gaps concerning multidimensional assessment of PP in primary care.

EA-58
ATRIAL FIBRILLATION. MORTALITY AND LONG-TERM MORBIDITY

A. Sánchez Morla, A. Blanco Echevarría, F. Aguilar Rodríguez, P. Hernández Sanz, L. Pérez Ordoño, C. González Gómez, P. Catalán, A. Pozuelo

Department of Internal Medicine. Hospital 12 de Octubre. Madrid, Spain.

Objectives: Atrial fibrillation is the most common sustained arrhythmia in the population, and its frequency is expected to increase in coming years. It's a disease with significant impact on overall mortality and morbidity (involved), and its prevention and treatment are increasingly important goals for modern medicine. The objective of this study is to describe cardiovascular complications and mortality recorded during one year follow up of a sample of patients with atrial fibrillation in our area, and to analyze the risk and protection factors involved.

Material and method: We included all the patients with atrial fibrillation admitted to the Internal Medicine ward at the Hospital 12 de Octubre, Madrid, during a period of two months (June and July 2010), collecting information recorded in the clinical history of the patients (diagnostic procedures, prognostic factors, events during the hospital stay, etc). Subsequently, in July 2011, by telephonic interview we collected information of posterior clinical events, complications and mortality reported during that year completing epidemiologic characteristics of the group. We used Stata 10.0 to analyze our results, considering statistical significance for $p < 0.05$.

Results: There were 82 patients with atrial fibrillation admitted during the period analyzed, of which 41 (50%) were women, with mean age of 78.9 years. We observed high comorbidity rates with a mean Charlson Index of 3.1. Comorbidity was mainly associated with cardiovascular risk factors. We found patients were greatly polymedicated with an intake of 6.8 drugs per patient on average. The most frequent complications recorded during the study were hemorrhagic events (32.9%), heart failure (31.7%) and death (41.46%). Heart failure episodes were more frequently associated with receiving anticoagulation treatment (42.5% vs 21.95%, $p = 0.048$) and with diagnosis of atrial fibrillation more than 30 months prior. We observed higher mortality in the groups with high Charlson index and with permanent/persistent vs paroxistic atrial fibrillation, but these results didn't reach statistical significance.

Discussion: The current study, when compared with previous similar studies, shows an aging population with intense comorbidity and with a high prevalence of cardiovascular risk factors. Complications are also reported considerably more frequently than in previously published data. The association of heart failure and anticoagulation treatment is not completely explained with our results, though it could be related to surreptitious bleeding events or drug interactions. On the other hand, mortality seems to be mainly associated with non-cardiovascular events, probably showing a greater importance of overall comorbidity and age of our population, than a higher cardiovascular risk associated with atrial fibrillation.

Conclusions: The population that is hospitalized in our Department of Internal Medicine with atrial fibrillation represents an especially aged group of patients, with significant associated cardiovascular risk factors and comorbidity. Complications recorded during one year are significantly higher than those found in other studies with strikingly higher mortality. Current guidelines for the management of patients with atrial fibrillation probably do not meet our patient profile. This must be taken into account when assuming the treatment and evaluation of our patients and should encourage us to perform future studies with similar populations.

EA-59
EXACERBATIONS OF CHRONIC OBSTRUCTIVE PULMONARY DISEASE: MORTALITY AND READMISSION IN PATIENTS CON LTOT, NIV AND CPAP

L. Royo Trallero, C. Josa Laorden, S. Luna García, M. Aibar Arregui, M. Sánchez Marteles, F. Ruiz la Iglesia, J. Pérez Calvo

Department of Internal Medicine. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: Chronic obstructive pulmonary disease (COPD) is a priority health problem worldwide. In addition to its high prevalence and morbidity, causes important socioeconomic costs which include loss of quality of life and early death. Among them, specially comorbid patients that involve specific cares are patients with home oxygen therapy (LTOT) and/or special ventilation measures as noninvasive ventilation (NIV) and airflow pressure continuous positive (CPAP). The aim of this study is to analyze mortality, readmissions and hospital stay in patients with acute COPD requiring LTOT and/or nocturnal CPAP and if they have needed NIV and/or admission to intensive care unit (ICU).

Material and method: Observational, retrospective and transversal study. We reviewed all reports of patients discharged from the Hospital Universitario "Lozano Blesa" from January to December 2011 as first or second diagnosis COPD (ICD 491), emphysema (ICD 492) and chronic airflow obstruction air (ICD 496). We took demographic data, mortality, ICU stay, number of readmissions and cases that previously had LTOT and/or CPAP and/or use of NIV during admission.

Results: We reviewed 516 cases, of which 20% were women (N = 77), and 80% male (N = 299), with a mean age of 74.49 years (median 75 years). The average patient stay mean was 12 days, with a median of 10 days. 249 cases (48.3%) were admitted in Pulmonology, 222 (43%) in Internal Medicine and the remaining 45(8.7%) in other services. There was 184 cases (35.66%) of patients with respiratory failure, 134 needed LTOT (25.97%), 68 NIV (13.18%) and/or 22 CPAP (4.26%). Their mean age was 72.03 years (median 73 years). Their average patient stay mean were 13.43 days with 9.69% of readmissions in the previous 3 months. 4.07% of these patients were admitted to ICU. The mortality rate during hospitalization was 0.78%. Patients who required NIMV had a 30.88% of ICU admission and 10.29% of mortality. Patients with LTOT had a 6.72% of ICU admission and mortality and CPAP patients had 4.55% and 0% respectively. Patients without respiratory failure had an average patient stay of 11.27 days with 8.33% of readmissions. Their mean age was 75.86 years (median 77 years). Mortality rate was 2.33%. The ICU admission rate was 0.39%.

Discussion: In our study, patients with COPD and chronic respiratory failure have a higher rate of complications involving younger patients, longer hospital stays and readmissions and ICU stay 4 times greater than the other group. However, mortality rate during hospitalization in this group was low. Perhaps the fact that they are patients requiring invasive treatments is a possible reason. It should be noted that patients who required NIV had a high percentage of ICU admission and mortality in comparison with LTOT and CPAP. Finally, note that more studies are needed to verify that the observed differences are statistically significant.

Conclusions: 1. COPD patients with chronic respiratory failure have a higher percentage of ICU admission and use of NIV during readmission for exacerbation. 2. COPD patients with chronic respiratory failure have more respiratory complications at hospital income, but not increased mortality. 3. COPD patients with chronic respiratory failure have longer average hospital stay and more readmissions because of their exacerbation.

EA-60
B12 DEFICIENCY AT THE INTERNAL MEDICINE DEPARTMENT, A PHENOMENON TO CONSIDER?

M. Navarro Aguilar, M. Rodero Roldán, M. Sánchez Marteles, M. Igúzquiza Pellejero, B. de Escalante Yangüela, A. Marín Ballvé, R. Boldova Aguar, C. Torrubia Pérez

Department of Internal Medicine. Hospital Clínico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: Vitamin B12 deficiency is a common cause of megaloblastic anemia. It causes several neuropsychiatry symptoms and elevated homocysteine, and is common in elderly patients. There are many risk factors for this, among which are the treatments with inhibitors of proton pump inhibitors (PPIs) or metformin. The aim of this paper is to describe the characteristics of patients with vitamin B12 deficiency admitted to Internal Medicine Department (IMD).

Material and method: This is an observational, cross-sectional and retrospective study made in the IMD at the Clinical Hospital Lozano Blesa. It reviewed the reports of patients who were discharged and have this diagnosis. With this, data were collected: age, sex, personal history, routine treatment, blood tests at admission, vitamin B12, folic acid and iron metabolism levels, plus the additional tests performed. After, we did the statistical analysis that is presented.

Results: We reviewed 143 patients (64 men, 79 women) with a mean age of 79.18 years (SD ± 12.78). Among the pathologic precedents, the 79.02% of the patients was multimorbidity, hypertension being the most frequent (57.55%). 23 patients had a previous diagnosis of B12 deficiency, but continued with said deficiency despite the therapy in 61%. The most common reason for admission was cardiac failure and respiratory infection (both 20.86%), followed by anemia (11.51%), other infections (7.19%) and respiratory failure (4.31%). The most commonly used drugs: 43.88% of the patients took a PPI, 40.28% took ACE inhibitors, while 25.17% took metformin, for which no significant association with B12 deficiency was founded (p = 0.197, p = 0.822 and p = 0.119 respectively, through the Mann-Whitney U' test). The average number of vitamin B12 in these patients was 140.37 pg/ml, anemia presenting the 67.13% of patients with a mean hemoglobin of 11.18 g/dl, a mean hematocrit of 34.7% and a mean corpuscular volume of 90.26 fl. In addition, 24 patients associated folic acid deficiency, 48 iron deficiency and 97 patients hypoproteinemia (total proteins below 6.4g/dl). Intrinsic factor antibodies were determined in 71 patients. The homocysteine or parietal cells antibodies were not determined. The gastroscopy with biopsy was performed in 32 patients (23.02%), being most of them normal (18), 3 had atrophy, 7 chronic gastritis, 1 had neoplasia and 3 hiatal hernia. Treatment was administered to 118 patients, the majority by intramuscular administration (79.66%). Treatment was associated with folic acid in 38 patients.

Discussion: The average age of the patients in our study was high, consistent with the fact that most were patients with significant comorbidity and with the literature. PPIs and metformin treatments are very common, especially in elderly patients, and recent studies have shown their association with the increase in diagnoses. The deficiency can occur in 10-30% of patients taking metformin for a prolonged period. Data from our study seem to be consistent with these data as they are two of the most common drugs in patients reviewed. This suggests that it may be necessary to adjust the treatment, or at least its re-evaluation. Nevertheless, this claim would require larger studies to confirm it. The data found in our patients indicate a multifactorial origin of anemia, produced by concomitant diseases, hypoproteinemia and iron deficiency.

Conclusions: 1. The patients with B12 vitamin deficiency are elderly, have multimorbidity and anemia is likely multifactorial. 2. The use of IBP and metformin used by these patients is very high, consistent with existing literature, and while it may not be the only reason it should be considered in the future. 3. Larger studies are needed to ensure the significance of these findings and to assess the comorbidity and chronic treatment of these patients.

EA-61
MANAGEMENT OF CHRONIC DISEASE IN A MEDICAL DAY HOSPITAL

B. Escolano Fernández[1], A. Maravi Oliván[2], C. Criado Dabrowska[1], R. Pacheco Cuadros[1], T. Bellver Álvarez[1], C. Barrasa Rodríguez[1], F. Pérez Rojas[1], S. García Tejada[1]

[1]Department of Internal Medicine. Hospital Virgen de la Torre. Madrid, Spain. [2]Zona Básica Sanlúcar la Mayor. Distrito Sanitario Aljarafe. Sevilla, Spain.

Objectives: To analyze the characteristics of a medical day hospital with chronic disease patients.

Material and method: An observational prospective study of patients treated in Hospital Virgen de la Torre (chronic medical day hospital) with four daily assessments in 2011.

Results: A total of 331 patients were attended, 213 women (64.4%) and 118 men (35.6%). Mean age 83.27 ± 11.99 years old. We review 6 patients in February, 22 in March, 50 in April, 75 in May, 34 in June, 27 in July, 10 in Agost, 24 in September, 35 in October, 29 in November and 19 in December. The most frequent consultation complaints: clinical evaluation of chronic disease (236 patients; 71.3%), healing of pressure ulcers (52; 15.7%), transfusion (21; 6.3%), inclusion in our program of advanced chronic disease (9; 2.7%), paracentesis (7;2.1%), i.v treatments (3; 0.9%), administration of iron (2; 0.6%) and thoracocentesis (1;0.3%). The most frequent tests complaints: analysis (122; 36.9%), analysis and X-ray (103; 31.1%), healing of pressure ulcers (55; 16.6%), transfusion (19; 5.7%), e.v treatments (14; 4.2%), X-ray (9; 2.7%) and collection of results (9; 2.7%). The average time of stay was 4 ± 1.37 hours. 153 patients (46.2%) were derived from our incomes, revisions of our day hospital (81; 24.5), care support team home (26; 7.9%), primary care settings (70; 21.1%) and emergency department of our reference hospital (1; 0.3%). After the visit 277 patients (83.7%) were discharged and 54 (16.3%) were hospitalized.

Discussion: With this day hospital of a chronic disease, we have observed better tracking and a reduction of admissions in patients with advanced chronic disease. We should create appropriate workfare routes according to the needs of these patients, which include identification and new feedback loops between different levels of care and a much better management of these patients.

Conclusions: There is not an accepted model for the care of chronic patients; so would be a good improve to share information, statistics and methodology between units in order to manage the resources and be able to create standard operating procedures in chronic disease. It is essential to improve the control of these fragile patients through the creation of specific units for them, with new criteria, organization and methods in order to avoid unnecessary incomes and improve the life quality of these patients.

EA-62
MAJOR BLEEDING EVENTS IN ELDERLY PATIENTS WITH ATRIAL FIBRILLATION AND VITAMIN K ANTAGONISTS

R. Martínez Fernández, J. Ampuero Ampuero, A. Jurado Porcel, L. Carracedo Melero, E. Guirao Arrabal, M. Martín Moreno, M. Montero Pérez-Barquero

Department of Clinical Management of Internal Medicine. Hospital Universitario Reina Sofía. Córdoba, Spain.

Objectives: To analyze the characteristics and main factors related to major bleeding episodes in elderly patients with atrial

fibrillation (AF) being treated with vitamin K antagonists (VKA), hospitalized in a General Internal Medicine Unit.

Material and method: Retrospective study that included patients over 75 years old, admitted to an Internal Medicine Unit for three consecutive years (2009-2011). All of them had previously been diagnosed with AF and were receiving VKA (acenocoumarol) and had a major bleeding event during this period. We analyzed demographic data, comorbidity indexes (Charlson and Charlson-age comorbidity indexes), the risk of bleeding by the HASBLED index, polypharmacy, overdosage of acenocoumarol (INR > 3) at the time of the major bleeding episode and death.

Results: A total of 1,069 patients with AF were admitted to our Unit during this period and 633 (59.2%) of them were receiving acenocumarol. 58 (9.1%) had a major bleeding episode (23 cases in 2009, 16 in 2010 and 19 in 2011). Mean age was 82.4 ± 4.5 years and 30 were males (51.7%). AF was classified as permanent in 53 (91.3%). 37 patients (63.8%) had a Charlson index ≥ 3 and mean Charlson-age index was 6.7 ± 1.7. The most commonly associated diseases were diabetes mellitus, hypertension and chronic heart failure. 19 (32.7%) patients were following treatment with 3-4 oral-drugs plus acenocumarol, and 31 (53.4%) with 5 or more. All of them had CHADS-VASC index ≥ 3 (mean CHADS-VASC was 4.96 ± 1.48). 34 patients (58.6%) had ≥ 3 HASBLED index. The bleeding origins were as follows: upper gastrointestinal tract 19 patients (32.7%), lower gastrointestinal tract 13 (22.4%), intracranial 11 (19%), muscular or subcutaneous 8 (13.8%), hemoptysis or epistaxis 4 (7%) and retroperitoneal 1 (1.7%). 30 patients (51.7%) had an INR > 3 at the time of the episode. This ratio was 2-3 in 13(22.4%) and < 2 in 15 (25.9%) that had a major bleeding episode. Overall mortality during admission was 12 (20.7%)) and 8 patients (13.8%) died as a direct result of bleeding. The main cause of death related was intracranial bleeding (6 cases, 75%).

Discussion: We observed a higher frequency of major bleeding events in elderly patients receiving VKA due to AF than that previously reported. There is a high related mortality, especially in patients presenting with intracranial bleeding. Comorbidity and polypharmacy is nearly constant in this population. There is a high rate of excessive anticoagulation in patients admitted to our Unit for major bleeding. However other patients develop this complication with INR in therapeutic or subtherapeutic ranges. It's possible that other factors may play an important role in these cases.

Conclusions: Major bleeding episodes have a high incidence and mortality in elderly patients with AF and VKA. This complication may be influenced by excessive anticoagulation but also by other factors inherent in them (comorbidity, polypharmacy, etc.). Nevertheless, this population may need a careful INR and clinical control. We suggest that new oral anticoagulants may play an important role in elderly patients with AF and high risk of bleeding, as VKA can be associated with high complication rates due to pharmacological interactions and individual INR fluctuations.

EA-63
SARCOPENIA AND DIABETES

H. Vieira Dias, B. Pedro, Y. Abuowda, A. Matos, C. Vitorino, C. Esteves, F. Roque

Department of Diabetes. Hospital de Santarem EPE. Santarem, Portugal.

Objectives: The number of obese elderly is increasing worldwide and the prevalence of type two diabetes (T2DM) has increased in the ageing population and might contribute to co-morbid conditions. Sarcopenia, loss of muscle mass with age, is considered as a major cause of frailty and decreased independence in the elderly. Both sarcopenia and obesity are linked with insulin resistance and consequently with T2DM. We aim to establish the prevalence of sarcopenia and determine whether is associated with metabolic control.

Material and method: We performed a cross- sectional analysis in a two month period using patients of 65 years or older with T2DM, attending a diabetic appointment in a countryside hospital. Data about epidemiology, metabolic and socio-economic parameters was collected. Anthropometric evaluation included weight, height, body mass index (BMI), body circumference (arm, hip, abdominal, leg, waist and calf) and triceps skinfold (TS); arm fat index (AFI) and arm muscle index (AMI) were calculated using Gurney and Yelliffe equation and Heymsfield equation respectively. We used SPSS v17 for statistical analysis.

Results: We evaluated 129 patients, 41.4% male. Mean age was 72.7 years (65-89), being women older. Patients were diagnosed, in mean, 14 years ago; 0.9% were active smokers, 83.9% had high blood pressure, 63.4% had dyslipidemia and 16.9% declared alcoholic consume (> 3 units per week). Only 23% declared to perform physical exercise of any kind. In general, patients had average hemoglobin A1C levels of 7.9% (42% had a good metabolic control with levels < 7%), with no differences in gender. Women had significantly lower education and income compared with men ($p < 0.05$). The BMI was greater in women ($p < 0.01$); the mean abdominal circumference was 107.8 cm with no difference in gender. The mean lower leg circumference (LC) 31.3 cm, the mean TS was 2.6 cm. Patients who had: bigger AFI, abdominal circumference and BMI, less leg circumference, and perform no exercise had worse metabolic control ($p < 0.027$) being more in women ($p < 0.003$).

Discussion: Loss of muscle mass and obesity were associated with adverse metabolic control, and the association was stronger in the patients over 80 years of age. Several studies had similar conclusions but almost all used bioelectrical impedance to measure muscle mass and determine sarcopenia. Anthropometric evaluation performed by trained health workers is inexpensive, non-invasive and provides detailed information on different components of body structure.

Conclusions: Our findings suggest that obesity and loss of muscle mass may potentiate each other and amplify their impact in the metabolic control. Physicians must be aware of this and determine the nutritional status of older diabetic patients using anthropometric measures which are simple and cheap. A careful nutritional intervention combined with stretching and resistance training exercise programmes in the older diabetic may be beneficial.

EA-64
IDENTIFICATION OF END OF LIFE TRAJECTORY IN PATIENTS WITH ADVANCED CHRONIC MEDICAL CONDITIONS. THE PALIAR SCORE

M. Bernabeu Wittel[1], P. Rivas Cobas[1], J. Murcia Zaragoza[2], B. Escolano Fernández[3], G. Jarava Rol[3], C. Hernández Quiles[4], J. Díez Manglano[5] and the PALIAR STUDY Investigators[6]

[1]UCAMI. Hospital Virgen del Rocío. Sevilla, Spain. [2]Department of Internal Medicine. Hospital Vega Baja de Orihuela. Orihuela (Alicante), Spain. [3]Department of Internal Medicine. Hospital de la Serranía de Ronda. Málaga, Spain. [4]Department of Internal Medicine. Hospital San Juan de Dios de El Aljarafe. Sevilla, Spain. [5]Department of Internal Medicine. Hospital Royo Villanova. Zaragoza, Spain. [6]Other 41 Spanish Hospitals, Spain.

Objectives: To develop a new reliable prognostic tool that allows us to identify the path of end of life (death in 6 months) in patients with advanced medical diseases.

Material and method: Prospective observational study in 41 Spanish hospitals, with inclusion of patients during hospitalization, office, or home hospitalization with one or more of the following conditions: heart failure with basal dyspnea ≥ III of the NYHA;

respiratory failure with basal dyspnea MRC ≥ III and/or $satO_2$ < 90% and/or chronic home oxygen treatment; chronic renal failure stage 4 or 5 of NKF; chronic liver disease with a Child-Pugh score ≥ 7; chronic neurological disease with established cognitive and/or functional impairment (Pfeiffer ≥ 6/MEC ≤ 18/Barthel ≤ 60). Patients were followed during 6 months, or until primary end-point (death) occurred. Potential risk factors of mortality were obtained of the multidimensional clinical data in the 1788 (96.8% of the 1847 recruited patients), who completed the follow-up. Each factor independently associated with mortality in the derivation cohort (884 patients of the hospitals in the eastern half of the country) was assigned a prognostic weight in function of its relative risk; subsequently the PALIAR index was calculated for each patient by summing the points of each prognostic factor. Then, patients were divided into quartiles of risk, according to the likelihood of dying predicted by the model, thus obtaining risk subgroups. The accuracy of the index in the derivation cohort and validation (894 patients of the hospitals in the western half of the country) were assessed by analysing its calibration (goodness of fit Hosmer-Lemeshow, and Kaplan-Meier curves with the logarithm of the rank test); and its discriminative power (using ROC curves and calculation of the area under the curve). Finally we compared the accuracy of PALIAR index with that obtained with the Charlson index (CI), the age-adjusted CI, and the Palliative Prognostic Index (PPI).

Results: Mortality in derivation/validation cohorts was 37.6%/37.7%, respectively. We identified 6 independent predictors of mortality, which were used to build the index (≥ 85 age years, 3 points; IV functional class on NYHA/MRC, 3.5 points; anorexia, 3.5 points; presence of skin pressure ulcer(s), 3 points; the need to stay more than 50% of the vigil time in bed or bedridden (ECOG-PS ≥ 3), 4 points; and albuminemia ≤ 2.5 g/dL, 4 points). Mortality in derivation/validation cohorts according to ascending risk-groups was 20/21.5% for patients with 0 points; 33/30.5% for those with 3-3.5 points; 46.3/43% for those with 6-7 points; and 67/61% for those who reached 7.5 or more points, respectively. The calibration was good in both cohorts (goodness of fit through the test of Hosmer-Lemeshov (H-L), p = 0.92/p = 0.39; log-rank test on the combined strata p = 0.0001), as well as the discriminative power (area under the ROC curve in derivation/validation cohort of 0.71 [0.67-0.75]/0.68 [0.66-0.72], respectively). The calibration of the CI (H-L with p 0.09), PPI (H-L with p 0.37), and age-adjusted CI (H-L with p 0.0001) were good except of the latest one; while their discriminative power (area under the ROC curve 0.52 [0.49-0.55], 0.67 [0.65-0.71], 0.57 [0.54-0.59], respectively), was lower than the obtained with PALIAR index.

Conclusions: The PALIAR index is a precise and reliable tool to identify the end-of-life trajectory in patients with advanced medical diseases.

EA-65
IMPACT OF MULTIDISCIPLINARY INTERVENTION IN FRAIL PATIENT WITH HIP FRACTURE

T. Casanova Querol[1], W. Fuentes[2], E. León[1], E. Soriano[4], R. Rivero[3], D. Richart[3], L. Reig Puig[2], J. Girós Torres[3]

[1]Department of Internal Medicine, [2]Department of Geriatrics, [4]Department of Anesthesia, [3]Department of Orthopedics. Hospital de Barcelona. Barcelona, Spain.

Objectives: To value the impact of the intervention of a multidisciplinary team (MDT) on health care assistance in frail patients with hip fracture.

Material and method: Descriptive and retrospective study of patients > 65 years old admitted for fracture of proximal femur. Period: October 2010-December 2011. We assessed: 1) Socio-demographic and Clinical data: type of fracture, Geriatric assessment, comorbidities and complications. 2) Process indicators: every patient had an anesthetic, traumathologic, geriatric assessment < 24 hours of admission. Intervention < 48 hours. Surgical waiting time, length of stay, destination at discharge. We also performed a retrospective analysis of the patients seen by conventional orthopedic unit (COU) during the period August 2009 to September 2010. We compared the differences: length of stay and time of surgical waiting time.

Results: MDT group: 152 patients, median age 84, 73% women, one third of the patients live alone, 50% have architectonic barriers, 26% are illiterate. Type of fracture: 40% subcapital, 57% intertrochanteric. 75% have mild functional dependence before admission, and at discharge, 83% moderate to very severe dependence. Charlson 1.93 ± 1.7, and 33% have dementia. 75% have some degree of malnutrition. Mean MNA 15.6 points. Complications: delirium 32%, nosocomial infections 13% (urinary most frequent), heart failure 11%. ASA ≥ 3: 53%. Process indicators: 47% underwent surgery in less than 48 h. Causes for delay: being on anticoagulation therapy (12%), logistics (21%), weekend (9.2%), decompensated underlying disease 8.6%. Length of stay: 14.5 days. Mean surgical waiting time: 3.8 days. For discharge: 60% Geriatric Rehabilitation Unit, 32% Home, death 4.6%. COU Group: 137 patients, median age 82, 82% women. Type of fracture: no difference compared with the MDT group. Length of stay: 19.6 days, 18.8% underwent surgery in less than 48 hours. Mean surgical waiting time 6.4 days. Deaths: 5.1%.

Discussion: There are statistically significant differences between length of stay (14.5MDT vs 19.5 COU, p < 0.0001) and surgical intervention less than 48 hours (47%MDT vs 18.8% COU, p < 0.0001). The difference in the total number of deaths is not statistically significant (4.6% vs 5.1%, p = 0.19).

Conclusions: Multidisciplinary intervention in frail patient with fracture of proximal femur has decreased significantly the mean time of hospitalization and the delay in surgical intervention.

EA-66
QUALITY ASSESSMENT OF HOSPITAL REPORTS OF NONAGENARIANS PATIENTS IN INTERNAL MEDICINE

P. Dios Díez, S. García Escudero, E. Castelar, E. Aguirre Alastuey, A. Muela Molinero

Department of Internal Medicine. Complejo Asistencial de León. León, Spain.

Objectives: Evaluate the clinical characteristics of our patients and the quality of global and geriatric information of hospital reports in our service.

Material and method: We analyzed discharge, transfer and death reports of all nonagenarians patients admitted in to our service between June and December of 2010. Epidemiological, social, clinical and administrative data were collected. Statistical analysis was made using SPSS 19.0.

Results: 217 nonagenarians patients were admitted (mean age 92.37 years). 58.1% were female. The average hospital stay was 9.37 days. Regarding the social situation of these patients, 21.7% lived in their own homes, 53.5% accompanied by other relatives and 24.4% were institutionalized. The most common diagnoses were infectious disease (38.2%) and heart failure (CHF) with 33.6%. The Charlson index (CI) of these patients was 3.03. Mortality during hospitalization was 18%. According to the minimum set of data (CMD) of hospital reports: 86.6% included the reason for admission (MI), 95.9% personal history (AP), 93.5% current disease (AD) 96.3% patient outcomes (E), 94.9% diagnosis (D) at discharge and only 73.7% had the recommended treatment (T). Geriatric and cognitive assessments were included only in 13.8% and 11.1% of reports. In the case of patients with CHF, which was the largest homogeneous group of diagnosis, we observed infra-utilization of functional and cognitive scales, and a lower incidence of delirium. In the case of

patients who died, the worst completed reports were statistically significant for AP, EA, EF and D ($p < 0.001$) and the absence of clinical course (p 0.03). Furthermore, these patients had significantly more episodes of acute confusional state (33.3 vs 18.5%) (p 0.03).

Discussion: The clinical reports are an essential communication between doctor, patient and family, and other health professionals. In our series, our reports are well- completed with relation to CMD. Although there is a deficit in comparison with other works, to adapt the document that often accompanies the patient, who is in a fragile state. However, the quality of death reports is considerably lower, because they do not include the majority of items. The relationship between delirium and mortality has been described before, however, in our cases, this relationship must be determined with caution. The data reflected in the reports are focused on the context in which death occurs. In any case, the fact of not being reflected in the report does not necessarily mean it did not happen.

Conclusions: In our center, hospital discharge reports usually have the CMD. Death reports are of poorer quality than the others, because they are incomplete. Geriatric assessment and use of scales is limited.

EA-67
CHRONIC OBSTRUCTIVE PULMONARY DISEASE, COMORBIDITIES AND COMPLEXITY OF THE PATIENTS: STUDY DESIGN AND PRELIMINARY RESULTS OF THE COMPLEXICO STUDY FROM THE SCIENTIFIC SOCIETY FADOI

R. Nardi[1], C. Baldo[2], G. Gussoni[2], L. Fabbri[3], A. Sacchetta[4], G. Vescovo[5], M. Campanini[6], C. Nozzoli[7]

[1]Department of Internal Medicine. Hospital Maggiore. Bologna, Italy. [2]Department of Research. FADOI Foundation. Milan, Italy. [3]Department of Oncology and Hematology, Unit of Respiratory D. University of Modena and Reggio Emilia. Modena, Italy. [4]Department of Internal Medicine. Hospital de Gironcoli. Conegliano Veneto, Italy. [5]Department of Internal Medicine. Hospital S. Bortolo. Vicenza, Italy. [6]Department of Internal Medicine. Hospital Maggiore della Carità. Novara, Italy. [7]Department of Internal Medicine. Hospital Careggi. Florence, Italy.

Objectives: Comorbidities and general lifestyle conditions affect disease management and clinical outcome in patients with chronic obstructive pulmonary disease (COPD). Patients hospitalized in Internal Medicine (IM) are frequently elderly, with a great burden of comorbidity and frailty. Aim of the study is to evaluate the prevalence of COPD among patients hospitalized in IM, the percentage of COPD patients with at least three concomitant chronic diseases, and the global complexity of COPD patients referring to IM departments.

Material and method: This is an observational study involving 44 IM Units in Italy. At least 1000 consecutive patients hospitalized for any cause with known or de novo diagnosis of COPD documented by spirometry will be included. Frailty of COPD patients was described by means of the Multidimensional Prognostic Index (MPI), whose prognostic value is considered higher than those provided by the individual parameters included in the score (e.g.: Activities/ Instrumental Activities of Daily Living, Short-Portable Mental Status Questionnaire, Mini-Nutritional Assessment, Exton-Smith Score, Comorbidity Index Rating Scale, medications, and co-habitation status) in predicting short- and long-term mortality.

Results: The study started in February 2012 and the estimated conclusion is in September 2012. At the time of abstract submission, around 700 patients have been included in the study, and data from the first 100 enrolled patients are available. According to these preliminary data, the prevalence of COPD in IM wards was found to be 22.2%. Sixty-seven percent of patients had at least three chronic diseases other than COPD. At the time of hospitalization, 15.0% of the patients were receiving antibiotic for COPD, 31.0% bronchodilators, 10.0% corticosteroid and 38.0% bronchodilators + corticosteroid; at discharge the percentages were 28.0%, 27.0%, 7.0% and 82.0%, respectively. Oxygen therapy for COPD was used in the 82.0% of the patients, and mechanic ventilation in 7.0%. The mean MPI score was 0.42 ± 0.15 and according to a stratification algorithm 37.0% of patients were classified as having low-risk, 52.0% at moderate-risk and 11.0% at severe-risk.

Discussion: COPD is one of the most frequent diseases in patients admitted in IM wards. Neither administrative indicators nor comorbidity indexes are able -for themselves -to define the complexity of patients with COPD who are hospitalized in IM Units. The MPI score has been recently proposed and studied in a number of diseases, to evaluate complexity and predict prognosis of the patients. Our study, by assessing the complexity of COPD patients, may help to raise awareness of physicians on this issue.

Conclusions: The study is ongoing and the final results will be presented at the time of EFIM Congress. Preliminary data confirm that COPD patients have a relevant level of comorbidity. A comprehensive multidimensional assessment of their complexity by MPI index is useful for the prognostic stratification of our patients.

EA-68
POSTPRANDIAL TRIGLYCERIDE INCREASE IS INFLUENCED BY AGE-ASSOCIATED FEATURES OF METABOLIC POSTPRANDIAL STATE IS AFFECTED BY AGE-ASSOCIATED FEATURES OF METABOLIC SYNDROME, BUT NOT BY AGE

J. Delgado Lista, A. Pérez Caballero, P. Pérez Martínez, A. García Ríos, N. Delgado Casado, J. Alcalá Díaz, F. Gómez Delgado, F. Pérez Jiménez

Department of Internal Medicine. Hospital Universitario Reina Sofia/IMIBIC/CIBEROBN/UCO. Córdoba, Spain.

Objectives: Postprandial lipemia influences the development of atherosclerosis. Age has been defined as a regulating factor of the extent of postprandial lipemia, but its independence of other age-associated phenotypic features, such as metabolic syndrome, has not been fully elucidated. To investigate if age is an independent factor influencing postprandial lipemia.

Material and method: We compared the lipemic response to a rich fatty meal (60% fat) of 88 healthy young men (< 30 years old) and 97 older participants (77 Metabolic Syndrome patients aged > 40; and 20 healthy elderly people > 65) (all ApoE3/E3), at fasting state and at 2nd and 4th postprandial hours.

Results: We didn't find differences between the healthy young men and the healthy elderly. The Metabolic Syndrome patients displayed a higher postprandial TG area below the curve than the other two cohorts $p < 0.001$. ANOVA for repeated measurements confirmed that these differences were significant at every time-point (fasting, 2h and 4h). Concomitant higher responses for Large and Small TRL-carried TG and Chol were found in these metabolic syndrome patients. Interestingly, the most significant differences were found for Small-TRL carried particles, which suggest that this fact may be mainly due to impaired lipid clearance.

Discussion: Although age has been proposed as a key factor influencing postprandial lipemia, this fact comes from studies in which other factors, such as metabolic syndrome criteria, have not been controlled. As the prevalence of these criteria increases with age, we aimed to explore if this association between age and high postprandial triglyceridemia remains after controlling by metabolic syndrome criteria. In our setting, age was not related to higher postprandial lipemia, but the existence of metabolic syndrome

was. These findings may increase our knowledge of the lipid metabolism and physiology, especially in elderly persons.

Conclusions: Metabolic Syndrome may account for the differences in postprandial lipemia that have been attributed to age. In our study, there were no significant differences in postprandial lipemia between a young population (mean age 22.6 years) and an elderly one (67.2 years) without metabolic syndrome.

EA-69
THE IMPACT OF COMORBIDITIES IN OLD CANCER PATIENTS MANAGEMENT: A SINGLE PORTUGUESE INSTITUTION EXPERIENCE

I. Miguel[1], B. Pedro[2], H. Vieira Dias[2], A. Alves Oliveira[2], A. Ferreira[2], F. Roque[2]

[1]Department of Medical Oncology. Instituto Português de Oncologia Francisco Gentil Lisboa, EPE. Lisboa, Portugal. [2]Department of Medicine III. Hospital Distrital de Santarém, EPE. Santarém, Portugal.

Objectives: Cancer is the leading cause of death in women and men with more than 65 years, which represents 17.9% of the Portuguese population. Biological characteristics of certain cancers are different in older patients, and are also less tolerant to chemotherapy. Advanced age alone should not be the only criteria to exclude effective cancer treatment that could improve quality of life or survival. We aim to describe the influence of comorbidities on the management of oncogeriatric patients.

Material and method: Retrospective study of clinical charts of cancer patients (pts) with 65 years old or more, attending for the first time an Oncology appointment during 2011 in a countryside hospital in Portugal. Epidemiological and clinical data, Charlson Comorbidity Index (CCI) excluding cancer diagnosis, performance status (PS) score and survival was assessed in all patients. Descriptive statistics methods, t-Student test for comparison between continuous variables and Chi-square/Fisher-exact test for categorical variables were applied using the statistical software SPSS v17 for Windows (Chicago, IL).

Results: From a total of 311 patients, 171 were included representing 55%, 52% were male. Age groups: "young old" patients (65-75yo) = 55.6%, "old" patients (76-85yo) = 42.7% and "oldest old" patients (≥ 86yo) = 1.8%. Main primary site of cancer was: colon (29.8%), breast (18.7%), rectum (16.4%), prostate (11.1%) and stomach (5.8%). Metastatic disease was present in 39.5% of cases: liver (49.9%), lung (27.4%) and bone (24.2%). Most patients were stage III or IV and 8.8% had a second cancer diagnosis. Performance status was 0 in 56.7%, 1 in 30.4% and ≥ 2 in 12.9%. Mean CCI was 0.78 ± 1.1 (≥ 2 = 7.6%). 72.5% received chemotherapy and in 52.8% of pts there was a dose reduction; 34% had type III/IV toxicities (mucosal-19.6%, hematological-15.9%). 39.2% underwent radiotherapy (type III radiodermitis in 34.1%). CCI in pts with dose reduction was 0.7 ± 0.98 vs 0.62 ± 1 in pts who continued on normal doses (p = 0.71). Patients with type III/IV scored 0.83 ± 1.2 on CCI vs 0.57 ± 0.9 in patients without toxicity (p = 0.209). There were 32 deaths (18.7%, median survival of 5 months; 84.4% stage IV) after median follow-up of 11 months. Patients who died had higher CCI score (1.25 ± 1.44 vs 0.67 ± 0.98; p = 0.038), were older (median age = 74 vs 75yo; p = 0.171), required more frequently dose reductions (64.7% vs 52.1%; p = 0.336) and presented more toxicities during treatment (47.1% vs 31.1%; p = 0.202).

Discussion: In our study, fatalities had higher CCI score, thus indicating that comorbidities may have contributed to mortality in a group of advanced cancer patients. In this group, we didn't found a clear relation between higher CCI and toxicities or dose reduction, but patients had in general low CCI and PS scores. Multiple studies have shown that comorbidity is directly associated with variables such as age, survival, recommended treatment, disability and health service utilization. Moreover, comorbidities can interact with chemotherapy regimens and increase the chance of toxicity, especially in older patients. The use of comorbidity scales has been recommended in the management of elderly cancer patients.

Conclusions: Management of old cancer patients should be individualized and based not only upon patients characteristics, but nature of disease, physiologic status, comorbidities and patient's preference in order to guarantee better outcomes in terms of survival and quality of life.

EA-70
DEFICIENCY OF FOLIC ACID IN PATIENTS ADMITTED TO AN INTERNAL MEDICINE

J. Oteiza Olaso, D. Etxeberria Lekuona, E. Martínez Litago, I. Villar García, S. Pérez Ricarte, T. Rubio Vela, C. García Labairu, J. Alonso Martínez

Department of Internal Medicine. Hospital de Navarra. Pamplona/Iruña. Navarra, Spain.

Objectives: to review the diagnosis of folic acid deficiency (FAD) in our Department of Internal Medicine to see the clinical features of these patients.

Material and method: We reviewed the medical records of patients discharged in 2011 with a diagnosis of FAD of Internal Medicine of our hospital. We considered FAD when plasma levels were lower than 3 µg/L (normal range 3-17). We collected demographic data, principal diagnosis (since FAD is a secondary diagnosis), review of medical history, levels of vitamin B12, blood count with hemoglobin, hematocrit, mean corpuscular volume (MCV) and corpuscular hemoglobin medium (CHM) malnutrition parameters as total protein (TP), albumin, cholesterol, and lymphocytes, and other information that may be related to folic acid deficiency.

Results: Twenty-eight patients have been diagnosed with FAD, all as secondary diagnosis. The mean age was 75.5 years with a median of 80. The mean folic acid levels were 2.3 µg/L. Only 4 patients (14%) had also vitamin B12 deficiency (< 179) with a mean of 383 ng/L. Anemia was found in 23 (82%) patients, whom had increased MCV 8 (28%) with average values of 95 ± 3 (normal: 80.2-99.4) and CHM was elevated in 6 samples (21%) with a mean of 32.2 pg. (normal: 26.1-34.2). Within the nutritional parameters, there was decrease in the TP in 19 patients (68%) with a mean of 5.6 g/dl. (Normal: 6-8). Low levels of albumin were found in 17 (60%). Cholesterol was decreased in 5 patients (18%) with a mean value of 147 mg/dl (normal value of 110-220) and there was lymphopenia (< 0.7 × 10^9/l lymphocytes) in 8 (28%) patients. The primary diagnosis for admission was respiratory infection in 10 patients (36%) followed by tumor disease in 5 (18%) patients and digestive diseases (colitis or gastroenteritis) in 4 (14%). Within clinical antecedents, the most frequent diagnosis were cognitive impairment in 8 (28%), heart disease or cancer in 7 (25%) and COPD or alcoholism in 4 (14%).

Discussion: Due to the characteristics of our patients of Internal Medicine we should have found a higher rate of FAD. However, we have had a low index of diagnosis of FAD (28 patients over 1700 patients admitted in one year). We believe that on being a secondary diagnosis often is not reflected as a diagnosis, even when it has been treated. The mean age of patients with FAD is 75.5 (median: 80) years, while the mean age of the totality of patients of Internal Medicine is 73.5 (median: 77) years, being slightly older than usual. We have observed a low association of FAD with B12 (14%) deficiency. Regarding the development of anemia, 83% of patients had it, but it is surprising that only 28% of them had an increased MCV and only 21% an increased CHM. Regarding nutritional parameters hypoproteinemia appears in 68% and hypoalbuminemia in 60%. Cholesterol is only decreased in 18% of patients and

lymphopenia in 28%. Thus, we consider more important as desnutrition parameter associated with DAF the PT. The main primary diagnosis associated with DAF were the respiratory infection (caused by dementia with lung aspiration and COPD) in 36% patients and with tumors in18% patients, being all of them a risk for malnutrition. In the patients with DAF, 28% of them had clinical antecedents of cognitive impairment, however only 25% of them had a history of previous heart disease (atrial fibrillation, heart failure, ischemic heart disease, valvular heart disease). However, patients with cardiac disease are the most prevalent patients in Internal Medicine (about 40%).

Conclusions: We believe important include into the diagnosis panel the DAF for calculating DRG (diagnostic related groups) patients. We recommend the measurement of folic acid levels in patients with low TP, anemia (whether the CHM or MCV are increased or not), in patients admitted with exacerbated COPD and patients with a history of cognitive impairment or alcoholism.

EA-71
IMPLICATIONS OF DEPRESSIVE SYMPTOMS IN HOSPITALIZED ELDERLY MEDICAL PATIENTS

A. Martín Plata, A. Conde Martel, M. Hemmersbach-Miller, S. Santana Báez, M. Hernández-Meneses, M. Serrano Fuentes, J. Ruiz Hernández, A. Puente Fernández

Department of Internal Medicine. Hospital Universitario de Gran Canaria Dr. Negrín. Las Palmas de Gran Canaria, Spain.

Objectives: The aim of the study was estimate the prevalence of depressive symptoms in hospitalized elderly patients and its relationship to various diseases, as well as their functional and mental status and mortality.

Material and method: We prospectively studied 115 patients over 64 years of age. The validated Spanish version of the geriatric depression scale of Yesavage (15-item version) was used. Patients were considered to have depressive symptoms if ≥ 6 points were obtained. The demographic characteristics, the Charlson comorbidity index, the diagnosis at admission, the functional status assessed by the Barthel and Lawton-Brodie index, the mental capacity assessed by the Pfeiffer questionnaire, the length of the hospital stay and hospital mortality were considered.

Results: Out of the 115 patients studied with a mean age of 70.5 years, 71 (61.7%) were female. Depressive symptoms were observed in 46 patients (40%, 95%CI 34.8 - 43.9). Patients who died showed a significantly higher score on the Yesavage scale (p = 0.04). The multivariate analysis showed a significantly independent association between depressive symptoms and functional capacity (p = 0.026), mental capacity (p = 0.023), renal failure (p = 0.001), hepatopathy (p = 0.018), malignancy (p = 0.01), and osteoarthritis, but losing the previously seen significant association with diabetes (p = 0.44).

Discussion: Depressive symptoms in hospitalized patients are very common, and they are often not recognized by healthcare professionals. They have been related to higher mortality and to worse outcome of many medical illnesses. However, depression is not an inevitable part of aging, it is often linked to physical illness and loss of functional and mental status. Elders with multiple comorbidities may be particularly vulnerable to the debilitating impact of depression. The coexistence of depression and somatic disease seems to be provoking a double route of interaction: the physical disease interferes in the recovery of the depression and, on the other hand, the depression interferes the recovery of the somatic disease.

Conclusions: The prevalence of depressive symptoms in hospitalized elderly patients is high, and is associated with the diagnoses of renal failure, malignancies, liver disease and osteoarthritis, with a higher comorbidity, and especially with a poorer functional capacity.

EA-72
PREVALENCE AND IMPACT OF SARCOPENIA IN A MEDIUM TO LONG STAY UNIT

A. Aljibe[1], R. Gil[1], P. Moral[2], I. Moreno[2], C. Rubio[3], E. Duarte[3], R. Beseler[3], F. Merino[4]

[1]Department of Internal Medicine, [2]Department of Medium to Long Stay, [3]Department of Rehabilitation. [4]Department o f Endocrinology and Nutrition. Universitary and Polytechnic Hospital La Fe. Valencia, Spain.

Objectives: Sarcopenia is a common syndrome but not well known, which is defined as a loss of skeletal muscle mass along with a decrease of both strength and muscle performance. It is associated with an impaired quality of life, increasing disability and mortality. Our goal was to assess the prevalence of sarcopenia in a population of elderly patients admitted in the Medium to Long Stay Unit (MLSU) of a universitary hospital. Also we studied its possible association with etiologic factors such as malnutrition and inactivity, and its potential impact in terms of disability, dysphagia and complications of pressure ulcers.

Material and method: We performed a descriptive, cross-sectional and observational study including 81 patients admitted to the MLSU over 3 months. They were evaluated by an interdisciplinary team composed by nurses, internists and rehabilitation physicians. Administrative and management data (age, sex), cognitive status (Pfeiffer), comorbidity (Charlson), functional capacity (Barthel), physical activity, malnutrition (MNA validated test), anthropometric assessment, presence of pressure ulcers and dysphagia (test volume viscosity) were recorded. Sarcopenia requires the demonstration of decreased muscle mass (bioelectrical impedance analysis) plus decreased strength (manual dynamometry) or impaired physical performance tests. Results are expressed in mean, standard deviation and percentages.

Results: The age of our patients was 78.51 (12), with 51.9% men and 48.1% women. The stay length was 18.54 days (11.99). The Charlson index showed that 60.5% of them had comorbidity. The Barthel index media was 32.5 (25), where 67.5% of patients had severe or total dependence, and 33.3% had mild to severe cognitive impairment (Pfeiffer). Their BMI was 21.23 (8), MNA test showing 55.6% of malnourished patients. Of all patients 81% maintained a sedentary physical activity, and 22.2% had pressure ulcers. The overall prevalence of sarcopenia was 81.6%, most of it was severe sarcopenia (91.9%). Only 15.8% of all patients did not present any diagnostic criteria. The percentage of sarcopenia among men and women was 73.8% and 76.3%, respectively. We obtained a statistically significant relationship between sarcopenia and age (p = 0.037), triceps skinfold (p = 0.009), malnutrition (p = 0.025) and the estimated weight (p = 0.000).

Discussion: The prevalence of sarcopenia in our population was very high, showing rates similar to those reported in the literature, and showing no significant differences between sexes. Advanced age and malnutrition were associated with statistically significant sarcopenia, and probably both act as important etiological factors. However, this difference was not obtained for other relevant factors: physical activity, comorbidity and disability, probably due to the high degree of comorbidity and dependence of all patients in our sample. Estimated weight and triceps skinfold could be a clinical marker for screening, because they are simple-to-obtain determinations and they are related with the presence of sarcopenia.

Conclusions: Sarcopenia is a highly prevalent syndrome in the elderly population hospitalized in chronic units, and not often evaluated in our medium. With its implications in terms of morbidity and mortality it's important to make a proper diagnosis. Estimated weight and triceps skinfold are two determinations of potential usefulness. It is necessary to conduct studies with a larger population and a prospective basis to provide a better understanding of both their prognosis and their possible therapeutic approaches.

EA-73
PREDICTORS OF MORTALITY IN ASPIRATION PNEUMONIAE

S. Rodríguez García[1], A. Calleja Fernández[2], J. Llorente García[1], M. Pérez Panizo[1], F. Estrada Álvarez[1], S. García Martínez[1], J. Herrera Rubio[1], M. Ballesteros Pomar[2]

[1]Department of Internal Medicine, [2]Department of Endocrinology and Nutrition. Complejo Asistencial de León. León, Spain.

Objectives: Aspiration pneumonia is developed as a result of the abnormal entry of fluids, secretions, exogenous or endogenous substances in the lower airways. This process involves a high mortality that can exceed 50%. The aim of the present study was to analyze the prevalence of aspiration pneumonia in patients admitted to Internal Medicine and predisposing factors for mortality and readmissions.

Material and method: Observational transversal study evaluating patients admitted to the Internal Medicine Department during 2010 and 2011 with the diagnosis (primary or secondary) of aspiration pneumonia, respiratory infection for aspiration or aspiration, obtained through the coding system of the Center. We analyzed relevant past medical history, treatment received, number of subsequent readmissions and mortality, in order to compare the efficacy of different therapeutic measures. We evaluated comorbidity through the Charlson score.

Results: We evaluated 217 patients (60.4% male), mean age being 81 years old (SD 11.9). The most common reasons for admission were aspiration pneumonia (47%), aspiration (15.7%), respiratory infection (7.8%), stroke (5.1%) and sepsis (2.3%). 60.7% of patients scored > 3 on Charlson Score. The most common causes of dysphagia were dementia (52.7%), stroke (29.5%), neurodegenerative disease (24.9%) and neuromuscular disease (1.8%). The average length of stay was 11.4 days (SD 10.2), with a mortality of 42% (61% male, 30% women). Neither age, sex, or Charlson Score were assessed as significantly associated with mortality. Mortality was related to the value of albumin so more deaths happened in patients with albumin lower than 3 mg/dL ($p < 0.05$) Regarding treatment, 15.7% of the patients received nutritional support by nasogastric or nasoenteric tube and 3.7% by gastrostomy tube. Only 11.2% of the patients were assessed by the Nutrition Unit, either before or during the admission. In this study, both in univariate and multivariate analysis, assessment by Nutrition Unit was a significant factor as a predictor of mortality. Among the patients assessed by the Nutrition Unit, there were fewer deaths (13.6% vs 44%, p 0.006). Patients who were placed a feeding tube or gastrostomy also had lower mortality (47% vs 53%, p 0.001; 14.7% vs 85%, p 0.022). With regard to the prescribed diet, the percentage of deaths was higher when food consistency was not adapted (31.3%), than if texture was modified (6%) or if tube feeding was prescribed (10%), $p < 0.0001$.

Conclusions: Aspiration pneumonia is a common complication in our setting that bears a high mortality. A multidisciplinary approach is required, as assessment by a Nutrition Unit and the setting of appropriate measures (tube feeding, diet consistency changes) are predictive factors, in this study, for lower mortality.

EA-74
PREVALENCE AND IMPACT OF OROPHARYNGEAL DYSPHAGIA IN A MEDIUM TO LONG STAY HOSPITAL UNIT

L. Díez[1], Y. Torres[1], I. Moreno[2], A. Álvarez[2], A. Úbeda[2], F. Merino[3]

[1]Department of Internal Medicine, [2]Department of Medium to Long Stay, [3]Department of Endocrinology and Nutrition. Universitary and Polytechnic La Fe Hospital. Valencia, Spain.

Objectives: Oropharyngeal dysphagia (OPD) is a common disorder in elderly hospitalized patients which may have a negative impact. This study aims to assess the prevalence of OPD in a population of patients admitted in the Medium to Long Stay Unit of a universitary hospital. We evaluated its possible relationship with potential etiological factors such as cognitive impairment, disorders in oral health and sarcopenia. The possible association with consequences such as malnutrition or aspirative pneumonia (AP) was studied.

Material and method: Descriptive, cross-sectional and observational study including 81 patients admitted over a period of 3 months and evaluated by a multidisciplinary team. General data (age, sex, stay length...), comorbidity (Charlson), cognitive impairment (Pfeiffer), functional status (Barthel), presence of AP and malnutrition (Mini Nutritional Assessment) were recorded. OPD was evaluated by the EAT-10 screening test and the volume-viscosity test (V-VST). The quality of life associated with oral-dental greeting was studied by the GOHAI index. The presence of sarcopenia was studied by a bioelectrical impedance analysis, manual dynamometry and physical performance tests.

Results: The mean age of the group was 78.5 years (SD 12.8) of whom 51.9% were men. Most of them had comorbidity (60.5%). Barthel index showed 67.5% of patients having severe or total dependence; 33.3% had mild to severe cognitive impairment (Pfeiffer). The screening test (EAT-10) was positive in 37% of patients, and the V-VST was pathologic in 46%. GOHAI test confirmed the impact in the life quality of all our patients.

Discussion: The elderly ages and currency of comorbidity, as cognitive impairment and functional decline, reflect the complexity and fragility of the population studied. OPD was highly prevalent in our group, similar to those reported in literature. The EAT 10 turned out to be not reliable in our setting as a screening method, probably because of the cognitive impairment of our patients. The V-VST was a useful way for the diagnosis of dysphagia, and no safety problems appeared in our study. A relationship between OPD and some clinical conditions (age, mental decline and functional status) was found, this could be explained in terms of causality. It was related too with malnutrition, although we were not able to prove a relationship with other possible consequences as AP and sarcopenia.

Conclusions: OPD is a problem of elevated prevalence and impact in our population. Systematic diagnosis by the V-VST seems highly recommendable in elderly and pluripathological patients. It is necessary to conduct larger and prospective studies to provide a better understanding of both its prognosis and its therapeutic approaches.

Table (EA-74)

	OPD + (%)	OPD – (%)	p
Sarcopenia	41.89	40.54	0.123
Severe cognitive impairment	20.25	1.27	0.00
Severe physical dependence	35.90	8.97	0.00
Malnutrition	36.71	17.72	0.00
Aspirative pneumonia	3.80	8.86	0.32

EA-75
INTEGRAL CARE TO PLURIPATHOLOGIC PATIENTS IN A SHORT STAY UNIT IS IT POSSIBLE?

I. Aomar Millán[1], Á. Ceballos Torres[1], L. Ruiz Rivera[1], C. Fernández Roldán[1], F. Anguita Santos[1], P. Ruiz Díaz[2], P. Giner Escobar[1]

[1]Department of Internal Medicine, [2]Department of Clinical Documentation. Hospital de Especialidades San Cecilio. Granada, Spain.

Objectives: To analyze the demographic, medical history, comorbidity, diagnosis, and diagnostic complexity average stay of pluripathologic patients admitted to a short stay unit dependent of Internal Medicine (UCEMI) in a third level hospital.

Material and method: Descriptive study of all patients with comorbidity criteria admitted consecutively in our Short Stay Unit of Internal Medicine (UCEMI), San Cecilio University Hospital from July 1 to November 30 of 2011y were derivatives at discharge to home. The unit consists of 8 inpatient beds, two senior doctors and a medical resident. Data were extracted from the databases and hospital UCEMI and analyzed with SPSS V19.0.

Results: During this period the unit had a total of 196 patients, accounting for 23% of the total casuistry Internal Medicine. Of these, 89 patients (45.4%) had pluripathologic. These were 49 women (56%) and 40 men (44%) with a mean age of 78 years and a mean Barthel index of 32 and a Charlson index of 9. The average stay of 3.62 days was obtained and there were only 7 readmissions (7.8%). Analyzing the main diagnoses of patients discharged to home we see that 35 (39.32%) patients had respiratory disease, 26 (29.21%), cardiovascular disease, 14 (15.73%) nephrourologic disease, 10 (11.23%) gastrointestinal disorders and 8 (8.98%) neurological diseases. Personal history were more frequently associated hypertension in 83.1%, 70% structural heart disease, diabetes mellitus 55%, COPD 43%, 36% renal insufficiency, atrial fibrillation and advanced dementia 31.5% to 30% of cases. In addition, comorbidity was very high with an average of 4.02 diagnoses.

Discussion: UCEMIs represent an alternative to conventional hospitalization in pluripathologic patients, to be effective in improving the care and management parameters without losses in quality of care. The results drawn from our analysis that these patients are observed, whenever a selection is strict income and have a good family support may be suitable candidates for management in these units, this being very important in hospital management because of the significant reduction in hospital stay, resulting in cost savings without reductions in the quality of care or increasing the number of readmissions compared with conventional hospital units. The objective of UCEMIs should not compete with the conventional hospital medical units, but be a support to them so we should work together to develop protocols. Finally, we believe that such units must be managed by internists given the variety of diseases that are addressed and overview of the patient. This study presents the limitations of a retrospective descriptive analysis, with no control group, so we believe it would be interesting and necessary to carry out new and larger studies analyzing baseline characteristics and adequacy of income to assess the impact UCEMIs real, yet in our study, in terms of length of stay, comorbidities and patient characteristics not very different from the published literature.

EA-76
PROLONGED HOSPITAL STAYS: STUDY IN A REGIONAL HOSPITAL

M. Gómez Hernández[1], M. Vergara Díaz[1], R. Fernández Ojeda[1], S. Andrades Segura[2], C. Escorial Moya[1], A. Fernández Moyano[1]

[1]Department of Internal Medicine, [2]Department of Family and Community Medicine. Hospital San Juan de Dios de El Aljarafe. Sevilla, Spain.

Objectives: Describe the number of patients who have long-term hospital stay and analyze the causes which may have contributed to it.

Material and method: We conducted a descriptive retrospective study, in order to assess the percentage of patients who maintained a long-term hospital stay (with a duration of 30 days or longer). Several variables were analyzed such as: age, sex, length of stay, reason for admission, comorbidity criteria, development of nosocomial infection, early readmission (< 15 days), social problems or if the process ended up with the death of the patient. SPSS 15.0 for Windows was used to carry out the analysis of the results.

Results: We obtained a sample of 50 patients with prolonged hospital stay in Internal Medicine at 2011, with a mean age of 70.6 years (28-97). Mean duration of hospital stay was 39.9 days (29-77). Reasons for admission, classified by type of pathology, show the following results: the most common infectious disease was (46%). In more than half of the cases, 27 patients (54%) criteria of multiple pathologies were met. 32% developed nosocomial infection (being urinary focality the most frequent). Only 6 patients (12%) were readmitted within 15 days after discharge. 18% of the patients appeared to have social problems according to the study. Finally, 26 patients with long-term hospital stay died (52%).

Discussion: Long-term hospital stay is an increasingly common problem in our environment, possibly determined by the process of population aging. This kind of admissions demands an increase of the attention and cares needed which has an impact on health expenditure. Programs of continue assistance shared with Primary Care Services are proposed for patients with comorbility and pluripathology as an attempt to mitigate the effects of these situations. It will also be advisable to perform a social assessment after the admission of the patient in order to define the needs of support which may be required after discharge.

Conclusions: Advanced age, comorbidity, the development of nosocomial infections and social problems are factors that may contribute to the extension of hospital stay.

EA-77
DESCRIPTIVE ANALYSIS OF THE USE OF NUTRITIONAL SUPPLEMENTS AFTER DISCHARGE

H. Ortega Abengózar[1], L. Oriente Frutos[1], M. Galindo Andúgar[1], M. Sánchez Ruiz de Gordoa[2], L. Fernández-Espartero Gómez[1], M. Martínez Gabarrón[1], L. Rodríguez Rojas[1], I. Domínguez Quesada[1]

[1]Department of Internal Medicine, [2]Hospital Pharmacy. Complejo Hospitalario La Mancha Centro. Alcázar de San Juan. Ciudad Real, Spain.

Objectives: Check the indication of nutritional supplements in hospitalized patients, and the indication of them at discharge.

Material and method: Cross-sectional study, conducted at the General Hospital "La Mancha Centro" (Alcázar de San Juan, Ciudad Real. Spain) during the second half of April 2012. The inclusion criterion was receiving oral or enteral nutrition in hospitalized patients. The case search was conducted through electronic prescription drug program in our hospital. We collected medical history, laboratory parameters, discharge diagnosis, destination on discharge and the indication of oral/enteral nutrition before and after admission. The degree of functional dependence was assessed using the Katz index. Patients were followed until hospital discharge. Analysis with PAW Statistics 18.

Results: We collected 18 cases, half male, mean age of 75.8 years (minimum 32 and maximum 93), and average stay of 19.8 days (minimum 3 and maximum 48). The Katz index was G in 9 cases (50%), A at 7, C and F in 1 patient. Before admission, 1 patient had a nasogastric tube (NGT) and 2 had PEG (percutaneous endoscopic gastrostomy). More than half of patients (61%) had cognitive impairment. 2 patients died during hospitalization. The admission diagnosis was infection in 12 patients (most commonly pneumonia and urinary tract infection). Before admission, 3 patients had enteral nutrition (corresponding to patients with NTG and PEG). During admission, oral supplements were prescribed in 10 cases, enteral nutrition in 7, and liquid-thickener only in 1. At

discharge, oral supplementary nutrition remained in 4 cases, and enteral in 4. (those who had before entering, and one patient who was placed NGS during hospitalization). The most commonly prescribed supplements during hospitalization were hyperproteic in 11 patients (61%) followed by standard nutrition in 3 (16.7%), 1 fiber, 1 diabetic and 1 renal protection nutrition.

Discussion: All patients who required NGT or PEG for feeding, carried enteral nutrition. During hospitalization, oral hyperproteic supplements were most commonly prescribed. In most cases the clinical reason was resolved before discharge, but in two patients with confirmed malnutrition by nutritional analytical parameters, could have been indicated prescribing it at discharge but was not done.

Conclusions: The indication for enteral nutrition is evident in patients requiring NGT/PEG. As for oral supplements, most often done based upon clinical reasons, not in blood biochemical parameters.

EA-78
NEW TOOLS FOR ASSESSMENT OF ELDERLY PATIENTS IN INAPPROPRIATE MEDICATIONS: INCOME CRITERIA BEERS?

M. Vergara Díaz[1], R. Fernández Ojeda[1], C. Escorial Moya[1], S. Andrades Segura[2], V. Parra García[2], C. Vega Quirós[2]

[1]Department of Internal Medicine, [2]Department of Family and Community Medicine. Hospital San Juan de Dios. Sevilla, Spain.

Objectives: Given the inversion of the population pyramid in our environment, the existence of elderly on several treatments is becoming more relevant. For this reason it is surprising that no consensus has been reached on the use of entirely satisfactory tools for the detection of inappropriate prescriptions. The main objective of our study was to assess the percentage of elderly patients with inappropriate drug prescriptions, according to different validated criteria (Beers, Stopp and Start).

Material and method: We performed a prospective study, selecting all patients over 65 admitted to our hospital Internal Medicine Area, in a period of 10 days, in order to assess how appropriate where the drug therapies prescribed on admission according to STOPP criteria/START and BEERS. Were also analyzed variables such as age, sex, comorbidity criteria and renal failure (NKF). SPSS 15.0 was used for statistical calculations.

Results: The sample consisted on 103 patients with a mean age of 77.8 years (65-95) with similar proportions of men and women (56.3% vs 43.7% H M). The criteria for inappropriate prescribing of Beers were in 46.2% of patients and STOPP criteria in 42.3%. Regarding the adequacy of drug prescriptions according to START criteria, there was an achievement of 41.7%. A percentage of 42.7% met criteria for comorbidity and 68% of ERC.

Discussion: There was a high percentage of patients with inappropriate drug prescriptions on admission according to the Beers criteria and STOPP. However, this figure of patients with adequate prescriptions was higher. The coexistence of CKD and comorbidity is relevant.

Conclusions: A high percentage of patients use inappropriate medicines on admission. No differences were appreciated on the percentages of inappropriate drugs prescription according to the Beers criteria and STOPP. There is a low rate of underprescription before admission, according to the criteria START. Usual medication checkups and appropriate therapeutic changes should be incorporated into our daily clinical practice.

EA-79
APPROPRIATENESS OF DRUG TREATMENT AT THE HOSPITAL DISCHARGE IN POLYPATHOLOGICAL PATIENTS

M. Nieto Martín[1], L. de la Higuera Vila[1], M. Galván Banqueri[2], M. González Benítez[3], E. Montero[4], M. Rincón[1], J. Machín[5], M. Bernabeu Wittel[1]

[1]UCAMI, [2]Department of Pharmacy. Complejo Hospitalario Regional Virgen del Rocío. Sevilla, Spain. [3]Department of Internal Medicine. Hospital de la Serranía de Ronda. Ronda (Málaga), Spain. [4]Department of Internal Medicine. Hospital de Mendaro. Mendaro (Guipúzcoa), Spain. [5]Department of Internal Medicine. Hospital Universitario. Guadalajara, Spain.

Objectives: To analyze the appropriateness of drug treatment at the hospital discharge in a cohort of polypathological patients and interventions to improve.

Material and method: We identified all polypathological patients (as defined in the Integrated Health Care Process in Andalucía) admitted during the period of one year and five months (September 2010-February 2012) at a tertiary teaching center in southern Spain. We preformed an adequacy report base on an self -audit modified MAI, STOPP-START criteria, interventions default and pharmacist standard, which was sent to the responsible physician. Interventions were categorized in different groups: no indication, no effective drug, diagnosis/symptoms untreated, dose, duration, schedule times, patient instructions, contraindications, interactions, duplicity, cost-effectiveness and route of administration. We consider the report is accepted when all interventions were accepted, non-accepted when no intervention was accepted and partial accepted when some of them were accepted and others no. Data were analyzed and processed using the Excel 2005®.

Results: 192 polypathological patients were included. Average age 72 ± 8, 51% male. Mean number of diagnosis per patient was 8 ± 3, and prescriptions 12 ± 4. A total of 692 interventions were made: 80 interventions of " no indication", 2 "no effective medication", 117 "diagnosis/symptoms untreated", 40 "dose", 48 "duration", 49 "schedule", 13 "patient instructions", 23 "contraindications", 283 "interactions", 9 "duplicity", 23 "cost effectiveness" and 2 "route of administration". The acceptance rate of interventions was 44%: 21% accepted and 23% partial accepted.

Conclusions: The number of interventions made and the rate of acceptance was high. This supports the benefit of interventions made by different health professionals in the adequacy of drug treatment of polypathological patients.

EA-80
RELATED FACTORS WITH TREATMENT ADHERENCE IN A COHORT OF POLYPATHOLOGICAL PATIENTS FROM INTERNAL MEDICINE DEPARTMENT

M. Nieto Martín[1], M. García Gutiérrez[1], M. Vega Coca[2], M. Maíz Jiménez[3], C. Hernández Quiles[4], J. Medina García[5], C. Palacios Gómez[1], R. Arahal Trigueros[1]

[1]UCAMI, [2]Department of Pharmacy. Complejo Hospitalario Regional Virgen del Rocío. Sevilla, Spain. [3]Department of Internal Medicine. Hospital de la Serranía de Ronda (Ronda), Málaga, Spain. [4]Department of Internal Medicine. Hospital San Juan de Dios de El Aljarafe. Sevilla, Spain. [5]Department of Internal Medicine. Complejo Hospital Universitario Nuestra Señora de Candelaria. Santa Cruz de Tenerife, Spain.

Objectives: To determine the treatment adherence in a polypathological patients (PPP) cohort. To identify factors related with treatment adherence.

Material and method: Unicentric transversal observational study. Inclusion criteria: PPP as defined in the Integrated Health Care Process in Andalucía, who were hospital discharge, outpatient clinics, or home hospitalization from internal medicine department, between October 2010-march 2012. Variables: -Treatment adherence according to Morisky questionnaire. Values are between 0-4. A good adherence is considered for 4 points. -Age and sex. -Number of drugs prescribed. -Pathologies: those that define PPP and another (cardiovascular/digestive/nephrourologic/neuropsychiatric/respiratory). -Degree of disability according to Barthel index. -Cognitive decline according to Pfeiffer questionnaire. -Needed of caregivers (Barthel index < 60 points or important cognitive decline). -Co morbidity degree according to Charlson index. -Social assessment according to Gijón scale. Statistical analysis: to determine association chi-squared, Fisher's exact or linear association tests were used depending on variable characteristics. We used SPSS 15.0.

Results: 263 patients were included. 50.4% male, age average: 76 years (range 27-98), number of drugs: 12 (range 4-25). 59.9% of patients have at least 3 categories for PPP and 59% have a good adherence. These variables presented statistically significant association with treatment adherence: Needed of caregivers. On those patients with high disability (BI < 60) that needed a caregiver, if they don't have it, 75% don't have a good treatment adherence vs 38% on those that have it. p = 0.047. Degree of disability. Those patients with a severe disability have a good adherence (64%). However those with a total disability have less percentage of adherence (56.6%). p = 0.008.

Conclusions: The treatment adherence in this kind of patients is very low, this results are similar to other publications about patients with chronic diseases. In the polypathological patients the treatment adherence is on relation to degree of disability and the needed of caregivers.

EA-81
DRUGS DOSAGE-RECOMMEND ADJUSTS IN POLYPATHOLOGICAL PATIENTS WITH KIDNEY FAILURE

M. Bernabeu Wittel[1], J. Praena Segovia[1], M. Galván Banqueri[2], M. Barón Ramos[3], R. Aparicio Santos[3], M. Ollero Baturone[1], R. Fernández Ojeda[4], A. Ruiz Cantero[3]

[1]UCAMI, [2]Department of Pharmacy. Complejo Hospitalario Regional Virgen del Rocío. Sevilla, Spain. [3]Department of Internal Medicine. Hospital de la Serranía de Ronda. Ronda (Málaga), Spain. [4]Department of Internal Medicine. Hospital San Juan de Dios de El Aljarafe. Sevilla, Spain.

Objectives: To describe and quantify the incidence of kidney failure (KF) in polypathological patients (PP) and the adjusted-dose requirement of different drugs. To identify most frequent affected pharmacokinetics parameters in KF in PP patients.

Material and method: A prospective cohorts study was developed in a tertiary teaching center by internist and pharmaceutics physicians. PP were identified using the Spanish Andalusian Health Care Council criteria. All PP were recruited from hospital, as well as in outpatient clinics, and at-home hospitalization along one year and five months. Information about patient (prescription of drugs and KF) were obtained from digital Clinic History and from a web created in this study. Renal function was estimated in all PP recruited. In case of KF, all drugs were investigated to identify those which needed dosage-recommend adjusting in order to emit recommendations by pharmaceutics. Interventions were sent to responsible facultative. If the recommendations were accepted it was notified to pharmaceutics by mail. Dates were tabulated and processed by Excel 2005®.

Results: A total of 1,632 PP were included. Mean age was 76 years. 51% of them were men. 73 patients (38%) had KF. 32 (44%) of them required dose adjusting. Drugs adjusted to kidney function were: simvastatin (20 patients), metformin (in 8 patients), ramipril (5), enalapril (2), spironolactone (2), hydrochlorothiazide (2), bisoprolol (1), indapamida (1) and sitagliptin (1). Pharmaceutics recommendations were made in forty-two patients. Internist-physician feed-back was made in 43% of cases and recommendations were accepted in 61% of those cases.

Conclusions: KF was a frequent complication in PP (38%), and a high percentage of them required dose adjustment (44%). The main drugs implicated were simvastatin, metformin and ramipril. Internists collaboration rate was low (43%) but in the cases with proposal interventions, the acceptance rate was high (61%).

EA-82
ACUTE MANAGEMENT AND FOLLOW-UP OF ANGIODYSPLASIA

M. Serrano Herrero[1], T. Revuelto Artigas[2], M. Bucar Barjud[1], E. Redondo Villahoz[3], Y. Arguedas Lázaro[2], P. Lacarta García[2], P. Sáez[4], Y. Ber Nieto[2]

[1]Department of Internal Medicine, [2]Department of Gastroenterology, [3]Department of General Surgery, [4]Department of Intensive Care. Hospital Clinico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: Angiodysplasias are a major cause of acute or recurrent gastrointestinal bleeding, mainly in elderly patients with associated comorbidity and with intake of antiplatelet drugs and anticoagulants. Bleeding angiodysplasia has become a common health care problem, requiring repeated hospital admissions, blood transfusions, tests, endoscopic or pharmacological treatment and its follow-up. Objective: to determine the frequency of gastrointestinal bleeding (acute and chronic) due to angiodysplasia in our hospital and to evaluate resource utilization in the acute and long term treatment.

Material and method: We performed a retrospective observational study of cases of angiodysplasia diagnosed between November 2006 to March 2012 in endoscopy service. We analyzed clinical and epidemiological data (sex, age, comorbidity, drugs), lesion characteristics (size and location); treatment (endoscopic, pharmacological or surgical), test, and follow-up (hospital admission, readmission, death).

Results: During the period of 54 months we have attended 314 patients, an average of 69 cases for year. The 63.7% were male and 36.3% women, with a mean age of 74 years (range 37-92), 84.7% were patients over 65 years old. The clinical presentation was 45% chronic anemia and 44% acute gastrointestinal bleeding, only 10.5% of cases were found incidentally. The 49% of patients had comorbidities and half of them were treated anticoagulants or antiplatelet drugs and 14.3% with NSAIDs. About size and location, 66% of cases had less than 5 lesions and lower than 1 cm, 17.5% of these were synchronous. 60.5% of patients had to be hospitalized, the most patients required treatment to improve the anemia, 42% received blood transfusions and 11% intravenous iron. 48.1% of cases were performed hemostatic endoscopic treatment, after this treatment only 13% of them rebleed. There were 7.6% of complications after the realization of the endoscopic treatment (3.5% abdominal pain, 2.2% acute pancreatitis, 1% pneumoperitoneum), 0.9% mortality in patients with significant comorbidity and very poor clinical condition. Patients who required hospital readmissions for clinical recurrence (new episode of anemia or gastrointestinal bleeding) were associated with patients older than 65 years old (26.9% vs 32.7% p = 0.021) with the presence of comorbidity (23.8% vs 42% p = 0.002), synchronous angiodysplasias (29.7% 32.8% p = 0.04) and the use of medications that affect haemostasis system (19.9% vs 45.6% p = 0.00). Half of patients

require long-term treatment (36% with supplementary oral iron, 5.6% intravenous iron infusions, and 6% with lanreotide).

Discussion: Angiodysplasias are becoming more prevalent especially in elderly patients, half of cases are associated with the use of antiplatelet or anticoagulant drugs and comorbidities, making it difficult hemostasis and increased morbidity. In most cases, the bleeding was controlled with endoscopic therapy, a safe and effective technique, but more than one session was necessary for control of rebleeding. Hospital readmissions were associated with older patients, comorbidity, use of drugs that alter hemostasis and synchronous angiodysplasia lesions. These higher risk patients would require stricter control. A third of these patients required long term treatment for anemia.

Conclusions: Angiodysplasias are very frequent. They consume a lot of resources both diagnostic and treatment. The endoscopic treatment is effective and safe, but is required more than one session. We should identify the patients who have more risk factors to rebleed to make an effective follow-up.

EA-83
ANNUAL HOSPITAL READMISSIONS AND MORTALITY IN PATIENTS OVER 65 YEARS ADMITTED TO AN INTERNAL MEDICINE UNIT

B. Pernas, P. Vázquez, L. Ramos, R. Vázquez, N. Malmierca, I. Justo, J. Saborido, J. Díaz

Department of Internal Medicine. Complexo Hospitalario Universitario A Coruña. A Coruña, Spain.

Objectives: To analyze the clinical characteristics and readmission and 1-year-mortality rates of patients over 65 years attended in an Internal Medicine unit.

Material and method: Prospective observational study. We include all patients over 65 years attended in an internal medicine unit during 2010. We analyzed clinic- epidemiological variables, socio-functional status, polypharmacy, annual hospital readmissions and 1-year mortality. Data were analyzed using SPSS 18.0. Quantitative variables were expressed as mean ± standard deviation or range, and qualitative variables as percentages.

Results: A total of 250 patients were included. Of these, 57% were women. Mean age was 81 ± 6.9 years. The most prevalent diseases were: arrhythmia (34%), chronic renal failure (25%), heart failure (20%), dementia (17%), stroke (15%) and COPD (15%). Of all patients, 36% needed help in walking (16% bedridden), 26% in feeding, 15% had incontinence and 8% were institutionalized. Mean number of prescriptions per patient at admission was 6.6 ± 3.5 drugs. Of all patients, 48% consumed psychotropic drugs and 21% oral anticoagulants. Mean hospital stay was 9.5 ± 6.4 days. The most common diagnoses at discharge were heart failure (24.4%), COPD (18.8%) and pneumonia (8.8%). Mean number of prescriptions at discharge was 5.9 ± 3.6. One hundred eleven patients (44%) were readmitted. The median time to readmission was 120 days (range 3-339 days). Of the readmissions, 46% were for the same reason that the previous admission. The most common causes of readmission were respiratory diseases (22%) and heart failure (11%). The average hospital readmissions per year was 1.9 (range 1-8). Year mortality was 26% (66 patients). The median time to death was 184 days after discharge (range 1-313).

Discussion: Patients admitted to internal medicine areas are elderly, polypathological and with functional status impairment. Multiple drug therapy is common, with a high consumption of psychotropic drugs and oral anticoagulants. These drugs have been associated with frequent adverse reactions, which sometimes require hospitalization for their management. Comorbidity is common in the elderly and contributes to the complexity of this population. This problem is a risk factor for major adverse events such as functional decline, disability, dependency, poor quality-of-life, institutionalization, hospitalization and death, but is not the most important factor. We must take into account functional, mental and psychosocial aspects. It is expected that the rate of readmission and mortality in the elderly is high. It is therefore important to establish the characteristics of these patients to start assistance strategies aimed at this group of patients to allow better optimization of health resources.

Conclusions: 1. The most common causes of admission and readmission in elderly patients are heart and respiratory diseases. 2. Annual readmission rate in patients over 65 years is very high (44%). The most common cause of readmission is the same that led to the previous admission. 3. One in four patients dies in the first year of follow up.

EA-84
MY GRANDFATHER LIVES IN A NURSING HOME: HOW IS HE?

L. Barrena Santana[1], R. Peña González[1], P. Pablo Díaz[2], M. García Morales[1], M. González García[3], F. Olgado Ferrero[1], R. Pérez Palacio[1], E. García Sandón[1]

[1]Department of Internal Medicine, [2]Department of Control Infecciones Nosocomiales. Complejo Hospital Universitario de Badajoz. Badajoz, Spain. [3]Department of Internal Medicine. Hospital Infanta Cristina. Badajoz, Spain.

Objectives: Aging and the increased survival of the population, are increasingly joining permanently in social institutions for care, or nursing home, either because of comorbidity or social status. The multiple types of homes and different levels of training of their staff, makes it interesting to know the characteristics of these patients, reasons for admission and other situations related to their detention.

Material and method: We studied 150 patients from social institutions, who were admitted for any reason at our hospital. Data were obtained from the database of Internal Medicine for the year 2010. Were studied based on their prior comorbidity, the reason for go to emergency (in several different categories) and definitive diagnosis. The presence of colonization was investigated by the control equipment nosocomial infections on admission.

Results: The group included 57.3% of men and 42, 7 females, mean age 81.6 years (79.35 and 84.64 respectively) and 79.3% of patients, had a moderate or high level of dependence, remaining independent for daily activities only 31 of the 150. The most common history were hypertension (71.3%), type 2 diabetes (39.3%) and 30% had dyslipidemia. As for heart disease, 8.7% had heart failure, 18% of ischemic heart disease, atrial fibrillation 19.3% and 22.7 any other type of heart disease different from previous. Of the 29 patients who had atrial fibrillation, 51% and the remainder anticoagulants, antiplatelet drugs. The lung was 39.3%, being the most frequent COPD (28%). 23.7% of these patients were prescribed home oxygen. The vascular neurological disorders (including dementia secondary) affected 31.3% of patients, and 38% had non-vascular neurological disease. 18% of patients had antecedent of renal failure but, at the time of admission, to 48.7% had estimation of glomerular filtration below 60%. 48% of total, had low hemoglobin (8.7% less than 9 g/dl). Other aspects to consider are the history of cancer (16% of them had a previous diagnosis of cancer) and the presence in the treatment of hypnotics, anxiolytics and antipsychotic medication (up to 58% of patients were taking these drugs, 56% of men and 63% of women). The reasons for go to emergency were: respiratory 30.7%, 31.3% neurological, digestive (15.3%), infection (4%), cardiac (2.7%) or nephrourological (1.3%). 6.7% were related to other different reasons (mainly trauma and relationship with cancer). As for the final diagnoses are similar to the complaint, except in the cardiac origin (14% vs 4% ultimate reason for consultation) and neurological (11.3% versus 31.3% end).

An important aspect is the presence at admission of nasal colonization by multiresistant pathogens. Only 13 of the 150 patients, 8.7%, had contamination and in 100% of the cases was Staphylococcus aureus. All were isolated and treated with nasal mupirocin to the nasal smear negativity or discharge.

Discussion: It is increasingly common to see in our units for elderly patients, multiple comorbilities, which also add another factor to consider as institutionalization. Our study highlights the high comorbidity in these patients. Another aspect to monitor is the presence of contamination by multiresistant microorganisms in all patients who come for social institutions because we must to treat them as a nosocomial infection disease, which is involved in evolution and costs.

Conclusions: The presence of infection control teams in hospitals nosocomial is an effective tool to eliminate such colonization and prevent the spread to other patients through isolation measures. This kind of patient have a multiple comorbililities and we take this into our mind when treating them.

EA-85
RISK FACTORS FOR ANNUAL READMISSION AND MORTALITY RATE IN PATIENTS OVER 65 YEARS

B. Pernas, P. Vázquez, L. Ramos, R. Vázquez, S. Ruanova, J. Penas, P. Vega, J. Díaz

Department of Internal Medicine. Complexo Hospitalario Universitario A Coruña. A Coruña, Spain.

Objectives: To identify risk factors associated with annual hospital readmissions and 1-year mortality in patients over 65 attended in an internal medicine unit.

Material and method: Prospective observational study. We include all patients over 65 years attended in an internal medicine unit during 2010. We analyze epidemiological variables, socio-functional status, clinical and analytical variables, multiple drug therapy, readmissions per year and 1-year mortality. Data were analyzed using SPSS 18.0. Quantitative variables were described as mean ± standard deviation and qualitative variables as percentages. Bivariate analysis of categorical variables was performed using chi-square test or Fisher's exact test. Quantitative variables were compared using t-student test. Statistical significance was defined as $p < 0.05$.

Results: A total of 250 patients over 65 years were admitted to an internal medicine unit. The follow up period was one year after hospital discharge. One hundred and eleven patients (44%) were readmitted. Of these, 46% were readmitted for the same reason that the previous admission. One-year mortality was 26% (66 patients). Patients with history of vertebral compression, diabetes mellitus, functional status impairment (dependency for ambulation and/or feed and/or bowel incontinence), home oxygen therapy and taking oral hypoglycemic agents were related to hospital readmission and/or death during the first year after hospital discharge ($p < 0.01$). Older age, lower hemoglobin levels, increased consumption of drugs both at admission and at discharge and a greater number of diagnoses at discharge were statistically related to the risk of hospital readmission and/or death (Table 1). Creatinine, glucose, albumin or sodium levels, and mean hospital stay were not associated with increased risk of readmission and/or death.

Discussion: Age, morbidity and functional disability have been described as risk factors for readmission. In our study, the presence of vertebral compression, diabetes mellitus, multiple drug therapy, and the number of diagnoses at discharge (related to the complexity of the patient), have also been linked to increased risk of readmission and/or one-year mortality. Defining the factors that affect the rate of hospital readmission in patients hospitalized in internal medicine units will enable us to identify those individuals at high risk. This will allow us to develop strategies to reduce the costs they generate.

Conclusions: 1. The readmission rate and annual mortality in patients over 65 years is very high. 2. Age, functional dependence, vertebral collapse, diabetes mellitus, multiple drug therapy, home oxygentherapy, taking oral hypoglycemic agents and number of diagnoses at discharge have been associated with increased risk for annual readmission and/or one-year mortality in this group of patients.

Table 1 (EA-85). Analysis of risk factors statistically associated with readmission and/or 1-year mortality

Variable (mean ± SD)	Readmission and/or death	No readmission or death	p
Age (years)	81.4 ± 6.9	79.5 ± 6.6	0.04
Drugs at admission	7.5 ± 3.6	5.4 ± 3.1	< 0.001
Hemoglobin (g/dL)	12.1 ± 2	12.8 ± 2.3	0.02
Diagnoses at discharge	6.6 ± 2.2	5.5 ± 1.9	< 0.001
Drugs at discharge	6.9 ± 3.4	5.4 ± 2.7	0.001

EA-86
CLINICAL VARIABILITY OF PATIENTS HOSPITALIZED ON TWO BEDS OF INTERNAL MEDICINE DEPARTMENT OF A SPECIALIZED HOSPITAL

G. Ruiz Villena, R. Aranda Blázquez, S. Romero Salado, V. Lechuga Flores, V. Manzano Román, M. Guzmán García, E. Sánchez Relinque, F. Gómez Rodríguez

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: We could ask if two different beds from IMD are occupied by similar patients and if it's also a clinic profile for all patients hospitalized on IMD.

Material and method: We selected two randomized beds (bed-AB; B bed-BB). Data from every patients admitted in both beds were collected during a year. Studied variables: age, sex, hospitalization department, origin, reason for admissions, diagnosis, develop and time spent on hospital. Descriptive prospective study was done from all those data.

Results: Patients selected: 30 AB/31 BB. Average age: 66 years old AB/72 BB. Sex: 53.3% women AB/45% women BB. Hospitalization department: IMD (86% BA/77% BB), reaming AB (10% neurology, cardiology, other) reaming BB (9.65% pulmonology, cardiology, other). Origin: Emergences services (90% AB/83.8% BB). Clinic consultation office (AB 3.3%/BB 6.45%), ICU (3.3% AB/3.23%BB). Medical Day Hospital (3.3% AB/3.23% BB). Reason for admission: dyspnea (23.3% AB/36.2% BB), fever (13.3% AB/16.1% BB), reaming AB (13.3% for feeling sick, neurological symptoms, other), reaming BB (sepsis 12.9%, other). Discharge diagnosis: sepsis (13.3% AB/25.8% BB), heart failure -HF- (13.3% AB/19.3% BB) respiratory infection (20% AB/16.1% BB). Develop: discharged (27% AB/30% BB), transferred to other center (1 AB/a BB), dead (2 AB/0 BB). Average time spent hospitalized: 9.9 AB/10.2 BB.

Discussion: Assisted patients profile on two beds of IDM is similar. Usually are multicomorbidity patients with similar sex distribution (50.7% men/49.23% women). Average age over 65 referred from Emergency department. Reason for admission: dyspnea (29.75%) fever (14.17%). Most frequent discharge diagnoses are sepsis (19.55%), respiratory infection (18.06%) and HF (16.32%) with an average time spent hospitalized 10 days. These data from beds in which patients from other services can be hospitalized, shows us patients profile hospitalized on IMD beds.

Conclusions: Day by day is more important global view that internal medicine professional is able to manage, of multicomorbidity and elderly patients. This patients usually become heart failure because respiratory infection which causes fever.

EA-87
CARDIOVASCULAR RISK FACTORS AND THERAPY IN ELDERLY PATIENTS

E. Martínez Velado, M. Chimeno Viñas, P. Sánchez Junquera, A. de la Vega Lanciego, J. Soto Delgado, M. Mateos Andrés, L. Mustapha Abadie, P. García Carbo

Department of Internal Medicine. Complejo Asistencial de Zamora. Zamora, Spain.

Objectives: Arterial hypertension (AH) represents the most prevalent factor of cardiovascular (CV) risk, and it presents with important economical repercussion on pharmaceutical expenses, by itself as well as cause of its frequent links to another risk factors, leading to a rise of total therapy expenses, most of the former being long-term and chronic due to significant elderly population and increased life expectancy for our present society. Cause of these features and lifestyle, incidence of cardiovascular conditions is increasing. A rise in prevalence adds to all this because of improvement in therapies which avoid deadly events, leading to more years of life. Present recommendations from protocols and guidelines on hypertension include systolic blood pressures not higher than 140 mmHg and diastolic figures less than 90 mmHg for adults, unless no other risk factors recommending further reduction of those levels. At present, few articles assessing the eldest patients are available.

Material and method: Descriptive, observational and retrospective assessment was performed based on 100 randomized patients more than 80-year-old, admitted at Internal Medicine department of Zamora´s Hospital Virgen de la Concha through year 2011. Age, gender, rural or urban origin, presence of diagnosed AH or other CV risk factors (diabetes mellitus -DM-, heart, cerebrovascular and/or renal condition), nutritional status and lipid profile, therapies used and active ingredients according to pharmacological group, together with main cause of admission were assessed, as well as presence of therapy changes at discharge.

Results: 48 out of 100 patients analized were male gender, with a mean age of 88 years and higher number of patients from rural origin (64%). AH was present at diagnosis in 73% of them at discharge. Only 10% of patients did not show cardiovascular condition, and just 13% of patients assessed had not AH therapy prescribed. The pharmacological group most frequently used was diuretics (70% of all patients), in association with other drugs as commonest therapeutic option (59 out of 70 diuretic-treated patients), and furosemide as the most used of them. The next group according to frequency of use was ACE inhibitors (37% of patients, 97% in association). 27 individuals had therapy with three or more anti-AH drugs. 33% of patients needed antidiabetics, and metfomin was the most frequently used. In 22% of our series had lipid-lowering medication, and simvastatin was the most commonly used. Nutritional status assessment detected severe protein malnutrition only in five patients, none of them with previously diagnosed of renal failure. Regarding recommended serum levels of cholesterol and triglycerides, according to each condition, 11% and 12% respectively did not fulfil their endpoints. The condition which led to a higher number of admissions was decompensated heart failure (27 patients). 35% of patiens needed therapy enhancement in order to better control of CV risk factors.

Discussion: A significant rise in diagnoses of CV conditions and their linked risk factors have been seen in recent decades. Considering an incremental life expectancy as well, it determines the need of several drug combinations to treat, control and prevent future unwished events linked to conditions which present in our population. These combinations have been proved effective for prevention of new CV events or decompensation of current ones, so that quality-of-life and life expectancy can be improved. Pharmacological combinations show better adherence in multidrug-treated patients.

Conclusions: High prevalence of CV risk factors for the population assessed. Frequent combinations of anti-AH drugs in our elderly population. Significant amount of patients treated with three or more anti-AH agents, enhancement possibly needed because they often are not prescribed at maximum recommended dosage, and according to current conditions they should need several drugs. Classic anti-AH, lipid-lowering and antidiabetic agents are the most frequently used in our series.

EA-88
QUALITY OF LIFE (QOL), READMISSION AND PROGNOSIS IN DEMENTIA: THE ROLE OF ARTIFICIAL NUTRITION. A RETROSPECTIVE, OBSERVATIONAL, PARALLEL-GROUP STUDY

A. Nouvenne[1], A. Ticinesi[1], B. Prati[1], G. Ragni[1], E. Ridolo[1], G. Lippi[2], L. Borghi[1], T. Meschi[1]

[1]Department of Clinical Sciences. University of Parma. Parma, Italy. [2]Department of Pathology and Laboratory Medicine. Parma University Hospital. Parma, Italy.

Objectives: To evaluate in patients with dementia discharged from hospital with or without tube feeding: 1) rate of survival, 2) rate of readmission, 3) quality of life (QoL) as perceived by the caregiver.

Material and method: At the Internal Medicine and Critical Subacute Care ward of Parma University Hospital, Italy, 240 patients with dementia were consecutively enrolled within a period of six months. 44 patients were excluded because dead during the hospitalization. The remaining 196 (M 68, F 128, age 82 ± 8 years) underwent FAST (Functional Assessment Stages) and CDR (Clinical Dementia Ratio) score calculation and nutritional evaluation. Total enteral nutrition through PEG (percutaneous endoscopic gastrostomy) was administered to patients not able to eat orally for any reason and with a life expectancy greater than 30 days. After about twelve months from the hospital discharge, survival, re-hospitalization and quality of life through a telephonic interview with the caregiver were assessed.

Results: PEG was placed in 59 patients (PEG group), while 137 patients maintained oral nutrition (oral group). Average follow-up was 17 ± 6 months (range 8-26). 38 patients of the PEG group (67%) died (median of survival 7.5 months) vs 51 patients of the oral group (37%) ($p = 0.0001$ - Kaplan-Maier survival curve). However, since FAST and CDR scores were significantly worse in the PEG group than in oral group (FAST 7a vs 6b, $p < 0.0001$, CDR 3 vs 2, $p = 0.0004$), the survival within the two groups did not result statistically different after correcting the mortality rate for the disease severity. The two scores resulted strongly correlated one with another (rho = 0.862, $p < 0.0001$). Readmission rate was not different among the two groups (29% in both). In both groups the caregiver defined the QoL of the patients as good in 55%, acceptable in 25% and poor in 20%.

Discussion: Dementia is a disease with a high prevalence in the elderly population. The effects of total enteral nutrition with tube in patients with advanced dementia are controversial. The clinical trend, chronic and progressive, of the disease often makes it difficult to establish clinical course and prognosis. Our data seem to confirm the assumption that advanced dementia is a terminal disease like cancer. In fact, in our patients worse functional scores are associated to an increase in mortality even at 6 months.

Moreover, our data suggest that mortality is less influenced by nutrition type and more by dementia severity, that is the parameter that leads clinicians to start tube feeding. As a matter of fact, the survival curves of patients on enteral nutrition are worse (64% vs 37%), but, on the other hand, these patients show a significantly more advanced dementia score. However, readmission rate is not different in both groups.

Conclusions: In our population enteral nutrition is associated with a poor prognosis quoad vitam but this difference is not confirmed after correction for dementia severity. These data suggest that perhaps in clinical practice enteral nutrition through tube is undertaken too late during the disease course. Finally, there does not seem to be differences in readmission rate and quality of life as perceived by the caregiver.

EA-89
STUDY OF URINARY DIETETIC-METABOLIC LITHOGENIC RISK PROFILE IN BEDRIDDEN INPATIENTS ON ARTIFICIAL NUTRITION (TUBE FEEDING OR TOTAL PARENTERAL NUTRITION)

A. Nouvenne[1], A. Ticinesi[1], A. Guerra[1], B. Prati[1], G. Ragni[1], G. Lippi[2], L. Borghi[1], T. Meschi[1]

[1]Department of Clinical Sciences, [2]Department of Pathology and Laboratory Medicine. University of Parma. Parma, Italy.

Objectives: To assess the urinary factors of lithogenic risk in multiple-disease bedridden inpatients receiving either total parenteral nutrition or tube enteral feeding and to verify their role as nutritional markers.

Material and method: At the Internal Medicine and Critical Subacute Care ward of Parma University Hospital, Italy, 49 patients receiving artificial nutrition (20 on parenteral nutrition (TPN), 14 M, 6 F, average age 80 ± 6 years; 29 on tube feeding (TF), 16M, 13 F, average age 81 ± 9 years), completely bedridden and unable to eat orally, and 19 healthy controls (CTRL) (9 M, 10 F, average age 80 ± 5 years) were enrolled. All subjects undertook a urine 12-hour sample collection for the determination of the complete lithogenic risk profile (volume, pH, creatinine, Na, K, Cl, Ca, P, Mg, uric acid, ammonium, oxalate, sulphate, urea, citrate, supersaturation for calcium oxalate, uric acid and struvite).

Results: Patients receiving artificial nutrition, either on TPN or on TF, showed significantly lower values of many urinary lithogenic risk factors than controls, both promoters and inhibitors (for example Ca 43 ± 37 mg vs 95 ± 58 $p < 0.001$, sulphate 3.8 ± 2.8 mM vs 8.1 ± 3.7 $p < 0.001$, urea 6.8 ± 4.3 g vs 9 ± 3.5 $p = 0.05$, ammonium 7.6 ± 7 mEq vs 13.7 ± 7 $p = 0.002$, citrate 131 ± 93 mg vs 261 ± 114 $p < 0.001$, K 16 ± 9 mEq vs 23.3 ± 9.7 $p = 0.005$). Also creatininuria, corrected for creatininaemia, resulted significantly lower (297 ± 170 mg vs 527 ± 143 $p < 0.001$). These differences were confirmed even in the analysis of controls versus the subgroups parenteral nutrition and enteral nutrition. Supersaturation values resulted normal in all groups. The comparison of urinary profiles in parenteral nutrition and tube feeding did not show differences, except higher pH and lower phosphorus and ammonium and higher volume in the TF group than in the TPN group (pH 6.8 ± 0.9 vs 6.2 ± 0.8, $p = 0.01$; P 191 ± 160 vs 337 ± 306, $p = 0.035$, ammonium 5.4 ± 4 mEq vs 11 ± 9 $p = 0.006$, volume 731 ± 380 ml vs 521 ± 300, $p = 0.049$).

Discussion: In the last decades the number of old multiple-disease patients is rising. Malnutrition and immobilization are crucial challenges for clinicians because of the relevant fallout on a clinical, social, economical and health care point of view. It is still unclear what are the best scores and/or instrumental/laboratory tests to assess nutritional status in this setting of frail, multiple-disease elderly. In the adult subject the urinary factors of lithogenic risk are considered as an adequate dietetic-metabolic profile and there are data suggesting that both unbalanced diet and bed resting are risk factors for nephrolithiasis. Data in the elderly population, both hospitalized or community-living, are still lacking. Malnutrition and bed rest play a role of both cause and consequence of "elderly frailty". Our data confirm that adaptive responses of the elderly patients are substantially different from those of the young/adult subjects. For example, an increase of stone risk after bed rest is well documented in adults, although in particular conditions (space flights, healthy volunteers), while in our cohort of bedridden inpatients, stone risk is even lower than that of healthy age-matched elderly patients. Surprisingly comparison between TPN and TF does not show significant differences except lower urinary volume in TPN perhaps due to a well known fluid retention after iv fluid infusion.

Conclusions: These data suggest that elderly, frail, bedridden multiple-diagnosis patients receiving artificial nutrition do not show an elevation of their lithogenic risk, showing on the other hand low values of the urinary factors excretion. Urinary dietetic-metabolic parameters appear therefore very useful in the nutritional status assessment also in this particular type of severely malnourished patient.

EA-90
ANEMIA IN HOSPITALIZED PATIENTS OVER 85 YEARS AND ITS RELATION TO ORAL CHRONIC INTAKE OF ANTIPLATELETS AND/OR ANTICOAGULANTS

L. Salas Reinoso[1], S. Pérez Correa[1], N. Lorenzo Villalba[1], S. Alonso Rodríguez[1], S. Moreno Casas[1], M. García Bello[2], M. Fiuza Pérez[2], P. Betancor León[1]

[1]Department of Internal Medicine, [2]Department of Investigation. Hospital Universitario Dr. Negrín. Las Palmas de Gran Canaria, Spain.

Objectives: Considering the significant prevalence of anemia among hospitalized elderly as well as the chronic use of antiplatelet and/or oral anticoagulant drugs by this group we considered the hypothesis that those medications could bring about anemia in this special group.

Material and method: A retrospective study was carried out. A total of 234 discharge reports of patients over 85 years or more were randomly chosen from the Internal Medicine Service at Dr. Negrín Hospital during 2010. Parameters such as previous use of antiplatelet, anticoagulant drugs, past medical history, diagnoses at discharge and laboratory test were considered. Anemia was defined considering the OMS current criteria which defines it as a level of hemoglobin minor than 12 g/l for women and 13 g/l for men. A descriptive study of the sample was conducted and the association among the different parameters and anemia was analysed using the chi square test.

Results: A total of 188 patients older than 85 years were studied, 131 women and 57 men. Anemia was found in 127 (67%) patients, 83 women and 44 men. 25 patients were found to have anemia before admission and 23 of them continued presenting it during hospitalization, while anemia was a new finding in 104. 78 (44%) patients were taking aspirin while 23 (13%) clopidogrel, and 22 (12%) acenocumarol. Among those taking aspirin, 73% women and 76% men had anemia. From those taking clopidogrel, 53% women and 90% men had anemia. From those taking acenocumarol, 64% women and 100% men had anemia, but differences were not significant. Anemia was found to be a more frequent finding among those women taking aspirin than in those not taking it (73% over 39%), this difference was statistical significant but only with a marginal behavior ($p = 0.07$). A significant statistical association was found between anemia and serum creatinine higher than 1.2 mg/dL, urea higher than 50 mg/dL, total proteins levels lower than 6.5 g/dL or elevation of the sedimentation rate higher than 30 mm/h. Neither a significant association between anemia and

diabetes nor with respiratory infection, dementia, exitus or heart failure at discharge was found. Anemia was not registered as a discharge diagnose in 59% of cases. Ferritin was requested in 89 patients, among them 69 were found to have anemia, and ferritin was lower than 30 ng/mL in 5 patients, higher than 300 ng/mL in 24. Low vitamin B12 levels were found in 10 (out of 121 determinations) and 7 had anemia. Folic acid levels were low in 1 case out of 112 determinations. Erythropoietin, Coombs test, reticulocyte count and smear were determined in less than 5 patients.

Discussion: Elderly patients suffer from many diseases so that they have to take a wide range of medication. One third of them may have been taking any kind of antiplatelet or oral anticoagulant medication. Among antiplatelet, aspirin is the most used. Since low dosage of aspirin was discovered to be effective in the prevention of cardiovascular disease, its use has spread out. Gastrointestinal bleeding has been particularly related to the use of aspirin and less with other antiplatelets. However, there are few studies reporting the relation between anemia and anticoagulation/antiaggregation in the elderly. Despite of it, in clinical practice, we assume anemia is caused by these drugs. Results from the study seem to indicate that women taking aspirin might have a higher percentage of anemia (marginal significance) which is not described for other antiplatelets/anticoagulants. Other important comments coming out of the research was the high prevalence of anemia in hospitalized patients over 85 years (70%), the low percentage of nutritional anemia (10% versus 30% expected) and the infravaloration of anemia in the elderly as a medical problem.

Conclusions: We found trend towards significance between aspirin intake in hospitalized women over 85 years and anemia. This study is only a snapshot into the problem; better results could be expected if the sample is extended.

EA-91
COHORTS STUDY IN A CO-MANAGEMENT MODEL IN PATIENTS WITH HIP FRACTURE

M. García Gutiérrez, J. Praena Segovia, L. de la Higuera Vila, J. Galindo Ocaña, L. Moreno Gaviño, M. Bernabeu Wittel, M. Ollero Baturone

Department of Internal Medicine. Hospital Virgen del Rocío. Sevilla, Spain.

Objectives: To assess the clinical impact of a co-management model (Internal Medicine and Traumatology) in patients over 65 years old hospitalized with hip fracture (HF) in a third level hospital.

Material and method: Retrospective Cohorts study. Inclusion criteria: patients in a co-management model (Co-FRAC cohort) hospitalized between January 2008-August 2010, and patients hospitalized in the preceding years with hip fracture, between January 2005-August 2006 (HIST cohort), at a tertiary teaching center in southern Spain. The co-management model consisted in daily universal evaluation, from admission to discharge, prevention of medical complications, conciliation treatment, protocolized management of medical complications, co-management with trauma and anaesthesia teams, discharge summary and post-discharge monitoring in medical office if necessary. Analysis of demographic, clinical and surgical characteristics. Comparison of the incidence of different medical complications on both cohorts, as well as in-hospital mortality as well as 30 days after discharge.

Results: 582 patients were included, 396 in HIST cohort and 186 in Co-FRAC cohort (mean age 82.5 years (SD 7.2), 78% female). The average number of drugs taken was 3.7, a high percentage of patients took benzodiazepines (HIST 25.5%, Co-FRAC 27.3%). The most frequent pathologies were arterial hypertension (HIST 61.6%, Co-FRAC 58.9), diabetes mellitus (HIST 28.8%, Co-FRAC 32.1%) and cognitive decline (HIST 14.9%, Co-FRAC 19.5%). The main type of hip fracture was pertrochanteric (HIST 44.9%, Co-FRAC 49.2%). The most frequent complications were anemia (HIST 76.3%, Co-FRAC 90.3%, $p < 0.001$), constipation (HIST 78.8%, Co-FRAC 62.2%, $p < 0.001$) and acute renal failure (HIST 55.1%, Co-FRAC 65.3%, $p = 0.06$). Intrahospitalary mortality was 1.6% in Co-FRAC cohort and 3% in HIST (95%CI, $p = 0.32$), post-discharge mortality was 1.3% in Co-FRAC cohort and 2.6% in HIST (95%CI, $p = 0.32$).

Conclusions: The described co-management model, incorporating an internist in the health-care team may improve in-hospital and post-discharge mortality in elderly patients with hip fracture.

EA-92
ATRIAL FIBRILLATION IN VERY OLD PATIENTS

P. Vasconcelos, I. Luz, S. Heitor, N. Bragança

Department of Medicine III. Hospital Prof. Doutor Fernando Fonseca. Amadora, Portugal.

Objectives: Atrial fibrillation (AF) is the arrhythmia most often observed in elderly patients and is an important cause of morbidity and mortality in this age group. Anticoagulation to reduce the thromboembolic risk is an essential part of the approach of this pathology. In this context, our aim is to assess the prevalence of AF and its treatment in very old patients admitted to our medicine ward.

Material and method: We analyzed the clinical files of very old patients (VOP - very old people - age ≥= life expectancy + 5 years for both sexes - 76 + 5 years for males and 82 + 5 years for females) admitted to our department from 01/01/2011 to 31/12/2011. The average of inward days and death rate was calculated. We analyzed the electrocardiograms performed at baseline and assessed outpatient medication.

Results: In 2011 we recorded 996 admissions, of which 189 (19%) were VOP. Of these, 26 (13.76%) died. The average hospitalization was found to be 15 days. We identified 61 cases (32%) with AF. No differences were found between genders. The majority (74%) had a CHADS2 score > 2. Only 1/10 of patients were treated with oral anticoagulants.

Conclusions: The prevalence of AF in our sample is relatively high compared to that described in other epidemiological studies. Despite the higher risk of stroke in elderly patients, thromboprophylaxis in AF is suboptimal. We admit that the new oral anticoagulants, because they do not require monitoring and have less drug interactions can potentially become very useful, particularly in the elderly.

EA-93
HOSPITAL STAY IN HIP FRACTURE UNITS

M. Royuela[1], D. Rosinés[2], F. Reguant[2], A. Tapiz[1], M. Castejón[1], C. Morales[1]

[1]Department of Internal Medicine, [2]Department of Traumatology. Althaia. Xarxa Assistencial Universitària de Manresa. Manresa (Barcelona), Spain.

Objectives: We observe the utility of units of hip fracture on fragile patient (UF3) to speed their hospitalization stay and reduced inpatient complications, facilitating a speedy recovery with a better prognostic.

Material and method: 239 patients total, over 65 years old, 203 with fractured proximal third of femur, from June 2010 until 30 April 2011. We have reviewed the ability to walk upon, the

amount of drugs and the relationship with femur fracture, the fracture type, hospital stay and resource use at discharge.

Results: 72% of women, average age of 85.26 years old. Previously 64.10% of them lives with family, even 23% alone. 46.81 were able to walk without help, against 11.7% weren't able to walk. Patients taking < 4 were 32.40%, and > 4 67.60%. Frequently drugs: psychotropic drugs 60%, 54% antihypertensive, 55% protective gastric, 44% PSA/ACO. Many of them related to risk of fracture of femur Days of surgical delay: Do not take AAP/ACO 2.31 days, operating at 48 hours 71%. Taking AAP 3.92 days, and taking ACO 2.72 days. Fractures were: 53.7% pertrochanteric 42.80% subcapital 4.46 subtrochanteric Average stay decreased to 12.65 days (were 19 days) only 7% were hospitalized over 20 days (in 2008 was 23%). Destination at discharge: 56.62% convalescence beds, 23.31% goes home with help, 15.53% residence for elderly.

Discussion: - Reducing average stay: mobilization of the patient should be do early and twice a day. – Utility of discharge resources: convalescence beds. – Reducing complications for intensive monitoring.

Conclusions: Improved functional and vital prognosis. Patient and family satisfaction higher.

EA-94
GERIATRIC CULTURE IN THE EMERGENCY AREA

G. Muñoz Gamito[1], I. Arancibia Freixa[1], A. Álvarez Soto[1], C. Estrada Díaz[2], P. Almagro Mena[2]

[1]Department of Emergency, [2]Department of Geriatrics. Hospital Mutua de Terrassa. Barcelona, Spain.

Objectives: Correct performance assessment of elderly patients in emergency services requires an awareness and specific training by professionals in this matter. A lack of identification by professionals make patients susceptible to the effects of poor quality care. The aim of our study was to evaluate what is the degree of awareness of the professionals in the Emergency Area (EA) of our center, regarding the assessment of geriatric patients.

Material and method: Transversal descriptive study. An anonymous and voluntary survey was performed and it was passed on to health professionals who worked mainly in the Emergency Area (EA). Data regarding gender and age, professional status, time of dedication in the EA per week, and years of experience were collected. The survey contained 24 questions with 4 possible answers (always, often, seldom, never) regarding the assessment of cognitive status, delirium, functional status, dysphagia, nutrition, treatment, urinary incontinence, ulcers, comfort and orders of vital support limitation (VSL) as well as communication between nurses and doctors. There was a question asking for an assessment of 1 to 10 according to the perception of quality given to patients and another open question inviting professionals to make proposals for improvement.

Results: 31 people answer the survey. 65% were women with a median age of 34.5 ± 9.7 years old. The 52% were nurses, 16% resident physicians and 20% physicians. Most of them worked 40 hours per week in the EA and the 32% had > 5years of experience. "Always or often" regarding the following items were reported: Cognitive status was assessed in the 64.5%. The 36.7% thought that delirium needs improving measures, the 32.3% asked for family collaboration and only the 9.7% talked with patient in order to improve orientation. Functional status was assessed by the 12.5% of the professionals. Dysphagia was asked by 38.7% and the number of meals per day was asked by the 9.7%. The 67.4% checked treatment with the patient or the caregiver orally. Status of urinary incontinence was assessed by the 41%. The 32.3% checked the presence of ulcers. Regarding VSL orders, the 80.4% was checked with other professionals, family or patients. The 68.2% thought that a good control of pain was achieved in the EA and the 29% asked for the quality of rest and sleep of the patient. Regarding doctor-nurse communication, the 41.9% thought it was good, the 25.8% thought it was coordinated and the 45.2% thought there were mistakes in the interpretation of medical orders. Professionals rated as 6.95 ± 1 the care given to the elderly. The 85% of the people answered that improving training and awareness measures among professionals would improve also the care given to the elderly. The multidisciplinary and collaborative work was proposed by the 45%.

Conclusions: The geriatric assessment of the elderly patients in the EA of our center can improve. More specific training measures regarding this issue as well as working strategies addressed to improve communication among professionals could benefit the quality of care given to old people in the EA.

EA-95
FEATURES OF HOSPITALIZED PLURIPATHOLOGIC DIABETIC PATIENTS

M. Matesanz, I. Íñiguez, D. Rubal, P. Ventura, J. Piñeiro, M. López, E. Casariego

Department of Internal Medicine. Hospital Universitario Lucus Augusti. Lugo, Spain.

Objectives: Nowadays, submitted patients with multiple chronic diseases represent a challenge in clinical and administration management. It's known, that the existence of health or other problems in the life of a patient can affect its life quality, and that its reduction can lead to an increasing number of hospital admissions. The aim of this study is to seek the features of hospitalized pluripathologic diabetic patients.

Material and method: This retrospective descriptive study analized the entire admissions of adult patients done in all the medical departments of the center during 10 years, between January 2000 and December 2009. Patients were divided into two groups: diabetic DM) and non-diabetic. Mean age, gender, number of chronic diseases, readmissions, mean hospital stay, mortality and CIRS score was analized.

Results: A total of 111,123 hospital admissions corresponding to 52,269 patients were registered, of which 10,187 were diabetic (27,502 hospital admissions). Comparing both groups: in DM 53 vs 56% male gender in non-diabetics, with a mean age of 75.1 ± 11.6 vs 67.7 ± 18.1 ($p = 0.001$) presented 4.1 ± 2 vs 2.4 ± 1.7 chronic diseases ($p = 0.01$), CIRS score of 12.4 ± 5.1 vs 9.3 ± 5 ($p = 0.001$), 2.68 ± 2.6 vs 1.99 ± 2.2 readmissions along with a mean hospital stay of 13.1 ± 29.1 vs 10.7 ± 15.2 days ($p = 0.001$) and a mortality rate of 5.7 vs 6% ($p > 0.05$). The most frequent causes of readmissions were heart failure, pneumonia, myocardial ischemia and chronic obstructive pulmonary disease.

Conclusions: Hospitalized pluripathologic diabetic patients can be associated with aging, a larger number of readmissions and mean hospital stay than in non-diabetic patients, and surprisingly due to non-related diabetic causes; notwithstanding mortality rates maintain equal.

EA-96
RETROSPECTIVE STUDY ON OBESITY IN A DISTRICT OF PORTUGAL

F. Alçada, S. Machado, D. Moura, J. Santos, C. Pereira, O. Gomes, C. Monteiro, C. Fernandes

Department of Medicine II. Centro Hospitalar Leiria Pombal, E.P.E.. Leiria, Portugal.

Objectives: This study aims to characterize the obese population in the district of Leiria, Portugal, and its co-existing risk factors. Obesity worldwide has become a major health issue, particularly in

the northern hemisphere, but also in the developing countries. Moreover, the obesity issue in the general population is linked to diabetes, dyslipidemia or high blood pressure, and it has recently been defined as an independent risk factor for cardiovascular and cerebral vascular diseases. Created in 2007, our obesity consultation spans a universe consisting on a 250,000+ population. Even though criteria for admittance in our consultation explicit a body mass index (BMI) over 35 kg/m^2, we tend to continue follow-up on those people with BMI ranging 25-35 kg/m^2.

Material and method: In a universe consisting on a population of 250,000+, the obesity consultation attends all those who are over 18 years-old and with a BMI over 35 kg/m^2. All the people with lower BMI's have been excluded from this study.

Results: The authors present the data of our consultation, with a total of 2,018 consultations consisting of 493 patients. We have excluded those with a BMI under 35 kg/m^2. The variables studied include gender, age, related health issues, response to medical treatment or intragastric balloon. We also include the study of analytic variables such as glycosilated hemoglobin, cholesterol and triglycerides, alanine transaminase and creatinine.

Discussion: The obese population in this district of Portugal is not very different from the obese populations elsewhere. We have similar success rates but, unfortunately, also high waiver rates. In those who achieved a steady and long-lasting weight-loss, there was also success in reducing glycosilated hemoglobin levels, cholesterol and blood pressure levels, as well as reducing the incidence of cardiovascular and cerebral vascular events. Thus, our role in the struggle for a better and healthier lifestyle is a hard but also very rewarding one.

Conclusions: The obese population in this district of Portugal is not very different from the obese populations elsewhere. We have similar success rates but, unfortunately, also high waiver rates. In those who achieved a steady and long-lasting weight-loss, there was also success in reducing glycosilated hemoglobin levels, cholesterol and blood pressure levels, as well as reducing the incidence of cardiovascular and cerebral vascular events. Thus, our role in the struggle for a better and healthier lifestyle is a hard but also very rewarding one.

EA-97
UTILITY OF CHARLSON COMORBIDITY INDEX IN PATIENTS HOSPITALIZED WITH PNEUMONIA

A. Rodrigues, J. Sequeira, F. San Martin, C. Teotónio, R. Amorim

Department of Internal Medicine. Hospital Caldas da Rainha. Caldas da Rainha, Portugal.

Objectives: Co-morbid conditions contribute among many other factors to the risk of infection with antibiotic-resistant bacteria, and mostly, they contribute to the morbi/mortality of an increasingly old population. The Charlson Index is a validated comorbidity index used to evaluate mortality rate according to the individual comorbid conditions of each patient.

Material and method: the present study was a retrospective study o hospitalized patients with the diagnosis of Pneumonia, during the period of 2010-2011 in a secondary care Hospital. A protocol was elaborated based on demographic variables, etiologic agents and their sensitivity to antibiotics, presence of comorbid conditions and stratification with Charlson Index.

Results: Among 285 patients with CAP, 52.6% men, 47.4% women, with a mean age of 77.72 ± 12.77. The most frequent comorbid condition observed was hypertension 42.1%, diabetes 35.4%; 30.2% of patients were totally dependent of others; 22.1% had chronic obstructive pulmonary disease and 16.8% had history of stroke. The Maximum Score of Charlson Index was 13, and the minimum was 0, with a mean of 6,64 ± 2.22. There were 52 deaths during hospitalization, and in this group of patients the mean Charlson Index was 7.6 ± 1.73. Etiological diagnosis could only be obtained in 22% of patients, and among these patients, 48.4% had an antibiotic-resistant etiology. The correlation between an antibiotic-resistant infection and de Charlson Index Score using the chi square test was statistically significant (p = 0.01).

Discussion: In the present study it was found that death during hospitalization occurred more frequently in patients with a higher Charlson Index Score. The number of etiologic diagnosis was very reduced compared to other studies published, which can reflects a reduced number of diagnostic procedures such as cultures. The presence of resistant microorganisms however was considerable.

EA-98
CAUSES OF UNINTENTIONAL WEIGHT LOSS IN ELDERLY PATIENTS

C. Fehér, J. Ortín, M. Navarro, M. Camafort, A. Jordán, A. López Soto, E. Sacanella

Department of Internal Medicine. Hospital Clínic. Barcelona, Spain.

Objectives: Unintentional weight loss (UWL) is a frequent reason for consulting the internal medicine specialist, being a possible cancer diagnosis of utmost concern in most of the cases. The vast majority of studies carried out in this field do not differentiate between middle-aged population and elderly patients, although the underlying pathologies may differ substantially. Our aim was to provide a description of the causes of UWL in the geriatric population and to determine what clinical and analytical data can predict malignancy.

Material and method: 50 consecutive cases of geriatric patients with good baseline functional status and low comorbidity who consulted at our outpatient geriatric clinic with UWL between May 2010 and December 2011 were enrolled in this study. We reviewed our database to collect clinical data and complementary exams (blood tests and radiologic and endoscopic studies when indicated) performed to all the study subjects. Statistical analyses were performed by means of Fisher's exact test, Student's t test and logistic regression analysis using the software IBM SPSS Statistics version 20.

Results: The mean age of the cohort was 80.7 years (SD 5.0 years) and 46% of the subjects were female. Seven of them lived alone at the time of the first visit and 14 were looked after by a carer (family member or professional). 72% of the subjects met the definition of polypharmacy (4 or more different drugs per day). The median Barthel index was 100 (Range 40 to 100), the median Charlson Comorbidity Score (CCS) was 1 (range 0 to 7), and the mean score on the EuroQol Visual Analogue Scale was 52.8 (SD 15.3). 68% of the patients had hypertension, 64% had diabetes mellitus, 50% had dyslipidemia, 24% had chronic heart failure, 24% had some chronic pulmonary condition, 22% had gastrointestinal comorbidity, 12% had cerebrovascular disease and 10% had thyroid malfunction. In addition to weight loss, 72% of the patients complained of other symptoms ('leading symptom'), most frequently asthenia, anorexia, abdominal pain and gastrointestinal bleeding among others. A malignant disease was found in 30% of the cases (7 gastrointestinal tumors, 6 hematologic malignancies and 2 lung cancers) and a non-malignant digestive disorder in 20% of them. Other diagnoses included neuropsychiatric problems (8%), cardiopulmonary diseases (6%), endocrine (4%) and miscellaneous disorders (10%). In 22% of the cases no specific diagnosis could be found. In our cohort elevated triglyceride (TG) levels (p = 0.009) and the presence of symptoms other than weight loss (p = 0.039) were associated with malignancy. C-reactive

protein (CRP) and alkaline phosphatase (AF) levels were found to be higher in patients with a malignant disease, though without reaching statistical significance.

Discussion: In the current study only 30% of the patients turned out to have a malignancy as the cause of UWL. Other frequent diagnoses were non-malignant digestive diseases and neuropsychiatric problems. On the other hand, in one out of 4-5 cases no specific diagnosis could be established. Elevated CRP, AF and TG levels have all been related to different kinds of malignancies before. To our knowledge, though, ours is the first study to describe a relationship between the fact of reporting symptoms other than pure weight loss and increased probability of cancer. We consider that in the presence of 'leading symptoms' it is vital to pursue a diagnosis even in the absence of other data pointing to a possible malignant disease. The lack of exact quantification of weight loss and assessment of the medication taken by our patients (another important cause of UWL to be taken into consideration) may limit the conclusions drawn, and the low subject number have certainly affected the statistical power of the analysis.

Conclusions: Cancer was not the most frequent cause of UWL in our cohort of elderly patients. Predictive factors of malignancy were the existence of additional symptoms other than weight loss and elevated TG plasma levels. We also found higher mean CRP and FA levels in cancer patients but this difference did not reach statistical significance. In around a quarter of UWL cases no specific underlying process can be identified.

EA-99
ANALYZE AGE CAREGIVERS LIFE QUALITY IMPORTANCE ON PALLIATIVE CARE PROGRAM PATIENTS FROM A SSPA HOSPITAL

O. Mera Gallardo, A. González Quiñones, E. de la Hoz Adame, G. García Domínguez, V. Lechuga Flores, V. Manzano Román, M. Guzmán García, M. Escobar Llompart

Department of Internal Medicine. Hospital Universitario de Puerto Real. Cádiz, Spain.

Objectives: Family plays a very important role on Palliative Care Program sick care. Caregivers on terminally illness are faced with lot of responsibility; this can change their life quality, decrease physical and mental health of caregiver. Evaluate caregiver age impact on quality life decline, on terminal illness patient family.

Material and method: Patients included on the palliative care program and assisted by CPMSE during two months on 2012. Caregivers completed life quality test (including information satisfaction degree, care prepared, emotional support, fatigue, tiredness, stress, anxiety, disappointment, anorexia and social relation items) We used χ^2 test by SPSS statistical program. Correlations with Caregivers variables were realized (age) with each items of "quality life" test. Cross- sectional descriptive chart study during two months.

Results: Age equal or less than 54 years old/more than 54: fatigue 64.3%/35.7%, fear 65%/35%, sadness 59.1%/40.9%, anxiety 60.9%/39.1%, loss of hope 58.3%/41.7%, disappointment 65.2%/34.8%, dream dysfunction 58.3%/41.7%, partner dysfunction 75%/25%, distraction 58.6%/41.4%, stress 66,7%/33.3%.

Discussion: Terminal illness care clearly influence on life quality and welfare of caregivers. According to results on our hospital area, as younger caregivers, more life quality disturbs.

Conclusions: Palliative care need a comprehensive treatment of the patient and family. It is necessary to prevent diseases resulting from inadequate comprehensive care.

EA-100
ROFLUMILAST: POTENTIAL ROLE AS SHORT-TERM SYMPTOMATIC TREATMENT OF DYSPNOEA IN PALLIATIVE CARE OF TERMINALLY ILL PATIENTS

J. Galindo Ocaña, C. Aguilera González, A. Fernández López, R. González León, J. Romero Mena-Bernal, J. Garrido Nieto, S. Sobra Calderón, M. Bernabeu Wittel

Department of Internal Medicine. Hospital Virgen del Rocío. Sevilla, Spain.

Objectives: Our aim was to describe the use of roflumilast in 5 terminally ill patients having dyspnoea at rest and productive cough or bronchorrhea with the purpose of obtaining better dyspnoea relief.

Material and method: From January to December 2011, 5 patients (4 cancer and 1 non-cancer) with dyspnoea at rest and intense productive cough or frank bronchorrhea who were attended by a southern Spanish hospital at home unit were selected to initiate treatment with roflumilast. We describe the clinical features and effects of roflumilast on patients' symptoms.

Results: Mean age was 74.6 ± 13.22 years, ranging from 63 to 90 years old. 4 were male and 1 female. 1 was a current smoker, 3 former heavy smokers and 1 non smoker. All had severe dyspnoea at rest, in episodes (4) or continuous (1), which was treated with oral morphine in 4 cases. The main disease was a colorectal cancer with lung metastases in 2 cases, larynx cancer and epidermoid lung cancer and severe COPD (GOLD stage IV) with chronic bronchitis in other case, another one advanced heart failure with severe COPD and chronic kidney disease, and the last one stroke with recurrent respiratory infections. Two patients had type 2 diabetes mellitus, one with insulin and other with oral antihyperglycemic agents (gliquidone). 4 were in ECOG performance status (ECOG-PS) 4 and 1 in ECOG-PS 3 at the first home visit. Initial mean Palliative Performance Scale (PPS) was 50 ± 10. The mean time of duration of treatment with roflumilast was 14.2 ± 11.74 days (8 to 34 days). Two patients with cancer also received low dose oral glucocorticoids (dexametasone 1 mg) because of anorexia and fatigue. After starting oral roflumilast 500 mcg/day, dyspnoea and sputum production improved in two days among 4 patients and in three days in other patient. Thus, needs of nebulized bronchodilator beta-adrenergic or anticholinergic treatment decreased notably. In 2 patients, nebulized bronchodilators could be passed to metered-dose inhalers. Among diabetic patients, oral glucocorticoids could be avoided and their glycemic control remained stable. Regarding adverse effects, only one patient (the one with heart failure, COPD and chronic kidney disease) presented with mild self-limited diarrhea for four days. No significant appetite loss or emesis was evident after introducing roflumilast, although all patients had been prescribed with metoclopramide or domperidone. 3 patients (all cancer patients) needed palliative sedation and scopolamine in the last days of life after a quick decline and agony with refractory symptoms (dyspnoea 5, pain 3, delirium 4 patients).

Discussion: Roflumilast is an oral phosphodiesterase-4 inhibitor approved for advanced COPD with chronic bronchitis and exacerbations. It is anti-inflammatory but the main clinical effect is the mid to long term improvement of perceived quality of life. Although it is well tolerated, emesis, anorexia, psychiatric disturbances and particularly diarrhoea are frequent. Among disabled terminally ill patients, bed rest causes constipation, possibly explaining better tolerance among our cases. This drug allowed us to reduce glucocorticoid use, an important issue for diabetic patients who were aware of possible hyperglycaemic decompensation. Perhaps this acute effect should be considered and its role in palliative care be explored in clinical trials.

Conclusions: Roflumilast was effective as symptomatic treatment in five terminally ill patients with severe dyspnoea with abundant sputum production, acting in just a few days.

EA-101
FOLLOW-UP OF PATIENTS TREATED WITH NON INVASIVE MECHANICAL VENTILATION (NIMV) IN INTERNAL MEDICINE

M. La Regina, F. Corsini, A. Marinaro, L. Scuotri, F. Orlandini

Department of Internal Medicine. Ospedale S.Andrea- ASL 5 Liguria. La Spezia, Italy.

Objectives: NIMV has been shown to be effective in chronic and acute respiratory failure (RF). In the past, all the forms of mechanical ventilation were managed in intensive care unit (ICU). Anyway, the decrease and expensiveness of ICU beds and the population ageing and comorbidities spread it outside ICUs. The aim of the present study is to investigate inhospital mortality, survival at 3, 6 and 12 months and re-admission within 1 month among patients by NIMV in a ward of Internal Medicine.

Material and method: From 1/1/2009 to 11/15/2011 we delivered 148 NIMV treatments. Inhospital mortality, survival at 3-6-12 months from discharge and readmissions to hospital within one month were collected. Study population: 104 pts (mean age: 84.3 ys) treated by BPAP for hypercapnic RF due to exacerbation of COPD (69 pts eligible for follow-up at 3/6 mo, 33 at 12, 17 at 24 mo) and 44 pts (mean age: 74.5 ys) treated by CPAP for hypoxemic RF due to pneumonia (30%) and pulmonary edema (70%), (31 eligible for follow-up at 3/6 mo, 21 at 12 mo, 6 at 24 mo). All of them have at least 2 comorbidities.

Results: In BPAP group, 33.6% died in hospital, 58% pts survived at 3 mo, 52% at 6 mo, 53% at 12 mo.; 5/17 patients are still alive after 24 mo.; readmission within 1 mo. occurred in 20% (14/69) of cases. In CPAP group, 29.5% died in hospital, 63% survived at 3 mo, 67% at 6 mo., 73% at 12 mo and 3/6 at 24 mo; readmission within 1 mo. occurred in 19% (6/31) of cases.

Discussion: Follow-up of patients treated by NIV is not yet fully investigated. Previous follow-up studies cover only patients with hypercapnic ARF. 1-year mortality (47% BPAP-group) in our study is consistent with previous reports (ranging from 30.8-49%), despite of a higher mean age of patients. The prognosis is better among patients treated by CPAP, because of the different nature and better options of treatment of the causing disease. Cost-effectiveness and social equity are critical issues.

Conclusions: Nowadays, NIMV is widely used in Internal Medicine. Considered that a large proportion of do-not-intubate patients are treated in this setting, survival resulted quite prolonged and readmission rate is not very high in both the groups.

EA-102
EARLY MORTALITY IN HIP FRACTURE PATIENTS

J. Durán[2], J. Torviso[1], E. García[1], M. Capo[2], M. Muñoz[1]

[2]Department of Geriatrics, [1]Department of Internal Medicine. Hospital de Terrassa. Consorci Sanitari de Terrassa. Terrassa (Barcelona), Spain.

Objectives: Analyze causes of death and characteristics of patients who died within 30 days after suffering a hip fracture.

Material and method: We have reviewed the medical records of patients admitted to the Acute Geriatric Unit (AGU) at Terrassa Hospital between January 2006 and August 2010, and who died within 30 days after suffering a hip fracture. The data collected included age, sex, Charlson Index, Barthel Index at the admission date, history of cognitive impairment, fracture type, treatment type and cause of the death.

Results: During the reviewed period, a total of 485 patients with hip fracture were admitted. A total of 38 patients died (7.8%), thirteen of which failed to undergo surgery and 25 (5.1%) died within 30 days after surgery. A 52.6% were women and 47.4% were male. The average age is 88.1. Standard deviation (SD) ± 5.7 years (min: 76, max: 100) and the mean is 88.5 years. A 53% of the cases were intracapsular fractures and 47% of extracapsular fractures. The mean Charlson index was 4.2 ± 2.6. A 50% of patients had a baseline Barthel index > 75% and 18.4% had cognitive impairment with GDS-FAST score ≥ 5. The causes of death were: Cardiac Pathology: 16 (42%) (acute coronary syndrome: 10 cases. Sudden death: 2 cases. Heart failure, 4 cases). Respiratory disease: 10 (26.3%) of the patients (aspirative pneumonia: 4 cases. pneumonia: 3 cases, pulmonary tromboembolism (PT): 3 cases). Abdominal pathology: 8 (21%) patients (Gastrointestinal hemorrhage: 4 cases. Intestinal obstruction: 2 cases, Acute abdominal pain: 1 case. Intestinal ischemia, 1 case). Other causes: cerebrovascular disease, aortic dissection, fat embolism, multiple organ failure.

Conclusions: The most common cause of death during the 30 days after suffering a hip fracture was acute ischemic heart disease, followed by pneumonia, aspirative pneumonia and PET. It is also remarkable that one of every 5 deaths were related to abdominal pathology of diverse kinds, specially gastrointestinal bleeding.

EA-103
COMPLEX CHRONICALLY ILL PATIENTS. TWO YEARS HEALTH CARE OUTCOMES TO THE CARE PROGRAMME (COMPARTE PROGRAMME)

A. Fernández Moyano[1], I. Vallejo Maroto[1], J. Paez Pinto[2], E. Martín Sánchez[2], C. Palmero Palmero[1], M. Álvarez Alcina[1], V. Ruiz Romero[1], M. Gómez Hernández[1]

[1]Department of Internal Medicine. Hospital San Juan de Dios de El Aljarafe. Sevilla, Spain. [2]Distrito Sanitario Atención Primaria Aljarafe. Sevilla, Spain.

Objectives: The primary objective was to improve morbidity and mortality. Secondary Objective: To stratify the risk of readmission. Homogenize the implementation of programs of care and effective pharmacological treatments. Establish a self-care education program. Improving drug reconciliation. Develop professional qualifications through the completion of a training program in their own virtual learning environment.

Material and method: Our hospital (San Juan de Dios de Aljarafe) and its catchment area (Aljarafe Health region) have operated a specific programme to provide integrated and longitudinal care. The programme aims to achieve the aforementioned objectives through the development 11 operational interventions: patient identification; integrated assessment and care; standardisation of procedures; rational use of medicines; self-care education; sectorisation of the inpatient and outpatient areas; transfer on discharge; linkage to electronic health records; follow-up in primary care; close observation to detect exacerbations; and development of professional skills. Currently, the programme is applied in the case of patients with heart failure, chronic obstructive pulmonary disease, multiple diseases, or cancer requiring palliative care.

Results: We have incorporated to 347 patients in the intervention group versus a 185 patients to control group unmasked during the periods from April to September of the three years prior to the start of the program (2006-2008) and the first two years of program's inception (2009 and 2010). The baseline demographic and clinical characteristics shown in Table 1. The results in morbidity and mortality are shown in Table 2.

Discussion: It is worth striving to promote team work as it can improve sometimes complex care by sharing the provision of care.

Conclusions: This model of continuous care to chronically ill patients is associated with less morbidity and lower mortality per year.

Table 1 (EA-103). Demographic and clinical characteristics of the patient in control and intervention group

	Control patients (n = 185)	COMPARTE patients (n = 347)	p value
Age--yr	78.7	78.3	ns
Sex (% female)	48.6	45.2	ns
COPD (%)	9.8	9.3	ns
Heart failure (%)	7.3	8.2	ns
Polypathological ((%)	82.9	82.5	sn
stay (days)	6,1	6,6	ns

Table 2 (EA-103). Healthcare outcomes of the patient in control and intervention group

	Control patients (n = 185)	COMPARTE patients (n = 347)	p-value
1 year readmission (%)	41.6	33.4	0.016
1 year mortality (%)	52.0	31.7	0.001

EA-104
CHRONIC PATIENTS: THERAPEUTIC GRADE BOND IN OUR HOSPITAL AREA

A. Vergara Díaz[1], M. Gómez Hernández[1], C. Escorial Moya[1], R. Fernández Ojeda[1], S. Andrades Segura[2], S. Vidal Serrano[1], A. Fernández Moyano[1]

[1]Department of Internal Medicine, [2]Department of Family and Community Medicine. Hospital San Juan de Dios de El Aljarafe. Sevilla, Spain.

Objectives: Getting to know the degree of adherence to treatment of chronic patients in our area.

Material and method: We performed a prospective observational study of patients attending our external Internal Medicine practices. They were selected randomly during a period of 3 months. They answered a questionnaire voluntarily and anonymously in order to determine their compliance to the prescribed treatment. The variables analyzed were sex, age, residence, family, form and method of administration of medication, adherence, monitoring visits, comorbidity and instruments considered to improve compliance.

Results: We obtained a sample of 129 patients, 58% men and 42% women with a mean age of 71. Only 6% of the sample was institutionalized. The 55% of the patients living at a private family home administered the medication by themselves, even if 91% of them lived with a relative. The most prevalent chronic diseases were hypertension, dyslipidemia and diabetes. 76% of patients were on several treatments. 61% of them (n = 60) had reached adherence to treatment, while only 45% (n = 14) of the patients which were exclusively on one treatment (p = NS) had. 51% of patients did not use reminder of medication. One of the most common methods was the labelling of daily doses on the medications' packaging. Only 57% of the population studied maintained good compliance. However, 84% of patients saw no need for any tools to improve adherence.

Discussion: In medical practice, part of treatment compliance is the responsibility of patients and failure becomes a real health problem increasing morbidity, mortality and health expenditure. We have found a high percentage of patients with poor compliance in our study. This result matches those obtained previously by other authors. Several studies observed a lower adherence to treatment in patients who were on several treatments, unlike the results of our work. We must integrate strategies to improve compliance and reduce complications and the costs of therapeutic failure.

Conclusions: There is a high percentage of patients with low adherence to treatment. No significant differences have been found in patients who meet criteria for polypharmacy.

EA-105
PROGRAM SHARED CARE. BENEFITS AND AREAS FOR IMPROVEMENT IN ONCOLOGY PALLIATIVE PATIENTS

M. Gómez Hernández[1], A. Vergara Díaz[1], C. Escorial Moya[1], R. Fernández Ojeda[1], S. Vidal[1], S. Andrades Segura[2], A. Fernández Moyano[1]

[1]Department of Internal Medicine, [2]Department of Community and Family Medicine. Hospital San Juan de Dios de El Aljarafe. Sevilla, Spain.

Objectives: 1. To clarify the reason why palliative oncological patients are admitted to our Department of Internal Medicine. 2. To determine if patients are admitted directly to hospital stay ward by telephone contact between Primary Care Services and the internist, or do so through the Emergency Department. 3. Analyze what proportion of these patients return for consultation with the Emergency Service or are readmitted within one month of discharge.

Material and method: We carried out a prospective study of patients included in the "Plan Shares" as palliative cancer for 8 months. We analyzed the sex, age, type of admission (emergency, scheduled admission), cause of admission, readmission and emergency department visits in the month following discharge, appointments at the day-hospital, death in hospital.

Results: The "Plan Shares" assumes 56 oncology patients who were properly included, 34 men (74 ± 11 years) and 22 women (76 ± 12 years). 80% of them were admitted through the Emergency Service while the rest 20% were directly to the ward. Causes of admission were manifold, being respiratory and infectious processes and dysphagia the most frequent. The day hospital was used by 2% only. 21% of the patients attended the Emergency Service within one month of discharge, and 25% of patients were admitted. 55% died in hospital.

Discussion: The aim of including these patients in the shared care program is to provide a more fluid communication between the Primary Care Services and the Internal Medicine Department in order to improve their quality of life. These will be achieved by improving symptom control and making the admission on hospital stay ward easier avoiding the Emergency Service. The most frequent cause of admission is dyspnea, which may justify a large majority of patients being admitted through the Emergency Service with no time to schedule the direct admission to ward. We should also promote the use of the day-hospital amongst these patients. As a quality parameter there is good symptomatic control of pain.

Conclusions: 1. The most frequent causes of admission amongst these patients are dyspnea, dysphagia and infectious processes. 2. The majority of them are admitted through the Emergency Department. 3. 25% of the patients are readmitted.

EA-106
DESCRIPTION OF PATIENTS WITH ADVANCED CHRONIC ORGANIC FAILURE KILLED IN A SERVICE OF INTERNAL MEDICINE

B. Muñoz González, L. Tomas Chaume, B. Borjabad, E. Llargués Rocabruna

Department of Internal Medicine. Hospital General de Granollers. Granollers. Barcelona, Spain.

Objectives: Describe the last year of life of patients who died with advanced chronic organ failure (IOCA in Spanish) admitted in a Internal Medicine service.

Material and method: Retrospective study. Review of medical records of patients who died in the internal medicine service from 1.

March 2011 to 28 February 2012. Were selected and studied patients whose cause of death was chronic advanced organic failure (IOCA: respiratory, hepatology, heart disease, neuropathy, nephropathy).

Results: 114 dead. Of which 42 (36.84%) died of an IOCA. Mean age 74.2 years (SD 12.8). 11 women (mean age 82.0. SD 8.0), and men 31 (mean age 71.5 years, SD 13.1). 36 (85.71%) were more than one chronic disease, with the following distribution. (Table) The average stay was 14, 8 days. 9 patients died without previous decompensation in the year before the patient died. The remaining patients (33 (78.6%)) were admitted 2.76 times (SD 1.82) and were taken to hospital in 3.32 times (SD 2.92). 32 patients (76.2%) were admitted from the emergency service, 5 (11.9%) from the ICU, 3 (7.14%) from Day Hospital program or chronic illness, 2 (4.76%) from other hospital services. Subgroup of patients admitted from the emergency service, they calculated the Profund Index (IP) to 26 (81.25%) One year before the patient died, his IP was 6.67 (2.29 SD), with mortality estimated at year: 21.5%. 5 (19.23%) patients had an IP > 10 (estimated mortality of 45%).

Discussion: Given in progressive aging of the population and the high prevalence of patients with IOCA is important to use indices to determine the probability of death. In our case, the index profound predicted a low probability of death (21.5%).

Conclusions: Of all patients who died in the internal medicine service, the 36.84% were by IOCA. The most prevalent were: cardiovascular and respiratory systems. During the last year of their life these patients visited the emergency services 3.32 times and admitted (through emergency) 2.76 times because of decompensation associated with their IOCA The IP calculated for these patients considered (one year before) a possibility of death of 21.5%.

DESCRIPTION OF PATIENTS WHO DIED DURING A YEAR IN THE INTERNAL MEDICINE SERVICE IN A REGIONAL HOSPITAL

L. Tomas Chaume, B. Muñoz González, B. Borjabad, E. Llargués Rocabruna

Department of Internal Medicine. Hospital General de Granollers. Granollers (Barcelona), Spain.

Objectives: Describe the demographic characteristics of patients who died in the internal medicine service in one year.

Material and method: Retrospective study, by reviewing the medical records of patients who died in the internal medicine service from March 1, 2011 until February 28, 2012. Statistical analysis was performed with the Access program.

Results: 114 deaths. 37 women, 77 men. Average age: 66.9 (13, SD). Average age of women 69.6 (SD 16.4) men 69.7 (SD 11.7). Of which 66 were multiple diseases (57.89%), with the following pattern (see Table). 36 patients had cancer. The diseases most prevalent among patients who died (in order of frequency) were cardiovascular (83.33%), hematologic-oncologic (54.54%) and respiratory (48.48%). There were 31 (46.97%) patients with diabetes.

Conclusions: Of all patients who die in an internal medicine ward, 57.9% of patients are multiple diseases, affecting mainly the cardiovascular system, Given that 31 (46.9%) patients were diabetic. Most patients who died in an internal medicine service are older patients with comorbidity.

IDENTIFICATION OF ADVERSE DRUG REACTIONS IN ELDERLY PATIENTS WHO ARRIVE TO AN EMERGENCY DEPARTMENT

N. Lois[1], M. Jimeno[1], C. Rinascente[1], V. Achaval[1], C. González[2], J. Medina[2], R. Merinero[2], I. Portero[2]

[1]Department of Internal Medicine, [2]Department of Emergency. Hospital Severo Ochoa. Leganés (Madrid), Spain.

Objectives: 1) To describe the characteristics of patients who developed ADR. 2) To describe the proportion of ADR produced by each therapeutic class of drugs. 3) To describe which are the most common ADR, developed by elderly people, who come up to an Emergency Department.

Material and method: This is a prospective observational study, in which are included consecutively those patients older than 75, who come to our Emergency Department, with at least a one ADR identified in the current ER episode (at investigator judgment), independently of the reason for consultation. Previously, a written informed consent was obtained from all patients. There were no exclusion criteria apart from the negative to offer consent, in order to capture as much as the real world ADRs possible. Data are collected directly from medical records and included in an electronic case report data. The data were analyzed using SPSS 10.0 program.

Results: Until April 2012, 61 patients were collected: 45 women (74%) and 16 men (26%). 12% of patients were institutionalized and 75% was independent for basic activities of daily living. Patients' personal medical records: as recorded, only in 9 patients (15%) any previous ARD had been described; 90% had at least a cardiovascular risk factor; being hypertension the most prevalent (75%); 51% had personal history of heart disease, 30% neurological, 28% metabolic, and 26% renal disease. Patients take an average number of 7 drugs to treat all these conditions. The drugs most frequently implicated in the observed episode of ADR were antihypertensive drugs, mostly diuretics, and anticoagulants (24% each of them), followed by heterogeneous group (to be noted a significant proportion of

opioids,18%). The symptoms most frequently associated with these ADR were of gastrointestinal (24%), nephrological (18%) and haematological (17%). The main factors associated with ADRs, according to the investigator's criteria, were the patient's idiosyncrasies (30%), polypharmacy (21%) and their own co morbidity (20%).

Discussion: There is a high incidence of adverse drug reactions (ADR) in elderly patients, reflected in various studies in recent years. This is due, in part, to greater fragility of this population, but also to the wide range of treatments that they are receiving because of their co morbidity. This work is a descriptive analysis of a subset of patients yet included in a study ongoing in our Emergency Department. It includes all the cases collected between December 2011 and April 2012.

Conclusions: Elderly patients show an important polypharmacy and co-morbidity that, according to investigator´s criteria, are the most important factors associated with the ADRs observed. Consistently with previous studies, we found that the most frequent therapeutic groups involved in these adverse drug reactions were anticoagulants and antihypertensive drugs, and in third place analgesics (especially opioids). Gastrointestinal symptoms were the most prevalent associated with ADRs.

EA-109
CLINICAL MANAGEMENT OF MULTIPLE CHRONIC DISEASE PATIENT. CASE MANAGEMENT EXPERIENCE

A. Soler, M. Vila, A. Villagrasa, E. Llargués, G. Pérez, M. Segura

Department of Internal Medicine. Hospital General de Granollers. Granollers (Barcelona), Spain.

Objectives: To evaluate the implementation of a disease management programme in patients with multiple chronic disease and several hospital admissions.

Material and method: Patients: we selected patients with 2 or more chronic diseases and 2 or more entries in the Internal Medicine Department between December of 2010 and April of 2012 (16 months). The patients were included in an outpatient programme led by a nurse and a doctor (1/2 journey). The care model is the 'case management' with a nursing and physician consultation. We set individual targets focused on health education: information about diseases, health habits, adherence to treatment, early detection of symptoms. Patients have a telephone contact for inquiries, and arrange prior visit in case of early detection of symptoms of decompensation or exacerbations.

Results: We included 83 patients (64 men) with an age of 77.0 ± 7.1 years. The average of number of diagnosis is 8.4 ± 3.1, number of drugs 10.3 ± 3.3, Barthel index 86.1 ± 18.3, Charlson index 4.52 ± 1.97. 48 of them have a low cultural level and 34 medium. 21 patients have died. Patients were followed an average of 10.4 months. The table presents the outcomes of care attention (columns) of the year prior to admission, follow-up period, and the estimated data at 1 year of follow-up, compared with the year prior to admission in the programme (*).

Discussion: Patients included in the program have a little dependence and high comorbidity profile, reflected by Charlson index and the observed mortality in the sixteen months period. Health education, early detection of symptoms and early care response reduce significantly emergency room visits, income and hospital stays. 38 entries were made as scheduled admissions. The personalized attention through 'management case' provides answers to the needs of patients, and reduces the use of health care resources.

Conclusions: A programme focusing on 'case management' with a proactive care of patients with multiple chronic diseases and several hospital admissions, based on health education and quick response to health needs of patients reduces the needs for emergency services income and the hospital stay.

EA-110
POLYPHARMACY IN ELDERLY PATIENTS: A PREVALENCE STUDY

J. Manchón Castilla, I. Machuca Sánchez, F. García Sánchez, M. Nieto Riesco, D. Navarro Moreno, M. Pérez Pino, A. Prieto Vicente, L. Pozo Rosado

Department of Internal Medicine. Hospital Virgen del Puerto. Plasencia. Cáceres, Spain.

Objectives: Making a prevalence study of polypharmacy and getting trends in drug consumption in a local hospital.

Material and method: Descriptive statistical study of a sample of patients admitted to a local hospital. Data analysis with Microsoft Excel and SPSS statistical software.

Results: 34 patients admitted to Internal Medicine and its units were studied. Only chronic treatments were considered, so analgesics, short course corticosteroids, chemotherapy or immunosuppressive were not included. The main age of patients was 80.88 years. 52.94% were male and 47.06% were women. The average number of medications taken was 5.94. A positive correlation between age and number of medications taken was observed, but it was not significant (p = 0.307). 64% of patients consumed diuretics. Other drugs commonly consumed were inhibitors of proton pump (58.82%) and blockers of renin-angiotensin system (50%). Of the latter, 52.94% consumed an angiotensin receptor antagonist and 47.06% used and inhibitor of angiotensin converting enzyme. 35.29% of patients who consumed blockers of renin-angiotensin system, used a combination. Anxiolytics were also frequently consumed. On the other hand, less frequently used drugs were digoxin (5.88%), levothyroxine (8.82%), oral iron (11.76%) and calcium antagonists (14.70%).

Discussion: Age often determines a deterioration in health status and an increase in the number of diseases or pathological conditions. This implies a higher consumption of medicines in order to control, resolve or alleviate these situations. It is, therefore, very common that older patients use several drugs. The data analysis shows that most patients studied are polymedicated. Polypharmacy involves obvious problems, such as the increased risk of adverse effects or interactions. Furthermore, there are aged-related changes in

Table 1 (EA-109). Results

	Year prior to admission to the programme	Programme period. Average 10.4 months follow-up	ata estimated to 1 year D follow-up
Emergency room (ER) visits	334	77	89 (-73.4%)*
Admissions from ER	185	39	45 (-75.7%)*
Hospital admissions	209	77	89 (-57.5%)*
Days of hospital stay	2761	968	1117 (-59.5%)*
Average stay	13.2	12.6	-0.6

absorption, distribution, metabolism and excretion of substances, which may increase, in some cases, the accumulation of certain active molecules.

Conclusions: To minimize these problems, medical prescription should be optimized. For this, we should avoid certain medications that may be inappropriate for elderly patients or ineffective substances. We should also use combinations to facilitate compliance and adjust doses correctly.

EA-111
CLASSROOM FOR CAREGIVERS OF DEPENDENT PEOPLE IN THE HOSPITAL INTERNAL MEDICINE UNIT: LEARNING TO CARE, LEARNING TO CARE YOURSELF

A. Ortegón Gallego[1], R. Tirado Miranda[2], C. Losada Morell[3], C. Nevado Barbero[1], D. Navarro Hidalgo[4], I. Mejías Real[2], D. Pérez Tejero[4],

[1]Nursing. Management of Internal Medicine Cases, [2]Department of Internal Medicine, [3]Department of Clinical Nutrition. Internal Medicine, [4]Department of Pneumology. Internal Medicine. Hospital Comarcal Infanta Margarita. Córdoba, Spain.

Objectives: To develop the patient's involvement in his self-care to the extent it could be carried out. To provide a caregiver with the coping strategies based on the information on the disease process as well as its possible relapse. To involve the other members of the family in the assistance in the consolidation of information and care of patients. To identify the caregivers at risk of the "caregiver syndrome". To encourage a caregiver to take necessary decisions without feeling guilty. To decrease the number of readmissions of these patients. To develop a caregiver's acceptance of the limitations that progressively will be presented in his patient.

Material and method: The recruitment of the patients and the caregivers directly through the Case Management. The recruitment of the patients and the caregivers who are not the objects of the Case Management but are subjected to the intervention of the assigned nurse. The information about patients provide by the Supervisors. The reports of the assigned Nurses on their patients. Ask another caregivers of different patients for attending these classes. Ask different family members help in patient care.

Results: The classes were conducted from August, 2010 till May, 2012. There were totally 32 sessions with 256 participants: 222 women (86.7%) and 34 men (13.3%) among them. The subjects discussed were: practices and health education, prescription medication, diet, medical treatment knowledge and understanding of the disease process of the patient to support the decisions taken in the return to home. The patients whose caregivers attended the training classes were readmitted less frequently.

Discussion: Insecurity and fears crop up in the family on the day of the patient's discharge from the hospital and his return home, especially if it hasn't been decided who will assume the role of the caregiver or this duty has been imposed on one of the women of the family without asking her. Generally the wives take care of their mothers- or fathers-in-law, rather than the husbands looking after their own parents. It shows once again the issue of gender in the caregiver activity.

Conclusions: Initial results encourage us to continue with the conviction to enrich specific knowledge about patient care and achieve a significant improvement in the wellbeing of carers. After each session information and tools based on the knowledge acquired is provided. This is perhaps achieving the realization of a slogan: *Care for the caregiver.*

EA-112
PLURIPATHOLOGICAL PATIENTS ATTENDED IN AN OUTPATIENT SETTING

M. López Gámez, J. Medina García, J. del Arco Delgado, L. Abraham Pérez, M. Bethencourt Feria, J. Delgado Casamayor, L. Abella Vázquez, P. Láynez Cerdeña

Department of Internal Medicine. Complejo Hospital Universitario Nuestra Señora de Candelaria. Santa Cruz de Tenerife, Spain.

Objectives: To describe the demographic and clinical features of pluripathological patients visiting a specific outpatient surgery in a General Internal Medicine Service.

Material and method: Data from patients referred from Primary Care or Short Stay Unit (SSU) during 18 months were recorded. Specific variables for this kind of patients were evaluated, such as the PROFUND index. Numerical variables are expressed by means ± SD (range) and compared using Spearson's correlation coefficient. Categorical variables are expressed in absolute numbers (percentage) and compared by means of Chi-square test or U-Mann-Whitney test were applicable.

Results: A total of 200 records were analysed, finding 60 cases of pluripathological patients. Among them, 27 (45%) were women. Mean age was 76.4 ± 8.3 years. Patients were referred most frequently (29; 48.3% and 24; 40% respectively) from Primary Care (telematic consultation followed by physical visit) and from the SSU. Patients fulfilled 2.45 ± 1.00 multimorbidity categories, being cardiopathy (50; 83.3%) the most prevalent. The cohort was highly polymedicated with 9.71 ± 4.07 drugs/day. Mean PROFUND Index was 4.98+/-5.14. Mean Barthel's Index score was 77.62+/-20.02. 52 (86.7%) had either no studies or only basic studies. Cardiovascular risk factor was relatively high among the cohort (SCORE > 4% in 26.8%). 13 patients (26.6%) needed some kind of treatment in the surgery center. Only 5 patients died during follow up. At least in 31 cases (51.7%) a hospital admission was avoided by managing the patient in this unit. Factors associated with not avoiding admission during follow-up were Hb levels (p = 0.019), PROFUND index value (p = 0.016) and the number of fulfilled pluripathology criteria (p = 0.03). Treatment in the surgery center was not associated with admission requiral (p = 0.092).

Discussion: Complex, pluripathological patients referred both via tertiary Hospital Contact or Primary Care can be safely managed in an expanded outpatient setting. The small number of deceased patients makes it difficult to interpret this management impact on global outcome.

Conclusions: Elderly, pluripathological patients can be attended in an outpatient setting. This measure helps avoiding hospital admissions. More data and finer-tuned tools are required to accurately identify patients at high risk of needing hospital care.

EA-114
ACUTE FEVER IN GERIATRIC PATIENTS: INFECTIOUS AND NONINFECTIOUS ETIOLOGY IN ELDERLY INPATIENTS

R. Veríssimo, M. Bastos, P. Caiano Gil, O. Gonçalves, V. Paixão Dias

Department of Internal Medicine. Centro Hospitalar de Vila Nova de Gaia/Espinho, EPE. Vila Nova de Gaia, Portugal.

Objectives: Our goal was to identify leading causes of fever in the elderly inpatients and correlate with underlying diseases and mortality.

Material and method: Elderly patients who were hospitalized for acute fever were included. Acute fever was defined as presentation within the first week of fever above 37.3 ºC.

Results: 94 patients were included (48 males and 46 females). Mean age was 77.44 years, with median 76 years. The cause of

fever was an infectious disease in 88.30%, noninfectious disease in 8.51% and unknown in 3.19% of the patients. The most common infectious etiologies were respiratory tract infections (n = 56), urinary tract infections (n = 16), and skin/soft tissue infections (n = 4). The main noninfectious causes of fever were hematological diseases (n = 4), solid tumors (n = 2), rheumatic diseases (n = 1). An unknown cause of fever was present in three patients. We also evaluate underlying diseases, analysis of the symptoms accompanying fever and mortality.

Discussion: Geriatric patients had more infectious causes of fever while noninfectious causes were responsible from fever in a few proportion with underlying diseases. In those patients with no underlying predisposing conditions except for age, an infectious etiology is to be sought. The evaluation must be prompt, and the treatment should begin as early as possible.

Conclusions: Fever is an important finding of infections and it may also be a sign of noninfectious etiology. Aging causes the increased susceptibility to infection. It is important to acknowledge that the malfunction of the cardiovascular, respiratory, and renal systems causes an immunocompromised state. This contributes for many infectious and noninfectious diseases, increasing morbidity and mortality in geriatric patients.

EA-115
REDUCTION OF COMPLICATIONS IN HIP FRACTURE

M. Royuela[1], D. Rosinés[2], F. Reguant[2], E. Bustamante[1], M. Castejón[1], C. Morales[1]

[1]Department of Internal Medicine, [2]Department of Traumathology. Althaia. Xarxa Assistencial Universitària de Manresa. Manresa (Barcelona), Spain.

Objectives: Observe the utility of units of hip fracture on fragile patients (UF3) to speed up their hospitalization and reduced inpatient complication, facilitating speedy recovery with better prognostic.

Material and method: 239 patients total, over 65 years old, 203 with fractured proximal third of femur, from June 2010 until 30 April 2011. We have reviewed the ability to walk upon, the amount of drugs and the relationship with femur fracture, the fracture type, hospital stay and resource use at discharge.

Results: 72% of women, average age of 85.26 years old. Previously 64.10% of them lives with family, even 23% alone. 46.81 were able to walk without help, against 11.7% weren't able to walk. Patients taking < 4 were 32.40%, and > 4 67.60%. Frequently drugs: psychotropic drugs 60%, 54% antihypertensive, 55% protective gastric, 44% PSA/ACO. Many of them related to risk of fracture of femur Days of surgical delay: Do not take AAP/ACO 2.31 days, operating at 48 hours 71%. Taking AAP 3.92 days, and taking ACO 2.72 days. Fractures were: 53.7% pertrochanteric 42.80% subcapital 4.46 subtrochanteric More frequent complications: Urinary tract infection (19.4%) Delirium (7%) Readmissions within 30 days (10%). In-hospital mortality (4.90) and month (7.80). We observed increased transfusions (Hb < 10) with increased intraoperative hemodynamic instability and the number of transfusions due to reduction in surgical delay. Average stay decreased to 12.65 days (were 19 days) only 7% were hospitalized over 20 days (in 2008 was 23%).

Discussion: Reducing complications for intensive monitoring: improved functional and vital prognosis. Reducing surgical delay is related to increased intraoperative hemodynamic instability, especially when hemoglobin is inferior than 10.

Conclusions: Prepare risk patients before surgery. Improved functional and vital prognosis. Patient and family satisfaction is higher.

Table (EA-115). Complications

Urinary tract infection	19.4%
Delirium	7%
Readmissions within 30 days	10%
In-hospital mortality	4.90%
Month mortality	7.80%

EA-116
SEPSIS MORTALITY PREDICTORS IN PATIENTS FROM AN INTERNAL MEDICINE UNIT

J. González Pérez, R. Hernández Luis, O. Pérez Hernández, C. Martín González, A. Pérez Ramírez, C. Chines, O. Elvira Cabrera, C. Fernández Rodríguez

Department of Internal Medicine. Hospital Universitario de Canarias. San Cristóbal de La Laguna. Santa Cruz de Tenerife, Spain.

Objectives: The value of severity scores in critically ill patients admitted to an Intensive Care Unit has proved useful in assessing prognosis, but it is unclear if these scores can be also used in elderly, comorbid patients, more frequently managed in Internal Medicine Units. The aim of this study is to analyze the prognostic value of these scores in these patients, comparing it with that of other comorbidity factors and physiological parameters.

Material and method: We performed a retrospective, observational study, including 188 septic patients admitted to the Internal Medicine Unit of the Hospital Universitario de Canarias. We assessed severity according to the Consensus Criteria SCCM/ACCP 1991 and general and sepsis severity scores (APACHE-II, SOFA). In addition, we also recorded the Charlson Comorbidity Score. Physiologic parameters and comorbidity factors related to these scores were also analyzed, including nutritional status (assessed by subjective evaluation, SNS), and the presence of dyslipidemia. We also recorded if patients were institutionalized and if the infection was health care associated or not. We analyzed mortality and compared the prognostic value of each of the variables by logistic regression analysis, including those variables which showed prognostic value in the univariate analyses.

Results: Mean age was 68.1 ± 16.2 years. The male-female ratio was 1:1.1. The most frequent focus was respiratory (58%), followed by urinary (14.9%) and cutaneous (12.8%). Other sites were abdominal (6.4%) and catheter infection (3.2%). All patients were treated with empirical antibiotics according to focus of infection. Thirty-one of them died (16.5%). The following variables were significantly different among survivors and dead: age, sex, blood pressure, kalemia, hematocrit, temperature, respiratory rate, arterial pH, Glasgow Coma Scale (GCS), APACHE II score, subjective nutritional evaluation and severity as determined by Sepsis Consensus Criteria. We also found a significant relation among mortality and dementia, hemiplegia, previous heart stroke, acute renal disease and previous institutionalization, but not with SOFA score and Charlson Comorbidity Score. We found, by logistic regression analysis, that all GCS (χ^2 = 78.33), APACHE II (X2 = 23.54), previous institutionalization (χ^2 = 12.14; p < 0.001 for all three), previous acute heart event (χ^2 = 6.39; p = 0.011) and hematocrit (χ^2 = 7.03; p = 0.008), in this order, showed independent significant relationship with mortality. If SNS (performed to a shorter number of patients) is also included, GCS enters in the first place, but SNS (χ^2 = 14.7; p < 0.001) is the second parameter related with mortality, displacing APACHE II.

Discussion: We found that SNS, hematocrit, and previous heart event are significant associated to increased mortality. In addition, patients who were living in an institution also showed increased mortality. SOFA and Charlson comorbidity Score did not predict mortality in our patients, in contrast with APACHE II. It is known

that APACHE II score includes GCS, but in our analysis, GCS was a better predictor of mortality. This may be due to some features of the patients included in the study, with many elderly already affected by dementia, a condition which may impair GCS assessment, and more prone to develop confusion and impaired consciousness after mild insults than younger patients. In addition, elderly patients are often malnourished and, moreover, develop dysphagia during hospital stay, which further complicate nourishment. These facts may explain the prognostic value of nutritional status in our patients.

Conclusions: We found that all GCS (χ^2 = 78.33), APACHE II (χ^2 = 23.54), previous institutionalization (χ^2 = 12.14; p < 0.001 for all three), previous acute heart event (χ^2 = 6.39; p = 0.011) and hematocrit (χ^2 = 7.03; p = 0.008), in this order, showed independent significant relationship with mortality. If SNS is also included, GCS still enters in the first place, but SNS is the second parameter independently related with mortality.

EA-117
CHARACTERIZATION OF PRIMARY SJÖGREN SYNDROME IN THE ELDERLY: STUDY OF 148 PATIENTS WITH AN AGE AT DIAGNOSIS > 70 YEARS OF AGE

P. Brito Zerón[1], R. Solans[2], M. Camps[3], A. Casanovas[4], B. Sopeña[5], C. Suárez Cuervo[6], F. Rascón[7], R. Qanneta[8]

[1]Department of Systemic Autoimmune Diseases. Hospital Clínic. Barcelona, Spain. [2]Department of Internal Medicine. Vall d'Hebron Hospital. Barcelona, Spain. [3]Department of Internal Medicine. Carlos Haya Hospital. Málaga, Spain. [4]Department of Internal Medicine. Parc Taulí Hospital. Sabadell (Barcelona), Spain. [5]Department of Internal Medicine. Complejo Hospitalario Universitario. Vigo (Pontevedra), Spain. [6]Department of Internal Medicine. Hospital Universitario Central de Asturias. Oviedo (Asturias), Spain. [7]Department of Internal Medicine. Son Espases Hospital. Palma de Mallorca, Spain. [8]Department of Internal Medicine. Joan XXIII Hospital. Tarragona, Spain.

Objectives: To analyze the main clinical, analytical and immunological characteristics of patients with primary Sjögren syndrome (SS) diagnosed in the elderly and to compare those characteristics with younger patients.

Material and method: The GEAS-SS multicenter registry was formed in 2005 with the aim of collecting a large series of Spanish patients with primary SS. The registry includes 21 Spanish reference centers with substantial experience in the management of SS patients. By March 2012, the database included 921 consecutive patients (recruited since 1994), fulfilling the 2002 classification criteria for primary SS. We retrospectively analyzed the main clinical and immunological characteristics in SS patients diagnosed in the elderly (age at diagnosis > 70 years). The new 2010 EULAR-SS disease activity index (ESSDAI) was also retrospectively calculated.

Results: Of the 921 SS patients from the GEAS-SS cohort, 148 (16%) were diagnosed after 70 years of age: 138 (93%) were women and 10 (7%) men, with a mean age of 75.49 ± 0.34 years (range: 70-89). The main features consisted of xerostomia and xerophtalmia in 140 (95%) patients, respectively, parotid scintigraphy grade III/IV in 113/124 (91%) patients, positive minor salivary gland biopsy in 74/87 (85%), anemia in 46 (31%), leucopenia in 24 (16%), thrombocytopenia in 20 (13%), raised erythrosedimentation rate (higher than 50 mm/h) in 52 (37%), positive antinuclear antibodies (ANA) in 137 (93%), positive anti-Ro/SSA in 86 (58%), positive anti-La/SSB in 63 (43%), positive rheumatoid factor (RF) in 82/144 (57%), low C3 levels in 111/140 (8%), low C4 in 14/140 (10%), positive cryoglobulins in 14/119 (12%) and monoclonal gammopathy of undetermined significance (MGUS) in 15/111 (13%) patients. SS patients over 70 years of age had a higher frequency of anemia (31% vs 14%, p < 0.001), thrombocytopenia (13% vs 7%, p = 0.012), ESR > 50 mm/h (37% vs 28%, p = 0.025) and MGUS (13% vs 8%, p = 0.07), and a lower frequency of neutropenia (5% vs 13%, p = 0.03) and positive anti-Ro/SSA antibodies (58% vs 75%, p < 0.001) in comparison with younger patients. In the multivariate analysis, anemia (p < 0.001), neutropenia (p < 0.005), high ESR (p = 0.045) and anti-Ro/SSA (p < 0.001) were statistically significant variables. With respect to the disease activity measurement, no significant differences in the cumulative global ESSDAI scores between elderly and younger patients (9.96 vs 9.14, p = 0.31) were observed. However, elderly patients had a lower mean ESSDAI score in the articular domain (0.55 vs 0.77, p = 0.001) and a higher mean ESSDAI scores in the lung (2.03 vs 1.14, p = 0.002) and peripheral nervous system domains (1.59 vs 0.89, p = 0.014) in comparison with younger patients.

Conclusions: Patients with primary SS diagnosed in the elderly have a higher prevalence of cytopenias and MGUS but a lower prevalence of anti-Ro/SSA antibodies. Although the global ESSDAI score does not vary according to the age at diagnosis < or > 70 years, elderly SS patients have higher mean scores in the pulmonary and peripheral nervous system domains.

EA-118
THE POLYPATHOLOGICAL PATIENT, A NEW REALITY IN AN SHORT STAY MEDICAL UNIT

B. Pernas, J. Serrano, L. Castelo, V. Ramos, R. Nicolás, C. Pellicer, S. Penado, F. de la Iglesia

SSMU. Complexo Hospitalario Universitario A Coruña. A Coruña, Spain.

Objectives: To compare epidemiological, clinical and prognostic variables between the patients, either polypathological or not, admitted in a SSMU.

Material and method: Prospective observational cohort study. 496 patients were included, either polypathological or not, admitted in the SSMU of a terciary hospital in Galicia between July/2011 and May/2012. The polypathological patient (PP) was defined as a patient who met 2 or more categories of the 8 proposed by an expert committee. Epidemiological, clinical and prognostic variables were compared between both groups (age, Charlson, Barthel, Pfieffer, polypharmacy, causes of admission, average length of stay, readmission rate, causes of readmission and mortality over one month follow up).

Results: A total of 191 patients (38.5%) met the definition of polypathological. The most common distinctive categories of polypathology were: cardiovascular disease (78%), nephropathy (53%) and neurological disease (30%). The results of the main variables after comparing them can be found in the table below.

Discussion: The socio-econocomic development in Europe in the last decades as well as the improvement in medical care make our patient live longer with multiple chronic diseases. Our study shows that the polypathological patient is already a reality. Not only do we know that nearly 4 out of every 10 patients admitted in an SSMU are polypathological, but they are also older, have higher comorbility, higher functional limitation and cognitive deterioration. Due to these peculiarities they become polymedicated patients, who stay longer in hospital, have a higher probability of readmission and probably have a higher cost of care.

Conclusions: Nearly 4 out of every 10 patients admitted in an SSMU are polypathological patients. Polypharmacy is more common among polypathological patients. The decompensation of some of the distinctive categories is the main cause of admission. The

Table (EA-118)

	Polypathological patients	Non polypathological patients	p
Age	76.8 ± 10.2	69.3 ± 14.4	< 0.01
Age adjusted Chalrson index	6.4 ± 2.5	3.7 ± 1.8	< 0.01
Barthel < 60	37%	8%	< 0.01
Pfeiffer > 3	40%	20%	< 0.01
Length of stay	7.4 ± 5.6	5.0 ± 5.1	< 0.01
Readmission rate (30 days)	10.5%	4.3%	< 0.01
Mortality after 1 month follow up	5.2%	2.3%	0.13

hospital stay is 2.4 days longer among polypathological patients as compare to no polypathological ones.

EA-119
PROGNOSTIC VALUE OF MICROORGANISM IDENTIFICATION IN SEPSIS

O. Pérez Hernández, A. Pérez Ramírez, R. Hernández Luis, J. González Pérez, C. Martín González, C. Jorge Ripper, I. Hernández Betancor, Y. Lalondriz Bueno

Department of Internal Medicine. Hospital Universitario de Canarias. San Cristóbal de La Laguna (Tenerife), Spain.

Objectives: Sepsis is an important public health problem. Therapeutic guides include both obtaining blood cultures and early administration of empiric antibiotic therapy, adjusting treatment in case of positive cultures. However, in a large number of cases the causal agent is not detected. The aim of this study is to analyze whether the infectious agent detection and corresponding targeted therapy confers a better prognosis compared with empirical treatment.

Material and method: We performed a retrospective, observational study, including 188 episodes of sepsis, looking for the presence or not of positive microbiological results. We compared the mortality rate among both groups. Also, we compared the duration of hospitalization among survivors in both groups.

Results: Mean age was 68.1 ± 16.2 years. The male-female ratio was 1:1.11. The most frequent focus was respiratory (58%), followed by urinary (14.9%) and cutaneous (12.8%). Other sites were abdominal (6.4%) and catheter infection (3.2%). All patients were treated with empirical antibiotics according to type of infection. Sixty two out of 188 patients had positive cultures (32.97%) and 9 of them died (14.51%); In 126 patients no infectious agent was detected (67.03%); 22 of them died (17.4%). No significant association was observed between microorganism identification and mortality rate (χ^2 = 0.262; p = 0.609) According to hospital stay, after excluding outliers, we also failed to find differences among survivors with microbiological orientation (18.34 ± 14.08 days) and those without an identified agent (16.92 ± 10.94 days; t = -0.64; p = 0.52).

Discussion: In our study we found that identification of microbiological agent did not affect mortality or hospital length of survivors in septic patients. These findings are probably due to early adequate empirical antibiotic treatment. However, microbiological orientation is necessary to assess local microbiological resistances and, therefore, the establishment of proper empiric therapy.

Conclusions: In our study, identification of microbiological agent did not affect mortality or hospital length of survivors in septic patients, although can be useful in the assessment of local microbiological resistances.

EA-120
A NEW CHALLENGE FOR THE INTERNIST: THE TRANSITIONAL PATIENT

B. Ruiz Estévez, F. Carmona Espinazo, R. Espinosa Rosso, B. López Alonso, B. Montenegro Puche, M. Martín Zamorano, E. Segura Fernández, A. Mogollo Galván

Department of Internal Medicine. Department of Palliative and Transitional Care. Hospital Universitario Puerta del Mar. Cádiz, Spain.

Objectives: Palliative and Transitional Care Unit (PTCU) of Puerta del Mar University Hospital takes care of patients who after staying in the Intensive Care Unit because of severe brain lesions or surgical sequelae (mainly as result of neurosurgery and cardiac surgery), need to continue with hospital cares in other specialized areas. We pretend to describe the characteristics of these patients when they arrive at the PTCU, as well as to know the most important information about their stay in our Unit.

Material and method: This is an observational, retrospective study. We have reviewed the clinical histories of all transitional patients that were admitted in the PTCU during the year 2011. We analyzed several variables, which stand out the follows: 1. Condition of the patients when they were admitted in PTCU (cognitive state, extremities movement, chronic diseases and actual complications). 2. Other conditions: Carrying a tracheostomy, nasogastric probe, venous access and/or urinary catheter. 3. Progress during their stay and clinical situation of the patients when they were discharged from the Unit.

Results: We analyzed 37 patients in total, 26 (70%) were men. The mean age was 60 years. 86.5% of patients had at least one chronic disease, in most of the cases coexisted some comorbidities. 54% of them had an acute cerebral damage and 59.4% had some motor deficit. 83.8% caught some infectious disease (a respiratory infection in most of the cases), needing a specific antibiotic treatment depending on the isolated germ. 61% had other complications, different from infections. Upon their arrival, they carried a tracheostomy cannula with supplementary oxygen in 64.9% of cases; a nasogastric probe and therefore, enteral nutrition, in 67.6%; venous access in 100%, with a central venous access in 70%; urinary catheter in 91.9%. It was possible to remove the tracheostomy cannula to 16% of the patient that they had it, nasogastric probe to 48%, venous access to 70.2% and urinary catheter to 62.2%. The average stay was 39 days. 10 patients died and 27 were discharged, of whom 15 (56%) returned home, 9 (33%) went to a private clinic, 2 (7%) to other hospital and 1 patient (4%) was moved to other department in the hospital.

Discussion: Transitional patients have mostly a high complexity because of their chronic diseases and comorbidities, as well as by the acute disease that caused their admission in the Intensive Care Unit. In addition, most of them catch infectious diseases and/or other complications during their stay, which all cause an important necessity of cares, that we try to provide them in order to improve their clinical situation and actual conditions.

Conclusions: 1. The typical patient that we receive in our UCPT is male, middle aged and highly complex because of his history and acute diseases. 2. Most patients have clinical instability produced by the severe neurological damage linked to nosocomial infections (many of them by multiresistant pathogens) associated with decompensations of their chronic diseases. 3. At discharge, they have conditions that allow them to continue with cares at home or in non-specialized units, even if they have irreversible neurological sequelae.

EA-121
ANALYSIS OF MORTALITY IN PATIENTS SUBMITTED TO SURGERY FOR HIP FRACTURE

F. Brun Romero[1], A. Fernández Rodríguez[2], J. Benítez Macías[3], D. García Gil[3], J. Andrés García[1]

[1]Department of Orthopedic Surgery, [2]Department of Internal Medicine, [3]Department of Emergency. Hospital Universitario Puerta del Mar. Cádiz, Spain.

Objectives: To analyze the mortality in patients admitted for hip fracture surgery: incidence (in hospitalization, at one, three, six and twelve months), clinical features of patients and risk factors.

Material and method: A retrospective review of medical records was carried out for all patients admitted for surgery for hip fracture between January 1st 2010 and December 31st 2011. Descriptive study was conducted to identify demographic features, comorbidity, mortality rate and causes (until June 1st 2012), mortality risk factors and postsurgical survival. A limitation of the study is the absence of a control group, which prevents us from analyzing the prognostic factors. Qualitative variables were expressed as frequencies (percentages) and quantitative variables as medians (25th and 75th percentiles). Statistical analysis was performed using SPSS 19.0 version.

Results: Three hundred and eighty nine subjects were included during study period; 295 (76%) females and 94 (24%) males. The median age of patients was 82 (77-88) years, 79 (66-84) and 83 (79-88) for male and females, respectively. Until June 1st 2012, 78 (20%) patients had died, 52 (67%) females and 26 (33%) males. The median age of these patients were 78 (79-88) years. Seventy-four (95%) patients had comorbidities, the most frequent were arterial hypertension (47, 60%), diabetes (37, 47%), heart disease (32, 41%), already had been diagnosed as having dementia (30, 39%), chronic respiratory disease (25, 32%) and cancer (20. 26%). The type of fracture was classified in: pertrochanteric (37, 47%), femoral neck (33, 42.3%) and subtrochanteric (8, 10%). The median time from surgery to death was 107 (31-287) days. Eleven (14%) patients died during postsurgical period into the hospital and 17 (22%) outpatients died before 30 days after surgery. Total mortality rate before 30 days was 7.2% (36% over total of deaths). Between 30-90 and 90-180 days after surgery groups died 15 (19% over total of death) patients in both groups, this means 4% of the total of the study population. Overall mortality rate in the first 180 days was 15% and 74% of the total of deaths. Five (6%) patients died between 180-360 days after surgery. The others deaths (17, 22%) occurs after the first year. Twenty one deaths (27%) were caused by infectious complications, 9 (12%) secondary to heart disease and 7 (9%) of them by cancer progression. In 22 (28%) cases, the cause of death is not registered.

Conclusions: The surgery for hip fracture takes place in a population with a high degree of comorbidity, reason why the mortality rate at 6 months is quite high. Independently, the third of the deaths occurred during the first month after surgery, so that might be needed to select a subset of patients in whom conservative treatment may be the best choice.

EA-122
DRUG INAPPROPRIATE PRESCRIPTION (DIP) IN ELDERLY PATIENTS ADMITTED IN ORTHOPEDIC WARDS

M. de Sousa Baena[1], L. Domínguez Senín[2], B. Barón Franco[1], C. Díaz Pérez[1], S. Bermejo Vázquez[1], J. García Moreno[1], J. Carrasco Sánchez[1], E. Pujol de la Llave[1]

[1]Department of Internal Medicine, [2]Department of Pharmacy. Área Hospitalaria Juan Ramón Jiménez. Huelva, Spain.

Objectives: 1. To know the prevalence of DIP in elderly patients admitted in orthopedic service. 2. To describe the characteristic of DIP found. 3. To asses a primary care physician notification system DIP.

Material and method: Treatment for patients older than 65 years old, admitted in an orthopedic ward during a 3 month period, was reviewed. The presence of DIP, by the use of START and STOPP tests, was assessed. Information was obtained from the medical digital records, as well as from the admission forms and by personal interview with the patient and/or his caregiver.

Results: 268 patients were admitted. 34% (92) were older than 65 years old. 25 patients had at least one DIP, 57% of them were women. The median age was 74 years old. The average drug taken was 8.12 per day. Ten patients (40%) had multiple medical conditions. The most frequent diagnosis was fracture (40%). The average length of hospital stay was 12 days. 13 patients (52%) had caregiver at home. 53% of patients were independent according to the Barthel scale. 88% of patients had preserved general cognitive abilities. 44 DIP were recorded, The most frequently concerns detected were: B7 for the STOPP criteria (prolonged use -over 1 month- of long-acting benzodiazepines) and F3 for the START criteria (addition of an antiplatelet agent in diabetes mellitus if one or more mayor factors of cardiovascular risk coexisted). Only 7 modifications of treatment were observed in these patients one month after notification.

Discussion: We detected a significant percentage of DIP in the patients studied, which means a high risk of drugs side effects in these patients. The notification system was done by letter instead of telephone. Probably this was the main cause of the low number of modifications achieved.

Conclusions: 1) The prevalence of DIP in elderly patients admitted in a Orthopedic service is high. 2) DIP usually occurr in fragile elderly patients with polypharmacy and multiple comorbidities. 3) The notification by letter was not successful to modify treatments in these patients 4) DIP detection system could be useful in non-medical scenarios.

EA-123
CLINICAL AND HEALTHCARE FEATURES OF PATIENTS ADMITTED TO A NEW MONITORED UNIT INSIDE INTERNAL MEDICINE WARDS (SPECIAL CARE UNIT FOR INTERNAL MEDICINE)

A. Hurtado Ganoza, P. Rodríguez Torres, L. Moreno Gaviño, M. García Gutiérrez, A. González Molina, L. de la Higuera Vila, C. Rivas Cobas, N. Ramírez Duque

Department of Internal Medicine. Hospital Virgen del Rocío. Sevilla, Spain.

Objectives: To determine clinical and healthcare organizational features of patients admitted to a monitored Internal Medicine unit at a tertiary teaching centre in southern Spain.

Material and method: Longitudinal observational study performed between 2012 January and 2012 March that includes all consecutive patients who were admitted to our monitored unit and were

followed-up during a month after hospital discharge. This monitored unit (MU) gives support to any patient attended in Internal Medicine areas including offices, perioperative support consultants, day unit, day hospital, and on wards. It consists on a 5 monitored bed and a sixth one for diagnostic and invasive procedures, with a nurse/bed ratio of 1:5. Patients who have intensive care unit admission criteria are not admitted in this unit. Descriptive analysis (percentages, measures of central tendency, measures of dispersion) of the main clinical and healthcare features performed by SPSS 18.0.

Results: 106 patients were included for analysis. Mean age was 67 ± 26.45 years, 49% were male.

53% fulfilled the criteria of polypathological patients, 40% had at least an advanced non-cancer chronic disease, 11% had an advanced cancer. Mean ECOG, Charlson and PROFUND index were 1.30 ± 0.9, 2.9 ± 2 and 6.41 ± 4.7 respectively. 30% of the patients were admitted from conventional offices, 56.6% from Internal Medicine wards and 3.8% from surgical departments. Admission criteria were as follows: heart or respiratory failure 40%, sepsis/septic shock 9% and invasive procedures including central venous catheterization 14%. 9% were admitted to initiate medical treatment while they were waiting a bed on conventional ward and 13.3% because of Day Hospital overload. Most common complex therapeutic procedures ordered in MU were noninvasive mechanical ventilation (30%), blood transfusions (15%) and pressor-amines administration (14%).

Mean length of hospital stay at MU was 2.18 ± 3.1 days. Global mortality rate was 41%. 27% of deaths happened during MU stay, 45% happened during the same episode in other hospital areas and 15% during the first month after hospital discharge. 30% of patients were readmitted to the hospital during the month follow-up period.

Conclusions: The monitored unit in Internal Medicine improved autonomy and continuity of care of the Internal Medicine service. This also allows monitoring and the performance of complex procedures and healthcare in high risk patients from all internal medicine areas in a safer clinical environment.

EA-124
IS NECESSARY A MEDICAL PREOPERATORY EVALUATION IN EDERLY PATIENTS WITH COLORECTAL CANCER?

M. Bucar[1], E. Redondo[2], T. Revuelto[3], B. Calvo[2], M. Serrano[1], J. Gracia[2], M. Elia[2], M. Aibar[1]

[1]Department of Internal Medicine, [2]Department of General Surgery, [3]Department of Gastroenterology. Hospital Clinico Universitario Lozano Blesa. Zaragoza, Spain.

Objectives: Colorectal cancer is a major public health problem, with a high incidence, particularly in elderly people. Perioperative management in elderly people is more complex than in younger people. The high morbidity and mortality of this type of surgery in this kind of patients, is due to the association of other diseases and a high surgery risk, such us another factors like malnutrition, polypharmacy, etc. that could deteriorate their prognosis. In current literature, there are just few studies published on perioperative care in elderly patients undergoing colorectal cancer resection surgery. The aim of this study is to determinate the frequency of postoperative period complications in elderly patients undergoing elective colorectal surgery in our hospital, and to evaluate the correlation with preoperative clinical and laboratory tests.

Material and method: We performed a prospective observational study from September 2011 to April 2012. We included all patients older than 65 years old undergone colorectal cancer surgery. Every patient underwent preoperative assessment through different anthropometric and biochemical tests. Postoperative complications data were recorded and analyzed in search of statistical significance.

Results: During this period we have seen a total of 66 patients: mean age 73.4 years old (range 65-91); 61% were male and 39% were female; about medication, patients had an average of 4.4 drugs per patient (range 0-13); anesthetic risk ASA II-III-IV of 43%-41%-16% respectively. 40% patients underwent laparoscopic surgery. Preoperative data that were obtained were: mean BMI 27.7 kg/m^2 (22-36.6), mean hemoglobine 12.6 g/dl (range 7.7 to 16.4), and mean total protein level of 6.5 g/dl (range 4.57 to 7.74) with albuminemia less than 3 g/dl in 7% of patients. Medical complications were recorded in 36.4% of patients. 40% were due to exacerbation of previous cardiovascular diseases, 25% to acute urinary retention, 20% to nosocomial pneumonia, 10% to acute confusional syndrome and 5% to other causes. There was no statistical significance ($p > 0.05$) between these complications and age, sex or the number of drugs taken by patients. We observed a high number of medical complications during postoperative period, but data were not statistically significant. We found statistical significance ($p < 0.05$), between low levels of hemoglobin, total protein levels and hipoalbulinemia with exacerbation of previous cardiovascular diseases. We did not find statistical relation between other complications.

Discussion: There were medical complications in 36.4% of patients undergoing elective colorectal cancer surgery in elderly patients, with numerous comorbidities and polypharmacy associated. This high rate of reported complications (40%), were due to exacerbations of previous cardiovascular diseases such as ischemic heart disease, arrhythmias and hypertension, being statistically associated with potentially modifiable preoperatively factors.

Conclusions: Due to elderly patients characteristics undergoing to this kind of surgery, we recommend a thorough preoperative evaluation in search of a correction of factors potentially modifiable by Internal Medicine specialists in order to reduce the number of complications during their hospitalization.

EA-125
HIP FRACTURE: THE ROLE OF INTERNAL MEDICINE

L. Hueso del Río, M. Espuelas Monge, N. Gómez Aguirre, J. Velilla Marco, J. Aguirre Errasti

Department of Internal Medicine. Hospital Universitario Miguel Servet. Zaragoza, Spain.

Objectives: Osteporotic hip fracture is typically considered a surgical disease. However, the affected population has an average age of 85 years and, therefore, patients have often multiple diseases and medical treatments, with high rate of complications in the perioperative period. In our hospital, the average hospital stay of this process is 17 days and a mortality rate of 10%. For these reasons, it´s necessary a global evaluation of these patients to prevent and treat these complications.

Material and method: We propose the secondment of a specialist in Internal Medicine to meet daily to patients with hip fracture from the start of admission to discharge, making a clinical assessment and social environment of these patients.

Results: In two years, 1,200 patients with hip fracture have been evaluated, resulting in a reduction of 4 days in the average hospital stay (13.1 days) and a mortality rate of 4.95%. It has also shown a lower incidence of perioperative complications, less delay in the time of intervention, and less functional impairment of these patients.

Conclusions: The assignment of an internist to a surgical service means a significant reduction in morbidity and mortality characteristic of these pathologies.

EA-126
PREVALENCE OF VITAMIN D DEFICIENCY IN GERIATRIC INPATIENTS AND CARDIOVASCULAR DISEASES

R. Veríssimo, T. Fonseca, P. Caiano Gil

Department of Internal Medicine. Centro Hospitalar de Vila Nova de Gaia/Espinho, EPE. Vila Nova de Gaia, Portugal.

Objectives: Cardiovascular diseases (DCV) are responsible for 30% of deaths worldwide and are the number one cause of death, disability and poor quality of life. Some resources suggests that lake of vitamin D can be associated with cardiovascular diseases, representing a nonclassical risk factor, but those give few information. Vitamin D, known as the sunshine vitamin, is now recognized not only for its importance in bone health of adults but also for other health benefits such as reducing the risk of chronic diseases, including autoimmune diseases, cancer and DCV. The active vitamin D metabolite, 1.25-dihydroxyvitamin D (1.25(OH)2D), which is synthesized from its precursor 25-hydroxyvitamin D (25(OH) D), has been associated with protection of the heart and vasculature. There are several mechanisms proposed to explain how the lower serum 25 (OH) D are associated with increased risk of DCV that have been verified in several studies, wich increase level of dependence of our elderly. The aim of the study was to evaluate vitamin D deficiency in an elderly inpatients at a Internal Medicine Department and to determine the association between low serum levels with cardiovascular commorbilities, desnutrition risk and activity daily living independence.

Material and method: This was a descriptive study of elderly patients admitted in Internal Medicine department during the first month of the year (n = 50). We request all serum vitamin D. We based on the review of consecutive hospital discharge reports to find past history, namely cardiovascular risk diseases. We also evaluated brachial fold and desnutrition risk, as the degree of dependence.

Results: The media of age was 79.85, with median of 80 years old. 78% were women. In our inpatients group 98% presents vitamin D deficiency. We found 72% arterial hypertension, 42% dyslipidemia and 30% of diabetes mellitus. We also evaluated ischemic cardiomiopathy and stroke prevalence (16% and 32%, respectively). Folic acid and B12 vitamin were normal. Brachial fold media was 25.37 cm, with a trend to increase desnutrition risk in more elderly patients.

Discussion: Almost all patients in our study presented vitamin D deficiency and we evidenced in all patients at least two cardiovascular risk factors. We also found a high level of dependence, but not associated with desnutrition risk. Our study was in concordance with some literature that shows low serum 25-hydroxyvitamin D (25(OH)D) levels) to be strongly related to risk of hypertension, diabetes mellitus and an unfavourable serum lipid profile.

Conclusions: The vitamin D receptor (VDR) is a nuclear receptor localized in cells in a number of organs indicating important functions also in extra-skeletal tissues. More studies need to be made, however, if a causal link between vitamin D and cardiovascular disease is affirmed, intervening in vitamin D deficiency in the population with supplementation, and increasing, taking into account the recommendations, sun exposure to slow the development of this cardiovascular chronic diseases in the general population.

EA-127
CLINICAL CHARACTERISTICS OF PATIENTS WITH ATRIAL FIBRILLATION (AF) ADMITTED TO AN INTERNAL MEDICINE DEPARTMENT

M. Gallego Villalobos[1], D. Pérez Martínez[1], J. Ferreiro Celeiro[1], N. Morán Suárez[2], E. Capín Sanpedro[3], V. Cárcaba Fernández[2]

[1]Department of Internal Medicine. Hospital San Agustín. Avilés (Asturias), Spain. [2]Department of Internal Medicine. Hospital Nuestra Señora de Covadonga. Oviedo (Asturias), Spain. [3]Department of Cardiology. Hospital General de Asturias. Oviedo (Asturias), Spain.

Objectives: To assess the clinical characteristics of patients admitted with AF in an Internal Medicine Department.

Material and method: We reviewed the discharge summaries of patients admitted to an Internal Medicine Department of between October 2010 till 31 March 2011 inclusive, including in our study patients with AF.

Results: We reviewed 863 discharge summaries finding 179 patients with AF (20.74%). The mean age was 81.63 years whilst 53.07% were women. Other comorbidities were found in these patients, 80% were also hypertensive (46% used ACE inhibitors and 20.67% Angiotensin II Receptor Blockers), 39% were diabetic, 33.52% had ischemic heart disease, and 23. 46% had at some moment suffered a thyroid disorder.

Discussion: AF is the most common cardiac arrhythmia, increasing in prevalence with age. Other prevalent comorbidities such as hypertension, diabetes, ischemic heart disease are also associated with AF as well as with thyroid disorders.

EA-128
INTERNIST IN SURGICAL PROCESS

H. Meijide Míguez[1], J. Porteiro Sánchez[1], A. Mena de Cea[2], P. Asensio Hernández[1]

[1]Department of Internal Medicine. Instituto Policlínico Santa Teresa, S.A. A Coruña, Spain. [2]Department of Internal Medicine. Complexo Hospitalario Universitario A Coruña. A Coruña, Spain.

Objectives: Several studies have demonstrated the favourable impact of the work of medical services on surgical elderly with multiple comorbidities patient care. Objectives: reduce microbiological risk in post surgery patient, medical complications care, prevent medication mistakes and perform medication reconciliation.

Material and method: Inclusion criteria are: age over 65 years; Charlson comorbidity index greater than 2, surgery intended stay more than 24 hours; any patient who develop postoperative complications. All patients admitted to our hospital with these items were evaluated for an internist in the period between October 2011 and March 2012. We check for demographic data, comorbidities, medical complications, nosocomial infection, surgical complications and clinical result. We made an simple descriptive analysis.

Results: We included 77 patients (64.9% women), with 63.7 (13-89) average age. Previous comorbidities: 55% hypertension; 37.3% dyslipidemia; 13% diabetes; 13% heart failure; 9% COPD. Charlson comorbidity index more than two was 36.4%. Red cross scale more than two was 39%. Patients came from Traumatology service (51), abdominal surgery (13), Gynecology (7), vascular surgery (5) and others (1). Complications during the postoperative stay: 19.5% exacerbation of previous comorbidity; 36,5% non infectious medical complication;11.7% surgical complication; 37.7% infectious complication. We observed favorable clinical response in 96% of cases. Hospital mortality was 1.3%. The internist took part in any

decision related to patient in 70% of cases. We decreased overall consumption of antibiotics (5.86 to 4.70 units per patient) and the admitted hospital period (3.9 to 3.6 days).

Conclusions: Age and comorbidity of patients undergoing surgical procedures require multidisciplinary care strategies to minimize complications. The program evaluates patients with higher risk of complications and assumes the prevention and treatment of them, and it also makes the medication reconciliation in this kind of polypharmacy patients. -Preliminary result from our program confirm the improvement in quality of vare of these patients, in terms o0 fhospital stay, morbidity, mortality, nosocomial infection rates, resource use and individual and collective satisfaction.

EA-129
CLINICAL FEATURES OF POLYPATHOLOGICAL PATIENTS WITH NON-ST-SEGMENT ELEVATION ACUTE CORONARY SYNDROME

M. Bernabeu Wittel[1], S. Quattrino[2], D. Mendoza Giraldo[1], R. Aparicio[3], M. Rincón[1], E. Pujol de la Llave[2], R. López Aguilar[4], A. Fernández Moyano[3]

[1]Department of Internal Medicine. Hospital Virgen del Rocío. Sevilla, Spain. [2]Department of Internal Medicine, [4]Department of Cardiology. Área Hospitalaria Juan Ramón Jiménez. Huelva, Spain. [3]Department of Internal Medicine. Hospital San Juan de Dios de El Aljarafe. Sevilla, Spain.

Objectives: To analyze clinical and functional differences between polypathological patients (PP) with non ST-segment elevation acute coronary syndrome (NSTEACS) who underwent percutaneous coronary angioplasty with optimal medical therapy or only optimal medical therapy.

Material and method: Prospective, multicenter, comparative cohort study of PP patients with non-ST-segment elevation acute coronary syndrome. The study population was conformed among PP patients with NSTEACS attended in Cardiology and Internal Medicine of four teaching hospitals of Andalucía. A group of patients who underwent coronary angioplasty and stenting with optimal medical therapy was compared with other group of patients who only received optimal medical therapy. Allocation to each group was based on the clinical judgment of the physician responsible for the patient. Both groups were followed for a year. Demographical, clinical, biological, functional, and care variables were analyzed. A descriptive analysis of all these items was performed using SPSS 18.0.

Results: 86 patients were included, 28 (32.6%) underwent angioplasty and 58 (67.4%) were treated with optimal medical therapy alone. 21 (75%) of patients undergoing angioplasty were male and 7 (25%) female, compared to 30 (51.7%) male and 27 female (46.6%) in the non angioplasty group, although this difference was no significant. One coronary was affected in 9 (31.2%) patients, two in 13 (46,4%) and three in 6 (21.4%), with a median rate of 2.15 (1-6) implanted stents. Patients undergoing angioplasty were younger (age in years 70.2 vs 75.64, p = 0.013), were more independent for the basic activities of daily living (basal Barthel index 88 vs 79, p = 0.001) and had a better prehospitalization cognitive status (Pfeiffer score 0.91 vs 2.64, p = 0.006). There were no differences regarding Charlson index score, number of chronic diseases, type of chronic disease, previous pharmacotherapy or presence or absence of caregiver between both groups.

Conclusions: A high rate of PP patients with NSTEACS are treated conservatively. Patients undergoing angioplasty and stenting are younger, functionally more independent and have a better mental status before the acute event, regardless the number or type of chronic disease, pharmacotherapy or presence of caregiver.

EA-130
CLINICAL OUTCOMES IN POLYPATHOLOGICAL PATIENTS WITH ACUTE CORONARY SYNDROME WITHOUT ST SEGMENT ELEVATION UNDERGOING CORONARY ANGIOPLASTY

D. Mendoza Giraldo[1], R. Aparicio[2], M. Rincón[1], S. Quattrino[3], M. Bernabeu Wittel[1], R. Valverde Ortíz[3], J. Carrasco Sánchez[3], B. Barón Franco[3]

[1]Department of Internal Medicine. Hospital Virgen del Rocío. Sevilla, Spain. [2]Department of Internal Medicine. Hospital San Juan de Dios de El Aljarafe. Sevilla, Spain. [3]Department of Internal Medicine. Área Hospitalaria Juan Ramón Jiménez. Huelva, Spain.

Objectives: To analize the impact of coronary angioplasty with stent in one year survival and functional status in polypathological patients (PP) with acute coronary syndromes without ST-segment elevation (NSTEACS) at high and medium risk, and investigate the predictors of mortality and complications in these patients.

Material and method: Prospective, multicenter, comparative cohort study of PP patients with non-ST-segment elevation acute coronary syndrome. The study population was conformed among PP patients with NSTEACS attended in Cardiology and Internal Medicine of four teaching hospitals of Andalucía. A group of patients who underwent coronary angioplasty and stenting with optimal medical therapy was compared with other group of patients who only received optimal medical therapy. Allocation to each group was based on the clinical judgment of the physician responsible for the patient. Both groups were followed during one year. Demographical, clinical, biological, functional, and care variables were analyzed. A multivariate analysis of all these items was performed using SPSS 18.0.

Results: 86 patients were included, 28 (32.6%) underwent angioplasty and 58 (67.4%) were treated with optimal medical therapy. The group treated conservatively was significantly older (75.64 vs 70.2, p = 0.013), and there were no differences in gender. Barthel index score of the group of patients who underwent angioplasty was significantly higher before the procedure (score 87 vs 71) but this difference was no significant in a year follow up (score 81 vs 69). One year follow up comparing both groups report no differences in ischemic heart disease readmissions, all-causes readmissions or acute heart infarction. Life expectancy was lightly higher in those undergoing angioplasty but this different was no significant (317+-15 vs 343+-13 days, p = 0.9). There were no differences in mortality.

Conclusions: Polypathological patients with NSTEACS undergoing angioplasty have a more independent functional status before the procedure than those treated conservatively, but this difference disappear one year later. Clinical outcomes including readmission, heart attack, mortality, or life expectancy in polypathological patients with NSTEACS undergoing angioplasty are similar to those treated conservatively in a year follow-up.

EA-131
MULTIMORBIDITY IN A MEDICINE WARD: RELEVANCE OF ILNESS SCORES TO THE INTERNIST

V. Cunha, R. Nortadas, M. Escarigo, A. Ferreira, A. Fonseca, M. Amaro, J. Raposo, F. Delerue

Department of Medicine. Hospital Garcia de Orta. Almada, Portugal.

Objectives: Analyze deaths in a Medicine Ward (MW), characterizing causes of death and patients comorbidities; calculate Charlson Comorbidity Index (CCI) and MEWS score.

Material and method: Retrospective descriptive analysis of all deaths occurred during two years in a MW. Use of CCI, a score to

predict one year-mortality in admitted patients with predefined diseases. Use of MEWS score, that pretends to identify patients at risk of clinical deterioration and need of urgent intervention. Use of International Classification of Diseases-10 (ICD-10) for diagnosis.

Results: A sample of 457 patients was obtained, 61.7% of male sex, with a mean age of 79.2 years old (minimum 32 and maximum 99, with a mode of 81). Sixty two percent of patients were totally or partially dependent for daily life. The most frequent admission diagnosis were: 33.1% Pneumonia, 12.9% Heart Failure, Ischemic Stroke in 9.0% and Cancer in 6.1%. An average Charlson score of 3.6 was obtained: 3.7% patients had a Charlson of 0 (corresponding to a 12% mortality rate/year), 33.6% had between 1 and 2 (26% mortality/year), 28.8 had 3 or 4 (52% mortality/year) and 33.6% had above 5 (85% mortality/year). An average Charlson-Age Adapted score of 6,8 was obtained; 84.1% had an index above 5. The average MEWS score was 3.2 (non critical patient at admission) but 40.9% had a score of 4 or more (indicating that extra support is required and there is risk of clinical deterioration). There was an average of 14 length of stay (minimum 1 and maximum 253). There's was no significant association between CCI and CCI Age-adapted and length of stay; but it was clear a significant association between higher MEWS score and shorter length of stay ($p < 0.001$). The most frequent causes of death were: Pneumonia 41.6%, Heart failure (HF) 14.2%, Septicemia 11.4%, Cancer 7.4% (unknown in 5.5%), Cerebral Thrombosis (CT) 5.9%. Of these main causes of death, Pneumonia, HF and CT had shorter length of stay (Medians 8, 9 and 8 respectively; versus Septicemia with 13 and Cancer with 14).

Conclusions: The sample showed an elderly population of multimorbidity patients, with moderated CCI scores but elevated CCI Age-adapted scores, corresponding to elevated mortality rates per year. The average MEWS score showed mainly non critical patients at admission, but in those who had higher score value the length of stay was significantly reduced. The main causes of death were either acute illness or acute decompensation on chronic pathologies.

EA-132
ANAEMIA IN AN INTERNAL MEDICINE WARD. RETROSPECTIVE STUDY OF THE 2ND SEMESTER OF 2011, AT A CENTRAL HOSPITAL OF LISBON

T. Souto Moura, L. Azevedo, J. Simões, C. Fevereiro, C. Rodrigues, H. Pego, P. Fonseca, L. Borges

Department of Medicine 1.4. Hospital de São José. Lisboa, Portugal.

Objectives: Identify and characterize the types of anaemia in an internal medicine ward. Correlate these data with some of the population characteristics, such as age and co-morbidities.

Material and method: Retrospective analysis of the patient files admitted to an internal medicine ward, at a central hospital of Lisbon, during the 2nd semester of 2011. We considered all the admissions with the discharge diagnosis of "anaemia", according to the WHO criteria (Hb < 13 g/dL for men and < 12 g/dL for women).

Results: Of the 254 files analysed (M: 99/W:155), all Caucasians, with average age 80yr: 38 (15%) had anaemia (M:10/W:28), being the cause of admission in 20% of the cases. It constituted the main final diagnosis in 5 cases (13%) and a secondary diagnosis in the left majority. The mean haemoglobin value at admission was 9.3 g/dL, the minimum value found was 5.6 g/dL and one third of the patients required transfusion support. Therapy with oral iron and/or folate was prescribed to 37% of the patients, after discharge. Morphologically, the majority presented normocytic anaemia (70%), being the microcytic and macrocytic causes responsible for 16% e 13%, respectively. Assessing the etiological causes, 37% had multifactorial anaemia, 18% iron deficiency and 16% anaemia of chronic disorders. No obvious cause was found in 10%.

Discussion: In this study anaemia was found to be a quite common diagnosis. Both prevalence and female sex predominance were similar to the data reported by other European studies. Considering that it rarely is the admission cause, anaemia largely contributes for the worsening of the patient's clinical condition. Regarding anaemia's morphological classification, most cases were found to be normocytic and the cause multifactorial, to which iron deficiency, renal chronic insufficiency and chronic disorders (infectious, inflammatory and malignant), contribute the most.

Conclusions: Advanced age and multiple co-morbidities –typical characteristics of our patients- makes it, sometimes, extremely hard to identify the aetiology of anaemia and less suitable the application of the standard classification. Furthermore, the age and clinical condition limit some invasive diagnostic procedures, when weighing the cost-benefit. This largely justifies the high rate of anaemia with unidentified aetiology.

EA-133
DETERMINE THE PREVALENCE AND CLINICAL CHARACTERISTICS AND CARE OF A COHORT OF PATIENTS WITH MULTIPLE COMORBIDITIES ADMITTED TO INTENSIVE CARE UNIT

V. Martínez, E. Pérez, F. Laghzaoui, J. Murcia, J. Cepeda, C. Jiménez

Department of Internal Medicine. Hospital Vega Baja de Orihuela. Alicante, Spain.

Objectives: To know the prevalence and clinical characteristics and care of a cohort of patients with multiple pathologies admitted to the ICU of the Hospital Regional de Orihuela during the period of time from January to June 2011.

Material and method: Retrospective study. Inclusion criteria: all patients admitted to the ICU during the study period. Exclusion criteria: patients from scheduled surgery and patients admitted for placement of intravascular devices. Primary endpoint: patients with multimorbidity (PP) defined by the presence of at least two or more chronic diseases in the same patient. Explanatory variables: We analyzed the clinical characteristics, care, functional, and ICU mortality and 6 months after admission. We performed a descriptive and comparative analysis between patients PP and the rest of the explanatory variables with SPSS 17.0.

Results: 326 patients were excluded: 42 patients admitted for placement of MP and 156 patients from surgery scheduled. Were included 128 patients, of whom 46 patients had PP criteria (35.9%). The most prevalent chronic diseases were: chronic heart failure (56.5%), chronic renal failure (54.3%) and chronic respiratory disease (37%). The PP had a higher age (71.3 ± 11 years versus 65 ± 15 years, $p = 0.05$), most often come from the ward (47.8% to 23.2% versus, $p = 0.004$), require greater burden of care: invasive ventilation (58.7 versus 29.3%, $p < 0.001$), use of vasoactive drugs (58.7 versus 29.3%); blood transfusion (39.1 versus 12.2%; $p < 0.001$). Main syndromic diagnosis between PP was respiratory failure (43.4% vs 9.7%). ICU mortality was 41.3% in the PP compared to the other patients 17.1% ($p = 0.003$) and mortality at 6 months increased the PP to 69.9% compared to 18.3% ($p < 0.001$).

Conclusions: A high prevalence of PP entering the ICU. These patients have different clinical characteristics and care as is his advanced age, the greater burden of care and higher mortality rate that persists in following six month. It is important to identify prognostic markers in the short and medium term in this emerging population.

Clinical management

G-1
TREATMENT OF PATIENTS WITH CHOLECYSTITIS BY HOSPITAL AT HOME

M. Rodríguez Cerrillo, A. Poza Montoro, E. Fernández Díaz, A. Iñurrieta Romero, M. Matesanz David

Hospital at Home. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: Verify the efficacy and safety of treating patients with cholecystitis by a Hospital at Home Unit (HaH).

Material and method: Prospective study since January 2010 to May 2011 including patients diagnosed with acute cholecystitis, not operated on and without comorbidity admitted to HaH after 12-24 hours at Observation ward within Emergency Department. All patients were treated with ertapenem.

Results: 25 patients were included. Mean age was 59 years. All patients had abdominal pain, 60% fever and 32% vomiting. 48% presented with leucocytosis. All patients had cholelithiasis and distended gallbladder, 56% showed thickening of the gallabladder wall. Fluid accumulation around the bladder was noted in 16% of the cases. Murphy´s sign was positive in 44%. All patients had a favorable course, and none required transfer to the hospital. All patients treated with HaH expressed their satisfaction with this type of treatment and would choose Hospital at Home again.

Discussion: Some studies have shown the efficacy of treating abdominal infections after several days in Hospital. HaH allows for treating patients diagnosed with cholecystitis at home with the same treatment that they would have received in Hospital.

Conclusions: Treatment of patients with acute cholecystitis without comorbidity at home after a short period of observation is safe and effective.

G-2
TREATMENT OF PATIENTS WITH UNCOMPLICATED DIVERTICULITIS AND COMORBIDITY BY HOSPITAL AT HOME

M. Rodríguez Cerrillo, A. Poza Montoro, A. Iñurrieta Romero, E. Fernández Díaz, M. Matesanz David

Hospital at Home. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: Verify the efficacy and safety of treating patients with uncomplicated diverticulitis and comorbidity by a Hospital at Home Unit (HaH).

Material and method: Prospective study since January 2007 to December 2009. Patients were transferred to HaH after 12-24 hours at Observation ward within Emergency Department. All patients were treated with intravenous antibiotic.

Results: 176 patients were diagnosed with uncomplicated diverticulitis at the Emergency Department. 18% of them (33) had comorbidity. Four patients stayed at Hospital because did not have a caregiver. One diabetic patient worsened at observation ward and suffered perforation, needing urgent surgery. 28 patients were transferred to HaH. Eighteen patients had cardiopathy, eight diabetes mellitus, one patient chronic hepatopathy and one chronic renal failure. Mean age was 74.2 years. All patients had abdominal pain and 31.2% fever. 46.8% presented with leucocytosis. 21.8% had previous history of diverticulitis. Mean stay of patients admitted to HaH Unit was 9 days. All patients had a favorable course, and none required transfer to the hospital. 98% of patients treated with HaH expressed their satisfaction with this type of treatment.

Discussion: Some studies have shown the efficacy of treating at home patients with uncomplicated diverticulitis. Patients with comorbidity were not included in those studies. HaH allows for treating these patients at home with the same treatment that they would have received in Hospital.

Conclusions: Treatment of patients with uncomplicated diverticulitis and comorbidity at home after a short period of observation is safe and effective.

G-3
TREATMENT OF PATIENTS WITH POSTOPERATIVE INTRA-ABDOMINAL ABSCESS IN HOSPITAL AT HOME

M. Rodríguez Cerrillo, M. Matesanz David, A. Iñurrieta Romero, A. Poza Montoro, E. Fernández Díaz

Hospital at Home. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: We analyzed the safety and efficacy of treating these patients in a Hospital in the Home (HIH) Unit.

Material and method: Prospective study from January 2010 to December 2011 including all patients diagnosed with postoperative intra-abdominal abscess admitted to the HIH Unit. Intravenous treatment initiated at Hospital was continued at home. Before discharge from HIH all patients underwent an abdominal-CT to verify abscess resolution. Main outcome measures: age, sex, microbiology, treatment, mean stay in HIH, clinical course, need for unexpected returns to hospital, hospital readmission occurring within one month after HIH discharge and patient satisfaction.

Results: 44 patients were included. 63.6% were male. Mean age was 67 years (42-89). 9% had cardiopathy, 6.8% diabetes mellitus and 2.3% chronic renal failure. 33 patients (75%) had more than one abscess. The most frequent microorganisms isolated were Escherichia coli (31.3%), bacteroides fragilis (13.6%) and Streptococcus spp (13.6%). 36.3% of the patients had polymicrobial infections. The most used antibiotics were piperacillin-tazobactam and ertapenem. Two patients made an unexpected telephone call during their admission to HIH. All patients had a favorable clinical course. No patient required readmission to the hospital. Mean stay in HIH was 14 days (8-21). All patients expressed their satisfaction with the treatment at home.

Discussion: Patients diagnosed with postoperative intra-abdominal abscess stay at Hospital until the end of intravenous treatment. Treating these patients at home may save days of hospital stay and increase patient comfortability.

Conclusions: Our study reveals the safety and efficacy of treating at home patients diagnosed with postoperative intra-abdominal abscess.

G-4
CLINICAL PROFILE OF NONAGENARIAN PATIENTS ADMITTED TO SPANISH INTERNAL MEDICINE DEPARTMENTS

S. Elgheadi, R. Sanz, G. Sotres, V. Isernia, C. Granda, A. Molino, J. Marco

Department of Internal Medicine. Hospital Clínico San Carlos. Madrid, Spain.

Objectives: To describe the demographic and clinical profile of nonagenarian patients admitted in internal medicine departments in Spanish hospitals, and to compare it with younger patients.

Material and method: We identified through the CMBD (Basic Minimum Data Set) every patient older than 90 years admitted to Internal Medicine Departments of the Spanish National Health Service public hospitals between 2005- 2008. Hospital discharge data were obtained from the CMBD. A diagnosis-related group (DRG) was identified for every patient. The DRG 21.0 version was used. We compare data from this nonagenarian group with data of younger adult people. In order to determine comorbidity the

Charlson Index (CCI) was used. All statistical analyses were performed using SPSS 14.0.

Results: Sample includes 131,434 patients over 90 (6% of total patients attended). 2,222 patients were over 100 years, 45.3% patients under 90 were women, against 67.3% of those over 90 ($p < 0.001$). The top ten DRGs listed in the older group include three new entities not-present in the younger population: pulmonary oedema (DRG: 87), severe urinary tract infection (DRG: 320), and severe respiratory tract infection (DRG: 540). The first 5 DRG were: pneumonia/bronchitis (541): 11.9%, heart failure (127): 8.9%, rhythm disorders (544): 7.5%, pulmonary oedema (87): 3.8%, and other respiratory diseases (89): 3.24. In all cases, rate of these entities were higher than those found in younger patients. Among this top ten only COPD and angina had a higher rate in the younger group. Rate of hospital deaths were 9.1% among the younger group and 21.8% among the nonagenarians ($p < 0.001$). If we take into account only the first 48 hours after admission mortality rates were 2.2% vs 6% ($p < 0.001$). 78.2% of nonagenarian patients went home after discharge.

Discussion: Some peculiarities exist among this population which marked the differences with the standard patient admitted to IM. The number of surgical procedures performed to them are lower (mainly pacemakers implanting and orthopedic procedures). Also, there is a greater proportion of patients sent to nursing homes, reflecting an increase need of care and an absence of care-givers. Finally, the comorbidity index or Charlson index is logically higher with 19.95% (11,233 patients) with a score above 3.

Conclusions: 1) There are a high number of nonagenarians patients admitted in hospital Internal Medicine Departments 2) the rate of women increases with age. 3) The type of diagnosis varies according with age. 4) Death's hospital rates increase with age, both if we consider early or global mortality. 5) A substantial number of these very old patients are able to return home after discharge.

G-6
BEYOND THE GERMAN VIEW: DECISION FINDING FOR A CRITICALLY ILL PATIENT

A. Von Sengbusch[1], V. Briner[2]

[1]Department of Internal Medicine. Vinzenz KH. Düsseldorf, Germany. [2]Department of Medicine. Luzerner Kantonsspital. Switzerland.

Objectives: The primary objective of this contribution is to clarify common views and differences among young doctors from several European countries in deciding on the management of a critically ill respectively dying patient.

Material and method: At ESIM in Saas Fee in January 2012 40 young Internists in training from 23 European countries came together for a week to experience an exciting and challenging medical and social programme. In one of four workshops we spoke about coping with difficult situations in clinical practise. The material for this abstract comes from the contributions to the discussion which was based on a case about a critically ill patient brought into hospital at night. The young doctor on call had to make a decision about life sustaining interventions and transferring the patient to ICU. The given clinical example was quite clear – this was a dying patient who had previously been in very poor condition and was now suffering from a pneumonia and chronic heart failure.

Results: In the group discussion the focus was mainly on three aspects. 1. The role of the family plays a very important role and differs a lot within our countries. It depends on cultural aspects as well as on legislations. In some countries like Turkey the communication with the family is often more important than with the patient himself. The family could insist on continuing invasive treatment even though we think that it is no longer medically indicated or has any perspective. We should not let this put us under pressure. In Switzerland it has been established that the family´s decision on the continuation and invasiveness of treatment is binding for the doctor. In Germany we focus a lot on the advance directive and there has been a large political and ethical controversy about this. This document is helpful but there are many situations where other aspects play a role and it is not easy to decide whether the directive actually applies. We find that the personal communication with the patient and the family cannot be replaced by a written document. 2. End of life care is a religious question. For patients without a religious background any life may be better than no life at all. So there were some residents who would have taken the patient to ICU and done everything to keep him alive even though the prognosis was very poor and the medical sense doubtful. 3. The modus of limiting therapy if we decide not to continue with maximum treatment was discussed controversly -whether it is possible to stop invasive therapy like ventilation or whether we would not add any further therapy. This procedure seems to be variable within different hospitals but not depend much on the country or culture.

Discussion: Among several European countries we have many common views on the treatment of a dying patient but we are also different in some approaches. We mostly depend on our different cultural and religious backgrounds but also on the legislations and resources that we have in our country as well as on the individual spirit of our hospital and the team involved.

Conclusions: Decision finding for a critically ill patient is determined by cultural as well as structural and legislative aspects and also depends on the education and personality of the doctor and his superiors. This reflection on an ESIM discussion is a chance to look beyond our personal view. In our hospitals we often see patients from all over Europe and it can help to consider these aspects when approaching the patient and the family. When thinking of establishing European standards in end of life care we may also be inspired by these ideas.

G-8
STATINS USE IN INPATIENTS WITH NON-CARDIOEMBOLIC ISCHAEMIC STROKE: RETROSPECTIVE TURKISH POPULATION STUDY

V. Binay Safer[1], F. Koseoglu[1], O. Oken[1], U. Safer[2]

[1]Department of Physical Medicine and Rehabilitation. Ankara Physical Medicine and Rehabilitation Education and Research Hospital. Ankara, Turkey. [2]Department of Geriatrics. Gulhane Medical Faculty Training Hospital. Ankara, Turkey.

Objectives: The aim of this study was to investigate dyslipidemia, treatment and control of dyslipidemia among Turkish non-cardioembolic ischemic stroke patients in a physical medicine and rehabilitation clinic.

Material and method: Stroke inpatient case notes were ascertained through retrospective clinical identification by International Classification of Diseases, 10th revision codes. Non-cardioembolic ischemic stroke patients underwent assessment. We determined low-density lipoprotein cholesterol (LDL-C) levels and the use of statins. Serum level and control of lipids were classified according to the AHA/ASA guidelines for the prevention of stroke in patients with stroke or transient ischemic attack.

Results: 134 stroke patients' records were screened. 76 (57.0%) fulfilled the inclusion criteria and underwent assessment. LDL-C was measured in 95% of all these patients. 39 (51.3%) patients' LDL levels were > 100 mg/dl, but they were not on LLT. Also, 15 (19.5%) patients were on LLT, but 5 patients' LDL levels were > 100 mg/dl.

Conclusions: Statins were highly underused in patients with non-cardioembolic ischaemic stroke, particularly among patients, statins were indicated according to existing guidelines.

G-9
USE OF ANTIPLATELET DRUGS IN PATIENT WITH NON-CARDIOEMBOLIC ISCHEMIC STROKE: TURKISH POPULATION STUDY

V. Binay Safer[1], O. Oken[1], F. Koseoglu[1], U. Safer[2]

[1]Department of Physical Medicine and Rehabilitation. Ankara Physical Medicine and Rehabilitation Education and Research Hospital. Ankara, Turkey. [2]Department of Geriatrics. Gulhane Medical Faculty Training Hospital. Ankara, Turkey.

Objectives: There was few information about antiplatelet and anticoagulant drugs use of non-cardioembolic ischemic stroke patients in Turkey. Aim of this study was to evaluate the use of these drugs in ischemic stroke patients in Turkish population.

Material and method: In this single-center, retrospective, non-cardioembolic ischemic stroke inpatient case notes were included trial. Patients' demographic features, stroke time, effected side, acute stroke care center and medication history were determined for all participants. Antiplatelet agents use rates and preferred medication (monotherapy or combination) were determine. Also appropriateness of therapy according to AHA/ASA secondary stroke prevention guidelines was determined.

Results: 77 non-cardioembolic stroke cases were underwent assessment. Mean age was 65.4 ± 1.3 years and 61% were men, post stroke time was 2.0 ± 0.1 months and 18.2% (n = 14) was recurrent stroke. 64.9% (n = 50) of the patients had a history of hypertension, 39% (n = 30) had diabetes 35.1% (n = 27) had ischaemic heart disease and 41.6% (n = 32) had dispepsia. 48.1% (n = 37) of patients had used ASA, 20.8% (16) had used clopidogrel, 14.3% (n = 11) had used ASA + clopidogrel, 4% (n = 5.2) had used ASA + dipiridamol and 3.9% (n = 3) were on dipidamol monotherapy. 6.5% (n = 5) non-cardioembolic ischaemic stroke patients had used neither antiplatelet nor anticoagulant medication.

Conclusions: Stroke patients should be closely monitored and antiplatelet drug use must be fully assessed in each visits.

G-10
ANALYSIS OF MORTALITY IN A NEW HOSPITAL DURING THE FIRST MONTHS

M. Galindo Andúgar[1], J. Castellanos Monedero[1], A. Martín Castillo[1], A. Navarro Martínez[2], L. Rodríguez Rojas[1], M. Elices Calzón[3], J. Fernández Ibáñez[1], I. Domínguez Quesada[1]

[1]Department of Internal Medicine. Complejo Hospitalario La Mancha Centro. Alcázar de San Juan. Ciudad Real, Spain. [2]Department of Internal Medicine. Hospital General de Albacete. Albacete, Spain. [3]Department of Internal Medicine. Hospital General de Tomelloso. Ciudad Real, Spain.

Objectives: The admissions in the Hospital de Tomelloso (HdT) started in April 2007. The first ward opened was Internal Medicine with 50 beds. There were no other specialists apart from general physicians in Emergency Department until two years after. The objective is to analyse the mortality of the inpatients during the 15 months (from April 2007 until July 2008).

Material and method: Retrospective study with case search by CMBD (Basic Minimum Data Set). Review of the medical history. Analysis with SPSS version 15.0.

Results: 114 deceased patients were included (8.3% of the 1,377 inpatients in that period). 63 were males (55.3%), the median age was 81 years-old (minimum 34 and maximum 98) and most of them belonged to the health area of HdT (95%). The patients stayed at the hospital around 9 days (median 4, range 1-93 days). The most frequent pathologies were diabetes mellitus (67%), arterial hypertension (55%), cognitive impairment (40%), ischemic heart disease (31%) and cancer (31%). There were 52 patients who had been admitted to the hospital at least once in the previous 12 months, twice in 11 cases and three times in 4 cases. The admission was for a related diagnosis in the 80%, and the main diagnosis were infection in 41, cardiological disease in 18, neurological disease in 21, dyspnea in 12, tumoral progression in 9 and others in 15. 29 inpatients suffered nosocomial infections (25%) being pneumonia in 13 (49%), urinary tract infection in 9 (31%) and bacteremia in 8 (28%). The most frequent cause of the decease was the multiorgan failure (36%) followed by acute respiratory failure (32.5%), septic shock (17%), congestive heart failure (11%), stroke with intracranial bleeding (2%), acute myocardial infarction (2%) and haemorrhagic shock (1%). The moment of death is usually at night (40%) especially between 05:00 a.m. and 07:30 a.m. The death was unexpected in 3 patients: an 88 years-old man with acute myocardial infarction with changes in electrocardiogram and blood analysis, a 91 years-old man with lung cancer suspected and a 77 years-old man with chronic respiratory disease and respiratory arrest for pneumothorax. Autopsy was offered in these 3 patients and other 6 patients more but their family didn't accept it in any case. The medical report was completed in 3 days on average.

Discussion: The age and morbility of the patients is high. The presence of cognitive impairment and subsequently of dysphagia is the cause of respiratory infections and dyspnea in most of the patients as well as the cancer. Although the cause of death was not completely clear in some cases, the recommendation for an autopsy was not accepted.

Conclusions: The most important factors are the age and the morbility before admission.

G-11
ANALYSIS OF THE PATIENTS ADMITTED TO A NEW HOSPITAL DURING THE FIRST YEAR

M. Galindo Andúgar[1], A. Martín Castillo[1], J. Castellanos Monedero[1], G. López Larramona[2], L. Rodríguez Rojas[1], H. Ortega Abengózar[1], M. Martínez Gabarrón[1], L. Fernández Espartero Gómez[1]

[1]Department of Internal Medicine. Complejo Hospitalario La Mancha Centro. Alcázar de San Juan (Ciudad Real), Spain. [2]Department of Internal Medicine. Hospital General de Tomelloso. Ciudad Real, Spain.

Objectives: The Hospital de Tomelloso (HdT) was opened in 2007 as part of a complex with the Hospital General La Mancha Centro (HGLMC). In the HdT the admissions started the 16th of April and the Emergency Department two weeks after. The first opened ward included 50 beds and was in charge of Internal Medicine. The physicians on guard duty were three general physicians in Emergency Department and one specialist in Internal Medicine. The rest of specialist and the Intensive Care Unit were in HGLMC. The objective is the analysis of the patients admitted in the 15 months, including clinical data, transferences to another hospital (for diagnosis or radiological tests), clinical evolution and requested ambulances after discharge.

Material and method: Retrospective study with case search by CMBD (Basic Minimum Data Set). Analysis with SPSS version 15.0.

Results: 1,377 inpatients were included, with age between 16 and 103 years (median 75 years). 703 were males (51%) and the median of admission was 8.79 days (range 1-125). There were more admissions during the winter especially in February 2008. 1,358 patients belonged to the health area of the hospital complex, being 1,232 from the HdT area (89.5%) and 126 (9.1%) from the HGLMC area, with only 19 patients from other health areas. The inpatient origin was the Emergency Department in most of the cases (89.1%, being HdT in 863 patients (62.7%) and HGLMC in 364 (26.4%)), followed by programmed admissions in 105 cases and transference from other hospitals in 45 patients. The patients were discharged in 1211 cases after good evolution or stabilization, 22 patients were

discharged with unfavourable evolution (the most of them were oncological patients) and 144 patients died at the hospital. During the admission, it was necessary a transference in ambulance in 471 inpatients (34.2%). The reasons included diagnosis test without availability in HdT as echocardiography (237), endoscopies (152), coronariography (25), magnetic resonance (18), making specimens (13), and consulting by other specialists (21). An ambulance was demanded in 595 of the discharges (about 50%) and the reason was locomotion disability. The main diagnosis was infectious in 583 (pneumonia in 186, sepsis in 60, urinary infection in 66), followed by cardiological (238, with congestive heart failure in 122 and acute coronary syndrome in 51), neurological (145, with stroke in 126) and gastrointestinal (103).

Discussion: The absence of Intensive Care Unit is a determinant factor in the selection of the patients especially in the first months. The number and kind of inpatients was increasing after July including younger cardiological patients. However there was no cardiologist in HdT during that period so it was necessary to transfer inpatients to HGLMC for diagnosis test like echocardiography in many times. Regarding to the discharges the request for ambulance is high (about half of the patients) what represents an important medical expense.

Conclusions: The availability of human resources and diagnosis tests is essential to understand the type of inpatients and necessity of transference to other hospitals. The possibility of ambulance transference in the discharge is usually considered as a right for the patients and their families.

G-12
LIPID PROFILE AND GENDER RELATION IN NON-CARDIOEMBOLIC ISCHEMIC STROKE SURVIVOR

V. Binay Safer[1], O. Oken[1], F. Koseoglu[1], U. Safer[2]

[1]Department of Physical Medicine and Rehabilitation. Ankara Physical Medicine and Rehabilitation Education and Research Hospital. Ankara, Turkey. [2]Department of Geriatrics. Gulhane Medical Faculty Training Hospital. Ankara, Turkey.

Objectives: Non-cardioembolic ischemic stroke patients' lipid levels and association with gender is unclear in Turkish population. The aim of this study was to investigate lipid profile in this population and assess the relationship between genders.

Material and method: Stroke survivor who were on rehabilitation program between 2009 and 2012 years were assessed in single center, retrospective and observational study. Non-cardioembolic ischemic stroke patients underwent assessment. Patients' genders and lipid levels were recorded and relationship between these parameters was assessed.

Results: Eighty three stroke survivors had non-cardioembolic ischemic stroke etiology. Six of these patients were excluded because of missing data. Final analysis was made on seventy seven patients. Demographic and clinical characteristic of the study was as in Table 1 and lipit profiles were in Table 2. Women had lower HDL-C levels and higher LDL-C levels, but it was not significant.

Conclusions: Turkish stroke survivors HDL-C levels and relationship with gender should be assessed in a prospective and multicenter study.

G-13
HF_MIRAP CONSULTATION: EVALUATION OF TEN NEW PATIENTS DAILY IN AFTERNOON TIME (PART 1, ADEQUACY OF REFERRALS)

N. Mesa, R. Martín, D. Rejas, E. Madroñal, R. Calderón, J. Ortiz, M. Fernández, A. Zapatero

Department of Internal Medicine. Hospital de Fuenlabrada. Madrid, Spain.

Objectives: Assess the adequacy of referrals to a consultation of internal medicine department of the Hospital de Fuenlabrada, designed to value daily 10 new patients (30 minutes per patient, 2 to 4 days per week depending on the month) in afternoon time, to provide coordination with primary care.

Material and method: Cross-sectional study of 1140 new patients attended from January to December 2011 at a consultation of internal medicine department in afternoon time. Statistics: %, mean + SD. Comparison: ANOVA, chi^2.

Results: Obtaining of the initial information: Horus program (51%), interconsultation paper (40%), Selene program (9%). Source of patients: primary care 91%, specialist care 9% (Urgencies 62%, Ophthalmology 7%, Neurology 5%). The patients were referred by 146 primary care physicians from 10 health centers. It is notorious that 25% of patients were referred by 10 physicians ("the most outstanding"). Consultation type: normal 71%, preferred 29%. There were no significant differences between health centers, but there were differences depending on the referring physician (p = 0.000). The delay from the request date to the first visit was 24 ± 2 days with differences (p = 0.000) depending on the month of the year (longer during the summer due to closure consultation) and the change of appointment by the patient (4%). 10% of the patients were immigrants

Table 1 (G-12). Demographic and clinical characteristic of the study population

	Men (n = 47)	Women (n = 30)	p
Age, year (Mean ± SD)	64.28 ± 1.76	67.43 ± 1.887	0.174
Stroke time, month (Mean ± SD)	4.09 ± 1.45	5.7 ± 2.57	0.312
Ischaemic heart disease (percentage)	18(38.3%)	9(30%)

.

Table 2 (G-12). Lipid profiles of study population

	Men (n = 47)	Women (n = 30)	p
Total cholesterol	171.21 ± 5.70	171.567 ± 7.1	0.925
High-density lipoprotein cholesterol	39.2 ± 1.7	36.9 ± 1.4	0.762
Low-density lipoprotein cholesterol	102.78 ± 4.87	107.10 ± 5.6	0.471
Triglyceride	145.72 ± 11.57	137.87 ± 10.65	0.251
Non-HDL cholesterol	132.02 ± 5.35	134.64 ± 7.0	0.715
Total cholesterol/High-density lipoprotein cholesterol	4.62 ± 0.2	4.82 ± 0.26	0.655

(18% Morocco, 37% rest of Africa, 25% South and Central America, 13% Europe, Asia 6%) with a residence time of 9 ± 7 years. 11% of patients missed the first visit (in relation to waiting time p = 0.000 and emigration p = 0.002, bear no relation to age, sex, type of consultation or health center), 11% did not make the test and 15% did not go to the review. 21% of lost patients request new appointment (80.5% request two appointments and 2.4% request three appointments). Appointments due to delay in another specialty (confirmed in Horus program) 3% (Digestive 50%) There were 4% patients cited simultaneously in another specialty (Digestive 29%, Pneumology 17%, Nephrology 12%) 26% of cases were wrong derived. The causes were: appointment preferred (58%), already studied (17%), simultaneous appointment (12%), no pathology of internal medicine (7%), routine monitoring in internal medicine (3%) and awaiting results requested by primary care (2%).

Conclusions: Utility of Horus program to obtain information. Most cases are from primary care (91%). High number of preferred consultations (29%) even though the waiting time is low (mean 24 days). Difference in waiting time in function of month of the year (delay after the summer months) and the change of appointment by the patient. High number of missed cases (20%). Relationship between those who did not attend the first visit (11%) with the waiting time and migration. 21% of lost patients request new appointments (up to 3 quotes) 3% of citations for delay in another specialty (50% Digestive) and 4% of simultaneous appointment (Digestive and Pneumology). Finally there were 26% of patients wrong derived.

RADIOLOGY EXAMS IN A MEDICINE WARD DURING ONE YEAR

R. Nortadas, V. Cunha, A. Fonseca, J. Raposo, F. Delerue

Department of Internal Medicine. Hospital Garcia de Orta. Almada, Portugal.

Objectives: Quantify Radiology Exams (RE) -X-rays (XR) and computerized tomographies (CT)- performed during hospital admissions: determine motive, diagnosis, usefulness in diagnosis and therapy.

Material and method: Retrospective study of all RE performed to patients admitted to the Medical ward during one year.

Results: A sample of 105 patients was obtained, 58% of female sex, with medium age 74 and average length of stay of 12 days. Most patients where admitted with Cardiovascular or respiratory disease. The most frequent diagnosis at admission where: 28% pneumonia, 13% stroke, 11% heart failure, 4% pulmonary embolism, 2% pleural effusion and COPD. Before being transferred to the ward 90% had already performed a RE (most of them for diagnosis purpose) and in 35% of them, more than 2 exams were performed (with an average of 1.4 RE per patient). At the medicine ward where requested an average of 1.4 RE per patient; 48% for clinical evolution evaluation, 32% per diagnosis, 29% per routine purpose. Half the patients only performed one RE, 62% performed one XR and 19% two or more; 19% performed one CT. The more frequent radiologic changes where: condensation, interstitial infiltrates, high cardiothoracic index; blunting of the costophrenic angles; chronic parenchimatous changes. In 20% there were no significant changes. The percentage of definitive diagnosis was coincident with the admission diagnosis. What concerns to the utility of RE performed, in 67% of the cases it did not led to a new diagnosis but in 66% modified the therapeutic strategy.

Conclusions: A significant amount of RE are performed in the ward. Most are performed to characterize clinical evaluation but a significant percentage is done with diagnostic purpose. Thus, a significant percentage of RE are repeated for the same patient not leading to a new diagnosis or change of clinic/therapeutic strategy.

THE INTERNIST´S ROLE IN THE EVALUATION OF INPATIENTS: AN EXPERIENCE IN A PRIVATE CLINIC

R. Daryanani Daryanani, A. Gil Díaz, R. Estevez Domínguez, J. Gil Reyes

Department of Internal Medicine. Clínica San Roque. Las Palmas de Gran Canaria. Las Palmas, Spain.

Objectives: The objectives of the study were to know the characteristics of Clínica San Roque inpatients requested to the Internal Medicine Department and to assess the workload that they involve.

Material and method: An observational descriptive prospective study was made. Clínica San Roque inpatients admitted by other specialties who needed evaluation from Internal Medicine Department from October 2011 to March 2012 were included. The evaluated variables were date of the first visit and follow-up days, the requesting service, cause of consultation, patient demographics, comorbility and Charlson index, diagnosis, quality criteria established by Irazabal and if they needed to be referred to the Internal Medicine Department.

Results: 77 patients were included in the study, which led to 405 visits. It involved a workload of 3.12 more patients a day. There were 29 men (38.2%) and 47 women (61.8%). The mean age was 69.8 years (SD 16.7, range 18-95), being 66.8 in men (18-94) and 71.2 in women (34-95). The main personal antecedents were hypertension (50.6%), cardiovascular disease (29.9%) and cognitive impairment (28.6%). The medium Charlson index was 1.74 (range: 0-8). The most frequent requesting services were Traumatology (61%), General Surgery (13%), Cardiology (9.1%) and Urology (6.5%). The mean follow-up period was 5.26 days (1-31). All consults were seen the same day of the request. The principal causes were pluripathologic evaluation (13.5%), confusional syndrome (11.2%), antibiotic adjustment (10.1%), cutaneous rash (9%) and anemia (6.7%). The medical history quality evaluated with Irazabal's criteria showed personal antecedents described by the responsible department (84.2%), usual treatment (57.9%), diagnostic tests performed before evaluation (40.8%) and diagnosis hypotheses of the referring department (48.7%). We conclude a good quality in 23.4%, regular quality in 66.2% and bad quality in 10.4% of the consults. The final diagnoses are resumed in Table 1. Four patients (5.2%) were transferred to the Internal Medicine Department. There were no deceases.

Discussion: We agree with previous researches performed in Internal Medicine services of public hospitals that Traumatology is the most frequent requesting service, and the one that most follow-up days needs, followed by General Surgery. Nevertheless, the main diagnoses in public hospitals are heart failure, chronic respiratory insufficiency and bacteraemia. We highlight that the 10.4% of our diagnoses were drug adverse effects.

Conclusions: Internal Medicine plays an important role in the private hospital setting. We agree with public hospitals that surgical departments are the most petitioner services, however the cause of consult and diagnoses were different. It implies an important workload to the Internal Medicine Department.

Table 1 (G-15). Main diagnosis

Diagnosis	Total (percentage)	Traumatology patients
Urinary tract infection	9 (11.7%)	7 (77.8%)
Anemia after surgical intervention	9 (11.7%)	6 (66.7%)
Acute confusional syndrome	8 (10.4%)	3 (37.5%)
Drug adverse effects	8 (10.4%)	4 (50%)
Acute renal failure	6 (7.8%)	2 (33.3%)
Acute bronchitis	5 (6.5%)	5 (100%)
Prosthesis infection	4 (5.2%)	4 (100%)

INTRAVENOUS FIBRINOLYTIC THERAPY IN ACUTE CEREBRAL ISCHEMIA. EXPERIENCE OF A STROKE UNIT

E. Oliveira, P. Manuel, J. Alexandre, L. Porto, P. Batista, F. Girão

Department of Internal Medicine. Centro Hospitalar Tondela-Viseu. Viseu, Portugal.

Objectives: Our aims was to evaluate the demographics, stroke type, risk factors and outcomes of patients admitted in our stroke unit over the last 36 months, that received intravenous fibrinolytic therapy.

Material and method: Retrospective study lasting 36 months in which we evaluated all patients with ischemic stroke submitted to fibrinolytic therapy with intravenous r-tPA. We evaluated the patient history, risk factors, physical findings, blood tests, CT scan, ECG, echocardiogram and triplex findings and efficacy of intra-hospital procedures such as timings, complications and outcomes.

Results: We studied 50 patients, 26 men (52%) and 24 woman (48%), aged 31 to 80 years old (mean age 67 ± 11.5). Among the major risk factors there was hypertension in 29 patients (58%), atrial fibrillation in 22 patients (44%), dyslipidemia in 10 patients (20%) and diabetes mellitus in 8 patients (16%). The predominant Bamford stroke types were TACI and LACI, each with 21 patients. The mean NIHSS score on admission was 12 ± 4.7; and 7 ± 6.2 on discharge. The average door-to-needle time was 89 ± 33.5 minutes. There were 8 immediate complications following the fibrinolytic administration, and the overall mortality rate was 6% (3 patients). Eight patients were discharged with no neurological deficits.

Discussion: Stroke is a catastrophic event, particularly in the previously active patient who suddenly loses his independence from others. The impact and prevalence of stroke in Portugal it's outstanding: it's the primary direct death cause in our country and important cause of morbidity. Major preventing strategies and campaigns were implemented in the past couple of years to alert the population for the disease. The only approved and effective treatment for stroke is fibrinolytic therapy, increasingly used in stroke units that were recently created in several hospitals throughout the country.

Conclusions: Administration of fibrinolytic therapy in stroke is relatively new in our hospital and to our personnel. Although fifty is still a modest number, we find these results good in overall, when compared to other series. In 74% of patients there was a significant decline in NIHSS following r-tPA and 8 patients left the hospital with no neurological deficits. The risk factors found were similar to those well known in cerebrovascular disease. Intravenous fibrinolytic therapy at the cerebral circulation dose within the first 3 hours of ischemic stroke onset offered substantial benefits for our patients with potentially disabling deficits, and helped to attenuate the burden of stroke in our population.

DESCRIPTIVE STUDY ON PATIENTS SEEN IN AN INTERNAL MEDICINE DAY CARE UNIT OVER TWO YEARS

V. Jarne Betrán[1], M. Arteaga Mazuelas[1], Á. Cecilio Irazola[1], V. Fernández Ladrón[1], P. Navarro San Pedro[2], C. González Rodríguez[1], F. del Cazo Cativiela[1], J. Pineda Arribas[3]

[1]Department of Internal Medicine, [2]Department of Pharmacy, [3]Department of Endocrinology. Hospital García Orcoyen. Estella (Navarra), Spain.

Objectives: To conduct a descriptive and retrospective study about the procedures and treatments undertaken in the Day Care Unit (DCU) of the Internal Medicine Department at García Orcoyen Hospital (Navarra, Spain) during 2010 and 2011. This is a community local hospital (second-level) with 97 beds, which has not got Haematology or Oncology departments.

Material and method: We retrospectively reviewed the medical records of patients seen at the unit during the mentioned period.
